**Figures . . . . . v**

**Tables . . . . . ix**

**Reference . . . . . 1**

Configuration reference. . . . . 1

- Example configuration information for all platforms . . . . . 1
- IBM MQ file system permissions applied to /var/mqm . . . . . 75
- Queue names. . . . . 79
- Other object names . . . . . 80
- Queue name resolution . . . . . 81
- System and default objects . . . . . 84
- Stanza information . . . . . 92
- Channel attributes . . . . . 95
- IBM MQ cluster commands . . . . . 135
- Channel programs. . . . . 152
- Environment Variables . . . . . 153
- Intercommunication jobs . . . . . 157
- Channel states on IBM i . . . . . 158
- Message channel planning example for distributed platforms. . . . . 158
- Message channel planning example for IBM MQ for IBM i . . . . . 162
- Message channel planning example for z/OS . . . . . 167
- Message channel planning example for z/OS using queue-sharing groups . . . . . 171
- Using an alias to refer to an MQ library . . . . . 175

Administration reference . . . . . 175

- Syntax diagrams . . . . . 175
- IBM MQ Control commands . . . . . 178
- IBM MQ for IBM i CL commands . . . . . 337
- MQSC reference . . . . . 340
- Programmable command formats reference . . . . . 1044
- Using the IBM MQ utilities for z/OS . . . . . 1618

IBM MQ Administration Interface . . . . . 1697

Developing applications reference . . . . . 1781

- MQI applications reference . . . . . 1782
- IBM i Application Programming Reference (ILE/RPG) . . . . . 2783
- Data conversion . . . . . 3247
- SOAP reference . . . . . 3267
- User exits, API exits, and installable services reference . . . . . 3318
- Reference material for IBM MQ bridge for HTTP . . . . . 3606

- The IBM MQ .NET classes and interfaces. . . . . 3642
- IBM MQ C++ classes . . . . . 3705
- Properties of IBM MQ classes for JMS objects . . . . . 3816

IBM MQ Telemetry Reference . . . . . 3873

- IBM MQ Telemetry Transport format and protocol. . . . . 3873
- MQXR properties . . . . . 3874
- AuthCallback MQXR class. . . . . 3874

Security reference . . . . . 3875

- The API exit . . . . . 3876
- The API-crossing exit . . . . . 3877
- Certificate validation and trust policy design on UNIX, Linux and Windows systems . . . . . 3878
- Cryptographic hardware . . . . . 3891
- IBM MQ rules for SSLPEER values. . . . . 3892
- GSKit: Digital certificate signature algorithms compliant with FIPS 140-2. . . . . 3893
- Migrating with AltGSKit from IBM MQ V7.0.1 to IBM MQ V7.1 . . . . . 3894
- CipherSpec mismatches . . . . . 3896
- Authentication failures . . . . . 3897

Monitoring reference . . . . . 3898

- Structure data types. . . . . 3898
- Object attributes for event data . . . . . 3923
- Event message reference . . . . . 3969

Troubleshooting and support reference . . . . . 4080

- An example of IBM MQ for Windows trace data . . . . . 4080
- Example trace data for IBM MQ for UNIX and Linux systems. . . . . 4081
- Examples of trace output . . . . . 4085
- Examples of CEDF output. . . . . 4087
- Return code 00000461 for TCP/IP . . . . . 4098

Messages . . . . . 4099

- IBM MQ AMQ messages . . . . . 4099
- AMQXR Messages . . . . . 4100
- IBM MQ for z/OS messages, completion, and reason codes . . . . . 4111
- MQJMS Messages . . . . . 5025

**Index . . . . . 5035**

**Notices . . . . . 5101**

- Programming interface information . . . . . 5102
- Trademarks . . . . . 5103

**Sending your comments to IBM . . . . . 5105**

## Figures

1. IBM MQ channel to be set up in the example configuration . . . . .	1
2. Configuration 1: z/OS using intra-group queuing. . . . .	50
3. Configuration 2 . . . . .	52
4. Configuration 3 . . . . .	54
5. Name resolution . . . . .	82
6. qm.ini stanzas for distributed queuing . . . . .	95
7. The message channel example for Windows, UNIX and Linux systems . . . . .	159
8. The message channel example for IBM MQ for IBM i . . . . .	163
9. The first example for IBM MQ for z/OS . . . . .	168
10. Message channel planning example for IBM MQ for z/OS using queue-sharing groups . . . . .	172
11. How to invoke the CSQUTIL utility program . . . . .	1622
12. Sample JCL for the FORMAT function of CSQUTIL . . . . .	1626
13. Sample JCL for the FORMAT function of CSQUTIL with the TYPE option . . . . .	1627
14. Sample JCL showing the use of the PAGEINFO function . . . . .	1628
15. Sample JCL showing the use of the COPYPAGE function. . . . .	1630
16. Sample JCL showing the use of the RESETPAGE function . . . . .	1632
17. Sample JCL for issuing IBM MQ commands using CSQUTIL . . . . .	1635
18. Sample JCL for using the MAKEDEF option of the COMMAND function . . . . .	1636
19. Sample JCL for using the MAKEALT option of the COMMAND function . . . . .	1637
20. Sample JCL for using the MAKECLNT option of the COMMAND function. . . . .	1637
21. Sample JCL for the SDEFS function of CSQUTIL . . . . .	1641
22. Sample JCL for the SDEFS function of CSQUTIL for objects in the Db2 shared repository . . . . .	1641
23. Sample JCL for the SDEFS function of CSQUTIL, when recovering all objects from a valid page set zero. . . . .	1641
24. Sample JCL for the CSQUTIL COPY functions. . . . .	1643
25. Sample JCL for the CSQUTIL SCOPY functions. . . . .	1646
26. Sample JCL for the CSQUTIL ANALYZE function . . . . .	1647
27. Sample JCL for the CSQUTIL EMPTY function . . . . .	1648
28. Sample JCL for the CSQUTIL LOAD function . . . . .	1651
29. Sample JCL for the CSQUTIL SLOAD function . . . . .	1653
30. Sample JCL for the CSQUTIL XPARAM function . . . . .	1654
31. Sample JCL for querying the switching status of cluster-sender channels using the CSQUTIL SWITCH function . . . . .	1656
32. Sample JCL for switching the transmission queue associated with a cluster-sender channel using the CSQUTIL SWITCH function . . . . .	1656
33. Sample JCL to invoke the CSQJU003 utility . . . . .	1657
34. Sample JCL to invoke the CSQJU004 utility . . . . .	1665
35. Sample JCL to invoke the CSQ1LOGP utility using a BSDS . . . . .	1667
36. Sample JCL to invoke the CSQ1LOGP utility using active log data sets . . . . .	1667
37. Sample JCL to invoke the CSQ1LOGP utility using archive log data sets. . . . .	1668
38. Sample JCL showing additional statements for the EXTRACT keyword . . . . .	1668
39. Accumulating bytes put to each queue . . . . .	1672
40. Sample JCL to invoke the CSQ5PQSG utility . . . . .	1676
41. Using the queue-sharing group utility to add a queue manager into a queue-sharing group. . . . .	1679
42. Example of the JCL used to invoke the CSQJUFMT utility . . . . .	1680
43. Specifying the queue manager and dead-letter queue names for the dead-letter queue handler in the JCL . . . . .	1681
44. Specifying the queue manager and dead-letter queue names for the dead-letter queue handler in the rules table . . . . .	1681
45. Sample JCL to invoke the CSQUDLQH utility. . . . .	1682
46. An example rule from a DLQ handler rules table . . . . .	1684
47. Sample JCL to invoke the CSQJUCNV utility . . . . .	1692
48. Indexing. . . . .	1777
49. Using mqExecute to create a local queue . . . . .	1780
50. Using mqExecute to inquire about queue attributes . . . . .	1781
51. Correct uses of groups and name/value pairs . . . . .	2307
52. Incorrect use of groups and name/value pairs . . . . .	2307
53. Example of a folder and a property folder . . . . .	2308
54. Folder1 namespace . . . . .	2308
55. Folder2 namespace . . . . .	2308
56. Folder3 namespace . . . . .	2308
57. Data type attribute . . . . .	2313
58. Single property name mapping . . . . .	2314
59. Multiple properties with the same root name . . . . .	2314
60. Multiple property name mapping . . . . .	2314
61. Sample Client/Server (Echo) program flowchart . . . . .	3230
62. Example deployment of Axis service . . . . .	3272
63. Example deployment of .NET service . . . . .	3272

64. Example URI in generated .NET client to call .NET service . . . . .	3276	108. ImqIMSBridgeHeader class . . . . .	3750
65. Example URI in generated .NET client to call Axis 1 service . . . . .	3277	109. ImqItem class . . . . .	3753
66. IBM MQ configuration commands to trigger a SOAP listener. . . . .	3277	110. ImqMessage class . . . . .	3754
67. Starting Axis SOAP listener on Windows	3277	111. ImqMessageTracker class . . . . .	3761
68. Starting .NET SOAP listener on Windows	3277	112. ImqNamelist class . . . . .	3764
69. Starting Axis SOAP listener on UNIX and Linux systems . . . . .	3277	113. ImqObject class . . . . .	3765
70. run all the default tests . . . . .	3289	114. ImqProcess class . . . . .	3771
71. run a specific test from the default tests	3289	115. ImqPutMessageOptions class . . . . .	3772
72. run a set of custom tests . . . . .	3289	116. ImqQueue class . . . . .	3774
73. Starting Java client using a configuration file	3300	117. ImqQueueManager class . . . . .	3786
74. myjms.config . . . . .	3300	118. ImqReferenceHeader class . . . . .	3803
75. URI for an Axis service, supplying only required parameters . . . . .	3306	119. ImqString class . . . . .	3806
76. URI for a .NET service, supplying only required parameters . . . . .	3306	120. ImqTrigger class . . . . .	3811
77. URI for an Axis service, supplying some optional connectionFactory parameters. . . . .	3306	121. ImqWorkHeader class . . . . .	3814
78. URI for an Axis service, supplying the sslPeerName option of the connectionFactory parameter . . . . .	3306	122. Sample IBM MQ for Windows trace	4081
79. Use jms:jndi to send a SOAP/JMS request	3312	123. Sample IBM MQ for HP-UX trace . . . . .	4082
80. Use jms:queue to send a SOAP/JMS request	3313	124. Sample IBM MQ for Solaris trace . . . . .	4083
81. Service definition for .NET Framework 2: Quote.asmx . . . . .	3315	125. Sample IBM MQ for Linux trace . . . . .	4084
82. Service implementation for .NET Framework 2: Quote.asmx.cs . . . . .	3315	126. Sample IBM MQ for AIX trace . . . . .	4085
83. Java JAX-RPC service interface using a complex type . . . . .	3315	127. Example trace data from an entry trace of an MQPUT1 request . . . . .	4086
84. Java JAX-RPC service implementation using a complex type . . . . .	3316	128. Example trace data from an exit trace of an MQPUT1 request . . . . .	4087
85. Java JAX-RPC service bean implementation of a complex type. . . . .	3316	129. Example CEDF output on entry to an MQOPEN call (hexadecimal) . . . . .	4088
86. C# Web service client sample . . . . .	3318	130. Example CEDF output on exit from an MQOPEN call (hexadecimal) . . . . .	4088
87. Java Web service client example . . . . .	3318	131. Example CEDF output on entry to an MQOPEN call (character) . . . . .	4088
88. Sample JCL used to invoke the CSQUCVX utility. . . . .	3324	132. Example CEDF output on exit from an MQOPEN call (character) . . . . .	4089
89. Example of an HTTP <b>DELETE</b> request	3609	133. Example CEDF output on entry to an MQCLOSE call (hexadecimal). . . . .	4089
90. Example of an HTTP <b>DELETE</b> response	3609	134. Example CEDF output on exit from an MQCLOSE call (hexadecimal). . . . .	4089
91. Example of an HTTP <b>GET</b> request . . . . .	3611	135. Example CEDF output on entry to an MQCLOSE call (character). . . . .	4090
92. Example of an HTTP <b>GET</b> response	3611	136. Example CEDF output on exit from an MQCLOSE call (character). . . . .	4090
93. Example of an HTTP <b>POST</b> request to a queue. . . . .	3614	137. Example CEDF output on entry to an MQPUT call (hexadecimal) . . . . .	4090
94. Example of an HTTP POST response	3614	138. Example CEDF output on exit from an MQPUT call (hexadecimal) . . . . .	4091
95. Client connection . . . . .	3694	139. Example CEDF output on entry to an MQPUT call (character). . . . .	4091
96. Overriding MQEnvironment properties	3694	140. Example CEDF output on exit from an MQPUT call (character). . . . .	4091
97. Automatically reconnecting a client to a queue manager . . . . .	3694	141. Example CEDF output on entry to an MQPUT1 call (hexadecimal) . . . . .	4092
98. ImqAuthenticationRecord class . . . . .	3720	142. Example CEDF output on exit from an MQPUT1 call (hexadecimal) . . . . .	4092
99. ImqBinary class . . . . .	3723	143. Example CEDF output on entry to an MQPUT1 call (character) . . . . .	4092
100. ImqCache class . . . . .	3725	144. Example CEDF output on exit from an MQPUT1 call (character) . . . . .	4093
101. ImqChannel class . . . . .	3728	145. Example CEDF output on entry to an MQGET call (hexadecimal) . . . . .	4093
102. ImqCICSBridgeHeader class . . . . .	3733	146. Example CEDF output on exit from an MQGET call (hexadecimal) . . . . .	4094
103. ImqDeadLetterHeader class . . . . .	3740	147. Example CEDF output on entry to an MQGET call (character). . . . .	4094
104. ImqDistributionList class . . . . .	3742		
105. ImqError class . . . . .	3743		
106. ImqGetMessageOptions class . . . . .	3745		
107. ImqHeader class . . . . .	3748		

148. Example CEDF output on exit from an MQGET call (character) . . . . .	4094	153. Example CEDF output on entry to an MQSET call (hexadecimal) . . . . .	4097
149. Example CEDF output on entry to an MQINQ call (hexadecimal) . . . . .	4095	154. Example CEDF output on exit from an MQSET call (hexadecimal) . . . . .	4097
150. Example CEDF output on exit from an MQINQ call (hexadecimal) . . . . .	4095	155. Example CEDF output on entry to an MQSET call (character) . . . . .	4097
151. Example CEDF output on entry to an MQINQ call (character) . . . . .	4096	156. Example CEDF output on exit from an MQSET call (character) . . . . .	4098
152. Example CEDF output on exit from an MQINQ call (character) . . . . .	4096		

## Tables

1. Configuration worksheet for IBM MQ for Windows. . . . .	8	41. Status command parameters. . . . .	184
2. Configuration worksheet for IBM MQ for AIX	15	42. Reg command parameters. . . . .	185
3. Configuration worksheet for IBM MQ for HP-UX . . . . .	22	43. Standby values . . . . .	218
4. Configuration worksheet for IBM MQ for Solaris . . . . .	27	44. Instance values . . . . .	218
5. Configuration worksheet for IBM MQ for Linux . . . . .	34	45. Queue manager states. . . . .	218
6. Configuration worksheet for IBM MQ for z/OS. . . . .	39	46. The object type on which to make the inquiry.	220
7. Configuration worksheet for z/OS using LU 6.2 . . . . .	43	47. Specifying authorities for different object types . . . . .	221
8. Configuration worksheet for IBM MQ for z/OS using queue-sharing groups . . . . .	47	48. Authorizations associated with each value.	221
9. Configuration worksheet for SNA on an IBM i system . . . . .	58	49. Valid object types. . . . .	225
10. Configuration worksheet for IBM MQ for IBM i . . . . .	71	50. Delivery parameter values. . . . .	231
11. System and default objects: queues. . . . .	84	51. Forward parameter values. . . . .	231
12. System and default objects: topics . . . . .	85	52. Persistence parameter values. . . . .	231
13. System and default objects: channels . . . . .	85	53. ReportOption parameter values. . . . .	232
14. System and default objects: authentication information objects . . . . .	86	54. Detail parameter values. . . . .	233
15. System and default objects: listeners . . . . .	86	55. PassExpiry parameter values. . . . .	233
16. System and default objects: namelists . . . . .	86	56. DisplayOption parameter values. . . . .	234
17. System and default objects: processes . . . . .	86	57. dspmqsp1 command flags. . . . .	236
18. System and default objects: services . . . . .	86	58. endmqm actions. . . . .	247
19. Objects created by the Windows default configuration application . . . . .	87	59. Valid object types . . . . .	255
20. Default values of SYSTEM.BASE.TOPIC . . . . .	88	60. Valid object types. . . . .	257
21. System and default objects: queues. . . . .	89	61. Syncpoint parameter values. . . . .	266
22. System and default objects: channels . . . . .	91	62. Conversion parameter values. . . . .	266
23. System and default objects: authentication information objects . . . . .	91	63. BackoutThreshold parameter values. . . . .	267
24. System and default objects: listeners . . . . .	91	64. ContextOption parameter values. . . . .	267
25. System and default objects: namelists . . . . .	91	65. Transmission protocol values. . . . .	268
26. System and default objects: processes . . . . .	92	66. ObjectType values. . . . .	282
27. System and default objects: services . . . . .	92	67. Specifying authorities for different object types . . . . .	284
28. Channel attributes for the channel types	96	68. Authorizations for MQI calls. . . . .	287
29. Negotiated HBINT value and the corresponding KAINIT value . . . . .	114	69. Authorizations for context. . . . .	288
30. Examples of how the LOCLADDR parameter can be used . . . . .	115	70. Authorizations for commands. . . . .	288
31. PCF equivalents of MQSC commands specifically to work with clusters . . . . .	136	71. Authorizations for generic operations.	289
32. Attributes for cluster workload management	149	72. setmqsp1 command flags. . . . .	298
33. Channel programs for Windows, UNIX and Linux systems . . . . .	152	73. TraceType parameter values. . . . .	308
34. Job names. . . . .	157	74. Queue manager commands . . . . .	313
35. Channel states on IBM i . . . . .	158	75. Commands for command server administration . . . . .	314
36. How to read railroad diagrams . . . . .	176	76. Commands for authority administration	314
37. Categories of control commands . . . . .	179	77. Cluster commands . . . . .	314
38. QueueManager stanza attributes . . . . .	181	78. Authentication information commands	315
39. Initiation command parameters. . . . .	184	79. Channel commands . . . . .	315
40. Multi-instance command parameters.	184	80. Listener commands . . . . .	316
		81. Namelist commands . . . . .	316
		82. Process commands. . . . .	317
		83. Queue commands . . . . .	317
		84. Service commands . . . . .	318
		85. Other commands . . . . .	318
		86. Options that can be used with <b>runmqckm</b> and <b>runmqakm</b> . . . . .	328
		87. DEFINE and ALTER CHANNEL parameters	366
		88. Automatic reconnection depends on the values set in the application and in the channel definition . . . . .	378
		89. Examples of how the LOCLADDR parameter can be used . . . . .	381

90. How the IP stack to be used for communication is determined . . . . .	382	127. ChannelDisposition and CommandScope for RESOLVE CHANNEL . . . . .	1534
91. Attribute types supported by SSLPEER	397	128. ChannelDisposition and CommandScope for START CHANNEL . . . . .	1559
92. DEFINE and ALTER QUEUE parameters	470	129. ChannelDisposition and CommandScope for STOP CHANNEL. . . . .	1568
93. DEFINE and ALTER CHANNEL parameters	551	130. The IBM MQ CSQUTIL utility program: Managing page sets . . . . .	1618
94. Automatic reconnection depends on the values set in the application and in the channel definition . . . . .	563	131. The IBM MQ CSQUTIL utility program: Issuing commands . . . . .	1619
95. Examples of how the LOCLADDR parameter can be used . . . . .	567	132. The IBM MQ CSQUTIL utility program: Managing queues. . . . .	1619
96. How the IP stack to be used for communication is determined . . . . .	567	133. The IBM MQ CSQUTIL utility program: Migrating CSQXPARM . . . . .	1619
97. Message exit format and length . . . . .	573	134. The IBM MQ CSQJU003 Change log inventory utility . . . . .	1620
98. Attribute types supported by SSLPEER	583	135. The remaining IBM MQ utilities . . . . .	1620
99. DEFINE and ALTER QUEUE parameters	636	136. SDEFS QSGDISP parameters and their actions . . . . .	1640
100. <b>QSGDISP</b> parameters . . . . .	652	137. dspmqsp1 command flags. . . . .	1695
101. Parameters that result in data being returned from the DISPLAY CHANNEL command . . . . .	741	138. setmqsp1 command flags. . . . .	1696
102. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS CURRENT . . . . .	764	139. CCSID processing. . . . .	1778
103. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SHORT . . . . .	764	140. PCF command type . . . . .	1779
104. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SAVED . . . . .	765	141. Format and MsgType parameters of the MQMD . . . . .	1779
105. Product Identifier values. . . . .	777	142. Message descriptor values . . . . .	1779
106. Parameters that can be returned by the <b>DISPLAY QUEUE</b> command. . . . .	874	143. C header files - call prototypes, data types, return codes, constants, and structures. . . . .	1849
107. Parameters that can be returned by the DISPLAY TOPIC command . . . . .	925	144. COBOL copy files - return codes, constants, and structures . . . . .	1849
108. CHLDISP and CMDSCOPE for PING CHANNEL . . . . .	944	145. PL/I include files - data types, return codes, constants, and structures . . . . .	1851
109. CHLDISP and CMDSCOPE for RESET CHANNEL . . . . .	962	146. RPG copy files - return codes, constants, and structures . . . . .	1852
110. CHLDISP and CMDSCOPE for RESOLVE CHANNEL . . . . .	976	147. Visual Basic module files - call declarations, data types, return codes, constants, and structures . . . . .	1853

## Reference

Use the reference information in this section to accomplish the tasks that address your business needs.

- Syntax diagrams

---

## Configuration reference

Use the reference information in this section to help you configure IBM® MQ.

The configuration reference information is provided in the following subtopics:

### Related information:

Configuring

► **z/OS** Configuring z/OS®

## Example configuration information for all platforms

The configuration examples describe tasks performed to establish a working IBM MQ network. The tasks are to establish IBM MQ sender and receiver channels to enable bidirectional message flow between the platforms over all supported protocols.

To use channel types other than sender-receiver, see the DEFINE CHANNEL command.

Figure 1 is a conceptual representation of a single channel and the IBM MQ objects associated with it.

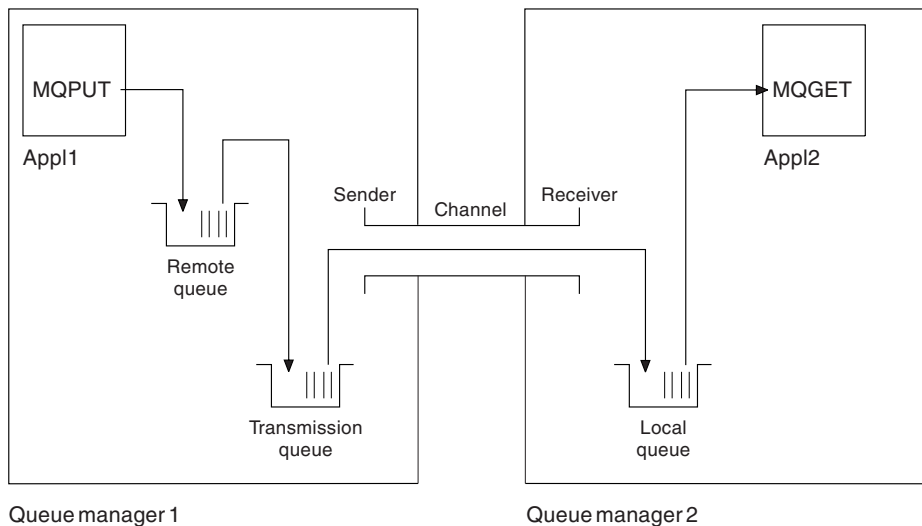

Figure 1. IBM MQ channel to be set up in the example configuration

This example is a simple one, intended to introduce only the basic elements of the IBM MQ network. It does not demonstrate the use of triggering which is described in Triggering channels.

The objects in this network are:

- A remote queue
- A transmission queue
- A local queue
- A sender channel

- A receiver channel

Appl1 and Appl2 are both application programs; Appl1 is putting messages and Appl2 is receiving them.

Appl1 puts messages to a remote queue. The definition for this remote queue specifies the name of a target queue manager, a local queue on that queue manager, and a transmission queue on this local queue manager.

When the queue manager receives the request from Appl1 to put a message to the remote queue, the queue manager determines from the queue definition that the destination is remote. It therefore puts the message, along with a transmission header, straight onto the transmission queue specified in the definition. The message remains on the transmission queue until the channel becomes available, which might happen immediately.

A sender channel has in its definition a reference to one, and one only, transmission queue. When a channel is started, and at other times during its normal operation, it looks at this transmission queue and send any messages on it to the target system. The message has in its transmission header details of the destination queue and queue manager.

The intercommunication examples describe in detail the creation of each of the preceding objects described, for various platform combinations.

On the target queue manager, definitions are required for the local queue and the receiver side of the channel. These objects operate independently of each other and so can be created in any sequence.

On the local queue manager, definitions are required for the remote queue, the transmission queue, and the sender side of the channel. Since both the remote queue definition and the channel definition refer to the transmission queue name, it is advisable to create the transmission queue first.

## Network infrastructure in the example

The configuration examples assume that particular network infrastructures are in place for particular platforms:

-  z/OS communicates by using a 3745 network controller (or equivalent) that is attached to a token ring
- Solaris is on an adjacent local area network (LAN) also attached to a 3745 network controller (or equivalent)
- All other platforms are connected to a token-ring network

It is also assumed that, for SNA, all the required definitions in VTAM and network control program (NCP) are in place and activated for the LAN-attached platforms to communicate over the wide area network (WAN).

Similarly, for TCP, it is assumed that name server function is available, either by using a domain name server or by using locally held tables (for example a host file).

## Communications software in the example

Working configurations are given in the examples for the following network software products:

- SNA
  - IBM Personal Communications for Windows V5.9
  - IBM Communications Server for AIX®, V6.3
  - Hewlett-Packard SNAplus2
  - IBM i

- Data Connection SNAP-IX Version 7 or later
- OS/390® Version 2 Release 4
- TCP
  - Microsoft Windows
  - AIX Version 4 Release 1.4
  - HP-UX Version 10.2 or later
  - Sun Solaris Release 2.4 or later
  - IBM i
  - TCP for z/OS
  - HP Tru64 UNIX
- NetBIOS
- SPX

**Related information:**

Configuring

 Configuring z/OS

**How to use the communication examples**

The example-configurations describe the tasks that are carried out on a single platform to set up communication to another of the platforms. Then they describe the tasks to establish a working channel to that platform.

Wherever possible, the intention is to make the information as generic as possible. Thus, to connect any two queue managers on different platforms, you need to refer to only the relevant two sections. Any deviations or special cases are highlighted as such. You can also connect two queue managers running on the same platform (on different machines or on the same machine). In this case, all the information can be derived from the one section.

If you are using a Windows, UNIX or Linux system, before you begin to follow the instructions for your platform, you must set various environment variables. Set the environment variables by entering one of the following commands :

- On Windows:
 

```
MQ_INSTALLATION_PATH/bin/setmqenv
```

where *MQ\_INSTALLATION\_PATH* refers to the location where IBM MQ is installed.

- On UNIX and Linux systems:
 

```
. MQ_INSTALLATION_PATH/bin/setmqenv
```

where *MQ\_INSTALLATION\_PATH* refers to the location where IBM MQ is installed. This command sets the environment variables for the shell you are currently working in. If you open another shell, you must enter the command again.

There are worksheets in which you can find the parameters used in the example configurations. There is a short description of each parameter and some guidance on where to find the equivalent values in your system. When you have a set of values of your own, record these values in the spaces on the worksheet. As you proceed through the section, you will find cross-references to these values as you need them.

The examples do not cover how to set up communications where clustering is being used. For information about setting up communications while using clustering, see Configuring a queue manager cluster. The communication configuration values given here still apply.

There are example configurations for the following platforms:

- “Example configuration - IBM MQ for Windows”
- “Example configuration - IBM MQ for AIX” on page 13
- “Example configuration - IBM MQ for HP-UX” on page 19
- “Example configuration - IBM MQ for Solaris” on page 25
- “Example configuration - IBM MQ for Linux” on page 31
-  “Example configuration - IBM MQ for z/OS” on page 37
-  “Example configuration - IBM MQ for z/OS using queue-sharing groups” on page 42
-  “Example configuration - IBM MQ for z/OS using intra-group queuing” on page 49
-  “Example configuration - IBM MQ for IBM i” on page 57

## IT responsibilities

To understand the terminology used in the examples, consider the following guidelines as a starting point.

- System administrator: The person (or group of people) who installs and configures the software for a specific platform.
- Network administrator: The person who controls LAN connectivity, LAN address assignments, network naming conventions, and other network tasks. This person can be in a separate group or can be part of the system administration group.

In most z/OS installations, there is a group responsible for updating the ACF/VTAM, ACF/NCP, and TCP/IP software to support the network configuration. The people in this group are the main source of information needed when connecting any IBM MQ platform to IBM MQ for z/OS. They can also influence or mandate network naming conventions on LANs and you must verify their span of control before creating your definitions.

- A specific type of administrator, for example CICS<sup>®</sup> administrator, is indicated in cases where we can more clearly describe the responsibilities of the person.

The example-configuration sections do not attempt to indicate who is responsible for and able to set each parameter. In general, several different people might be involved.

### Related concepts:

“Example configuration information for all platforms” on page 1

The configuration examples describe tasks performed to establish a working IBM MQ network. The tasks are to establish IBM MQ sender and receiver channels to enable bidirectional message flow between the platforms over all supported protocols.

### Related information:

setmqenv

Use the **setmqenv** command to set up the IBM MQ environment on UNIX, Linux, and Windows.

## Example configuration - IBM MQ for Windows

This section gives an example of how to set up communication links from IBM MQ for Windows to IBM MQ products.

Set up of communication links are shown on the following platforms:

- AIX
- HP Tru64 UNIX
- HP-UX
- Solaris
- Linux
- IBM i

- z/OS
- VSE/ESA

When the connection is established, you must define some channels to complete the configuration. Example programs and commands for configuration are described in “IBM MQ for Windows configuration” on page 6.

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

### **Establishing an LU 6.2 connection:**

Reference to information about configuring AnyNet<sup>®</sup> SNA over TCP/IP.

For the latest information about configuring AnyNet SNA over TCP/IP, see the following online IBM documentation: AnyNet SNA over TCP/IP, SNA Node Operations, and Communications Server for Windows

### **Establishing a TCP connection:**

The TCP stack that is shipped with Windows systems does not include an *inet* daemon or equivalent.

The IBM MQ command used to start the IBM MQ for TCP listener is:

```
runmq1sr -t tcp
```

The listener must be started explicitly before any channels are started. It enables receiving channels to start automatically in response to a request from an inbound sending channel.

### **What next?**

When the TCP/IP connection is established, you are ready to complete the configuration. Go to “IBM MQ for Windows configuration” on page 6.

### **Establishing a NetBIOS connection:**

A NetBIOS connection is initiated from a queue manager that uses the ConnectionName parameter on its channel definition to connect to a target listener.

To set up a NetBIOS connection, follow these steps:

1. At each end of the channel specify the local NetBIOS name to be used by the IBM MQ channel processes in the queue manager configuration file qm.ini. For example, the NETBIOS stanza in Windows at the sending end might look like the following:

```
NETBIOS:
  LocalName=WNTNETB1
```

and at the receiving end:

```
NETBIOS:
  LocalName=WNTNETB2
```

Each IBM MQ process must use a different local NetBIOS name. Do not use your system name as the NetBIOS name because Windows already uses it.

2. At each end of the channel, verify the LAN adapter number being used on your system. The IBM MQ for Windows default for logical adapter number 0 is NetBIOS running over an Internet Protocol network. To use native NetBIOS you must select logical adapter number 1. See Establishing the LAN adapter number.

Specify the correct LAN adapter number in the NETBIOS stanza of the Windows registry. For example:

```
NETBIOS:
  AdapterNum=1
```

3. So that sender channel initiation works, specify the local NetBIOS name by the MQNAME environment variable:

```
SET MQNAME=WNTNETB1I
```

This name must be unique.

4. At the sending end, define a channel specifying the NetBIOS name being used at the other end of the channel. For example:

```
DEFINE CHANNEL (WINNT.OS2.NET) CHLTYPE(SDR) +
  TRPTYPE(NETBIOS) +
  CONNAME(WNTNETB2) +
  XMITQ(OS2) +
  MCATYPE(THREAD) +
  REPLACE
```

You must specify the option MCATYPE(THREAD) because, on Windows, sender channels must be run as threads.

5. At the receiving end, define the corresponding receiver channel. For example:

```
DEFINE CHANNEL (WINNT.OS2.NET) CHLTYPE(RCVR) +
  TRPTYPE(NETBIOS) +
  REPLACE
```

6. Start the channel initiator because each new channel is started as a thread rather than as a new process.

```
runmqchi
```

7. At the receiving end, start the IBM MQ listener:

```
runmqlsr -t netbios
```

Optionally you can specify values for the queue manager name, NetBIOS local name, number of sessions, number of names, and number of commands. See *Defining a NetBIOS connection on Windows* for more information about setting up NetBIOS connections.

## IBM MQ for Windows configuration:

Example programs and commands for configuration.

### Note:

1. You can use the sample program, AMQSBCG, to show the contents and headers of all the messages in a queue. For example:

```
AMQSBCG q_name qmgr_name
```

shows the contents of the queue *q\_name* defined in queue manager *qmgr\_name*.

Alternatively, you can use the message browser in the IBM MQ Explorer.

2. You can start any channel from the command prompt using the command

```
runmqchl -c channel.name
```

3. Error logs can be found in the directories *MQ\_INSTALLATION\_PATH*\qmgrs\*qmgrname* \errors and *MQ\_INSTALLATION\_PATH*\qmgrs\@system\errors. In both cases, the most recent messages are at the end of amqerr01.log.

*MQ\_INSTALLATION\_PATH* represents the high-level directory in which IBM MQ is installed.

4. When you are using the command interpreter **runmqsc** to enter administration commands, a + at the end of a line indicates that the next line is a continuation. Ensure that there is a space between the last parameter and the continuation character.

### *Default configuration:*

You can create a default configuration by using the IBM MQ Postcard application to guide you through the process.

For information about using the Postcard application, see [Verify the installation using the Postcard application](#).

### *Basic configuration:*

You can create and start a queue manager from the IBM MQ Explorer or from the command prompt.

.If you choose the command prompt:

1. Create the queue manager using the command:

```
crtmqm -u dlqname -q winnt
```

where:

*winnt* Is the name of the queue manager

**-q** Indicates that this is to become the default queue manager

**-u *dlqname***

Specifies the name of the undeliverable message queue

This command creates a queue manager and a set of default objects.

2. Start the queue manager using the command:

```
strmqm winnt
```

where *winnt* is the name given to the queue manager when it was created.

### *Channel configuration for Windows:*

Example configuration to be performed on the Windows queue manager to implement a given channel.

The following sections detail the configuration to be performed on the Windows queue manager to implement the channel described in “[Example configuration information for all platforms](#)” on page 1.

In each case the MQSC command is shown. Either start **runmqsc** from a command prompt and enter each command in turn, or build the commands into a command file.

Examples are given for connecting IBM MQ for Windows and IBM MQ for AIX. To connect to IBM MQ on another platform use the appropriate set of values from the table in place of those for Windows.

**Note:** The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and should be entered as shown.

Table 1. Configuration worksheet for IBM MQ for Windows

	Parameter Name	Reference	Example Used	User Value
<b>Definition for local node</b>				
A	Queue Manager Name		WINNT	
B	Local queue name		WINNT.LOCALQ	
<b>Connection to IBM MQ for AIX</b>				
The values in this section of the table must match those used in "Channel configuration for AIX" on page 15, as indicated.				
C	Remote queue manager name	A	AIX	
D	Remote queue name		AIX.REMOTEQ	
E	Queue name at remote system	B	AIX.LOCALQ	
F	Transmission queue name		AIX	
G	Sender (SNA) channel name		WINNT.AIX.SNA	
H	Sender (TCP) channel name		WINNT.AIX.TCP	
I	Receiver (SNA) channel name	G	AIX.WINNT.SNA	
J	Receiver (TCP) channel name	H	AIX.WINNT.TCP	
<b>Connection to IBM MQ for HP Tru64 UNIX</b>				
The values in this section of the table must match those used in your HP Tru64 UNIX system.				
C	Remote queue manager name	A	DECUX	
D	Remote queue name		DECUX.REMOTEQ	
E	Queue name at remote system	B	DECUX.LOCALQ	
F	Transmission queue name		DECUX	
H	Sender (TCP) channel name		DECUX.WINNT.TCP	
J	Receiver (TCP) channel name	H	WINNT.DECUX.TCP	
<b>Connection to IBM MQ for HP-UX</b>				
The values in this section of the table must match those used in "Channel configuration for HP-UX" on page 21, as indicated.				
C	Remote queue manager name	A	HPUX	
D	Remote queue name		HPUX.REMOTEQ	
E	Queue name at remote system	B	HPUX.LOCALQ	
F	Transmission queue name		HPUX	
G	Sender (SNA) channel name		WINNT.HPUX.SNA	
H	Sender (TCP) channel name		WINNT.HPUX.TCP	
I	Receiver (SNA) channel name	G	HPUX.WINNT.SNA	
J	Receiver (TCP/IP) channel name	H	HPUX.WINNT.TCP	
<b>Connection to IBM MQ for Solaris</b>				
The values in this section of the table must match those used in "Channel configuration for Solaris" on page 27, as indicated.				
C	Remote queue manager name	A	SOLARIS	
D	Remote queue name		SOLARIS.REMOTEQ	
E	Queue name at remote system	B	SOLARIS.LOCALQ	
F	Transmission queue name		SOLARIS	

Table 1. Configuration worksheet for IBM MQ for Windows (continued)

	Parameter Name	Reference	Example Used	User Value
G	Sender (SNA) channel name		WINNT.SOLARIS.SNA	
H	Sender (TCP) channel name		WINNT.SOLARIS.TCP	
I	Receiver (SNA) channel name	G	SOLARIS.WINNT.SNA	
J	Receiver (TCP) channel name	H	SOLARIS.WINNT.TCP	
<b>Connection to IBM MQ for Linux</b>				
The values in this section of the table must match those used in "Channel configuration for Linux" on page 34, as indicated.				
C	Remote queue manager name	A	LINUX	
D	Remote queue name		LINUX.REMOTEQ	
E	Queue name at remote system	B	LINUX.LOCALQ	
F	Transmission queue name		LINUX	
G	Sender (SNA) channel name		WINNT.LINUX.SNA	
H	Sender (TCP) channel name		WINNT.LINUX.TCP	
I	Receiver (SNA) channel name	G	LINUX.WINNT.SNA	
J	Receiver (TCP) channel name	H	LINUX.WINNT.TCP	
<b>IBM i Connection to IBM MQ for IBM i</b>				
<b>IBM i</b> The values in this section of the table must match those used in "Channel configuration for IBM i" on page 71, as indicated.				
C	Remote queue manager name	A	AS400	
D	Remote queue name		AS400.REMOTEQ	
E	Queue name at remote system	B	AS400.LOCALQ	
F	Transmission queue name		AS400	
G	Sender (SNA) channel name		WINNT.AS400.SNA	
H	Sender (TCP) channel name		WINNT.AS400.TCP	
I	Receiver (SNA) channel name	G	AS400.WINNT.SNA	
J	Receiver (TCP) channel name	H	AS400.WINNT.TCP	
<b>z/OS Connection to IBM MQ for z/OS</b>				
<b>z/OS</b> The values in this section of the table must match those used in "Channel configuration for z/OS" on page 38, as indicated.				
C	Remote queue manager name	A	MVS	
D	Remote queue name		MVS.REMOTEQ	
E	Queue name at remote system	B	MVS.LOCALQ	
F	Transmission queue name		MVS	
G	Sender (SNA) channel name		WINNT.MVS.SNA	
H	Sender (TCP) channel name		WINNT.MVS.TCP	
I	Receiver (SNA) channel name	G	MVS.WINNT.SNA	
J	Receiver (TCP/IP) channel name	H	MVS.WINNT.TCP	

Table 1. Configuration worksheet for IBM MQ for Windows (continued)

	Parameter Name	Reference	Example Used	User Value
<b>z/OS</b> Connection to IBM MQ for z/OS using queue-sharing groups				
<b>z/OS</b> The values in this section of the table must match those used in "Shared channel configuration example" on page 47, as indicated.				
C	Remote queue manager name	A	QSG	
D	Remote queue name		QSG.REMOTEQ	
E	Queue name at remote system	B	QSG.SHAREDQ	
F	Transmission queue name		QSG	
G	Sender (SNA) channel name		WINNT.QSG.SNA	
H	Sender (TCP) channel name		WINNT.QSG.TCP	
I	Receiver (SNA) channel name	G	QSG.WINNT.SNA	
<b>z/OS</b>	Receiver (TCP/IP) channel name	H	QSG.WINNT.TCP	
<b>Connection to MQSeries® for VSE/ESA</b>				
The values in this section of the table must match those used in your VSE/ESA system.				
C	Remote queue manager name	A	VSE	
D	Remote queue name		VSE.REMOTEQ	
E	Queue name at remote system	B	VSE.LOCALQ	
F	Transmission queue name		VSE	
G	Sender channel name		WINNT.VSE.SNA	
I	Receiver channel name	G	VSE.WINNT.SNA	

IBM MQ for Windows sender-channel definitions using SNA:

A code sample.

```
def ql (AIX) +                                     F
  usage(xmitq) +
  replace

def qr (AIX.REMOTEQ) +                             D
  rname(AIX.LOCALQ) +                             E
  rqmname(AIX) +                                   C
  xmitq(AIX) +                                     F
  replace

def chl (WINNT.AIX.SNA) chltype(sdr) +             G
  trptype(lu62) +
  conname(AIXCPIC) +                               18
  xmitq(AIX) +                                     F
  replace
```

*IBM MQ for Windows receiver-channel definitions using SNA:*

A code sample.

```
def ql (WINNT.LOCALQ) replace B
def chl (AIX.WINNT.SNA) chltype(rcvr) + I
  trptype(lu62) +
  replace
```

*IBM MQ for Windows sender-channel definitions using TCP/IP:*

A code sample.

```
def ql (AIX) + F
  usage(xmitq) +
  replace

def qr (AIX.REMOTEQ) + D
  rname(AIX.LOCALQ) + E
  rqmname(AIX) + C
  xmitq(AIX) + F
  replace

def chl (WINNT.AIX.TCP) chltype(sdr) + H
  trptype(tcp) +
  conname(remote_tcpip_hostname) +
  xmitq(AIX) + F
  replace
```

*IBM MQ for Windows receiver-channel definitions using TCP:*

A code sample.

```
def ql (WINNT.LOCALQ) replace B
def chl (AIX.WINNT.TCP) chltype(rcvr) + J
  trptype(tcp) +
  replace
```

*Automatic startup:*

IBM MQ for Windows allows you to automate the startup of a queue manager and its channel initiator, channels, listeners, and command servers.

Use the IBM MQ Services snap-in to define the services for the queue manager. When you have successfully completed testing of your communications setup, set the relevant services to **automatic** within the snap-in. This file can be read by the supplied IBM MQ service when the system is started.

For more information, see *Administering IBM MQ* .

*Running channels as processes or threads:*

IBM MQ for Windows provides the flexibility to run sending channels as Windows processes or Windows threads. This is specified in the `MCTYPE` parameter on the sender channel definition.

Most installations run their sending channels as threads, because the virtual and real memory required to support many concurrent channel connections is reduced. However, a NetBIOS connection needs a separate process for the sending Message Channel Agent.

*Multiple thread support - pipelining:*

You can optionally allow a message channel agent (MCA) to transfer messages using multiple threads. This process, called *pipelining*, enables the MCA to transfer messages more efficiently, with fewer wait states, which improves channel performance. Each MCA is limited to a maximum of two threads.

You control pipelining with the `PipeLineLength` parameter in the `qm.ini` file. This parameter is added to the CHANNELS stanza:

**PipeLineLength= 1 | number**

This attribute specifies the maximum number of concurrent threads a channel uses. The default is 1. Any value greater than 1 is treated as 2.

With IBM MQ for Windows, use the IBM MQ Explorer to set the `PipeLineLength` parameter in the registry. See The Channels stanza for a complete description of the CHANNELS stanza.

**Note:**

1. `PipeLineLength` applies only to V5.2 or later products.
2. Pipelining is effective only for TCP/IP channels.

When you use pipelining, the queue managers at both ends of the channel must be configured to have a `PipeLineLength` greater than 1.

**Channel exit considerations**

Pipelining can cause some exit programs to fail, because:

- Exits might not be called serially.
- Exits might be called alternately from different threads.

Check the design of your exit programs before you use pipelining:

- Exits must be reentrant at all stages of their execution.
- When you use MQI calls, remember that you cannot use the same MQI handle when the exit is invoked from different threads.

Consider a message exit that opens a queue and uses its handle for MQPUT calls on all subsequent invocations of the exit. This fails in pipelining mode because the exit is called from different threads. To avoid this failure, keep a queue handle for each thread and check the thread identifier each time the exit is invoked.

## Example configuration - IBM MQ for AIX

This section gives an example of how to set up communication links from IBM MQ for AIX to IBM MQ products.

The following platforms are covered in the examples:

- Windows
- HP Tru64 UNIX
- HP-UX
- Solaris
- Linux
- IBM i
- z/OS
- VSE/ESA

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

### Establishing an LU 6.2 connection:

Describes the parameters needed for an LU 6.2 connection.

For the latest information about configuring SNA over TCP/IP, refer to the following online IBM documentation: Communications Server for AIX.

### Establishing a TCP connection:

The listener must be started explicitly before any channels are started. It enables receiving channels to start automatically in response to a request from an inbound sending channel.

The IBM MQ command used to start the IBM MQ for TCP listener is:

```
runmq1sr -t tcp
```

Alternatively, if you want to use the UNIX supplied TCP/IP listener, complete the following steps:

1. Edit the file `/etc/services`.

**Note:** To edit the `/etc/services` file, you must be logged in as a superuser or root. If you do not have the following line in that file, add it as shown:

```
MQSeries      1414/tcp      # MQSeries channel listener
```

2. Edit the file `/etc/inetd.conf`. If you do not have the following line in that file, add it as shown, replacing `MQ_INSTALLATION_PATH` with the high-level directory in which IBM MQ is installed:

```
MQSeries stream tcp nowait root MQ_INSTALLATION_PATH/bin/amqcrsta amqcrsta  
[-m queue.manager.name]
```

3. Enter the command `refresh -s inetd`.

**Note:** You must add `root` to the `mqm` group. You need not have the primary group set to `mqm`. As long as `mqm` is in the set of groups, you can use the commands. If you are running only applications that use the queue manager you do not need `mqm` group authority.

### What next?

The connection is now established. You are ready to complete the configuration. Go to “IBM MQ for AIX configuration” on page 14.

## IBM MQ for AIX configuration:

Defining channels to complete the configuration.

### Note:

1. Before beginning the installation process ensure that you have first created the *mqm* user and group, and set the password.
2. If installation fails as a result of insufficient space in the file system you can increase the size as follows, using the command `smit C sna`. (Use `df` to display the status of the file system. This indicates the logical volume that is full.)
  - Physical and Logical Storage
  - File Systems
    - Add / Change / Show / Delete File Systems
    - Journalled File Systems
      - Change/Show Characteristics of a Journalled File System
3. Start any channel using the command:  
`runmqchl -c channel.name`
4. Sample programs are installed in `MQ_INSTALLATION_PATH/samp`, where `MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.
5. Error logs are stored in `/var/mqm/qmgrs/qmgrname/errors`.
6. On AIX, you can start a trace of the IBM MQ components by using standard IBM MQ trace commands, or using AIX system trace. See Using trace for more information about IBM MQ Trace and AIX system trace.
7. When you are using the command interpreter `runmqsc` to enter administration commands, a `+` at the end of a line indicates that the next line is a continuation. Ensure that there is a space between the last parameter and the continuation character.

### Basic configuration

1. Create the queue manager from the AIX command line using the command:

```
crtmqm -u dlqname -q aix
```

where:

*aix* Is the name of the queue manager

**-q** Indicates that this is to become the default queue manager

**-u dlqname**

Specifies the name of the undeliverable message queue

This command creates a queue manager and a set of default objects.

2. Start the queue manager from the AIX command line using the command:

```
strmqm aix
```

where *aix* is the name given to the queue manager when it was created.

3. Start `runmqsc` from the AIX command line and use it to create the undeliverable message queue by entering the command:

```
def ql (dlqname)
```

where *dlqname* is the name given to the undeliverable message queue when the queue manager was created.

*Channel configuration for AIX:*

Includes information about configuring a queue manager for a given channel and platform.

The following section details the configuration to be performed on the AIX queue manager to implement the channel described in “Example configuration information for all platforms” on page 1.

In each case the MQSC command is shown. Either start **runmqsc** from an AIX command line and enter each command in turn, or build the commands into a command file.

Examples are given for connecting IBM MQ for AIX and IBM MQ for Windows. To connect to IBM MQ on another platform use the appropriate set of values from the table in place of those for Windows.

**Note:** The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and should be entered as shown.

*Table 2. Configuration worksheet for IBM MQ for AIX*

ID	Parameter Name	Reference	Example Used	User Value
<i>Definition for local node</i>				
A	Queue Manager Name		<b>AIX</b>	
B	Local queue name		<b>AIX.LOCALQ</b>	
<i>Connection to IBM MQ for Windows</i>				
The values in this section of the table must match those used in “Channel configuration for Windows” on page 7, as indicated.				
C	Remote queue manager name	A	<b>WINNT</b>	
D	Remote queue name		<b>WINNT.REMOTEQ</b>	
E	Queue name at remote system	B	<b>WINNT.LOCALQ</b>	
F	Transmission queue name		<b>WINNT</b>	
G	Sender (SNA) channel name		<b>AIX.WINNT.SNA</b>	
H	Sender (TCP/IP) channel name		<b>AIX.WINNT.TCP</b>	
I	Receiver (SNA) channel name	G	<b>WINNT.AIX.SNA</b>	
J	Receiver (TCP) channel name	H	<b>WINNT.AIX.TCP</b>	
<i>Connection to IBM MQ for HP Tru64 UNIX</i>				
The values in this section of the table must match those used in your HP Tru64 UNIX system.				
C	Remote queue manager name	A	<b>DECUX</b>	
D	Remote queue name		<b>DECUX.REMOTEQ</b>	
E	Queue name at remote system	B	<b>DECUX.LOCALQ</b>	
F	Transmission queue name		<b>DECUX</b>	
H	Sender (TCP) channel name		<b>DECUX.AIX.TCP</b>	
J	Receiver (TCP) channel name	H	<b>AIX.DECUX.TCP</b>	
<i>Connection to IBM MQ for HP-UX</i>				
The values in this section of the table must match those used in “Channel configuration for HP-UX” on page 21, as indicated.				
C	Remote queue manager name	A	<b>HPUX</b>	
D	Remote queue name		<b>HPUX.REMOTEQ</b>	

Table 2. Configuration worksheet for IBM MQ for AIX (continued)

ID	Parameter Name	Reference	Example Used	User Value
E	Queue name at remote system	B	HPUX.LOCALQ	
F	Transmission queue name		HPUX	
G	Sender (SNA) channel name		AIX.HPUX.SNA

G	Sender channel name		AIX.VSE.SNA	
I	Receiver channel name	G	VSE.AIX.SNA	

*IBM MQ for AIX sender-channel definitions using SNA:*

Example commands.

```
def ql (WINNT) +                               F
  usage(xmitq) +
  replace

def qr (WINNT.REMOTEQ) +                       D
  rname(WINNT.LOCALQ) +                       E
  rqmname(WINNT) +                             C
  xmitq(WINNT) +                               F
  replace

def chl (AIX.WINNT.SNA) chltype(sdr) +        G
  trptype(lu62) +
  conname('WINNTCPIC') +                     17
  xmitq(WINNT) +                               F
  replace
```

*IBM MQ for AIX receiver-channel definitions using SNA:*

Example commands.

```
def ql (AIX.LOCALQ) replace                    B

def chl (WINNT.AIX.SNA) chltype(rcvr) +      I
  trptype(lu62) +
  replace
```

*IBM MQ for AIX TPN setup:*

Alternative ways of ensuring that SNA receiver channels activate correctly when a sender channel initiates a conversation.

During the AIX Communications Server configuration process, an LU 6.2 TPN profile was created, which contained the full path to a TP executable program. In the example, the file was called `u/interops/AIX.crs6a`. You can choose a name, but consider including the name of your queue manager in it. The contents of the executable file must be:

```
#!/bin/sh
MQ_INSTALLATION_PATH/bin/amqcrs6a -m aix
```

where `aix` is the queue manager name (A) and `MQ_INSTALLATION_PATH` is the high-level directory in which IBM MQ is installed. After creating this file, enable it for execution by running the command:

```
chmod 755 /u/interops/AIX.crs6a
```

As an alternative to creating an executable file, you can specify the path on the Add LU 6.2 TPN Profile panel, using command-line parameters.

Specifying a path in one of these two ways ensures that SNA receiver channels activate correctly when a sender channel initiates a conversation.

*IBM MQ for AIX sender-channel definitions using TCP:*

Example commands.

```
def ql (WINNT) +                F
  usage(xmitq) +
  replace

def qr (WINNT.REMOTEQ) +       D
  rname(WINNT.LOCALQ) +       E
  rqmname(WINNT) +            C
  xmitq(WINNT) +              F
  replace

def chl (AIX.WINNT.TCP) chltype(sdr) + H
  trptype(tcp) +
  conname(remote_tcpip_hostname) +
  xmitq(WINNT) +              F
  replace
```

*IBM MQ for AIX receiver-channel definitions using TCP:*

Example commands.

```
def ql (AIX.LOCALQ) replace    B

def chl (WINNT.AIX.TCP) chltype(rcvr) + J
  trptype(tcp) +
  replace
```

## **Example configuration - IBM MQ for HP-UX**

This section gives an example of how to set up communication links from IBM MQ for HP-UX to IBM MQ products.

The following platforms are included:

- Windows
- AIX
- HP Tru64 UNIX
- Solaris
- Linux
- IBM i
- z/OS
- VSE/ESA

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

## Establishing an LU 6.2 connection:

Describes the parameters needed for an LU 6.2 connection

For the latest information about configuring SNA over TCP/IP, refer to the following online IBM documentation: Communications Server, and the following online HP documentation: HP-UX SNAplus2 Installation Guide.

## Establishing a TCP connection:

Alternative ways of establishing a connection and next steps.

The listener must be started explicitly before any channels are started. It enables receiving channels to start automatically in response to a request from an inbound sending channel.

Alternatively, if you want to use the UNIX supplied TCP/IP listener, complete the following steps:

1. Edit the file `/etc/services`.

**Note:** To edit the `/etc/services` file, you must be logged in as a superuser or root. If you do not have the following line in that file, add it as shown:

```
MQSeries      1414/tcp      # MQSeries channel listener
```

2. Edit the file `/etc/inetd.conf`. If you do not have the following line in that file, add it as shown, replacing `MQ_INSTALLATION_PATH` with the high-level directory in which IBM MQ is installed.

```
MQSeries stream tcp nowait root MQ_INSTALLATION_PATH/bin/amqcrsta amqcrsta  
[-m queue.manager.name]
```

3. Find the process ID of the `inetd` with the command:

```
ps -ef | grep inetd
```

4. Run the command:

```
kill -1 inetd processid
```

**Note:** You must add **root** to the `mqm` group. You do not need not have the primary group set to `mqm`. As long as `mqm` is in the set of groups, you can use the commands. If you are running only applications that use the queue manager you do not need to have `mqm` group authority.

## What next?

The connection is now established. You are ready to complete the configuration. Go to “IBM MQ for HP-UX configuration” on page 21.

## IBM MQ for HP-UX configuration:

Describes defining the channels to complete the configuration.

Before beginning the installation process ensure that you have first created the *mqm* user and group, and set the password.

Start any channel using the command:

```
runmqchl -c channel.name
```

### Note:

1. Sample programs are installed in *MQ\_INSTALLATION\_PATH/samp*, where *MQ\_INSTALLATION\_PATH* represents the high-level directory in which IBM MQ is installed.
2. Error logs are stored in */var/mqm/qmgrs/qmgrname/errors*.
3. When you are using the command interpreter **runmqsc** to enter administration commands, a + at the end of a line indicates that the next line is a continuation. Ensure that there is a space between the last parameter and the continuation character.

### Basic configuration

1. Create the queue manager from the UNIX prompt using the command:

```
crtmqm -u dlqname -q hpux
```

where:

*hpux* Is the name of the queue manager

**-q** Indicates that this is to become the default queue manager

**-u *dlqname***

Specifies the name of the undeliverable message queue

This command creates a queue manager and a set of default objects. It sets the DEADQ attribute of the queue manager but does not create the undeliverable message queue.

2. Start the queue manager from the UNIX prompt using the command:

```
strmqm hpux
```

where *hpux* is the name given to the queue manager when it was created.

### Channel configuration for HP-UX:

Includes information about configuring a queue manager for a given channel and platform.

The following section details the configuration to be performed on the HP-UX queue manager to implement the channel described in "Example configuration information for all platforms" on page 1.

In each case the MQSC command is shown. Either start **runmqsc** from a UNIX prompt and enter each command in turn, or build the commands into a command file.

Examples are given for connecting IBM MQ for HP-UX and IBM MQ for Windows. To connect to IBM MQ on another platform use the appropriate set of values from the table in place of those for Windows.

**Note:** The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and should be entered as shown.

Table 3. Configuration worksheet for IBM MQ for HP-UX

ID	Parameter Name	Reference	Example Used	User Value
<b>Definition for local node</b>				
A	Queue Manager Name		HPUX	
B	Local queue name		HPUX.LOCALQ	
<b>Connection to IBM MQ for Windows</b>				
The values in this section of the table must match those used in "Channel configuration for Windows" on page 7, as indicated.				
C	Remote queue manager name	A	WINNT	
D	Remote queue name		WINNT.REMOTEQ	
E	Queue name at remote system	B	WINNT.LOCALQ	
F	Transmission queue name		WINNT	
G	Sender (SNA) channel name		HPUX.WINNT.SNA	
H	Sender (TCP/IP) channel name		HPUX.WINNT.TCP	
I	Receiver (SNA) channel name	G	WINNT.HPUX.SNA	
J	Receiver (TCP) channel name	H	WINNT.HPUX.TCP	
<b>Connection to IBM MQ for AIX</b>				
The values in this section of the table must match those used in Table 2 on page 15, as indicated.				
C	Remote queue manager name	A	AIX	
D	Remote queue name		AIX.REMOTEQ	
E	Queue name at remote system	B	AIX.LOCALQ	
F	Transmission queue name		AIX	
G	Sender (SNA) channel name		HPUX.AIX.SNA	
H	Sender (TCP) channel name		HPUX.AIX.TCP	
I	Receiver (SNA) channel name	G	AIX.HPUX.SNA	
J	Receiver (TCP) channel name	H	AIX.HPUX.TCP	
<b>Connection to IBM MQ for HP Tru64 UNIX</b>				
The values in this section of the table must match those used in your HP Tru64 UNIX system.				
C	Remote queue manager name	A	DECUX	
D	Remote queue name		DECUX.REMOTEQ	
E	Queue name at remote system	B	DECUX.LOCALQ	
F	Transmission queue name		DECUX	
H	Sender (TCP) channel name		DECUX.HPUX.TCP	
J	Receiver (TCP) channel name	H	HPUX.DECUX.TCP	
<b>Connection to IBM MQ for Solaris</b>				
The values in this section of the table must match those used in Table 4 on page 27, as indicated.				
C	Remote queue manager name	A	SOLARIS	
D	Remote queue name		SOLARIS.REMOTEQ	
E	Queue name at remote system	B	SOLARIS.LOCALQ	
F	Transmission queue name		SOLARIS	
G	Sender (SNA) channel name		HPUX.SOLARIS.SNA	

Table 3. Configuration worksheet for IBM MQ for HP-UX (continued)

ID	Parameter Name	Reference	Example Used	User Value
H	Sender (TCP/IP) channel name		HPUX.SOLARIS.TCP	
I	Receiver (SNA) channel name	G	SOLARIS.HPUX.SNA	
J	Receiver (TCP/IP) channel name	H	SOLARIS.HPUX.TCP	
<b>Connection to IBM MQ for Linux</b>				
The values in this section of the table must match those used in Table 5 on page 34, as indicated.				
C	Remote queue manager name	A	LINUX	
D	Remote queue name		LINUX.REMOTEQ	
E	Queue name at remote system	B	LINUX.LOCALQ	
F	Transmission queue name		LINUX	
G	Sender (SNA) channel name		HPUX.LINUX.SNA	
H	Sender (TCP/IP) channel name		HPUX.LINUX.TCP	
I	Receiver (SNA) channel name	G	LINUX.HPUX.SNA	
J	Receiver (TCP/IP) channel name	H	LINUX.HPUX.TCP	
<b>IBM i Connection to IBM MQ for IBM i</b>				
<b>IBM i</b> The values in this section of the table must match those used in Table 10 on page 71, as indicated.				
C	Remote queue manager name	A	AS400	
D	Remote queue name		AS400.REMOTEQ	
E	Queue name at remote system	B	AS400.LOCALQ	
F	Transmission queue name		AS400	
G	Sender (SNA) channel name		HPUX.AS400.SNA	
H	Sender (TCP/IP) channel name		HPUX.AS400.TCP	
I	Receiver (SNA) channel name	G	AS400.HPUX.SNA	
<b>IBM i</b>	Receiver (TCP) channel name	H	AS400.HPUX.TCP	
<b>z/OS Connection to IBM MQ for z/OS</b>				
<b>z/OS</b> The values in this section of the table must match those used in Table 6 on page 39, as indicated.				
C	Remote queue manager name	A	MVS	
D	Remote queue name		MVS.REMOTEQ	
E	Queue name at remote system	B	MVS.LOCALQ	
F	Transmission queue name		MVS	
G	Sender (SNA) channel name		HPUX.MVS.SNA	
H	Sender (TCP) channel name		HPUX.MVS.TCP	
I	Receiver (SNA) channel name	G	MVS.HPUX.SNA	
<b>z/OS</b>	Receiver (TCP) channel name	H	MVS.HPUX.TCP	
<b>Connection to MQSeries for VSE/ESA</b>				
The values in this section of the table must match those used in your VSE/ESA system.				
C	Remote queue manager name	A	VSE	
D	Remote queue name		VSE.REMOTEQ	

Table 3. Configuration worksheet for IBM MQ for HP-UX (continued)

ID	Parameter Name	Reference	Example Used	User Value
E	Queue name at remote system	B	VSE.LOCALQ	
F	Transmission queue name		VSE	
G	Sender channel name		HPUX.VSE.SNA	
I	Receiver channel name	G	VSE.HPUX.SNA	

IBM MQ for HP-UX sender-channel definitions using SNA:

Example commands.

```
def ql (WINNT) +                F
    usage(xmitq) +
    replace

def qr (WINNT.REMOTEQ) +        D
    rname(WINNT.LOCALQ) +      E
    rqmname(WINNT) +           C
    xmitq(WINNT) +             F
    replace

def chl (HPUX.WINNT.SNA) chltype(sdr) + G
    trptype(lu62) +
    conname('WINNTCPIC') +    16
    xmitq(WINNT) +           F
    replace
```

IBM MQ for HP-UX receiver-channel definitions using SNA:

Example commands.

```
def ql (HPUX.LOCALQ) replace    B

def chl (WINNT.HPUX.SNA) chltype(rcvr) + I
    trptype(lu62) +
    replace
```

IBM MQ for HP-UX invocable TP setup:

Ensuring that SNA receiver channels activate correctly when a sender channel initiates a conversation.

This is not required for HP SNAplus2 Release 6.

During the HP SNAplus2 configuration process, you created an invocable TP definition, which points to an executable file. In the example, the file was called /users/interop/HPUX.crs6a. You can choose what you call this file, but consider including the name of your queue manager in the name. The contents of the executable file must be:

```
#!/bin/sh
MQ_INSTALLATION_PATH/bin/amqcrs6a -m hpux
```

where *hpux* is the name of your queue manager *A* and *MQ\_INSTALLATION\_PATH* is the high-level directory in which IBM MQ is installed.

This ensures that SNA receiver channels activate correctly when a sender channel initiates a conversation.

*IBM MQ for HP-UX sender-channel definitions using TCP:*

Example commands.

```
def ql (WINNT) +                               F
  usage(xmitq) +
  replace

def qr (WINNT.REMOTEQ) +                       D
  rname(WINNT.LOCALQ) +                       E
  rqmname(WINNT) +                             C
  xmitq(WINNT) +                               F
  replace

def chl (HPUX.WINNT.TCP) chltype(sdr) +       H
  trptype(tcp) +
  conname(remote_tcpip_hostname) +
  xmitq(WINNT) +                               F
  replace
```

*IBM MQ for HP-UX receiver-channel definitions using TCP/IP:*

Example commands.

```
def ql (HPUX.LOCALQ) replace                   B

def chl (WINNT.HPUX.TCP) chltype(rcvr) +      J
  trptype(tcp) +
  replace
```

## **Example configuration - IBM MQ for Solaris**

This section gives an example of how to set up communication links from IBM MQ for Solaris to IBM MQ products.

Examples are given on the following platforms:

- Windows
- AIX
- HP Tru64 UNIX
- HP-UX
- Linux
- IBM i
- z/OS
- VSE/ESA

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

## Establishing an LU 6.2 connection using SNAP-IX:

Parameters for configuring an LU 6.2 connection using SNAP-IX.

For the latest information about configuring SNA over TCP/IP, refer to the following online IBM documentation: Communications Server, the following online MetaSwitch documentation: SNAP-IX Administration Guide, and the following online Sun documentation: Configuring Intersystem Communications (ISC).

## Establishing a TCP connection:

Information about configuring a TCP connection and next steps.

To establish a TCP connection, follow these steps.

1. Edit the file `/etc/services`.

**Note:** To edit the `/etc/services` file, you must be logged in as a superuser or root. If you do not have the following line in that file, add it as shown:

```
MQSeries      1414/tcp      # MQSeries channel listener
```

2. Edit the file `/etc/inetd.conf`. If you do not have the following line in that file, add it as shown:

```
MQSeries stream tcp nowait mqm MQ_INSTALLATION_PATH/bin/amqcrsta amqcrsta  
[-m queue.manager.name]
```

`MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

3. Find the process ID of the `inetd` with the command:

```
ps -ef | grep inetd
```

4. Run the appropriate command, as follows:

- For Solaris 9:

```
kill -1 inetd processid
```

- For Solaris 10 or later:

```
inetconv
```

## What next?

The TCP/IP connection is now established. You are ready to complete the configuration. Go to “IBM MQ for Solaris configuration.”

## IBM MQ for Solaris configuration:

Describes channels to be defined to complete the configuration.

Before beginning the installation process ensure that you have first created the `mqm` user and group, and set the password.

Start any channel using the command:

```
runmqchl -c channel.name
```

## Note:

1. Sample programs are installed in `MQ_INSTALLATION_PATH/samp`.

`MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

2. Error logs are stored in `/var/mqm/qmgrs/qmgrname/errors`.

3. When you are using the command interpreter `runmqsc` to enter administration commands, a `+` at the end of a line indicates that the next line is a continuation. Ensure that there is a space between the last parameter and the continuation character.

4. For an SNA or LU6.2 channel, if you experience an error when you try to load the communications library, probably file liblu62.so cannot be found. A likely solution to this problem is to add its location, which is probably /opt/SUNWlu62, to LD\_LIBRARY\_PATH.

### Basic configuration

1. Create the queue manager from the UNIX prompt using the command:

```
crtmqm -u dlqname -q solaris
```

where:

*solaris*

Is the name of the queue manager

**-q** Indicates that this is to become the default queue manager

**-u dlqname**

Specifies the name of the undeliverable message queue

This command creates a queue manager and a set of default objects.

2. Start the queue manager from the UNIX prompt using the command:

```
strmqm solaris
```

where *solaris* is the name given to the queue manager when it was created.

### Channel configuration for Solaris:

The following section details the configuration to be performed on the Solaris queue manager to implement a channel.

The configuration described is to implement the channel described in Figure 1 on page 1.

The MQSC command to create each object is shown. Either start **runmqsc** from a UNIX prompt and enter each command in turn, or build the commands into a command file.

Examples are given for connecting IBM MQ for Solaris and IBM MQ for Windows. To connect to IBM MQ on another platform use the appropriate set of values from the table in place of those for Windows.

**Note:** The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and should be entered as shown.

Table 4. Configuration worksheet for IBM MQ for Solaris

ID	Parameter Name	Reference	Example Used	User Value
<i>Definition for local node</i>				
A	Queue Manager Name		<b>SOLARIS</b>	
B	Local queue name		<b>SOLARIS.LOCALQ</b>	
<i>Connection to IBM MQ for Windows</i>				
The values in this section of the table must match those used in Table 1 on page 8, as indicated.				
C	Remote queue manager name	A	<b>WINNT</b>	
D	Remote queue name		<b>WINNT.REMOTEQ</b>	
E	Queue name at remote system	B	<b>WINNT.LOCALQ</b>	
F	Transmission queue name		<b>WINNT</b>	
G	Sender (SNA) channel name		<b>SOLARIS.WINNT.SNA</b>	

Table 4. Configuration worksheet for IBM MQ for Solaris (continued)

ID	Parameter Name	Reference	Example Used	User Value
H	Sender (TCP/IP) channel name		SOLARIS.WINNT.TCP	
I	Receiver (SNA) channel name	G	WINNT.SOLARIS.SNA	
J	Receiver (TCP) channel name	H	WINNT.SOLARIS.TCP	
<b>Connection to IBM MQ for AIX</b>				
The values in this section of the table must match those used in Table 2 on page 15, as indicated.				
C	Remote queue manager name	A	AIX	
D	Remote queue name		AIX.REMOTEQ	
E	Queue name at remote system	B	AIX.LOCALQ	
F	Transmission queue name		AIX	
G	Sender (SNA) channel name		SOLARIS.AIX.SNA	
H	Sender (TCP) channel name		SOLARIS.AIX.TCP	
I	Receiver (SNA) channel name	G	AIX.SOLARIS.SNA	
J	Receiver (TCP) channel name	H	AIX.SOLARIS.TCP	
<b>Connection to MQSeries for Compaq Tru64 Unix</b>				
The values in this section of the table must match those used in your Compaq Tru64 UNIX system.				
C	Remote queue manager name	A	DECUX	
D	Remote queue name		DECUX.REMOTEQ	
E	Queue name at remote system	B	DECUX.LOCALQ

  xmitq(WINNT) +                               F
  replace
```

*IBM MQ for Solaris receiver-channel definitions using TCP/IP:*

Example coding.

```
def ql (SOLARIS.LOCALQ) replace B
def chl (WINNT.SOLARIS.TCP) chltype(rcvr) + J
  trptype(tcp) +
  replace
```

## Example configuration - IBM MQ for Linux

This section gives an example of how to set up communication links from IBM MQ for Linux to IBM MQ products.

The examples given are on the following platforms:

- Windows
- AIX
- Compaq Tru64 UNIX
- HP-UX
- Solaris
- IBM i
- z/OS
- VSE/ESA

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

### Establishing an LU 6.2 connection:

Use this worksheet to record the values you use for your configuration.

**Note:** The information in this section applies only to IBM MQ for Linux (x86 platform). It does not apply to IBM MQ for Linux (x86-64 platform), IBM MQ for Linux ( zSeries s390x platform), or IBM MQ for Linux ( Power platform).

For the latest information about configuring SNA over TCP/IP, refer to the the Administration Guide for your version of Linux from the following documentation: Communications Server for Linux library.

### Establishing a TCP connection on Linux:

Some Linux distributions now use the extended inet daemon (XINETD) instead of the inet daemon (INETD). The following instructions tell you how to establish a TCP connection using either the inet daemon or the extended inet daemon.

#### Using the inet daemon (INETD)

*MQ\_INSTALLATION\_PATH* represents the high-level directory in which IBM MQ is installed.

To establish a TCP connection, follow these steps.

1. Edit the file `/etc/services`. If you do not have the following line in the file, add it as shown:

```
MQSeries      1414/tcp      # MQSeries channel listener
```

**Note:** To edit this file, you must be logged in as a superuser or root.

2. Edit the file `/etc/inetd.conf`. If you do not have the following line in that file, add it as shown:

```
MQSeries stream tcp nowait mqm MQ_INSTALLATION_PATH/bin/amqcrsta amqcrsta  
[-m queue.manager.name]
```

3. Find the process ID of the inetd with the command:

```
ps -ef | grep inetd
```

4. Run the command:

```
kill -1 inetd processid
```

If you have more than one queue manager on your system, and therefore require more than one service, you must add a line for each additional queue manager to both `/etc/services` and `inetd.conf`.

For example:

```
MQSeries1    1414/tcp  
MQSeries2    1822/tcp
```

```
MQSeries1 stream tcp nowait mqm MQ_INSTALLATION_PATH/bin/amqcrsta amqcrsta -m QM1  
MQSeries2 stream tcp nowait mqm MQ_INSTALLATION_PATH/bin/amqcrsta amqcrsta -m QM2
```

This avoids error messages being generated if there is a limitation on the number of outstanding connection requests queued at a single TCP port. For information about the number of outstanding connection requests, see `Using the TCP listener backlog option`.

The `inetd` process on Linux can limit the rate of inbound connections on a TCP port. The default is 40 connections in a 60 second interval. If you need a higher rate, specify a new limit on the number of inbound connections in a 60 second interval by appending a period (.) followed by the new limit to the `nowait` parameter of the appropriate service in `inetd.conf`. For example, for a limit of 500 connections in a 60 second interval use:

```
MQSeries stream tcp nowait.500 mqm /MQ_INSTALLATION_PATH/bin/amqcrsta amqcrsta -m QM1
```

`MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

### Using the extended inet daemon (XINETD)

The following instructions describe how the extended inet daemon is implemented on Red Hat Linux. If you are using a different Linux distribution, you might have to adapt these instructions.

To establish a TCP connection, follow these steps.

1. Edit the file `/etc/services`. If you do not have the following line in the file, add it as shown:

```
MQSeries    1414/tcp    # MQSeries channel listener
```

**Note:** To edit this file, you must be logged in as a superuser or root.

2. Create a file called `IBM MQ` in the XINETD configuration directory, `/etc/xinetd.d`. Add the following stanza to the file:

```
# WebSphere MQ service for XINETD  
service MQSeries  
{  
    disable          = no  
    flags            = REUSE  
    socket_type      = stream  
    wait            = no  
    user            = mqm  
    server          = MQ_INSTALLATION_PATH/bin/amqcrsta  
    server_args     = -m queue.manager.name  
    log_on_failure += USERID  
}
```

3. Restart the extended inet daemon by issuing the following command:

```
/etc/rc.d/init.d/xinetd restart
```

If you have more than one queue manager on your system, and therefore require more than one service, you must add a line to `/etc/services` for each additional queue manager. You can create a file in the `/etc/xinetd.d` directory for each service, or you can add additional stanzas to the IBM MQ file you created previously.

The `xinetd` process on Linux can limit the rate of inbound connections on a TCP port. The default is 50 connections in a 10 second interval. If you need a higher rate, specify a new limit on the rate of inbound connections by specifying the 'cps' attribute in the `xinetd` configuration file. For example, for a limit of 500 connections in a 60 second interval use:

```
cps = 500 60
```

### What next?

The TCP/IP connection is now established. You are ready to complete the configuration. Go to “IBM MQ for Linux configuration.”

### IBM MQ for Linux configuration:

Before beginning the installation process ensure that you have first created the `mqm` user ID and the `mqm` group, and set the password.

Start any channel using the command:

```
runmqchl -c channel.name
```

### Note:

1. Sample programs are installed in `MQ_INSTALLATION_PATH/samp`, where `MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.
2. Error logs are stored in `/var/mqm/qmgrs/qmgrname/errors`.
3. When you are using the command interpreter `runmqsc` to enter administration commands, a `+` at the end of a line indicates that the next line is a continuation. Ensure that there is a space between the last parameter and the continuation character.

### Basic configuration

1. Create the queue manager from the UNIX prompt using the command:

```
crtmqm -u dlqname -q linux
```

where:

*linux* Is the name of the queue manager

**-q** Indicates that this is to become the default queue manager

**-u *dlqname***

Specifies the name of the dead letter queue

This command creates a queue manager and a set of default objects.

2. Start the queue manager from the UNIX prompt using the command:

```
strmqm linux
```

where *linux* is the name given to the queue manager when it was created.

*Channel configuration for Linux:*

The following section details the configuration to be performed on the Linux queue manager to implement the channel described in “Example configuration information for all platforms” on page 1.

The MQSC command to create each object is shown. Either start **runmqsc** from a UNIX prompt and enter each command in turn, or build the commands into a command file.

Examples are given for connecting IBM MQ for Linux and IBM MQ for HP-UX. To connect to IBM MQ on another platform use the appropriate set of values from the table in place of those for HP-UX.

**Note:** The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and should be entered as shown.

*Table 5. Configuration worksheet for IBM MQ for Linux*

ID	Parameter Name	Reference	Example Used	User Value
<i>Definition for local node</i>				
A	Queue Manager Name		<b>LINUX</b>	
B	Local queue name		<b>LINUX.LOCALQ</b>	
<i>Connection to IBM MQ for Windows</i>				
The values in this section of the table must match those used in “Channel configuration for Windows” on page 7, as indicated.				
C	Remote queue manager name	A	<b>WINNT</b>	
D	Remote queue name		<b>WINNT.REMOTEQ</b>	
E	Queue name at remote system	B	<b>WINNT.LOCALQ</b>	
F	Transmission queue name		<b>WINNT</b>	
G	Sender (SNA) channel name		<b>LINUX.WINNT.SNA</b>	
H	Sender (TCP/IP) channel name		<b>LINUX.WINNT.TCP</b>	
I	Receiver (SNA) channel name	G	<b>WINNT.LINUX.SNA</b>	
J	Receiver (TCP) channel name	H	<b>WINNT.LINUX.TCP</b>	
<i>Connection to IBM MQ for AIX</i>				
The values in this section of the table must match those used in “Channel configuration for AIX” on page 15, as indicated.				
C	Remote queue manager name	A	<b>AIX</b>	
D	Remote queue name		<b>AIX.REMOTEQ</b>	
E	Queue name at remote system	B	<b>AIX.LOCALQ</b>	
F	Transmission queue name		<b>AIX</b>	
G	Sender (SNA) channel name		<b>LINUX.AIX.SNA</b>	
H	Sender (TCP) channel name		<b>LINUX.AIX.TCP</b>	
I	Receiver (SNA) channel name	G	<b>AIX.LINUX.SNA</b>	
J	Receiver (TCP) channel name	H	<b>AIX.LINUX.TCP</b>	
<i>Connection to MQSeries for Compaq Tru64 UNIX</i>				
The values in this section of the table must match those used in your Compaq Tru64 UNIX system.				
C	Remote queue manager name	A	<b>DECUX</b>	
D	Remote queue name		<b>DECUX.REMOTEQ</b>	

Table 5. Configuration worksheet for IBM MQ for Linux (continued)

ID	Parameter Name	Reference	Example Used	User Value
E	Queue name at remote system	B	DECUX.LOCALQ	
F	Transmission queue name		DECUX	
H	Sender (TCP) channel name		DECUX.LINUX.TCP	
J	Receiver (TCP) channel name	H	LINUX.DECUX.TCP	
<b>Connection to IBM MQ for HP-UX</b>				
The values in this section of the table must match those used in Table 3 on page 22, as indicated.				
C	Remote queue manager name	A	HPUX	
D	Remote queue name		HPUX.REMOTEQ	
E	Queue name at remote system	B	HPUX.LOCALQ	
F	Transmission queue name		HPUX	
G	Sender (SNA) channel name		LINUX.HPUX.SNA	
H	Sender (TCP) channel name		LINUX.HPUX.TCP	
I	Receiver (SNA) channel name	G	HPUX.LINUX.SNA	
J	Receiver (TCP/IP) channel name	H	HPUX.LINUX.TCP	
<b>Connection to IBM MQ for Solaris</b>				
The values in this section of the table must match those used in Table 4 on page 27, as indicated.				
C	Remote queue manager name	A	SOLARIS	
D	Remote queue name		SOLARIS.REMOTEQ	
E	Queue name at remote system	B	SOLARIS.LOCALQ	
F	Transmission queue name		GIS	
G	Sender (SNA) channel name		LINUX.SOLARIS.SNA	
H	Sender (TCP/IP) channel name		LINUX.SOLARIS.TCP	
I	Receiver (SNA) channel name	G	SOLARIS.LINUX.SNA	
J	Receiver (TCP/IP) channel name	H	SOLARIS.LINUX.TCP	
<b>IBM i Connection to IBM MQ for IBM i</b>				
<b>IBM i</b> The values in this section of the table must match those used in Table 10 on page 71, as indicated.				
C	Remote queue manager name	A	AS400	
D	Remote queue name		AS400.REMOTEQ	
E	Queue name at remote system	B	AS400.LOCALQ	
F	Transmission queue name		AS400	
G	Sender (SNA) channel name		LINUX.AS400.SNA	
H	Sender (TCP) channel name		LINUX.AS400.TCP	
I	Receiver (SNA) channel name	G	AS400.LINUX.SNA	
<b>IBM i</b>	Receiver (TCP) channel name	H	AS400.LINUX.TCP	
<b>z/OS Connection to IBM MQ for z/OS</b>				
<b>z/OS</b> The values in this section of the table must match those used in Table 6 on page 39, as indicated.				
C	Remote queue manager name	A	MVS	

Table 5. Configuration worksheet for IBM MQ for Linux (continued)

ID	Parameter Name	Reference	Example Used	User Value
D	Remote queue name		<b>MVS.REMOTEQ</b>	
E	Queue name at remote system	B	<b>MVS.LOCALQ</b>	
F	Transmission queue name		<b>MVS</b>	
G	Sender (SNA) channel name		<b>LINUX.MVS.SNA</b>	
H	Sender (TCP) channel name		<b>LINUX.MVS.TCP</b>	
I	Receiver (SNA) channel name	G	<b>MVS.LINUX.SNA</b>	
 J	Receiver (TCP) channel name	H	<b>MVS.LINUX.TCP</b>	
<b>Connection to MQSeries for VSE/ESA ( IBM MQ for Linux (x86 platform) only)</b>				
The values in this section of the table must match those used in your VSE/ESA system.				
C	Remote queue manager name	A	<b>VSE</b>	
D	Remote queue name		<b>VSE.REMOTEQ</b>	
E	Queue name at remote system	B	<b>VSE.LOCALQ</b>	
F	Transmission queue name		<b>VSE</b>	
G	Sender channel name		<b>LINUX.VSE.SNA</b>	
I	Receiver channel name	G	<b>VSE.LINUX.SNA</b>	

IBM MQ for Linux (x86 platform) sender-channel definitions using SNA:

Example coding.

```
def ql (HPUX) +                               F
  usage(xmitq) +
  replace

def qr (HPUX.REMOTEQ) +                       D
  rname(HPUX.LOCALQ) +                       E
  rqmname(HPUX) +                             C
  xmitq(HPUX) +                               F
  replace

def chl (LINUX.HPUX.SNA) chltype(sdr) +       G
  trptype(lu62) +
  conname('HPUXCPIC') +                       14
  xmitq(HPUX) +                               F
  replace
```

*IBM MQ for Linux (x86 platform) receiver-channel definitions using SNA:*

Example coding.

```
def ql (LINUX.LOCALQ) replace B
def chl (HPUX.LINUX.SNA) chltype(rcvr) + I
    trptype(lu62) +
    replace
```

*IBM MQ for Linux sender-channel definitions using TCP:*

Example coding.

```
def ql (HPUX) + F
    usage(xmitq) +
    replace

def qr (HPUX.REMOTEQ) + D
    rname(HPUX.LOCALQ) + E
    rqmname(HPUX) + C
    xmitq(HPUX) + F
    replace

def chl (LINUX.HPUX.TCP) chltype(sdr) + H
    trptype(tcp) +
    conname(remote_tcpip_hostname) +
    xmitq(HPUX) + F
    replace
```

*IBM MQ for Linux receiver-channel definitions using TCP/IP:*

Example coding.

```
def ql (LINUX.LOCALQ) replace B
def chl (HPUX.LINUX.TCP) chltype(rcvr) + J
    trptype(tcp) +
    replace
```

## **Example configuration - IBM MQ for z/OS**

This section gives an example of how to set up communication links from IBM MQ for z/OS to IBM MQ products on other platforms.

The following are the other platforms covered by this example:

- Windows
- AIX
- Compaq Tru64 UNIX
- HP-UX
- Solaris
- Linux
- IBM i
- VSE/ESA

You can also connect any of the following:

- z/OS to z/OS
- z/OS to MVS
- MVS to MVS

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

### Establishing a connection:

To establish a connection there are a number of things to configure.

#### Establishing an LU 6.2 connection

For the latest information about configuring SNA over TCP/IP, refer to the following online IBM documentation: Communications Server for z/OS.

#### Establishing a TCP connection

Alter the queue manager object to use the correct distributed queuing parameters using the following command. You must add the name of the TCP address space to the TCPNAME queue manager attribute.

```
ALTER QMGR TCPNAME(TCPIP)
```

The TCP connection is now established. You are ready to complete the configuration.

#### IBM MQ for z/OS configuration:

The following steps outline how to configure IBM MQ; starting and configuring channels and listeners.

1. Start the channel initiator using the command:

```
/cpf START CHINIT 1
```

2. Start an LU 6.2 listener using the command:

```
/cpf START LSTR LUNAME( M1 ) TRPTYPE(LU62)
```

The LUNAME of M1 refers to the symbolic name you gave your LU (5). You must specify TRPTYPE(LU62), otherwise the listener assumes that you want TCP.

3. Start a TCP listener using the command:

```
/cpf START LSTR
```

If you want to use a port other than 1414 (the default IBM MQ port), use the command:

```
/cpf START LSTR PORT( 1555 )
```

IBM MQ channels do not initialize successfully if the channel negotiation detects that the message sequence number is different at each end. You might need to reset these channels manually.

#### *Channel configuration for z/OS:*

To implement the example channels, there is some configuration necessary on the z/OS queue manager.

The following sections detail the configuration to be performed on the z/OS queue manager to implement the channel described in “Example configuration information for all platforms” on page 1.

Examples are given for connecting IBM MQ for z/OS and IBM MQ for Windows. To connect to IBM MQ on another platform use the appropriate set of values from the table in place of the values for Windows.

**Note:** The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and must be entered as shown.

Table 6. Configuration worksheet for IBM MQ for z/OS

ID	Parameter Name	Reference	Example Used	User Value
<b>Definition for local node</b>				
A	Queue Manager Name		MVS	
B	Local queue name		MVS.LOCALQ	
<b>Connection to IBM MQ for Windows</b>				
The values in this section of the table must match the values used in "Channel configuration for Windows" on page 7, as indicated.				
C	Remote queue manager name	A	WINNT	
D	Remote queue name		WINNT.REMOTEQ	
E	Queue name at remote system	B	WINNT.LOCALQ	
F	Transmission queue name		WINNT	
G	Sender (LU 6.2) channel name		MVS.WINNT.SNA	
H	Sender (TCP) channel name		MVS.WINNT.TCP	
I	Receiver (LU 6.2) channel name	G	WINNT.MVS.SNA	
J	Receiver (TCP/IP) channel name	H	WINNT.MVS.TCP	
<b>Connection to IBM MQ for AIX</b>				
The values in this section of the table must match the values used in "Channel configuration for AIX" on page 15, as indicated.				
C	Remote queue manager name	A	AIX	
D	Remote queue name		AIX.REMOTEQ	
E	Queue name at remote system	B	AIX.LOCALQ	
F	Transmission queue name		AIX	
G	Sender (LU 6.2) channel name		MVS.AIX.SNA	
H	Sender (TCP/IP) channel name		MVS.AIX.TCP	
I	Receiver (LU 6.2) channel name	G	AIX.MVS.SNA	
J	Receiver (TCP/IP) channel name	H	AIX.MVS.TCP	
<b>Connection to MQSeries for Compaq Tru64 Unix</b>				
The values in this section of the table must match the values used in your Compaq Tru64 UNIX system.				
C	Remote queue manager name	A	DECUX	
D	Remote queue name		DECUX.REMOTEQ	
E	Queue name at remote system	B	DECUX.LOCALQ	
F	Transmission queue name		DECUX	
H	Sender (TCP) channel name		DECUX.MVS.TCP	
J	Receiver (TCP) channel name	H	MVS.DECUX.TCP	
<b>Connection to IBM MQ for HP-UX</b>				
The values in this section of the table must match the values used in "Channel configuration for HP-UX" on page 21, as indicated.				
C	Remote queue manager name	A	HPUX	
D	Remote queue name		HPUX.REMOTEQ	
E	Queue name at remote system	B	HPUX.LOCALQ	
F	Transmission queue name		HPUX	

Table 6. Configuration worksheet for IBM MQ for z/OS (continued)

ID	Parameter Name	Reference	Example Used	User Value
G	Sender (LU 6.2) channel name		MVS.HPUX.SNA	
H	Sender (TCP) channel name		MVS.HPUX.TCP	
I	Receiver (LU 6.2) channel name	G	HPUX.MVS.SNA	
J	Receiver (TCP) channel name	H	HPUX.MVS.TCP	
<b>Connection to IBM MQ for Solaris</b>				
The values in this section of the table must match the values used in "Channel configuration for Solaris" on page 27, as indicated.				
C	Remote queue manager name	A	SOLARIS	
D	Remote queue name		SOLARIS.REMOTEQ	
E	Queue name at remote system	B	SOLARIS.LOCALQ	
F	Transmission queue name		SOLARIS	
G	Sender (LU 6.2) channel name		MVS.SOLARIS.SNA	
H	Sender (TCP) channel name		MVS.SOLARIS.TCP	
I	Receiver (LU 6.2) channel name	G	SOLARIS.MVS.SNA	
J	Receiver (TCP/IP) channel name	H	SOLARIS.MVS.TCP	
<b>Connection to IBM MQ for Linux</b>				
The values in this section of the table must match the values used in "Channel configuration for Linux" on page 34, as indicated.				
C	Remote queue manager name	A	LINUX	
D	Remote queue name		LINUX.REMOTEQ	
E	Queue name at remote system	B	LINUX.LOCALQ	
F	Transmission queue name		LINUX	
G	Sender (LU 6.2) channel name		MVS.LINUX.SNA	
H	Sender (TCP) channel name		MVS.LINUX.TCP	
I	Receiver (LU 6.2) channel name	G	LINUX.MVS.SNA	
J	Receiver (TCP/IP) channel name	H	LINUX.MVS.TCP	
<b>Connection to IBM MQ for IBM i</b>				
The values in this section of the table must match the values used in "Channel configuration for IBM i" on page 71, as indicated.				
C	Remote queue manager name	A	AS400	
D	Remote queue name		AS400.REMOTEQ	
E	Queue name at remote system	B	AS400.LOCALQ	
F	Transmission queue name		AS400	
G	Sender (LU 6.2) channel name		MVS.AS400.SNA	
H	Sender (TCP/IP) channel name		MVS.AS400.TCP	
I	Receiver (LU 6.2) channel name	G	AS400.MVS.SNA	
J	Receiver (TCP/IP) channel name	H	AS400.MVS.TCP	
<b>Connection to MQSeries for VSE/ESA</b>				
The values in this section of the table must match the values used in your VSE/ESA system.				
C	Remote queue manager name	A	VSE	

Table 6. Configuration worksheet for IBM MQ for z/OS (continued)

ID	Parameter Name	Reference	Example Used	User Value
D	Remote queue name		VSE.REMOTEQ	
E	Queue name at remote system	B	VSE.LOCALQ	
F	Transmission queue name		VSE	
G	Sender channel name		MVS.VSE.SNA	
I	Receiver channel name	G	VSE.MVS.SNA	

IBM MQ for z/OS sender-channel definitions:

This topic details the sender-channel definitions required to configure IBM MQ for z/OS using LU 6.2 or TCP.

For LU 6.2:

```

Local Queue
  Object type : QLOCAL
  Name : WINNT           F
  Usage : X (XmitQ)

Remote Queue
  Object type : QREMOTE
  Name : WINNT.REMOTEQ  D
Name on remote system : WINNT.LOCALQ  E
  Remote system name : WINNT          C
  Transmission queue : WINNT          F

Sender Channel
  Channel name : MVS.WINNT.SNA        G
  Transport type : L (LU6.2)
Transmission queue name : WINNT       F
  Connection name : M3                 13
  
```

For TCP:

```

Local Queue
  Object type : QLOCAL
  Name : WINNT           F
  Usage : X (XmitQ)

Remote Queue
  Object type : QREMOTE
  Name : WINNT.REMOTEQ  D
Name on remote system : WINNT.LOCALQ  E
  Remote system name : WINNT          C
  Transmission queue : WINNT          F

Sender Channel
  Channel name : MVS.WINNT.TCP        H
  Transport type : T (TCP)
Transmission queue name : WINNT       F
  Connection name : winnt.tcpip.hostname
  
```

*IBM MQ for z/OS receiver-channel definitions:*

This topic details the receiver-channel definitions required to configure IBM MQ for z/OS using LU6.2 or TCP.

For LU 6.2:

```
Local Queue
  Object type : QLOCAL
  Name       : MVS.LOCALQ      B
  Usage      : N (Normal)

Receiver Channel
  Channel name : WINNT.MVS.SNA  I
```

For TCP:

```
Local Queue
  Object type : QLOCAL
  Name       : MVS.LOCALQ      B
  Usage      : N (Normal)

Receiver Channel
  Channel name : WINNT.MVS.TCP  J
```

### **Example configuration - IBM MQ for z/OS using queue-sharing groups**

This section gives an example of how to set up communication links to a queue-sharing group on IBM MQ for z/OS from IBM MQ products on Windows and AIX. You can also connect from z/OS to z/OS.

Setting up communication links from a queue-sharing group to a platform other than z/OS is the same as described in “Example configuration - IBM MQ for z/OS” on page 37. There are examples to other platforms in that section.

When the connection is established, you must define some channels to complete the configuration. This process is described in “IBM MQ for z/OS shared channel configuration” on page 47.

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

### **Configuration parameters for an LU 6.2 connection:**

The following worksheet lists all the parameters required to set up communication from a z/OS system to one of the other IBM MQ platforms. The worksheet shows examples of the parameters, which have been tested in a working environment, and leaves space for you to enter your own values.

Use the worksheet in this section with the worksheet in the section for the platform to which you are connecting.

The steps required to set up an LU 6.2 connection are described in “Establishing an LU 6.2 connection into a queue-sharing group” on page 45, with numbered cross-references to the parameters on the worksheet.

Numbers in the Reference column indicate that the value must match that in the appropriate worksheet elsewhere in this section. The examples that follow in this section refer to the values in the ID column. The entries in the Parameter Name column are explained in “Explanation of terms” on page 43.

Table 7. Configuration worksheet for z/OS using LU 6.2

ID	Parameter Name	Reference	Example Used	User Value
<i>Definition for local node using generic resources</i>				
1	Command prefix		/cpf	
2	Network ID		NETID	
3	Node name		MVSPU	
6	Modename		#INTER	
7	Local Transaction Program name		MQSERIES	
8	LAN destination address		400074511092	
9	Local LU name		MVSLU1	
10	Generic resource name		MVSGR	
11	Symbolic destination		G1	
12	Symbolic destination for generic resource name		G2	
<i>Connection to a Windows system</i>				
13	Symbolic destination		M3	
14	Modename	21	#INTER	
15	Remote Transaction Program name	7	MQSERIES	
16	Partner LU name	5	WINNTLU	
21	Remote node ID	4	05D 30F65	
<i>Connection to an AIX system</i>				
13	Symbolic Destination		M4	
14	Modename	18	#INTER	
15	Remote Transaction Program name	6	MQSERIES	
16	Partner LU name	4	AIXLU	

*Explanation of terms:*

An explanation of the terms used in the configuration worksheet.

**1 Command prefix**

This term is the unique command prefix of your IBM MQ for z/OS queue-manager subsystem. The z/OS system programmer defines this value at installation time, in SYS1.PARMLIB(IEFSSNss), and can tell you the value.

**2 Network ID**

The VTAM startup procedure in your installation is partly customized by the ATCSTRxx member of the data set referenced by the DDNAME VTAMLST. The Network ID is the value specified for the NETID parameter in this member. For Network ID, you must specify the name of the NETID that owns the IBM MQ communications subsystem. Your network administrator can tell you the value.

**3 Node name**

VTAM, being a low-entry network node, does not have a Control Point name for Advanced Peer-to-Peer Networking (APPN) use. It does however have a system services control point name (SSCPNAME). For node name, you must specify the name of the SSCP that owns the IBM MQ communications subsystem. This value is defined in the same ATCSTRxx member as the Network ID. Your network administrator can tell you the value.

## **9 Local LU name**

A logical unit (LU) is software that serves as an interface or translator between a transaction program and the network. It manages the exchange of data between transaction programs. The local LU name is the unique VTAM APPLID of this IBM MQ subsystem. Your network administrator can tell you this value.

## **11 12 13 Symbolic destination**

This term is the name you give to the CPI-C side information profile. You need a side information entry for each LU 6.2 listener.

## **6 14 Modename**

This term is the name given to the set of parameters that control the LU 6.2 conversation. An entry with this name and similar attributes must be defined at each end of the session. In VTAM, this corresponds to a mode table entry. Your network administrator can assign this table entry to you.

## **7 15 Transaction Program name**

IBM MQ applications trying to converse with this queue manager specify a symbolic name for the program to be run at the receiving end. This has been specified in the TPNAME attribute on the channel definition at the sender. For simplicity, wherever possible use a transaction program name of MQSERIES, or in the case of a connection to VSE/ESA, where the length is limited to 4 bytes, use MQTP.

See Defining an LU6.2 connection for z/OS using APPC/MVS for more information.

## **8 LAN destination address**

This term is the LAN destination address that your partner nodes use to communicate with this host. When you are using a 3745 network controller, it is the value specified in the LOCADD parameter for the line definition to which your partner is physically connected. If your partner nodes use other devices such as 317X or 6611 devices, the address is set during the customization of those devices. Your network administrator can tell you this value.

## **10 Generic resource name**

A generic resource name is a unique name assigned to a group of LU names used by the channel initiators in a queue-sharing group.

## **16 Partner LU name**

This term is the LU name of the IBM MQ queue manager on the system with which you are setting up communication. This value is specified in the side information entry for the remote partner.

## **21 Remote node ID**

For a connection to Windows, this ID is the ID of the local node on the Windows system with which you are setting up communication.

## Establishing an LU 6.2 connection into a queue-sharing group:

There are two steps to establish an LU 6.2 connection. Defining yourself to the network and defining a connection to the partner.

*Defining yourself to the network using generic resources:*

You can use VTAM Generic Resources to have one connection name to connect to the queue-sharing group.

1. SYS1.PARMLIB(APPCCPMxx) contains the start-up parameters for APPC. You must add a line to this file to tell APPC where to locate the sideinfo. This line must be of the form:

```
SIDEINFO
  DATASET (APPC.APPCSI)
```

2. Add another line to SYS1.PARMLIB(APPCCPMxx) to define the local LU name you intend to use for the IBM MQ LU 6.2 group listener. The line you add must take the form

```
LUADD ACBNAME(mvslu1)
      NOSCHED
      TPDATA(csq.appctp)
      GRNAME(mvsgr)
```

Specify values for ACBNAME (9), TPDATA and GRNAME(10).

The NOSCHED parameter tells APPC that our new LU is not using the LU 6.2 scheduler (ASCH), but has one of its own. TPDATA refers to the Transaction Program data set in which LU 6.2 stores information about transaction programs. Again, IBM MQ does not use this parameter, but it is required by the syntax of the LUADD command.

3. Start the APPC subsystem with the command:

```
START APPC,SUB=MSTR,APPC=xx
```

where xx is the suffix of the PARMLIB member in which you added the LU in step 1.

**Note:** If APPC is already running, it can be refreshed with the command:

```
SET APPC=xx
```

The effect of this is cumulative, that is, APPC does not lose its knowledge of objects already defined to it in this member or another PARMLIB member.

4. Add the new LU to a suitable VTAM major node definition. These are typically in SYS1.VTAMLST. The APPL definition will look like the sample shown.

```
      MVSLU APPL ACBNAME=MVSLU1,      9
              APPXC=YES,
              AUTOSSES=0,
              DDRAINL=NALLOW,
              DLOGMOD=#INTER,      6
              DMINWML=10,
              DMINWNR=10,
              DRESPL=NALLOW,
              DSESLIM=60,
              LMDENT=19,
              MODETAB=MTCICS,
              PARSESS=YES,
              VERIFY=NONE,
              SECACPT=ALREADYV,
              SRBEXIT=YES
```

5. Activate the major node. This activation can be done with the command:

```
V,NET,ACT,majornode
```

6. Add entries defining your LU and generic resource name to the CPI-C side information data set. Use the APPC utility program ATBSDFMU to do so. Sample JCL is in *thlqual.SCSQPROC(CSQ4SIDE)* (where *thlqual* is the target library high-level qualifier for IBM MQ data sets in your installation.)

The entries you add will look like this example:

```
SIADD
  DESTNAME(G1)          11
  MODENAME(#INTER)
  TPNAME(MQSERIES)
  PARTNER_LU(MVSLU1)   9
SIADD
  DESTNAME(G2)          12
  MODENAME(#INTER)
  TPNAME(MQSERIES)
  PARTNER_LU(MVSGR)   10
```

7. Alter the queue manager object to use the correct distributed queuing parameters using the following command. You must specify the local LU (9) assigned to your queue manager in the LUGROUP attribute of the queue manager.

```
ALTER QMGR LUGROUP(MVSLU1)
```

*Defining a connection to a partner:*

You can define a connection to a partner by adding an entry to the CPI-C side information data set.

**Note:** This example is for a connection to a Windows system but the task is the same for other platforms.

Add an entry to the CPI-C side information data set to define the connection. Sample JCL to do this definition is in *thlqual.SCSQPROC(CSQ4SIDE)*.

The entry you add will look like this:

```
SIADD
  DESTNAME(M3)          13
  MODENAME(#INTER)     14
  TPNAME(MQSERIES)     15
  PARTNER_LU(WINNTLU)  16
```

*What next?:*

The connection is now established. You are ready to complete the configuration.

Go to “IBM MQ for z/OS shared channel configuration” on page 47.

### **Establishing a TCP connection Using Sysplex Distributor:**

You can set up Sysplex distributor to use one connection name to connect to the queue-sharing group.

1. Define a Distributed DVIPA address as follows:
  - a. Add a DYNAMICXCF statement to the IPCONFIG. This statement is used for inter-image connectivity using dynamically created XCF TCP/IP links.
  - b. Use the VIPADYNAMIC block on each image in the Sysplex.
    - 1) On the owning image, code a VIPADEFINE statement to create the DVIPA. Then code a VIPADISTRIBUTE statement to distribute it to all other or selected images.
    - 2) On the backup image, code a VIPABACKUP statement for the DVIPA address.
2. If more than one channel initiator will be started on any LPAR in the sysplex then add the SHAREPORT option for the port to be shared in the PORT reservation list in the PROFILE data set.

See *z/OS CS: IP Configuration Guide* and *z/OS CS: IP Configuration Reference* for more information.

Sysplex Distributor balances the inbound connections between each LPAR. If there is more than one channel initiator on an LPAR, then the use of SHAREPORT passes that inbound connection to the listener port with the smallest number of connections.

When you have completed these steps, the TCP connection is established. You are ready to complete the configuration.

Go to “IBM MQ for z/OS shared channel configuration.”

### IBM MQ for z/OS shared channel configuration:

Configure the shared channel by starting the channel initiator and issuing appropriate commands for your configuration.

1. Start the channel initiator using the command:

```
/cpf START CHINIT
```

2. Start an LU6.2 group listener using the command:

```
/cpf START LSTR TRPTYPE(LU62) LUNAME( G1 ) INDISP(GROUP)
```

The LUNAME of G1 refers to the symbolic name you gave your LU (11).

3. If you are using Virtual IP Addressing using Sysplex Distributor and want to listen on a specific address, use the command:

```
/cpf START LSTR TRPTYPE(TCP) PORT(1555) IPADDR( mvsvipa ) INDISP(GROUP)
```

There can be only one instance of the shared channel running at a time. If you try to start a second instance of the channel it fails (the error message varies depending on other factors). The shared synchronization queue tracks the channel status.

IBM MQ channels do not initialize successfully if the channel negotiation detects that the message sequence number is different at each end. You might need to reset this manually.

*Shared channel configuration example:*

To configure a shared channel, a number of steps must be completed.

The subsequent topics detail the configuration to be performed on the z/OS queue manager to implement the channel described in “Example configuration information for all platforms” on page 1.

Examples are given for connecting IBM MQ for z/OS and Windows. To connect to IBM MQ on another platform use the appropriate set of values from the table in place of the values for Windows.

**Note:** The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and must be entered as shown.

*Table 8. Configuration worksheet for IBM MQ for z/OS using queue-sharing groups*

ID	Parameter Name	Reference	Example Used	User Value
<i>Definition for local node</i>				
A	Queue Manager Name		<b>QSG</b>	
B	Local queue name		<b>QSG.SHAREDQ</b>	
<i>Connection to IBM MQ for Windows</i>				
The values in this section of the table must match the values used in “Channel configuration for Windows” on page 7, as indicated.				
C	Remote queue manager name	A	<b>WINNT</b>	
D	Remote queue name		<b>WINNT.REMOTEQ</b>	
E	Queue name at remote system	B	<b>WINNT.LOCALQ</b>	
F	Transmission queue name		<b>WINNT</b>	

Table 8. Configuration worksheet for IBM MQ for z/OS using queue-sharing groups (continued)

ID	Parameter Name	Reference	Example Used	User Value
G	Sender (LU 6.2) channel name		QSG.WINNT.SNA	
H	Sender (TCP) channel name		QSG.WINNT.TCP	
I	Receiver (LU 6.2) channel name	G	WINNT.QSG.SNA	
J	Receiver (TCP/IP) channel name	H	WINNT.QSG.TCP	
<b>Connection to IBM MQ for AIX</b>				
The values in this section of the table must match the values used in "Channel configuration for AIX" on page 15, as indicated.				
C	Remote queue manager name		AIX	
D	Remote queue name		AIX.REMOTEQ	
E	Queue name at remote system	B	AIX.LOCALQ	
F	Transmission queue name		AIX	
G	Sender (LU 6.2) channel name		QSG.AIX.SNA	
H	Sender (TCP/IP) channel name		QSG.AIX.TCP	
I	Receiver (LU 6.2) channel name	G	AIX.QSG.SNA	
J	Receiver (TCP/IP) channel name	H	AIX.QSG.TCP	

IBM MQ for z/OS shared sender-channel definitions:

An example definition of shared sender-channels for LU 6.2 and TCP.

### Using LU 6.2

#### Local Queue

```
Object type : QLOCAL
Name       : WINNT           F
Usage     : X (XmitQ)
Disposition : SHARED
```

#### Remote Queue

```
Object type : QREMOTE
Name       : WINNT.REMOTEQ  D
Name on remote system : WINNT.LOCALQ  E
Remote system name : WINNT      C
Transmission queue : WINNT      F
Disposition : GROUP
```

#### Sender Channel

```
Channel name : MVS.WINNT.SNA  G
Transport type : L (LU6.2)
Transmission queue name : WINNT  F
Connection name : M3          13
Disposition : GROUP
```

### Using TCP

#### Local Queue

```
Object type : QLOCAL
Name       : WINNT           F
Usage     : X (XmitQ)
Disposition : SHARED
```

#### Remote Queue

```
Object type : QREMOTE
Name       : WINNT.REMOTEQ  D
```

```

Name on remote system : WINNT.LOCALQ      E
Remote system name   : WINNT              C
Transmission queue   : WINNT              F
Disposition          : GROUP

Sender Channel
Channel name         : QSG.WINNT.TCP      H
Transport type       : T (TCP)
Transmission queue   : WINNT              F
Connection name      : winnt.tcpi.hostname
Disposition          : GROUP

```

*IBM MQ for z/OS shared receiver-channel definitions:*

An example definition of shared receiver-channels for LU 6.2 and TCP.

### Using LU 6.2

```

Local Queue
Object type : QLOCAL
Name        : QSG.SHAREDQ      B
Usage       : N (Normal)
Disposition : SHARED

Receiver Channel
Channel name : WINNT.QSG.SNA    I
Disposition  : GROUP

```

### Using TCP

```

Local Queue
Object type : QLOCAL
Name        : QSG.SHAREDQ      B
Usage       : N (Normal)
Disposition : SHARED

Receiver Channel
Channel name : WINNT.QSG.TCP    J
Disposition  : GROUP

```

## Example configuration - IBM MQ for z/OS using intra-group queuing

This section describes how a typical payroll query application, that currently uses distributed queuing to transfer small messages between queue managers, could be migrated to use queue sharing groups and shared queues.

Three configurations are described to illustrate the use of distributed queuing, intra-group queuing with shared queues, and shared queues. The associated diagrams show only the flow of data in one direction, that is, from queue manager QMG1 to queue manager QMG3.

## Configuration 1:

Configuration 1 describes how distributed queuing is currently used to transfer messages between queue managers QMG1 and QMG3.

Configuration 1 shows a distributed queuing system that is used to transfer messages received by queue manager QMG1 from the payroll query to queue manager QMG2 and then finally on to queue manager QMG3, to be sent to the payroll server.

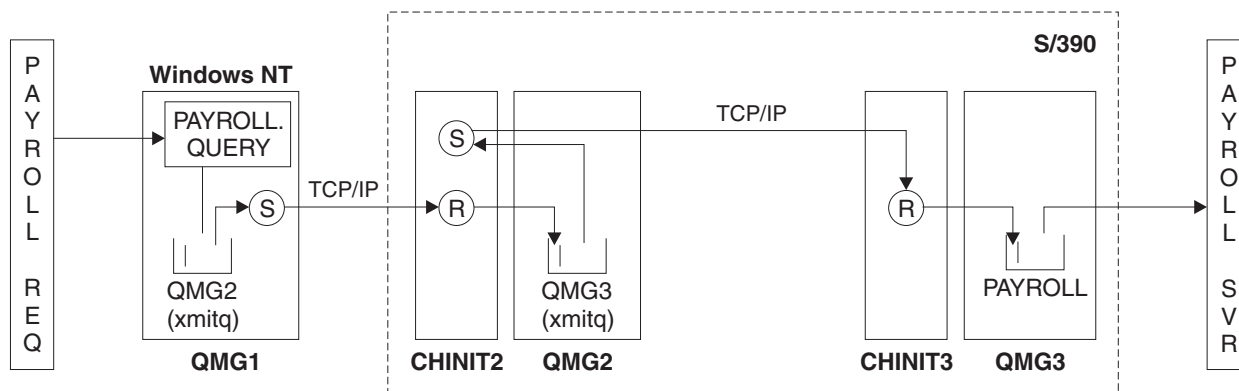

Figure 2. Configuration 1: z/OS using intra-group queuing

The flow of operations is as follows:

1. A query is entered using the payroll request application connected to queue manager QMG1.
2. The payroll request application puts the query on to remote queue PAYROLL.QUERY. As queue PAYROLL.QUERY resolves to transmission queue QMG2, the query is put on to transmission queue QMG2.
3. Sender channel (S) on queue manager QMG1 delivers the query to the partner receiver channel (R) on queue manager QMG2.
4. Receiver channel (R) on queue manager QMG2 puts the query on to queue PAYROLL on queue manager QMG3. As queue PAYROLL on QMG3 resolves to transmission queue QMG3, the query is put on to transmission queue QMG3.
5. Sender channel (S) on queue manager QMG2 delivers the query to the partner receiver channel (R) on queue manager QMG3.
6. Receiver channel (R) on queue manager QMG3 puts the query on to local queue PAYROLL.
7. The payroll server application connected to queue manager QMG3 retrieves the query from local queue PAYROLL, processes it, and generates a suitable reply.

### *Configuration 1 definitions:*

The definitions required for Configuration 1 are as follows (note that the definitions do not take into account triggering, and that only channel definitions for communication using TCP/IP are provided).

#### **On QMG1**

Remote queue definition:

```
DEFINE QREMOTE(PAYROLL.QUERY) DESCR('Remote queue for QMG3') REPLACE +  
PUT(ENABLED) RNAME(PAYROLL) RQMNAME(QMG3) XMITQ(QMG2)
```

Transmission queue definition:

```
DEFINE QLOCAL(QMG2) DESCR('Transmission queue to QMG2') REPLACE +  
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

Sender channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG1.TO.QMG2) CHLTYPE(SDR) TRPTYPE(TCP) REPLACE +  
DESCR('Sender channel to QMG2') XMITQ(QMG2) CONNAME('MVSQMG2(1415)')
```

Here you replace MVSQMG2(1415) with your queue manager connection name and port.

Receiver channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG2.TO.QMG1) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QMG2')
```

Reply-to queue definition:

```
DEFINE QLOCAL(PAYROLL.REPLY) REPLACE PUT(ENABLED) GET(ENABLED) +  
DESCR('Reply queue for replies to payroll queries sent to QMG3')
```

#### **On QMG2**

Transmission queue definition:

```
DEFINE QLOCAL(QMG1) DESCR('Transmission queue to QMG1') REPLACE +  
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

```
DEFINE QLOCAL(QMG3) DESCR('Transmission queue to QMG3') REPLACE +  
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

Sender channel definitions (for TCP/IP):

```
DEFINE CHANNEL(QMG2.TO.QMG1) CHLTYPE(SDR) TRPTYPE(TCP) REPLACE +  
DESCR('Sender channel to QMG1') XMITQ(QMG1) CONNAME('WINTQMG1(1414)')
```

Here you replace WINTQMG1(1414) with your queue manager connection name and port.

```
DEFINE CHANNEL(QMG2.TO.QMG3) CHLTYPE(SDR) TRPTYPE(TCP) REPLACE +  
DESCR('Sender channel to QMG3') XMITQ(QMG3) CONNAME('MVSQMG3(1416)')
```

Here you replace MVSQMG3(1416) with your queue manager connection name and port.

Receiver channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG1.TO.QMG2) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QMG1')
```

```
DEFINE CHANNEL(QMG3.TO.QMG2) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QMG3')
```

## On QMG3

Local queue definition:

```
DEFINE QLOCAL(PAYROLL) DESCR('Payroll query request queue') REPLACE +  
PUT(ENABLED) USAGE(NORMAL) GET(ENABLED) SHARE
```

```
DEFINE QLOCAL(QMG2) DESCR('Transmission queue to QMG2') REPLACE +  
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

Sender channel definitions (for TCP/IP):

```
DEFINE CHANNEL(QMG3.TO.QMG2) CHLTYPE(SDR) TRPTYPE(TCP) REPLACE +  
DESCR('Sender channel to QMG2) XMITQ(QMG2) CONNAME('MVSQMG2(1415)')
```

Here you replace MVSQMG2(1415) with your queue manager connection name and port.

Receiver channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG2.TO.QMG3) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QMG2)
```

### Configuration 2:

Configuration 2 describes how queue-sharing groups and intra-group queuing can be used, with no effect on the back-end payroll server application, to transfer messages between queue managers QMG1 and QMG3.

Configuration 2 shows a distributed queuing system that uses queue-sharing groups and intra-group queuing to transfer messages from the payroll request application to the payroll server. This configuration removes the need for channel definitions between queue managers QMG2 and QMG3 because intra-group queuing is used to transfer messages between these two queue managers.

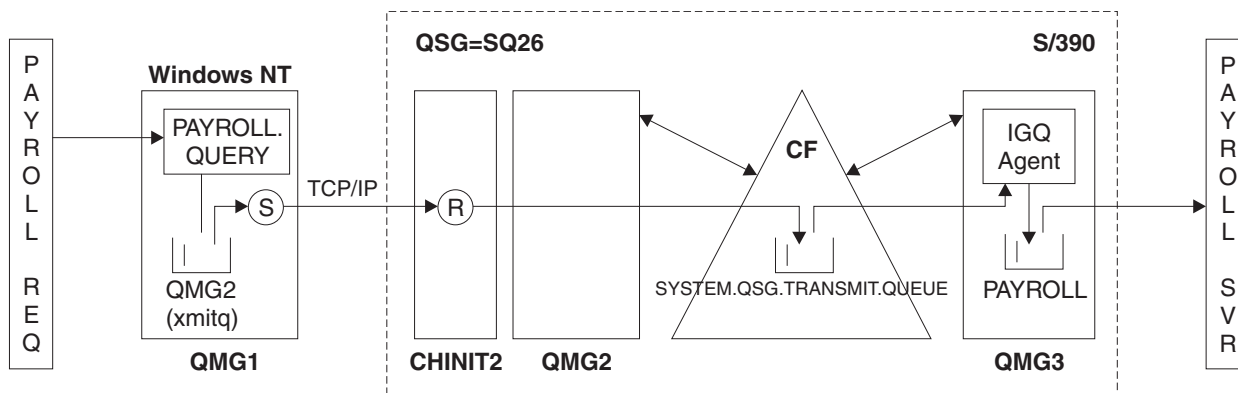

Figure 3. Configuration 2

The flow of operations is as follows:

1. A query is entered using the payroll request application connected to queue manager QMG1.
2. The payroll request application puts the query on to remote queue PAYROLL.QUERY. As queue PAYROLL.QUERY resolves to transmission queue QMG2, the query is put on to transmission queue QMG2.
3. Sender channel (S) on queue manager QMG1 delivers the query to the partner receiver channel (R) on queue manager QMG2.

4. Receiver channel (R) on queue manager QMG2 puts the query on to queue PAYROLL on queue manager QMG3. As queue PAYROLL on QMG3 resolves to shared transmission queue SYSTEM.QSG.TRANSMIT.QUEUE, the query is put on to shared transmission queue SYSTEM.QSG.TRANSMIT.QUEUE.
5. IGQ agent on queue manager QMG3 retrieves the query from shared transmission queue SYSTEM.QSG.TRANSMIT.QUEUE, and puts it on to local queue PAYROLL on queue manager QMG3.
6. The payroll server application connected to queue manager QMG3 retrieves the query from local queue PAYROLL, processes it, and generates a suitable reply.

**Note:** The payroll query example transfers small messages only. If you need to transfer both persistent and non-persistent messages, a combination of Configuration 1 and Configuration 2 can be established, so that large messages can be transferred using the distributed queuing route, while small messages can be transferred using the potentially faster intra-group queuing route.

*Configuration 2 definitions:*

The definitions required for Configuration 2 are as follows (note that the definitions do not take into account triggering, and that only channel definitions for communication using TCP/IP are provided).

It is assumed that queue managers QMG2 and QMG3 are already configured to be members of the same queue-sharing group.

## On QMG1

Remote queue definition:

```
DEFINE QREMOTE(PAYROLL.QUERY) DESCR('Remote queue for QMG3') REPLACE +
PUT(ENABLED) RNAME(PAYROLL) RQMNAME(QMG3) XMITQ(QMG2)
```

Transmission queue definition:

```
DEFINE QLOCAL(QMG2) DESCR('Transmission queue to QMG2') REPLACE +
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

Sender channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG1.TO.QMG2) CHLTYPE(SDR) TRPTYPE(TCP) REPLACE +
DESCR('Sender channel to QMG2') XMITQ(QMG2) CONNAME('MVSQMG2(1415)')
```

Here you replace MVSQMG2(1415) with your queue manager connection name and port.

Receiver channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG2.TO.QMG1) CHLTYPE(RCVR) TRPTYPE(TCP) +
REPLACE DESCR('Receiver channel from QMG2')
```

Reply-to queue definition:

```
DEFINE QLOCAL(PAYROLL.REPLY) REPLACE PUT(ENABLED) GET(ENABLED) +
DESCR('Reply queue for replies to payroll queries sent to QMG3')
```

## On QMG2

Transmission queue definition:

```
DEFINE QLOCAL(QMG1) DESCR('Transmission queue to QMG1') REPLACE +
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

```
DEFINE QLOCAL(SYSTEM.QSG.TRANSMIT.QUEUE) QSGDISP(SHARED) +
DESCR('IGQ Transmission queue') REPLACE PUT(ENABLED) USAGE(XMITQ) +
GET(ENABLED) INDXTYPE(CORRELID) CFSTRUCT('APPLICATION1') +
DEFSOPT(SHARED) DEFPSIST(NO)
```

Here you replace APPLICATION1 with your defined CF structure name. Also note that this queue, being a shared queue, need only be defined on one of the queue managers in the queue sharing group.

Sender channel definitions (for TCP/IP):

```
DEFINE CHANNEL(QMG2.TO.QMG1) CHLTYPE(SDR) TRPTYPE(TCP) REPLACE +
DESCR('Sender channel to QMG1') XMITQ(QMG1) CONNAME('WINTQMG1(1414)')
```

Here you replace WINTQMG1(1414) with your queue manager connection name and port.

Receiver channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG1.TO.QMG2) CHLTYPE(RCVR) TRPTYPE(TCP) +
REPLACE DESCR('Receiver channel from QMG1')
```

Queue Manager definition:

```
ALTER QMGR IGQ(ENABLED)
```

### On QMG3

Local queue definition:

```
DEFINE QLOCAL(PAYROLL) DESCR('Payroll query request queue') REPLACE +
PUT(ENABLED) USAGE(NORMAL) GET(ENABLED) SHARE
```

Queue Manager definition:

```
ALTER QMGR IGQ(ENABLED)
```

### Configuration 3:

Configuration 3 describes how queue-sharing groups and shared queues can be used, with no effect on the back-end payroll server application, to transfer messages between queue managers QMG1 and QMG3.

Configuration 3 shows a distributed queuing system that uses queue-sharing groups and shared queues to transfer messages between queue manager QMG1 and queue manager QMG3.

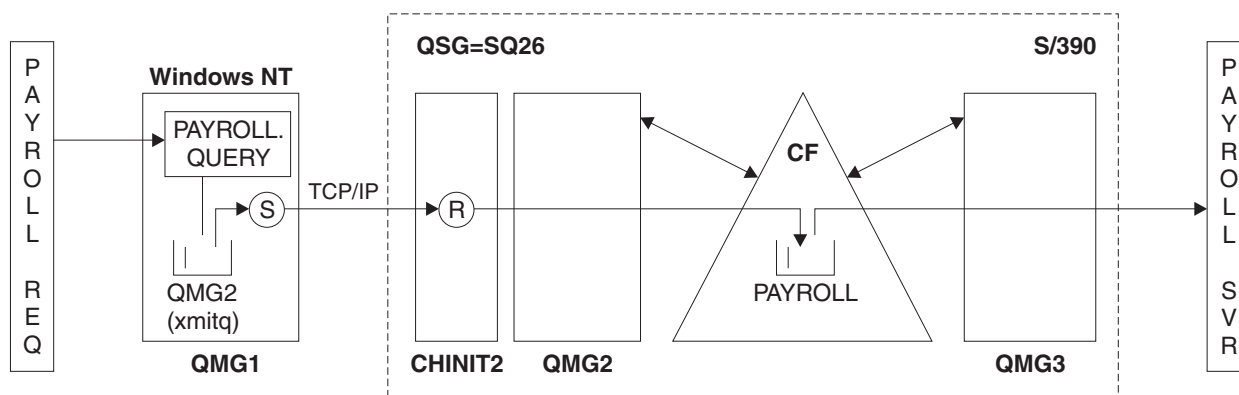

Figure 4. Configuration 3

The flow of operations is:

1. A query is entered using the payroll request application connected to queue manager QMG1.
2. The payroll request application puts the query on to remote queue PAYROLL.QUERY. As queue PAYROLL.QUERY resolves to transmission queue QMG2, the query is put on to transmission queue QMG2.

3. Sender channel (S) on queue manager QMG1 delivers the query to the partner receiver channel (R) on queue manager QMG2.
4. Receiver channel (R) on queue manager QMG2 puts the query on to shared queue PAYROLL.
5. The payroll server application connected to queue manager QMG3 retrieves the query from shared queue PAYROLL, processes it, and generates a suitable reply.

This configuration is certainly the simplest to configure. However, distributed queuing or intra-group queuing would need to be configured to transfer replies (generated by the payroll server application connected to queue manager QMG3) from queue manager QMG3 to queue manager QMG2, and then on to queue manager QMG1. (See "What this example shows" on page 171 for the configuration used to transfer replies back to the payroll request application.)

No definitions are required on QMG3.

*Configuration 3 definitions:*

The definitions required for Configuration 3 are as follows (note that the definitions do not take into account triggering, and that only channel definitions for communication using TCP/IP are provided).

It is assumed that queue managers QMG2 and QMG3 are already configured to be members of the same queue-sharing group.

### **On QMG1**

Remote queue definition:

```
DEFINE QREMOTE(PAYROLL.QUERY) DESCR('Remote queue for QMG3') REPLACE +
PUT(ENABLED) RNAME(PAYROLL) RQMNAME(QMG3) XMITQ(QMG2)
```

Transmission queue definition:

```
DEFINE QLOCAL(QMG2) DESCR('Transmission queue to QMG2') REPLACE +
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

Sender channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG1.TO.QMG2) CHLTYPE(SDR) TRPTYPE(TCP) +
REPLACE DESCR('Sender channel to QMG2') XMITQ(QMG2) CONNAME('MVSQMG2(1415)')
```

Here you replace MVSQMG2(1415) with your queue manager connection name and port.

Receiver channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG2.TO.QMG1) CHLTYPE(RCVR) TRPTYPE(TCP) +
REPLACE DESCR('Receiver channel from QMG2')
```

Reply-to queue definition:

```
DEFINE QLOCAL(PAYROLL.REPLY) REPLACE PUT(ENABLED) GET(ENABLED) +
DESCR('Reply queue for replies to payroll queries sent to QMG3')
```

### **On QMG2**

Transmission queue definition:

```
DEFINE QLOCAL(QMG1) DESCR('Transmission queue to QMG1') REPLACE +
PUT(ENABLED) USAGE(XMITQ) GET(ENABLED)
```

Sender channel definitions (for TCP/IP):

```
DEFINE CHANNEL(QMG2.TO.QMG1) CHLTYPE(SDR) TRPTYPE(TCP) +
REPLACE DESCR('Sender channel to QMG1') XMITQ(QMG1) CONNAME('WINTQMG1(1414)')
```

Here you replace WINTQMG1(1414) with your queue manager connection name and port.

Receiver channel definition (for TCP/IP):

```
DEFINE CHANNEL(QMG1.TO.QMG2) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QMG1')
```

Local queue definition:

```
DEFINE QLOCAL(PAYROLL) QSGDISP(SHARED) DESCR('Payroll query request queue') +  
REPLACE PUT(ENABLED) USAGE(NORMAL) GET(ENABLED) SHARE +  
DEFSOPT(SHARED) DEFPSIST(NO) CFSTRUCT(APPLICATION1)
```

Here you replace APPLICATION1 with your defined CF structure name. Also note that this queue, being a shared queue, need only be defined on one of the queue managers in the queue sharing group.

### On QMG3

No definitions are required on QMG3.

### Running the example:

After setting up the sample, you can run the sample.

For Configuration 1:

1. Start queue managers QMG1, QMG2, and QMG3.
2. Start channel initiators for QMG2 and QMG3.
3. Start the listeners on QMG1 to listen to port 1414, QMG2 to listen on port 1415, and QMG3 to listen on port 1416.
4. Start sender channels on QMG1, QMG2, and QMG3.
5. Start the payroll query requesting application connected to QMG1.
6. Start the payroll server application connected to QMG3.
7. Submit a payroll query request to QMG3 and wait for the payroll reply.

For Configuration 2:

1. Start queue managers QMG1, QMG2, and QMG3.
2. Start the channel initiator for QMG2.
3. Start the listeners on QMG1 to listen on port 1414, and QMG2 to listen on port 1415.
4. Start the sender channel on QMG1 and QMG2.
5. Start the payroll query requesting application connected to QMG1.
6. Start the payroll server application connected to QMG3.
7. Submit a payroll query request to QMG3 and wait for the payroll reply.

For Configuration 3:

1. Start queue managers QMG1, QMG2, and QMG3.
2. Start the channel initiator for QMG2.
3. Start the listeners on QMG1 to listen on port 1414, and QMG2 to listen on port 1415.
4. Start sender channels on QMG1 and QMG2.
5. Start the payroll query requesting application connected to QMG1.
6. Start the payroll server application connected to QMG3.
7. Submit a payroll query request to QMG3 and wait for the payroll reply.

## Expanding the example:

The example can be expanded in a number of ways.

The example can be:

- Expanded to use channel triggering as well as application (PAYROLL and PAYROLL.REPLY queue) triggering.
- Configured for communication using LU6.2.
- Expanded to configure more queue managers to the queue sharing group. Then the server application can be cloned to run on other queue manager instances to provide multiple servers for the PAYROLL query queue.
- Expanded to increase the number of instances of the payroll query requesting application to demonstrate the processing of requests from multiple clients.
- Expanded to use security (IGQAUT and IGQUSER).

## Example configuration - IBM MQ for IBM i

This section gives an example of how to set up communication links from IBM MQ for IBM i to IBM MQ products on other platforms.

Other platforms covered are the following platforms:

- Windows
- AIX
- Compaq Tru64 UNIX
- HP-UX
- Solaris
- Linux
- z/OS or MVS
- VSE/ESA

See “Example configuration information for all platforms” on page 1 for background information about this section and how to use it.

## Configuration parameters for an LU 6.2 connection:

The following worksheet lists all the parameters needed to set up communication from IBM i system to one of the other IBM MQ platforms. The worksheet shows examples of the parameters, which have been tested in a working environment, and leaves space for you to enter your own values.

Use the worksheet in this section to record the values for this configuration. Use the worksheet with the worksheet in the section for the platform to which you are connecting.

Where numbers appear in the Reference column they indicate that the value must match that in the appropriate worksheet elsewhere in this section. The examples that follow in this section refer to the values in the ID column of this table.

The entries in the Parameter Name column are explained in “Explanation of terms” on page 60.

Table 9. Configuration worksheet for SNA on an IBM i system

ID	Parameter Name	Reference	Example Used	User Value
<i>Definition for local node</i>				
1	Local network ID		NETID	
2	Local control point name		AS400PU	
3	LU name		AS400LU	
4	LAN destination address		10005A5962EF	
5	Subsystem description		QCMN	
6	Line description		TOKENRINGL	
7	Resource name		LIN041	
8	Local Transaction Program name		MQSERIES	
<i>Connection to a Windows system</i>				
9	Network ID	2	NETID	
10	Control point name	3	WINNTCP	
11	LU name	5	WINNTLU	
12	Controller description		WINNTCP	
13	Device		WINNTLU	
14	Side information		NTCPIC	
15	Transaction Program	7	MQSERIES	
16	LAN adapter address	9	08005AA5FAB9	
17	Mode	17	#INTER	
<i>Connection to an AIX system</i>				
9	Network ID	1	NETID	
10	Control point name	2	AIXPU	
11	LU name	4	AIXLU	
12	Controller description		AIXPU	
13	Device		AIXLU	
14	Side information		AIXCPIC	
15	Transaction Program	6	MQSERIES	
16	LAN adapter address	8	123456789012	
17	Mode	14	#INTER	
<i>Connection to an HP-UX system</i>				
9	Network ID	4	NETID	
10	Control point name	2	HPUXPU	
11	LU name	5	HPUXLU	
12	Controller description		HPUXPU	
13	Device		HPUXLU	
14	Side information		HPUXCPIC	
15	Transaction Program	7	MQSERIES	
16	LAN adapter address	8	100090DC2C7C	
17	Mode	17	#INTER	
<i>Connection to a Solaris system</i>				

Table 9. Configuration worksheet for SNA on an IBM i system (continued)

ID	Parameter Name	Reference	Example Used	User Value
9	Network ID	2	NETID	
10	Control point name	3	SOLARPU	
11	LU name	7	SOLARLU	
12	Controller description		SOLARPU

16	LAN adapter address	5	400074511092	
17	Mode		#INTER	

### *Explanation of terms:*

An explanation of the terms used in the configuration worksheet.

**1 2 3** See “How to find network attributes” on page 61 for the details of how to find the configured values.

#### **4 LAN destination address**

The hardware address of the IBM i system token-ring adapter. You can find the value using the command DSPLIND *Line description* (6).

#### **5 Subsystem description**

This parameter is the name of any IBM i subsystem that is active while using the queue manager. The name QCMN has been used because it is the IBM i communications subsystem.

#### **6 Line description**

If this parameter has been specified it is indicated in the Description field of the resource Resource name. See “How to find the value of Resource name” on page 61 for details. If the value is not specified you need to create a line description.

#### **7 Resource name**

See “How to find the value of Resource name” on page 61 for details of how to find the configured value.

#### **8 Local Transaction Program name**

IBM MQ applications trying to converse with this workstation specify a symbolic name for the program to be run at the receiving end. This name is defined on the channel definition at the sender. For simplicity, wherever possible use a transaction program name of MQSERIES, or in the case of a connection to VSE/ESA, where the length is limited to 4 bytes, use MQTP.

See Settings on the local IBM i system for a remote queue manager platform for more information.

#### **12 Controller description**

This parameter is an alias for the Control Point name (or Node name) of the partner system. For convenience, we have used the actual name of the partner in this example.

#### **13 Device**

This parameter is an alias for the LU of the partner system. For convenience, we have used the LU name of the partner in this example.

#### **14 Side information**

This parameter is the name given to the CPI-C side information profile. You specify your own 8-character name.

*How to find network attributes:*

The local node has been partially configured as part of the IBM i installation. To display the current network attributes enter the command DSPNETA.

If you need to change these values use the command CHGNETA. An IPL might be required to apply your changes.

```
Display Network Attributes
System: AS400PU
Current system name . . . . . : AS400PU
Pending system name . . . . . :
Local network ID . . . . . : NETID
Local control point name . . . . . : AS400PU
Default local location . . . . . : AS400LU
Default mode . . . . . : BLANK
APPN node type . . . . . : *ENDNODE
Data compression . . . . . : *NONE
Intermediate data compression . . . . . : *NONE
Maximum number of intermediate sessions . . . . . : 200
Route addition resistance . . . . . : 128
Server network ID/control point name . . . . . : NETID NETCP

More...
Press Enter to continue.

F3=Exit F12=Cancel
```

Check that the values for **Local network ID** (1), **Local control point name** (2), and **Default local location** (3), correspond to the values on your worksheet.

*How to find the value of Resource name:*

To find the value of resource name, type WRKHDWRSC TYPE(\*CMN) and press enter.

The Work with Communication Resources panel is displayed. The value for **Resource name** is found as the token-ring Port. It is LIN041 in this example.

```

Work with Communication Resources
System: AS400PU
Type options, press Enter.
2=Edit 4=Remove 5=Work with configuration description
7=Add configuration description ...

```

```

Configuration
Opt Resource      Description Type Description
CC02              2636 Comm Processor
LIN04             2636 LAN Adapter
LIN041  TOKEN-RING 2636 Token-ring Port

```

```

Bottom
F3=Exit  F5=Refresh F6=Print  F11=Display resource addresses/statuses
F12=Cancel F23=More options

```

### Establishing an LU 6.2 connection:

This section describes how to establish an LU 6.2 connection.

#### *Local node configuration:*

To configure the local node you need to create a line description and add a routing entry.

#### Creating a line description

1. If the line description has not already been created use the command CRTLINTRN.
2. Specify values for **Line description** (6) and **Resource name** (7).

```

Create Line Desc (token-ring) (CRTLINTRN)

```

```

Type choices, press Enter.

```

```

Line description . . . . . TOKENRINGL Name
Resource name . . . . . LIN041 Name, *NWID
NWI type . . . . . *FR *FR, *ATM
Online at IPL . . . . . *YES *YES, *NO
Vary on wait . . . . . *NOWAIT *NOWAIT, 15-180 (1 second)
Maximum controllers . . . . . 40 1-256
Attached NWI . . . . . *NONE Name, *NONE

```

```

Bottom
F3=Exit F4=Prompt F5=Refresh F10=Additional parameters F12=Cancel
F13=How to use this display F24=More keys
Parameter LIND required. +

```

#### Adding a routing entry

1. Type the command ADDRTGE and press enter.

### Add Routing Entry (ADDRTGE)

Type choices, press Enter.

```
Subsystem description . . . . . QCMN      Name
Library . . . . . *LIBL      Name, *LIBL, *CURLIB
Routing entry sequence number . 1      1-9999
Comparison data:
Compare value . . . . . 'MQSERIES'

Starting position . . . . . 37      1-80
Program to call . . . . . AMQCRC6B      Name, *RTGDTA
Library . . . . . QMAS400      Name, * LI BL, *CURLIB
Class . . . . . *SBSD      Name, *SBSD
Library . . . . . *LIBL      Name, *LIBL, *CURLIB
Maximum active routing steps . . *NOMAX      0-1000, *NOMAX
Storage pool identifier . . . . . 1      1-10
```

Bottom

F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display

F24=More keys

Parameter SBSDB required.

+

2. Specify your value for **Subsystem description** (5), and the values shown here for **Routing entry sequence number**, **Compare value** (8), **Starting position**, **Program to call**, and the **Library** containing the program to call.
3. Type the command STRSBS *subsystem description* (5) and press enter.

*Connection to partner node:*

To connect to a partner node, you need to: create a controller description, create a device description, create CPI-C side information, add a communications entry for APPC, and add a configuration list entry.

This example is for a connection to a Windows system, but the steps are the same for other nodes.

### Creating a controller description

1. At a command-line, type CRTCTLAPPC and press enter.

### Create Ctl Desc (APPC) (CRTCTLAPPC)

Type choices, press Enter.

```
Controller description . . . . . WINNTCP      Name
Link type . . . . . *LAN      *FAX, *FR, *IDLC,
*LAN...
Online at IPL . . . . . *NO      *YES, *NO
```

Bottom

F3=Exit F4=Prompt F5=Refresh F10=Additional parameters F12=Cancel

F13=How to use this display F24=More keys

Parameter CTLD required.

+

2. Specify a value for **Controller description** (12), set **Link type** to \*LAN, and set **Online at IPL** to \*NO.
3. Press enter twice, followed by F10.

### Create Ctl Desc (APPC) (CRTCTLAPPC)

Type choices, press Enter.

```
Controller description . . . . . > WINNTCP      Name
Link type . . . . . > *LAN      *FAX, *FR, *IDLC, *LAN...
Online at IPL . . . . . > *NO      *YES, *NO
APPN-capable . . . . . *YES      *YES, *NO
Switched line list . . . . . TOKENRINGL Name
+ for more values
Maximum frame size . . . . . *LINKTYPE 265-16393, 256, 265, 512...
Remote network identifier . . . NETID      Name, *NETATR, *NONE, *ANY
Remote control point . . . . . WINNTCP      Name, *ANY
Exchange identifier . . . . . 00000000-FFFFFF
Initial connection . . . . . *DIAL      *DIAL, *ANS
Dial initiation . . . . . *LINKTYPE *LINKTYPE, *IMMED, *DELAY
LAN remote adapter address . . . 10005AFC5D83 000000000001-FFFFFFFFFFFF
APPN CP session support . . . *YES      *YES, *NO
APPN node type . . . . . *ENDNODE  *ENDNODE, *LENNODE...
APPN transmission group number 1      1-20, *CALC
More...
F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display
F24=More keys
```

4. Specify values for **Switched line list** (6), **Remote network identifier** (9), **Remote control point** (10), and **LAN remote adapter address** (16).
5. Press enter.

### Creating a device description

1. Type the command CRTDEVAPPC and press enter.

### Create Device Desc (APPC) (CRTDEVAPPC)

Type choices, press Enter.

```
Device description . . . . . WINNTLU      Name
Remote location . . . . . WINNTLU      Name
Online at IPL . . . . . *YES      *YES, *NO
Local location . . . . . AS400LU      Name, *NETATR
Remote network identifier . . . NETID      Name, *NETATR, *NONE
Attached controller . . . . . WINNTCP      Name
Mode . . . . . *NETATR      Name, *NETATR
+ for more values
Message queue . . . . . QSYSOPR      Name, QSYSOPR
Library . . . . . *LIBL      Name, *LIBL, *CURLIB
APPN-capable . . . . . *YES      *YES, *NO
Single session:
Single session capable . . . *NO      *NO, *YES
Number of conversations . . . 1-512

Bottom
F3=Exit F4=Prompt F5=Refresh F10=Additional parameters F12=Cancel
F13=How to use this display F24=More keys
Parameter DEVD required.      +
```

2. Specify values for **Device description** (13), **Remote location** (11), **Local location** (3), **Remote network identifier** (9), and **Attached controller** (12).

**Note:** You can avoid having to create controller and device descriptions manually by taking advantage of the IBM i auto-configuration service. Consult the IBM i documentation for details.

## Creating CPI-C side information

1. Type CRTCSI and press F10.

```
Create Comm Side Information (CRTCSI)

Type choices, press Enter.

Side information . . . . . NTCPIC      Name
Library . . . . . *CURLIB    Name, *CURLIB
Remote location . . . . . WINNTLU    Name
Transaction program . . . . . MQSERIES

Text 'description' . . . . . *BLANK

Additional Parameters

Device . . . . . *LOC        Name, *LOC
Local location . . . . . AS400LU    Name, *LOC, *NETATR
Mode . . . . . #INTER       Name, *NETATR
Remote network identifier . . . . . NETID    Name, *LOC, *NETATR, *NONE
Authority . . . . . *LIBCRTAUT  Name, *LIBCRTAUT, *CHANGE...

Bottom
F3=Exit  F4=Prompt  F5=Refresh  F12=Cancel  F13=How to use this display
F24=More keys
Parameter CSI required.
```

2. Specify values for **Side information** (14), **Remote location** (11), **Transaction program** (15), **Local location** (3), **Mode**, and **Remote network identifier** (9).
3. Press enter.

## Adding a communications entry for APPC

1. At a command-line, type ADDCMNE and press enter.

```
Add Communications Entry (ADDCMNE)

Type choices, press Enter.

Subsystem description . . . . . QCMN      Name
Library . . . . . *LIBL      Name, *LIBL, *CURLIB
Device . . . . . WINNTLU     Name, generic*, *ALL...
Remote location . . . . .      Name
Job description . . . . . *USRPRF  Name, *USRPRF, *SBSD
Library . . . . .      Name, *LIBL, *CURLIB
Default user profile . . . . . *NONE  Name, *NONE, *SYS
Mode . . . . . *ANY          Name, *ANY
Maximum active jobs . . . . . *NOMAX  0-1000, *NOMAX

Bottom
F3=Exit  F4=Prompt  F5=Refresh  F12=Cancel  F13=How to use this display
F24=More keys
Parameter SBSD required.
```

2. Specify values for **Subsystem description** (5) and **Device** (13), and press enter.

## Adding a configuration list entry

1. Type ADDCFGLE \*APPNRMT and press F4.

#### Add Configuration List Entries (ADDCFGLE)

Type choices, press Enter.

```
Configuration list type . . . . > *APPNRMT  *APPNLCL, *APPNRMT...
APPN remote location entry:
Remote location name . . . . . WINNTLU      Name, generic*, *ANY
Remote network identifier . . . . . NETID     Name, *NETATR, *NONE
Local location name . . . . . AS400LU      Name, *NETATR
Remote control point . . . . . WINNTCP     Name, *NONE
Control point net ID . . . . . NETID       Name, *NETATR, *NONE
Location password . . . . . *NONE
Secure location . . . . . *NO             *YES, *NO
Single session . . . . . *NO             *YES, *NO
Locally controlled session . . . . . *NO    *YES, *NO
Pre-established session . . . . . *NO     *YES, *NO
Entry 'description' . . . . . *BLANK
Number of conversations . . . . . 10       1-512
+ for more values

Bottom
F3=Exit  F4=Prompt  F5=Refresh  F12=Cancel  F13=How to use this display
F24=More keys
```

2. Specify values for **Remote location name** (11), **Remote network identifier** (9), **Local location name** (3), **Remote control point** (10), and **Control point net ID** (9).
3. Press enter.

*What next?:*

The LU 6.2 connection is now established. You are ready to complete the configuration.

Go to “IBM MQ for IBM i configuration” on page 68.

#### Establishing a TCP connection:

If TCP is already configured there are no extra configuration tasks. If TCP/IP is not configured you need to: add a TCP/IP interface, add a TCP/IP loopback interface, and add a default route.

#### Adding a TCP/IP interface

1. At a command-line, type ADDTCPIFC and press enter.

#### Add TCP/IP Interface (ADDTCPIFC)

Type choices, press Enter.

```
Internet address . . . . . 19.22.11.55
Line description . . . . . TOKENRINGL Name, *LOOPBACK
Subnet mask . . . . . 255.255.0.0
Type of service . . . . . *NORMAL *MINDELAY, *MAXTHRPUT..
Maximum transmission unit . . . *LIND 576-16388, *LIND
Autostart . . . . . *YES *YES, *NO
PVC logical channel identifier 001-FFF
+ for more values
X.25 idle circuit timeout . . . 60 1-600
X.25 maximum virtual circuits . 64 0-64
X.25 DDN interface . . . . . *NO *YES, *NO
TRLAN bit sequencing . . . . . *MSB *MSB, *LSB
```

Bottom

F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display  
F24=More keys

2. Specify the **IP address** and **Line description**, and a **Subnet mask** of the machine.
3. Press enter.

#### Adding a TCP/IP loopback interface

1. At a command-line, type ADDTCPIFC and press enter.

#### Add TCP Interface (ADDTCPIFC)

Type choices, press Enter.

```
Internet address . . . . . 127.0.0.1
Line description . . . . . *LOOPBACK Name, *LOOPBACK
Subnet mask . . . . . 255.0.0.0
Type of service . . . . . *NORMAL *MINDELAY, *MAXTHRPUT..
Maximum transmission unit . . . *LIND 576-16388, *LIND
Autostart . . . . . *YES *YES, *NO
PVC logical channel identifier 001-FFF
+ for more values
X.25 idle circuit timeout . . . 60 1-600
X.25 maximum virtual circuits . 64 0-64
X.25 DDN interface . . . . . *NO *YES, *NO
TRLAN bit sequencing . . . . . *MSB *MSB, *LSB
```

Bottom

F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display  
F24=More keys

2. Specify the values for **IP address**, **Line description**, and **Subnet mask**.

#### Adding a default route

1. At a command-line, type ADDTCP RTE and press enter.

#### Add TCP Route (ADDTCP RTE)

Type choices, press Enter.

```
Route destination . . . . . *DFTRROUTE
Subnet mask . . . . . *NONE
Type of service . . . . . *NORMAL *MINDELAY, *MAXTHRPUT.
Next hop . . . . . 19.2.3.4
Maximum transmission unit . . . 576 576-16388, *IFC
```

Bottom

F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display

F24=More keys

Command prompting ended when user pressed F12.

2. Enter values appropriate to your network and press enter to create a default route entry.

#### What next?

The TCP connection is now established. You are ready to complete the configuration. Go to “IBM MQ for IBM i configuration.”

#### IBM MQ for IBM i configuration:

To configure IBM MQ for IBM i, use the WRKMQMQ command to display the configuration menu.

Start the TCP channel listener using the command STRMQMLSR.

Start any sender channel using the command STRMQMCHL CHLNAME( *channel\_name* ).

Use the WRKMQMQ command to display the IBM MQ configuration menu.

**Note:** AMQ\* errors are placed in the log relating to the job that found the error. Use the WRKACTJOB command to display the list of jobs. Under the subsystem name QSYSWRK, locate the job and enter 5 against it to work with that job. IBM MQ logs are prefixed AMQ.

#### Creating a queue manager:

Use the following steps to set up the basic configuration queue manager.

1. First you need to create a queue manager. Type CRTMQM and press enter.

```

Create Message Queue Manager (CRTMQM)

Type choices, press Enter.

Message Queue Manager name . . .

Text 'description' . . . . . *BLANK

Trigger interval . . . . . 999999999 0-999999999
Undelivered message queue . . . *NONE

Default transmission queue . . . *NONE

Maximum handle limit . . . . . 256 1-999999999
Maximum uncommitted messages . . 1000 1-10000
Default Queue manager . . . . . *NO *YES, *NO

Bottom
F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display
F24=More keys

```

2. In the **Message Queue Manager name** field, type AS400. In the **Undelivered message queue** field, type DEAD.LETTER.QUEUE.
3. Press enter.
4. Now start the queue manager by entering STRMQM MQMNAME(AS400).
5. Create the undelivered message queue using the following parameters. (For details and an example refer to "Defining a queue.")

```

Local Queue
Queue name : DEAD.LETTER.QUEUE
Queue type : *LCL

```

*Defining a queue:*

You can define a queue using the CRTMQMQ command.

Type CRTMQMQ on the command line.

Create MQM Queue (CRTMQMQ)

Type choices, press Enter.

Queue name . . . . .

Queue type . . . . . \*ALS, \*LCL, \*RMT

Bottom

F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display

F24=More keys

Parameter QNAME required.

Complete the two fields of this panel and press enter. Another panel is shown, with entry fields for the other parameters you have. Defaults can be taken for all other queue attributes.

*Defining a channel:*

You can define a channel using the CRTMQMCHL command.

Type CRTMQMCHL on the command line.

Create MQM Channel (CRTMQMCHL)

Type choices, press Enter.

Channel name . . . . .

Channel type . . . . . \*RCVR, \*SDR, \*SVR, \*RQSTR

Bottom

F3=Exit F4=Prompt F5=Refresh F12=Cancel F13=How to use this display

F24=More keys

Parameter CHLNAME required.

Complete the two fields of this panel and press enter. Another panel is displayed on which you can specify the values for the other parameters given earlier. Defaults can be taken for all other channel attributes.

*Channel configuration for IBM i:*

You need to configure your channels to implement the example configuration channels.

This section details the configuration to be performed on the IBM i queue manager to implement the channel described in “Example configuration information for all platforms” on page 1.

Examples are given for connecting IBM MQ for IBM i and IBM MQ for Windows. To connect to IBM MQ on another platform, use the appropriate values from the table in place of those values for Windows

**Note:**

1. The words in **bold** are user-specified and reflect the names of IBM MQ objects used throughout these examples. If you change the names used here, ensure that you also change the other references made to these objects throughout this section. All others are keywords and must be entered as shown.
2. The IBM MQ channel ping command (PNGMQMCHL) runs interactively, whereas starting a channel causes a batch job to be submitted. If a channel ping completes successfully but the channel does not start, the network and IBM MQ definitions are probably correct, but that the IBM i environment for the batch job is not. For example, make sure that QSYS2 is included in the system portion of the library list and not just your personal library list.

For details and examples of how to create the objects listed refer to “Defining a queue” on page 69 and “Defining a channel” on page 70.

*Table 10. Configuration worksheet for IBM MQ for IBM i*

ID	Parameter Name	Reference	Example Used	User Value
<i>Definition for local node</i>				
A	Queue Manager Name		<b>AS400</b>	
B	Local queue name		<b>AS400.LOCALQ</b>	
<i>Connection to IBM MQ for Windows</i>				
The values in this section of the table must match the values used in “Channel configuration for Windows” on page 7, as indicated.				
C	Remote queue manager name	A	<b>WINNT</b>	
D	Remote queue name		<b>WINNT.REMOTEQ</b>	
E	Queue name at remote system	B	<b>WINNT.LOCALQ</b>	
F	Transmission queue name		<b>WINNT</b>	
G	Sender (SNA) channel name		<b>AS400.WINNT.SNA</b>	
H	Sender (TCP/IP) channel name		<b>AS400.WINNT.TCP</b>	
I	Receiver (SNA) channel name	G	<b>WINNT.AS400.SNA</b>	
J	Receiver (TCP/IP) channel name	H	<b>WINNT.AS400.TCP</b>	
<i>Connection to IBM MQ for AIX</i>				
The values in this section of the table must match the values used in “Channel configuration for AIX” on page 15, as indicated.				
C	Remote queue manager name	A	<b>AIX</b>	
D	Remote queue name		<b>AIX.REMOTEQ</b>	
E	Queue name at remote system	B	<b>AIX.LOCALQ</b>	
F	Transmission queue name		<b>AIX</b>	
G	Sender (SNA) channel name		<b>AS400.AIX.SNA</b>	
H	Sender (TCP/IP) channel name		<b>AS400.AIX.TCP</b>	

Table 10. Configuration worksheet for IBM MQ for IBM i (continued)

ID	Parameter Name	Reference	Example Used	User Value
I	Receiver (SNA) channel name	G	AIX.AS400.SNA	
J	Receiver (TCP) channel name	H	AIX.AS400.TCP	
<b>Connection to MQSeries for Compaq Tru64 Unix</b>				
The values in this section of the table must match the values used in your Compaq Tru64 UNIX system.				
C	Remote queue manager name	A	DECUX	
D	Remote queue name		DECUX.REMOTEQ	
E	Queue name at remote system	B	DECUX.LOCALQ	
F	Transmission queue name		DECUX	
H	Sender (TCP) channel name		DECUX.AS400.TCP	
J	Receiver (TCP) channel name	H	AS400.DECUX.TCP	
<b>Connection to IBM MQ for HP-UX</b>				
The values in this section of the table must match the values used in "Channel configuration for HP-UX" on page 21, as indicated.				
C	Remote queue manager name	A	HPUX	
D	Remote queue name		HPUX.REMOTEQ	
E	Queue name at remote system	B	HPUX.LOCALQ	
F	Transmission queue name		HPUX	
G	Sender (SNA) channel name		AS400.HPUX.SNA	
H	Sender (TCP) channel name		AS400.HPUX.TCP	
I	Receiver (SNA) channel name	G	HPUX.AS400.SNA	
J	Receiver (TCP) channel name	H	HPUX.AS400.TCP	
<b>Connection to IBM MQ for Solaris</b>				
The values in this section of the table must match the values used in "Channel configuration for Solaris" on page 27, as indicated.				
C	Remote queue manager name	A	SOLARIS	
D	Remote queue name		SOLARIS.REMOTEQ	
E	Queue name at remote system	B	SOLARIS.LOCALQ	
F	Transmission queue name		SOLARIS	
G	Sender (SNA) channel name		AS400.SOLARIS.SNA	
H	Sender (TCP/IP) channel name		AS400.SOLARIS.TCP	
I	Receiver (SNA) channel name	G	SOLARIS.AS400.SNA	
J	Receiver (TCP/IP) channel name	H	SOLARIS.AS400.TCP	
<b>Connection to IBM MQ for Linux</b>				
The values in this section of the table must match the values used in "Channel configuration for Linux" on page 34, as indicated.				
C	Remote queue manager name	A	LINUX	
D	Remote queue name		LINUX.REMOTEQ	
E	Queue name at remote system	B	LINUX.LOCALQ	
F	Transmission queue name		LINUX	
G	Sender (SNA) channel name		AS400.LINUX.SNA	

Table 10. Configuration worksheet for IBM MQ for IBM i (continued)

ID	Parameter Name	Reference	Example Used	User Value
H	Sender (TCP/IP) channel name		AS400.LINUX.TCP	
I	Receiver (SNA) channel name	G	LINUX.AS400.SNA	
J	Receiver (TCP/IP) channel name	H	LINUX.AS400.TCP	
<b>Connection to IBM MQ for z/OS</b>				
The values in this section of the table must match the values used in "Channel configuration for z/OS" on page 38, as indicated.				
C	Remote queue manager name	A	MVS	
D	Remote queue name		MVS.REMOTEQ	
E	Queue name at remote system	B	MVS.LOCALQ	
F	Transmission queue name		MVS	
G	Sender (SNA) channel name		AS400.MVS.SNA	
H	Sender (TCP) channel name		AS400.MVS.TCP	
I	Receiver (SNA) channel name	G	MVS.AS400.SNA	
J	Receiver (TCP) channel name	H	MVS.AS400.TCP	
<b>Connection to MQSeries for VSE/ESA</b>				
The values in this section of the table must match the values used in your VSE/ESA system.				
C	Remote queue manager name	A	VSE	
D	Remote queue name		VSE.REMOTEQ	
E	Queue name at remote system	B	VSE.LOCALQ	
F	Transmission queue name		VSE	
G	Sender channel name		AS400.VSE.SNA	
I	Receiver channel name	G	VSE.AS400.SNA	

IBM MQ for IBM i sender-channel definitions:

Example sender-channel definitions for SNA and TCP.

### Using SNA

```

Local Queue
  Queue name :   WINNT
  Queue type  :   *LCL
  Usage      :   *TMQ

Remote Queue
  Queue name :   WINNT.REMOTEQ
  Queue type  :   *RMT
  Remote queue :   WINNT.LOCALQ
Remote Queue Manager :   WINNT
Transmission queue :   WINNT

Sender Channel
  Channel Name :   AS400.WINNT.SNA
  Channel Type :   *SDR
  Transport type :   *LU62
  Connection name :   WINNTCPIC
  Transmission queue :   WINNT
  
```

## Using TCP

```
Local Queue
  Queue name : WINNT                    F
  Queue type : *LCL
  Usage      : *TMQ

Remote Queue
  Queue name : WINNT.REMOTEQ            D
  Queue type : *RMT
  Remote queue : WINNT.LOCALQ          E
Remote Queue Manager : WINNT            C
  Transmission queue : WINNT            F

Sender Channel
  Channel Name : AS400.WINNT.TCP        H
  Channel Type : *SDR
  Transport type : *TCP
  Connection name : WINNT.tcpip.hostname
  Transmission queue : WINNT            F
```

*IBM MQ for IBM i receiver-channel definitions:*

Example receiver-channel definitions for SNA and TCP

## Using SNA

```
Local Queue
  Queue name : AS400.LOCALQ             B
  Queue type : *LCL

Receiver Channel
  Channel Name : WINNT.AS400.SNA        I
  Channel Type : *RCVR
  Transport type : *LU62
```

## Using TCP

```
Local Queue
  Queue name : AS400.LOCALQ             B
  Queue type : *LCL

Receiver Channel
  Channel Name : WINNT.AS400.TCP        J
  Channel Type : *RCVR
  Transport type : *TCP
```

## IBM MQ file system permissions applied to /var/mqm

The following information describes the security applied to the files and directories under /var/mqm/ and why the file-system permissions are set as they are. In order to ensure the correct operation of IBM MQ you should not alter the file system permissions as set by IBM MQ

### IBM MQ file system Security on UNIX, Linux, and IBM i

The files under the IBM MQ data directory (/var/mqm) are used to store:

- IBM MQ configuration data
- Application data (IBM MQ objects and the data contained within IBM MQ messages)
- Run-time control information
- Monitoring information (messages and FFST files)

Access to this data is controlled using file system permissions with some of the data being accessible to all users while other data is restricted only to members of the IBM MQ Administrator group 'mqm' (or QMQM on IBM i).

Access is granted in the following three categories:

#### mqm group only

The files and directories in this category are only accessible to IBM MQ Administrators (members of the 'mqm' group) and the IBM MQ queue manager processes.

The file permissions for these files and directories are:

```
-rwxrwx---   mqm:mqm      (UNIX and Linux)
-rwxrwx---   QMQMADM:QMQM (IBM i)
```

An example of the files and directories in this category is:

```
/var/mqm/qmgrs/<QMGR>/qm.ini
/var/mqm/qmgrs/<QMGR>/channel/
/var/mqm/qmgrs/<QMGR>/channel/SYSTEM!DEF!SCRVONN
/var/mqm/qmgrs/<QMGR>/queues/
/var/mqm/qmgrs/<QMGR>/queues/SYSTEM!DEFAULT!LOCAL!QUEUES/
/var/mqm/qmgrs/<QMGR>/errors/
/var/mqm/qmgrs/<QMGR>/errors/AMQERR01.LOG
/var/mqm/qmgrs/<QMGR>/ssl/
/var/mqm/qmgrs/<QMGR>/@qmgr/
/var/mqm/qmgrs/<QMGR>/@qmpersist/
...
```

#### All users read access - mqm group members read and write access

The files and directories in this category can be read by all users, but only members of the 'mqm' group can modify these files and manipulate these directories.

The file permissions for these files and directories are:

```
-rwxrwxr-x   mqm:mqm      (UNIX and Linux)
-rwxrwxr-x   QMQMADM:QMQM (IBM i)
```

An example of the files and directories in this category is:

```
/var/mqm/mqs.ini
/var/mqm/exits/
/var/mqm/qmgrs/
/var/mqm/qmgrs/<QMGR>/
/var/mqm/qmgrs/<QMGR>/@app/
/var/mqm/qmgrs/<QMGR>/@ipcc/
```

IBM WebSphere® MQ V7.1 and V7.5, and IBM MQ Version 8.0:

```
/var/mqm/sockets/@SYSTEM  
/var/mqm/sockets/<QMGR>/@app/<hostname>  
/var/mqm/sockets/<QMGR>/@ipcc/<hostname>
```

## All users read and write access

### Files that have read and write access for all users

IBM MQ has no *regular* files that have world writable file permissions (777). However there are a number of *special* files that appear as having world writable file permissions.

These special files provide no security exposure. Although the permissions are shown as 777, they are not *regular* files and you cannot write directly to them.

These special files are:

### Symbolic links

Symbolic links are identified by the 'l' character at the start of their permissions. The permissions on the symbolic link have no effect on who is able to access the target file, as access to the command is controlled by the permissions on the target of the symbolic link.

On most UNIX and Linux systems it is not possible to change the permissions on symbolic links, so they always appear as lrwxrwxrwx.

### Socket files

Socket files are special files created by the operating system, as a result of a process creating a UNIX domain socket. These files can be identified by the 's' at the start of the file permissions, that is srwxrwxrwx.

The permissions on the file do not grant access to the file itself, but define who can connect to the UNIX domain socket.

IBM MQ uses a number of these socket files and the permissions are always set according to who is allowed to communicate with the socket.

The following directories contain socket files that have read/write permissions for all users (srwxrwxrwx).

IBM WebSphere MQ V7.r and IBM MQ Version 8.0:

```
/var/mqm/sockets/<QMGR>/zsocketEC/<hostname>/Zsocket_*
```

Socket files used by applications that connect to IBM MQ using isolated bindings.

```
/var/mqm/sockets/<QMGR>/@ipcc/ssem/<hostname>/*
```

### Directories that have read and write access for all users

There are times when IBM MQ applications need to create files under the IBM MQ data directory. To ensure that applications are able to create files when they are required, a number of directories are granted world write access, which means that any user on the system can create files within that directory.

With the exception of the errors logs files, that can be written to by any member of the 'mqm' group, all files created in these directories are created with restricted permissions that allows only the file creator write access. This allows the system administrator to track the user ID of all data written to files in these directories.

```
/var/mqm/errors/
```

This directory contains the system error log files and FFST files. The permission of this directory is 'drwxrwsrwt' meaning that all users on the system can create files in this directory.

The SetGroupId bit 's' indicates that all files created in this directory have the group ownership of 'mqm'.

The 't' sticky bit is not set by default on this directory, but an IBM MQ administrator can set this explicitly, to allow users to delete only the files that they create.

**Note:** This feature is not available on IBM i.

#### **AMQERR0\*.LOG**

These error log files can only be written to directly by members of the group but any user can read the messages written to these files (permission: -rw-rw-r--).

#### **AMQnnnnn\*.FDC**

These files contain FFST information written when an error occurs in the queue manager or in an application written by a user. These files are created with the permissions -rw-r-----.

#### */var/mqm/trace/*

Trace files are written to this directory when IBM MQ trace is enabled. IBM MQ trace is written by all process associated with a queue manager for which trace is enabled.

The permissions of this directory are 'drwxrwsrwt' meaning that all users on the system can create files in this directory.

The SetGroupId bit 's' indicates that all files created in this directory have the group ownership of 'mqm'.

The 't' sticky bit is not set by default on this directory, but an IBM MQ administrator can set this explicitly, to allow users to delete only the files that they create.

**Note:** This feature is not available on IBM i.

#### **AMQnnnnn\*.TRC**

These files contain the trace data written by each process which is tracing and are created with permissions -rw-r-----

The permissions on this directory are drwxrwsrwt and the permissions of the socket files created in this directory are srwx-----.

#### **IBM WebSphere MQ V7.1 and V7.5, and IBM MQ Version 8.0:**

*/var/mqm/sockets/<QMGR>/zsocketapp/<hostname>/*

This directory is used by applications that connect to the IBM MQ queue manager using *isolated* bindings. During connect processing a socket file is created by the connecting application in this directory. The socket file is removed after the connection is made to the queue manager.

The permissions on this directory are drwxrwsrwt and the permissions of the socket files created in this directory are srwx-----.

The SetGroupId bit 's' on this directory ensures that all files created in this directory have the group ownership of 'mqm'.

On all platforms except IBM i, this directories also has the 't' sticky bit set which prevents a user from deleting any files except the ones for which they are the owner. This prevents an unauthorized user from deleting files that they do not own.

*/var/mqm/sockets/<QMGR>/@ipcc/ssem/<hostname>/*  
*/var/mqm/sockets/<QMGR>/@app/ssem/<hostname>/*

For processes that connect to IBM MQ using *shared* bindings then UNIX domain sockets might be used to synchronize between the application and the queue manager. When UNIX domain sockets are being used then the associated socket file is created in these directories.

The permissions on these directories are drwxrwsrwt and the permissions of the socket files created in these directories are srwxrwxrwx.

The SetGroupId bit 's' on these directories ensures that all files created in these directories have the group ownership of 'mqm'.

On all platforms except IBM i, these directories also have the 't' sticky bit set which prevents a user from deleting any files except the ones for which they are the owner. This prevents an unauthorized user from deleting files that they do not own.

## Use of System V IPC resources by IBM MQ

IBM MQ uses System V shared memory and semaphores for inter-process communication. These resources are grouped according to how they are used with each group having appropriate ownership and access permissions.

To verify which of the System V IPC resources on a system belong to IBM MQ you can:

- Check the ownership.

The owning user of IBM MQ System V IPC resources is always the 'mqm' user on UNIX platforms and Linux. On IBM i the owning user is 'QMQM'.

- IBM WebSphere MQ V7.5 and later, use the amqspdbg utility.

The amqspdbg utility which is shipped with IBM MQ can be used to display the shared memory and semaphore id's for a given queue manager.

You must issue the command once for the 'system' group of System V resources created by IBM MQ

```
# amqspbg -z -I
```

and then four times for each queue manager on the system to get the complete list of System V resources used by IBM MQ. Assume a queue manager name of QMGR1 in the following examples:.

```
# amqspdbg -i QMGR1 -I
# amqspdbg -q QMGR1 -I
# amqspdbg -p QMGR1 -I
# amqspdbg -a QMGR1 -I
```

The access permissions on the System V resources created by IBM MQ are set to grant only the correct level of access to the permitted users. A number of the System V IPC resources created by IBM MQ are accessible to all users on the machine and have permissions of -rw-rw-rw-.

The **-g** *ApplicationGroup* parameter on the crtmqm command can be used to restrict access to a queue manager to membership of a specific operating system group. The use of this restricted group functionality restricts the permissions granted on the System V IPC resources further.

## Queue names

Use this information to understand the restrictions of queue names and reserved queue names.

Queues can have names up to 48 characters long.

### Reserved Queue names

Names that start with "SYSTEM." are reserved for queues defined by the queue manager. You can use the **ALTER** or **DEFINE REPLACE** commands to change these queue definitions to suit your installation. The following names are defined for IBM MQ:

Queue Name	Description
SYSTEM.ADMIN.ACTIVITY.QUEUE	Queue for activity reports
SYSTEM.ADMIN.CHANNEL.EVENT	Queue for channel events
SYSTEM.ADMIN.COMMAND.EVENT	Queue for command events
SYSTEM.ADMIN.COMMAND.QUEUE	Queue to which PCF command messages are sent
SYSTEM.ADMIN.CONFIG.EVENT	Queue for configuration events
SYSTEM.ADMIN.PERFM.EVENT	Queue for performance events
SYSTEM.ADMIN.PUBSUB.EVENT	System publish/subscribe related event queue
SYSTEM.ADMIN.QMGR.EVENT	Queue for queue manager events
SYSTEM.ADMIN.TRACE.ROUTE.QUEUE	Queue for trace-route reply messages
SYSTEM.AUTH.DATA.QUEUE	The queue that holds access control lists for the queue manager. (Not for z/OS )
SYSTEM.CHANNEL.INITQ	Initiation queue for channels
SYSTEM.CHANNEL.SYNCQ	The queue that holds the synchronization data for channels
SYSTEM.CHLAUTH.DATA.QUEUE	IBM MQ channel authentication data queue
SYSTEM.CICS.INITIATION.QUEUE	Queue used for triggering (not for z/OS )
SYSTEM.CLUSTER.COMMAND.QUEUE	Queue used to communicate repository changes between queue managers ( AIX, HP-UX, Linux, IBM i, Solaris, Windows, and z/OS only)
SYSTEM.CLUSTER.HISTORY.QUEUE	The queue is used to store the history of cluster state information for service purposes.
SYSTEM.CLUSTER.REPOSITORY.QUEUE	Queue used to hold information about the repository ( AIX, HP-UX, Linux, IBM i, Solaris, Windows, and z/OS only)
SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE	The queue is used to create individual transmit queues for each cluster-sender channel.
SYSTEM.CLUSTER.TRANSMIT.QUEUE	Transmission queue for all destinations managed by cluster support ( AIX, HP-UX, Linux, IBM i, Solaris, Windows, and z/OS only)
SYSTEM.COMMAND.INPUT	Queue to which command messages are sent on z/OS
SYSTEM.COMMAND.REPLY.MODEL	Model queue definition for command replies (for z/OS )
SYSTEM.DEAD.LETTER.QUEUE	Dead-letter queue (not for z/OS )
SYSTEM.DEFAULT.ALIAS.QUEUE	Default alias queue definition
SYSTEM.DEFAULT.INITIATION.QUEUE	Queue used to trigger a specified process (not for z/OS )
SYSTEM.DEFAULT.LOCAL.QUEUE	Default local queue definition
SYSTEM.DEFAULT.MODEL.QUEUE	Default model queue definition
SYSTEM.DEFAULT.REMOTE.QUEUE	Default remote queue definition

Queue Name	Description
SYSTEM.DURABLE.SUBSCRIBER.QUEUE	A local queue used to hold a persistent copy of the durable subscriptions in the queue manager
SYSTEM.HIERARCHY.STATE	Queue used to hold information about the state of inter-queue manager relationships in a publish/subscribe hierarchy
SYSTEM.JMS.TEMPQ.MODEL	Model for JMS temporary queues
SYSTEM.INTERNAL.REPLY.QUEUE	IBM MQ internal reply queue (not for z/OS )
SYSTEM.INTER.QMGR.CONTROL	Queue used in a publish/subscribe hierarchy to receive requests from a remote queue manager to create a proxy subscription
SYSTEM.INTER.QMGR.PUBS	Queue used in a publish/subscribe hierarchy to receive publications from a remote queue manager
SYSTEM.INTER.QMGR.FANREQ	Queue used in a publish/subscribe hierarchy to process requests to create a proxy subscription on a remote queue manager
SYSTEM.MQEXPLORER.REPLY.MODEL	Model queue definition for replies for MQ Explorer
SYSTEM.MQSC.REPLY.QUEUE	Model queue definition for MQSC command replies (not for z/OS )
SYSTEM.QSG.CHANNEL.SYNCQ	Shared local queue used for storing messages that contain the synchronization information for shared channels ( z/OS only)
SYSTEM.QSG.TRANSMIT.QUEUE	Shared local queue used by the intra-group queuing agent when transmitting messages between queue managers in the same queue-sharing group ( z/OS only)
SYSTEM.RETAINED.PUB.QUEUE	A local queue used to hold a copy of each retained publication in the queue manager.
SYSTEM.SELECTION.EVALUATION.QUEUE	IBM MQ internal selection evaluation queue (not for z/OS )
SYSTEM.SELECTION.VALIDATION.QUEUE	IBM MQ internal selection validation queue (not for z/OS )

## Other object names

Processes, namelists, clusters, topics, services, and authentication information objects can have names up to 48 characters long. Channels can have names up to 20 characters long. Storage classes can have names up to 8 characters long. CF structures can have names up to 12 characters long.

## Reserved object names

Names that start with SYSTEM. are reserved for objects defined by the queue manager. You can use the ALTER or DEFINE REPLACE commands to change these object definitions to suit your installation. The following names are defined for IBM MQ:

Object Name	Description
SYSTEM.ADMIN.SVRCONN	Server-connection channel used for remote administration of a queue manager
SYSTEM.AUTO.RECEIVER	Default receiver channel for auto definition ( Windows, UNIX and Linux systems only)
SYSTEM.AUTO.SVRCONN	Default server-connection channel for auto definition ( IBM i, Windows, UNIX and Linux systems only)
SYSTEM.BASE.TOPIC	Base topic for ASPARENT resolution. If a particular administrative topic object has no parent administrative topic objects, any ASPARENT attributes are inherited from this object
SYSTEM.DEF.CLNTCONN	Default client-connection channel definition

Object Name	Description
SYSTEM.DEF.CLUSRCVR	Default cluster-receiver channel definition
SYSTEM.DEF.CLUSSDR	Default cluster-sender channel definition
SYSTEM.DEF.RECEIVER	Default receiver channel definition
SYSTEM.DEF.REQUESTER	Default requester channel definition
SYSTEM.DEF.SENDER	Default sender channel definition
SYSTEM.DEF.SERVER	Default server channel definition
SYSTEM.DEF.SVRCONN	Default server-connection channel definition
SYSTEM.DEFAULT.AUTHINFO.CRLLDAP	Default authentication information object definition for defining authentication information objects of type CRLLDAP
SYSTEM.DEFAULT.AUTHINFO.OCSP	Default authentication information object definition for defining authentication information objects of type OCSP
SYSTEM.DEFAULT.LISTENER.LU62	Default SNA listener ( Windows only)
SYSTEM.DEFAULT.LISTENER.NETBIOS	Default NetBIOS listener ( Windows only)
SYSTEM.DEFAULT.LISTENER.SPX	Default SPX listener ( Windows only)
SYSTEM.DEFAULT.LISTENER.TCP	Default TCP/IP listener ( IBM i, Windows, UNIX and Linux systems only)
SYSTEM.DEFAULT.NAMELIST	Default namelist definition
SYSTEM.DEFAULT.PROCESS	Default process definition
SYSTEM.DEFAULT.SERVICE	Default service ( IBM i, Windows, UNIX and Linux systems only)
SYSTEM.DEFAULT.TOPIC	Default topic definition
SYSTEM.QPUBSUB.QUEUE.NAMELIST	A list of queues for the Queued Publish/Subscribe interface to monitor
SYSTEMST	Default storage class definition ( z/OS only)

## Queue name resolution

This topic contains information about queue name resolution as performed by queue managers at both sending and receiving ends of a channel.

In larger networks, the use of queue managers has a number of advantages over other forms of communication. These advantages derive from the name resolution function in DQM and the main benefits are:

- Applications do not need to make routing decisions
- Applications do not need to know the network structure
- Network links are created by systems administrators
- Network structure is controlled by network planners
- Multiple channels can be used between nodes to partition traffic

The following figure shows an example of queue name resolution. The figure shows two machines in a network, one running a put application, the other running a get application. The applications communicate with each other through the IBM MQ channel, controlled by the MCAs. As far as the application is concerned, the process is the same as putting messages on a local queue.

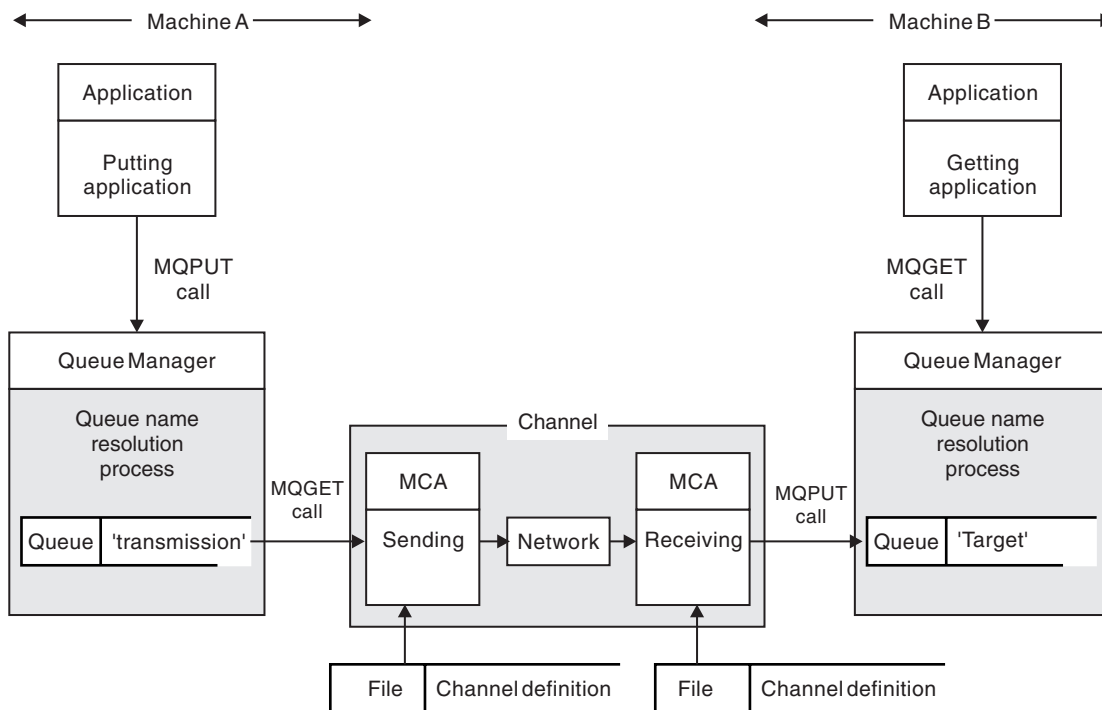

Figure 5. Name resolution

Referring to Figure 5, the basic mechanism for putting messages on a remote queue, as far as the application is concerned, is the same as for putting messages on a local queue:

- The application putting the message issues MQOPEN and MQPUT calls to put messages on the target queue.
- The application getting the messages issues MQOPEN and MQGET calls to get the messages from the target queue.

If both applications are connected to the same queue manager then no inter-queue manager communication is required, and the target queue is described as *local* to both applications.

However, if the applications are connected to different queue managers, two MCAs and their associated network connection are involved in the transfer, as shown in the figure. In this case, the target queue is considered to be a *remote queue* to the putting application.

The sequence of events is as follows:

1. The putting application issues MQOPEN and MQPUT calls to put messages to the target queue.
2. During the MQOPEN call, the *name resolution* function detects that the target queue is not local, and decides which transmission queue is appropriate. Thereafter, on the MQPUT calls associated with the MQOPEN call, all messages are placed on this transmission queue.
3. The sending MCA gets the messages from the transmission queue and passes them to the receiving MCA at the remote computer.
4. The receiving MCA puts the messages on the target queue, or queues.
5. The getting application issues MQOPEN and MQGET calls to get the messages from the target queue.

**Note:** Only step 1 and step 5 involve application code; steps 2 through 4 are performed by the local queue managers and the MCA programs. The putting application is unaware of the location of the target queue, which could be in the same processor, or in another processor on another continent.

The combination of sending MCA, the network connection, and the receiving MCA, is called a *message channel*, and is inherently a unidirectional device. Normally, it is necessary to move messages in both directions, and two channels are set up for this movement, one in each direction.

### **What is queue name resolution?**

Queue name resolution is vital to DQM. It removes the need for applications to be concerned with the physical location of queues, and insulates them against the details of networks.

A systems administrator can move queues from one queue manager to another, and change the routing between queue managers without applications needing to know anything about it.

In order to uncouple from the application design the exact path over which the data travels, it is necessary to introduce a level of indirection between the name used by the application when it refers to the target queue, and the naming of the channel over which the flow occurs. This indirection is achieved using the queue name resolution mechanism.

In essence, when an application refers to a queue name, the name is mapped by the resolution mechanism either to a transmission queue or to a local queue that is not a transmission queue. For mapping to a transmission queue, a second name resolution is needed at the destination, and the received message is placed on the target queue as intended by the application designer. The application remains unaware of the transmission queue and channel used for moving the message.

**Note:** The definition of the queue and channel is a system management responsibility and can be changed by an operator or a system management utility, without the need to change applications.

An important requirement for the system management of message flows is that alternative paths need to be provided between queue managers. For example, business requirements might dictate that different *classes of service* are sent over different channels to the same destination. This decision is a system management decision and the queue name resolution mechanism provides a flexible way to achieve it. The Application Programming Guide describes this in detail, but the basic idea is to use queue name resolution at the sending queue manager to map the queue name supplied by the application to the appropriate transmission queue for the type of traffic involved. Similarly at the receiving end, queue name resolution maps the name in the message descriptor to a local (not a transmission) queue or again to an appropriate transmission queue.

Not only is it possible for the forward path from one queue manager to another to be partitioned into different types of traffic, but the return message that is sent to the reply-to queue definition in the outbound message can also use the same traffic partitioning. Queue name resolution satisfies this requirement and the application designer need not be involved in these traffic partitioning decisions.

The point that the mapping is carried out at both the sending and receiving queue managers is an important aspect of the way name resolution works. This mapping allows the queue name supplied by the putting application to be mapped to a local queue or a transmission queue at the sending queue manager, and again remapped to a local queue or a transmission queue at the receiving queue manager.

Reply messages from receiving applications or MCAs have the name resolution carried out in the same way, allowing return routing over specific paths with queue definitions at all the queue managers on route.

## System and default objects

Lists the system and default objects created by the **crtmqm** command.

When you create a queue manager using the **crtmqm** control command, the system objects and the default objects are created automatically.

- The system objects are those IBM MQ objects needed to operate a queue manager or channel.
- The default objects define all the attributes of an object. When you create an object, such as a local queue, any attributes that you do not specify explicitly are inherited from the default object.

The following tables list the system and default objects created by **crtmqm**:

- Table 11 lists the system and default queue objects.
- Table 12 on page 85 lists the system and default topic objects.
- Table 13 on page 85 lists the system and default channel objects.
- Table 14 on page 86 lists the system and default authentication information objects.
- Table 15 on page 86 lists the system and default listener objects.
- Table 16 on page 86 lists the system and default namelist objects.
- Table 17 on page 86 lists the system and default process objects.
- Table 18 on page 86 lists the system and default service objects.

*Table 11. System and default objects: queues*

Object name	Description
SYSTEM.ADMIN.ACCOUNTING.QUEUE	The queue that holds accounting monitoring data.
SYSTEM.ADMIN.ACTIVITY.QUEUE	The queue that holds returned activity reports.
SYSTEM.ADMIN.CHANNEL.EVENT	Event queue for channels.
SYSTEM.ADMIN.COMMAND.EVENT	Event queue for command events.
SYSTEM.ADMIN.COMMAND.QUEUE	Administration command queue. Used for remote MQSC commands and PCF commands.
SYSTEM.ADMIN.CONFIG.EVENT	Event queue for configuration events.
SYSTEM.ADMIN.PERFM.EVENT	Event queue for performance events.
SYSTEM.ADMIN.PUBSUB.EVENT	System publish/subscribe related event queue
SYSTEM.ADMIN.QMGR.EVENT	Event queue for queue manager events.
SYSTEM.ADMIN.STATISTICS.QUEUE	The queue that holds statistics monitoring data.
SYSTEM.ADMIN.TRACE.ACTIVITY.QUEUE	The queue that displays trace activity.
SYSTEM.ADMIN.TRACE.ROUTE.QUEUE	The queue that holds returned trace-route reply messages.
SYSTEM.AUTH.DATA.QUEUE	The queue that holds access control lists for the queue manager.
SYSTEM.CHANNEL.INITQ	Channel initiation queue.
SYSTEM.CHANNEL.SYNCQ	The queue that holds the synchronization data for channels.
SYSTEM.CHLAUTH.DATA.QUEUE	IBM MQ channel authentication data queue
SYSTEM.CICS.INITIATION.QUEUE	Default CICS initiation queue.
SYSTEM.CLUSTER.COMMAND.QUEUE	The queue used to carry messages to the repository queue manager.
SYSTEM.CLUSTER.HISTORY.QUEUE	The queue is used to store the history of cluster state information for service purposes.
SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE	The queue is used to create individual transmit queues for each cluster-sender channel.

Table 11. System and default objects: queues (continued)

Object name	Description
SYSTEM.CLUSTER.REPOSITORY.QUEUE	The queue used to store all repository information.
SYSTEM.CLUSTER.TRANSMIT.QUEUE	The transmission queue for all messages to all clusters.
SYSTEM.DEAD.LETTER.QUEUE	Dead-letter (undelivered-message) queue.
SYSTEM.DEFAULT.ALIAS.QUEUE	Default alias queue.
SYSTEM.DEFAULT.INITIATION.QUEUE	Default initiation queue.
SYSTEM.DEFAULT.LOCAL.QUEUE	Default local queue.
SYSTEM.DEFAULT.MODEL.QUEUE	Default model queue.
SYSTEM.DEFAULT.REMOTE.QUEUE	Default remote queue.
SYSTEM.JMS.TEMPQ.MODEL	Model for JMS temporary queues
SYSTEM.MQEXPLORER.REPLY.MODEL	The MQ Explorer reply-to queue. This is a model queue that creates a temporary dynamic queue for replies to the MQ Explorer.
SYSTEM.MQSC.REPLY.QUEUE	MQSC command reply-to queue. This is a model queue that creates a temporary dynamic queue for replies to remote MQSC commands.
SYSTEM.PENDING.DATA.QUEUE	Support deferred messages in JMS.

Table 12. System and default objects: topics

Object name	Description
SYSTEM.BASE.TOPIC	Base topic for ASPARENT resolution. If a particular topic has no parent administrative topic objects, or those parent objects also have ASPARENT, any remaining ASPARENT attributes are inherited from this object.
SYSTEM.DEFAULT.TOPIC	Default topic definition.

Table 13. System and default objects: channels

Object name	Description
SYSTEM.AUTO.RECEIVER	Dynamic receiver channel.
SYSTEM.AUTO.SVRCONN	Dynamic server-connection channel.
SYSTEM.DEF.CLUSRCVR	Default receiver channel for the cluster, used to supply default values for any attributes not specified when a CLUSRCVR channel is created on a queue manager in the cluster.
SYSTEM.DEF.CLUSSDR	Default sender channel for the cluster, used to supply default values for any attributes not specified when a CLUSSDR channel is created on a queue manager in the cluster.
SYSTEM.DEF.RECEIVER	Default receiver channel.
SYSTEM.DEF.REQUESTER	Default requester channel.
SYSTEM.DEF.SENDER	Default sender channel.
SYSTEM.DEF.SERVER	Default server channel.
SYSTEM.DEF.SVRCONN	Default server-connection channel.
SYSTEM.DEF.CLNTCONN	Default client-connection channel.
 SYSTEM.DEF.AMQP	Default AMQP channel.

Table 14. System and default objects: authentication information objects

Object name	Description
SYSTEM.DEFAULT.AUTHINFO.CRLLDAP	Default authentication information object for defining authentication information objects of type CRLLDAP.
SYSTEM.DEFAULT.AUTHINFO.OCSP	Default authentication information object for defining authentication information objects of type OCSP.

Table 15. System and default objects: listeners

Object name	Description
SYSTEM.DEFAULT.LISTENER.TCP	Default TCP listener.
SYSTEM.DEFAULT.LISTENER.LU62 <sup>1</sup>	Default LU62 listener.
SYSTEM.DEFAULT.LISTENER.NETBIOS <sup>1</sup>	Default NETBIOS listener.
SYSTEM.DEFAULT.LISTENER.SPX <sup>1</sup>	Default SPX listener.

## 1. Windows only

Table 16. System and default objects: namelists

Object name	Description
SYSTEM.DEFAULT.NAMELIST	Default namelist.

Table 17. System and default objects: processes

Object name	Description
SYSTEM.DEFAULT.PROCESS	Default process definition.

Table 18. System and default objects: services

Object name	Description
SYSTEM.DEFAULT.SERVICE	Default service.
SYSTEM.BROKER	Publish/subscribe broker

## Windows default configuration objects

On Windows systems, you can set up a default configuration using the IBM MQ Postcard application.

**Note:** You cannot set up a default configuration if other queue managers exist on your computer.

Many of the names used for the Windows default configuration objects involve the use of a short TCP/IP name. This is the TCP/IP name of the computer, without the domain part; for example the short TCP/IP name for the computer `mycomputer.hursley.ibm.com` is `mycomputer`. In all cases, where this name has to be truncated, if the last character is a period (`.`), it is removed.

Any characters within the short TCP/IP name that are not valid for IBM MQ object names (for example, hyphens) are replaced by an underscore character.

Valid characters for IBM MQ object names are: a to z, A to Z, 0 to 9, and the four special characters `/` `%` `.` and `_`.

The cluster name for the Windows default configuration is `DEFAULT_CLUSTER`.

If the queue manager is not a repository queue manager, the objects listed in Table 19 on page 87 are created.

Table 19. Objects created by the Windows default configuration application

Object	Name
Queue manager	<p>The short TCP/IP name prefixed with the characters QM_. The maximum length of the queue manager name is 48 characters. Names exceeding this limit are truncated at 48 characters. If the last character of the name is a period (.), this is replaced by a space ( ).</p> <p>The queue manager has a command server, a channel listener, and channel initiator associated with it. The channel listener listens on the standard IBM MQ port, port number 1414. Any other queue managers created on this machine must not use port 1414 while the default configuration queue manager still exists.</p>
Generic cluster receiver channel	The short TCP/IP name prefixed with the characters TO_QM_. The maximum length of the generic cluster receiver name is 20 characters. Names exceeding this limit are truncated at 20 characters. If the last character of the name is a period (.), this is replaced by a space ( ).
Cluster sender channel	The cluster sender channel is initially created with the name TO_+QMNAME+. When IBM MQ has established a connection to the repository queue manager for the default configuration cluster, this name is replaced with the name of the repository queue manager for the default configuration cluster, prefixed with the characters TO_. The maximum length of the cluster sender channel name is 20 characters. Names exceeding this limit are truncated at 20 characters. If the last character of the name is a period (.), this is replaced by a space ( ).
Local message queue	The local message queue is called default.
Local message queue for use by the IBM MQ Postcard application	The local message queue for use by the IBM MQ Postcard application is called postcard.
Server connection channel	The server connection channel allows clients to connect to the queue manager. Its name is the short TCP/IP name, prefixed with the characters S_. The maximum length of the server connection channel name is 20 characters. Names exceeding this limit are truncated at 20 characters. If the last character of the name is a period (.), this is replaced by a space ( ).

If the queue manager is a repository queue manager, the default configuration is similar to that described in Table 19, but with the following differences:

- The queue manager is defined as a repository queue manager for the default configuration cluster.
- There is no cluster-sender channel defined.
- A local cluster queue that is the short TCP/IP name prefixed with the characters clq\_default\_ is created. The maximum length of this name is 48 characters. Names exceeding this length are truncated at 48 characters.

If you request remote administration facilities, the server connection channel, SYSTEM.ADMIN.SVRCONN is also created.

## SYSTEM.BASE.TOPIC

Base topic for ASPARENT resolution. If a particular topic has no parent administrative topic objects, or those parent objects also have ASPARENT, any remaining ASPARENT attributes are inherited from this object.

Table 20. Default values of SYSTEM.BASE.TOPIC

Parameter	Value
TOPICSTR	"
CLROUTE	DIRECT
CLUSTER	The default value is an empty string.
COMMINFO	SYSTEM.DEFAULT.COMMINFO.MULTICAST
DEFPRESP	SYNC
DEFPRTY	0
DEFPSIST	NO
DESCR	'Base topic for resolving attributes'
DURSUB	YES
MCAST	DISABLED
MDURMDL	SYSTEM.DURABLE.MODEL.QUEUE
MNDURMDL	SYSTEM.NDURABLE.MODEL.QUEUE
NPMSGDLV	ALLAVAIL
PMSGDLV	ALLDUR
PROXYSUB	FIRSTUSE
PUB	ENABLED
PUBSCOPE	ALL
 QSGDISP ( z/OS platform only)	QMGR
SUB	ENABLED
SUBSCOPE	ALL
USEDLQ	YES
WILDCARD	PASSTHRU

If this object does not exist, its default values are still used by IBM MQ for ASPARENT attributes that are not resolved by parent topics further up the topic tree.

Setting the PUB or SUB attributes of SYSTEM.BASE.TOPIC to DISABLED prevents applications publishing or subscribing to topics in the topic tree, with two exceptions:

1. Any topic objects in the topic tree that have PUB or SUB explicitly set to ENABLE. Applications can publish or subscribe to those topics, and their children.
2. Publication and subscription to SYSTEM.BROKER.ADMIN.STREAM is not disabled by the setting the PUB or SUB attributes of SYSTEM.BASE.TOPIC to DISABLED.

See also Special handling for the **PUB** parameter.

## IBM MQ for IBM i system and default objects

When you create a queue manager using the **CRTMQM** command, the system objects and the default objects are created automatically.

- The system objects are those IBM MQ objects required for the operation of a queue manager or channel.
- The default objects define all the attributes of an object. When you create an object, such as a local queue, any attributes that you do not specify explicitly are inherited from the default object.

The following tables list the system and default objects created by **CRTMQM** :

- Table 21 lists the system and default queue objects.
- Table 22 on page 91 lists the system and default channel objects.
- Table 23 on page 91 gives the system and default authentication information objects.
- Table 24 on page 91 gives the system and default listener object.
- Table 25 on page 91 gives the system and default namelist object.
- Table 26 on page 92 gives the system and default process object.
- Table 27 on page 92 gives the system and default service object.

*Table 21. System and default objects: queues*

Object name	Description
SYSTEM.ADMIN.ACCOUNTING.QUEUE	Accounting message data generated when an application disconnects from the queue manager.
SYSTEM.ADMIN.ACTIVITY.QUEUE	Activity report message data.
SYSTEM.ADMIN.CHANNEL.EVENT	Event queue for channels.
SYSTEM.ADMIN.COMMAND.QUEUE	Administration command queue. Used for remote MQSC commands and PCF commands.
SYSTEM.ADMIN.LOGGER.EVENT	Logger event (journal receiver) message data.
SYSTEM.ADMIN.PERFM.EVENT	Event queue for performance events.
SYSTEM.ADMIN.PUBSUB.EVENT	System publish/subscribe related event queue
SYSTEM.ADMIN.QMGR.EVENT	Event queue for queue manager events.
SYSTEM.ADMIN.STATISTICS.QUEUE	MQI, queue and channel statistics message data queue.
SYSTEM.ADMIN.TRACE.ROUTE.QUEUE	Trace-route reply message data queue.
SYSTEM.AUTH.DATA.QUEUE	Used by the object authority manager (OAM).
SYSTEM.BROKER.ADMIN.STREAM	Admin stream used by the queued publish/subscribe interface.
SYSTEM.BROKER.CONTROL.QUEUE	Publish/subscribe interface control queue.
SYSTEM.BROKER.DEFAULT.STREAM	The default stream used by the queued publish/subscribe interface.
SYSTEM.BROKER.INTER.BROKER.COMMUNICATIONS	Broker to broker communications queue.
SYSTEM.CHANNEL.INITQ	Channel initiation queue.
SYSTEM.CHANNEL.SYNCQ	The queue that holds the synchronization data for channels.
SYSTEM.CHLAUTH.DATA.QUEUE	IBM MQ channel authentication data queue
SYSTEM.DURABLE.MODEL.QUEUE	A queue used as a model for managed durable subscriptions.

Table 21. System and default objects: queues (continued)

Object name	Description
SYSTEM.DURABLE.SUBSCRIBER.QUEUE	A queue used to hold a persistent copy of the durable subscriptions in the queue manager.
SYSTEM.CICS.INITIATION.QUEUE	Default CICS initiation queue.
SYSTEM.CLUSTER.COMMAND.QUEUE	The queue used to carry messages to the repository queue manager.
SYSTEM.CLUSTER.HISTORY.QUEUE	The queue is used to store the history of cluster state information for service purposes.
SYSTEM.CLUSTER.REPOSITORY.QUEUE	The queue used to store all repository information.
SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE	The queue is used to create individual transmit queues for each cluster-sender channel.
SYSTEM.CLUSTER.TRANSMIT.QUEUE	The transmission queue for all messages to all clusters.
SYSTEM.DEAD.LETTER.QUEUE	Dead-letter (undelivered message) queue.
SYSTEM.DEFAULT.ALIAS.QUEUE	Default alias queue.
SYSTEM.DEFAULT.AUTHINFO.CRLLDAP	Default authentication information definition.
SYSTEM.DEFAULT.INITIATION.QUEUE	Default initiation queue.
SYSTEM.DEFAULT.LOCAL.QUEUE	Default local queue.
SYSTEM.DEFAULT.MODEL.QUEUE	Default model queue.
SYSTEM.DEFAULT.REMOTE.QUEUE	Default remote queue.
SYSTEM.JMS.TEMPQ.MODEL	Model for JMS temporary queues
SYSTEM.HIERARCHY.STATE	IBM MQ distributed publish/subscribe hierarchy relationship state.
SYSTEM.INTER.QMGR.CONTROL	IBM MQ distributed publish/subscribe control queue.
SYSTEM.INTER.QMGR.FANREQ	IBM MQ distributed publish/subscribe internal proxy subscription fan-out process input queue.
SYSTEM.INTER.QMGR.PUBS	IBM MQ distributed publish/subscribe publications.
SYSTEM.MQEXPLORER.REPLY.MODEL	MQ Explorer reply-to queue. This is a model queue that creates a temporary dynamic queue for replies to the MQ Explorer.
SYSTEM.MQSC.REPLY.QUEUE	MQSC command reply-to queue. This is a model queue that creates a temporary dynamic queue for replies to remote MQSC commands.
SYSTEM.NDURABLE.MODEL.QUEUE	A queue used as a model for managed non durable subscriptions.
SYSTEM.PENDING.DATA.QUEUE	Support deferred messages in JMS.
SYSTEM.RETAINED.PUB.QUEUE	A queue used to hold a copy of each retained publication in the queue manager.

Table 22. System and default objects: channels

Object name	Description
SYSTEM.AUTO.RECEIVER	Dynamic receiver channel.
SYSTEM.AUTO.SVRCONN	Dynamic server-connection channel.
SYSTEM.DEF.CLNTCONN	Default client connection channel, used to supply default values for any attributes not specified when a CLNTCONN channel is created on a queue manager.
SYSTEM.DEF.CLUSRCVR	Default receiver channel for the cluster used to supply default values for any attributes not specified when a CLUSRCVR channel is created on a queue manager in the cluster.
SYSTEM.DEF.CLUSSDR	Default sender channel for the cluster used to supply default values for any attributes not specified when a CLUSSDR channel is created on a queue manager in the cluster.
SYSTEM.DEF.RECEIVER	Default receiver channel.
SYSTEM.DEF.REQUESTER	Default requester channel.
SYSTEM.DEF.SENDER	Default sender channel.
SYSTEM.DEF.SERVER	Default server channel.
SYSTEM.DEF.SVRCONN	Default server-connection channel.

Table 23. System and default objects: authentication information objects

Object name	Description
SYSTEM.DEFAULT.AUTHINFO.CRLLDAP	Default authentication information object for authentication type CRLLDAP.
SYSTEM.DEFAULT.AUTHINFO.OCSP	Default authentication information object for authentication type OCSP.

Table 24. System and default objects: listeners

Object name	Description
SYSTEM.DEFAULT.LISTENER.TCP	Default listener for TCP transport.

Table 25. System and default objects: namelists

Object name	Description
SYSTEM.DEFAULT.NAMELIST	Default namelist definition.
SYSTEM.QPUBSUB.QUEUE.NAMELIST	A list of queue names monitored by the queued publish/subscribe interface.
SYSTEM.QPUBSUB.SUBPOINT.NAMELIST	A list of topic objects used by the queued publish/subscribe interface to match topic objects to subscription points.

Table 26. System and default objects: processes

Object name	Description
SYSTEM.DEFAULT.PROCESS	Default process definition.

Table 27. System and default objects: services

Object name	Description
SYSTEM.DEFAULT.SERVICE	Default service.

## Stanza information

The following information helps you configure the information within stanzas, and lists the contents of the `mq5.ini`, `qm.ini`, and `mqclient.ini` files.

### Configuring stanzas

Use the links to help you configure the system, or systems, in your enterprise:

- Changing IBM MQ configuration information helps you configure the:
  - *AllQueueManagers* stanza
  - *DefaultQueueManager* stanza
  - *ExitProperties* stanza
  - *LogDefaults* stanza
  - *Security* stanza in the `qm.ini` file
- Changing queue manager configuration information helps you configure the:
  - *AccessMode* stanza (Windows only)
  - *Service* stanza - for Installable services
  - *Log* stanza
  - *RestrictedMode* stanza (UNIX and Linux systems only)
  - *XAResourceManager* stanza
  - *TCP*, *LU62*, and *NETBIOS* stanzas
  - *ExitPath* stanza
  - *QMErrorLog* stanza
  - *SSL* stanza
  - *ExitPropertiesLocal* stanza
- Configuring services and components helps you configure the:
  - *Service* stanza
  - *ServiceComponent* stanza

and contains links to how they are used for different services on UNIX and Linux, and Windows platforms.

- Configuring API exits helps you configure the:
  - *AllActivityTrace* stanza
  - *ApplicationTrace* stanza
- Configuring activity trace behavior helps you configure the:
  - *ApiExitCommon* stanza
  - *ApiExitTemplate* stanza
  - *ApiExitLocal* stanza
- Configuration information for clients helps you configure the:

- *CHANNELS* stanza
- *ClientExitPath* stanza
- *LU62*, *NETBIOS* and *SPX* stanza (Windows only)
- *MessageBuffer* stanza
- *SSL* stanza
- *TCP* stanza
- “Configuration file stanzas for distributed queuing” on page 94 helps you configure the:
  - *CHANNELS* stanza
  - *TCP* stanza
  - *LU62* stanza
  - *NETBIOS*
  - *ExitPath* stanza
- Setting queued publish/subscribe message attributes helps you configure the:
  - *PersistentPublishRetry* attribute
  - *NonPersistentPublishRetry* attribute
  - *PublishBatchSize* attribute
  - *PublishRetryInterval* attribute
 in the *Broker* stanza.

**Attention:** You must create a *Broker* stanza if you need one.

## Configuration files

See:

- **mqs.ini** file
- **qm.ini** file
- **mqclient.ini** file

for a list of the possible stanzas in each configuration file.

### **mqs.ini** file

Example of an IBM MQ configuration file for UNIX and Linux systems shows an example *mqs.ini* file.

An *mqs.ini* file can contain the following stanzas:

- *AllQueueManagers*
- *DefaultQueueManager*
- *ExitProperties*
- *LogDefaults*

In addition, there is one *QueueManager* stanza for each queue manager.

### **qm.ini** file

Example queue manager configuration file for IBM MQ for UNIX and Linux systems shows an example *qm.ini* file.

A *qm.ini* file can contain the following stanzas:

- *ExitPath*
- *Log*
- *QMErrorLog*
- *QueueManager*

- *Security*
  - *Service* and *ServiceComponent*  
To configure *InstallableServiceson*:
    - UNIX and Linux platforms, use the *Service* and *ServiceComponent* stanzas.
    - Windows, use **regedit**.
  - *Connection* for *DefaultBindType*  
**Attention:** You must create a *Connection* stanza if you need one.
  - *SSL and TLS*
  - *TCP, LU62, and NETBIOS*
  - *XAResourceManager*
- In addition, you can change the:
- *AccessMode* (Windows only)
  - *RestrictedMode* (UNIX and Linux systems only)
- by using the `crtmqm` command.

### mqclient.ini file

An `mqclient.ini` file can contain the following stanzas:

- *CHANNELS*
- *ClientExitPath*
- *LU62, NETBIOS, and SPX*
- *MessageBuffer*
- *SSL*
- *TCP*

In addition, you might need a *PreConnect* stanza to configure a preconnect exit.

### Configuration file stanzas for distributed queuing

A description of the stanzas of the queue manager configuration file, `qm.ini`, related to distributed queuing.

This topic shows the stanzas in the queue manager configuration file that relate to distributed queuing. It applies to the queue manager configuration file for IBM MQ on  IBM i, Windows, UNIX and Linux systems. The file is called `qm.ini` on all platforms.

The stanzas that relate to distributed queuing are:

- *CHANNELS*
- *TCP*
- *LU62*
- *NETBIOS*
- *EXITPATH*

Figure 6 on page 95 shows the values that you can set using these stanzas. When you are defining one of these stanzas, you do not need to start each item on a new line. You can use either a semicolon (;) or a hash character (#) to indicate a comment.

```

CHANNELS:
MAXCHANNELS=n      ; Maximum number of channels allowed, the
                   ; default value is 100.
MAXACTIVECHANNELS=n ; Maximum number of channels allowed to be active at
                   ; any time, the default is the value of MaxChannels.
MAXINITIATORS=n    ; Maximum number of initiators allowed, the default
                   ; and maximum value is 3.
MQIBINDTYPE=type1 ; Whether the binding for applications is to be
                   ; "fastpath" or "standard".
                   ; The default is "standard".
ADOPTNEWMCA=ch1type ; Stops previous process if channel fails to start.
                   ; The default is "NO".
ADOPTNEWMCATIMEOUT=n ; Specifies the amount of time that the new
                   ; process should wait for the old process to end.
                   ; The default is 60.
ADOPTNEWMCACHECHECK= ; Specifies the type checking required.
                   typecheck ; The default is "NAME","ADDRESS", and "QM".
TCP:                ; TCP entries
PORT=n              ; Port number, the default is 1414
KEEPALIVE=Yes       ; Switch TCP/IP KeepAlive on
LIBRARY2=DLLName2  ; Used if code is in two libraries
EXITPATH:2         ; Location of user exits (MQSeries for AIX,
                   ; HP-UX, and Solaris only)
EXITPATHS=          ; String of directory paths.

```

Figure 6. *qm.ini* stanzas for distributed queuing

**Note:**

1. MQIBINDTYPE applies only to IBM MQ for AIX,  IBM MQ for IBM i, IBM MQ for HP-UX, and IBM MQ for Solaris.
2. EXITPATH applies only to IBM MQ for AIX, IBM MQ for HP-UX, and IBM MQ for Solaris.

 Changing configuration information on IBM i

## Channel attributes

This section describes the channel attributes held in the channel definitions.

You choose the attributes of a channel to be optimal for a particular set of circumstances for each channel. However, when the channel is running, the actual values might have changed during startup negotiations. See Preparing channels.

Many attributes have default values, and you can use these values for most channels. However, in those circumstances where the defaults are not optimal, see this section for guidance in selecting the correct values.

For cluster channels, you specify the cluster channel attributes on the cluster-receiver channels at the target queue managers. Any attributes you specify on the matching cluster-sender channels are likely to be ignored. See Cluster channels.

**Note:** In IBM MQ for IBM i, most attributes can be specified as \*SYSDFTCHL, which means that the value is taken from the system default channel in your system.

## Channel attributes and channel types

Different types of channel support different channel attributes.

The channel types for IBM MQ channel attributes are listed in the following table.

**Note:** For cluster channels (the CLUSSDR and CLUSRCVR columns in the table), if an attribute can be set on both channels, set it on both and ensure that the settings are identical. If there is any discrepancy between the settings, those that you specify on the CLUSRCVR channel are likely to be used. This is explained in Cluster channels.

V8.0.0.4

Table 28. Channel attributes for the channel types

Attribute field	MQSC command parameter	SDR	SVR	RCVR	RQSTR	CLNT-CONN	SVR-CONN	CLUS-SDR	CLUS-RCVR	AMQP

Table 28. Channel attributes for the channel types (continued)

Attribute field	MQSC command parameter	SDR	SVR	RCVR	RQSTR	CLNT-CONN	SVR-CONN	CLUS-SDR	CLUS-RCVR	AMQP
Queue manager name	QMNAME					Yes				
Receive exit name	RCVEXIT	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	
Receive exit user data	RCVDATA	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	
Security exit name	SCYEXIT	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	
Security exit user data	SCYDATA	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	
Send exit name	SENDEXIT	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	
Send exit user data	SENDDATA	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	
Sequence number wrap	SEQWRAP	Yes	Yes	Yes	Yes			Yes	Yes	
Shared connections	SHARECNV					Yes	Yes			
Short retry count	SHORTRTY	Yes	Yes					Yes	Yes	
Short retry interval	SHORTTMR	Yes	Yes					Yes	Yes	
SSL Cipher Specification	SSLCIPH	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
SSL Client Authentication	SSLCAUTH		Yes	Yes	Yes		Yes		Yes	Yes
SSL Peer	SSLPEER	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
V8.0.0.4 Topic root	TPROOT									Yes
Transmission queue name	XMITQ	Yes	Yes							
Transport type	TRPTYPE	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	
V8.0.0.4 Use client ID	USECLTID									Yes
Use Dead-Letter Queue	USEDLQ	Yes	Yes	Yes	Yes			Yes	Yes	
User ID	USERID	Yes	Yes		Yes	Yes		Yes		

**Note:**

1. Valid on z/OS only.

**Related concepts:**

“Channel attributes in alphabetical order”

This section describes each attribute of a channel object, with its valid values and notes on its use where appropriate.

**Related information:**

MQSC reference

Use MQSC commands to manage queue manager objects, including the queue manager itself, queues, process definitions, channels, client connection channels, listeners, services, namelists, clusters, and authentication information objects.

**Channel attributes in alphabetical order**

This section describes each attribute of a channel object, with its valid values and notes on its use where appropriate.

IBM MQ for some platforms might not implement all the attributes shown in this section. Exceptions and platform differences are mentioned in the individual attribute descriptions, where relevant.

The keyword that you can specify in MQSC is shown in brackets for each attribute.

The attributes are arranged in alphabetical order.

**Alter date (ALTD`ATE`):**

This attribute is the date on which the definition was last altered, in the form `yyyy-mm-dd`.

This attribute is valid for all channel types.

**Alter time (ALT`TIME`):**

This attribute is the time at which the definition was last altered, in the form `hh:mm:ss`.

This attribute is valid for all channel types.

**AMQP keep alive (AMQP`KA`):** distributed

Use this attribute to specify a keep alive time for the AMQP client connection.

Specify the keep alive time in seconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a `amqp:resource-limit-exceeded` AMQP error condition.

### **Batch Heartbeat Interval (BATCHEHB):**

This attribute allows a sending channel to verify that the receiving channel is still active just before committing a batch of messages.

The batch heartbeat interval thus allows the batch to be backed out rather than becoming in-doubt if the receiving channel is not active. By backing out the batch, the messages remain available for processing so they could, for example, be redirected to another channel.

If the sending channel has had a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active, otherwise a 'heartbeat' is sent to the receiving channel to check. The sending channel waits for a response from the receiving end of the channel for an interval, based on the number of seconds specified in the channel Heartbeat Interval (HBINT) attribute.

The value is in milliseconds and must be in the range zero through 999999. A value of zero indicates that batch heart beating is not used.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

### **Batch interval (BATCHINT):**

This attribute is a period, in milliseconds, during which the channel keeps a batch open even if there are no messages on the transmission queue.

You can specify any number of milliseconds, from zero through 999 999 999. The default value is zero.

If you do not specify a batch interval, the batch closes when the number of messages specified in BATCHSZ has been sent or when the transmission queue becomes empty. On lightly loaded channels, where the transmission queue frequently becomes empty the effective batch size might be much smaller than BATCHSZ.

You can use the BATCHINT attribute to make your channels more efficient by reducing the number of short batches. Be aware, however, that you can slow down the response time, because batches last longer and messages remain uncommitted for longer.

If you specify a BATCHINT, batches close only when one of the following conditions is met:

- The number of messages specified in BATCHSZ have been sent.
- There are no more messages on the transmission queue and a time interval of BATCHINT has elapsed while waiting for messages (since the first message of the batch was retrieved).

**Note:** BATCHINT specifies the total amount of time that is spent waiting for messages. It does not include the time spent retrieving messages that are already available on the transmission queue, or the time spent transferring messages.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

**Batch limit (BATCHLIM):**

This attribute is the limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point.

A sync point is taken after the message that caused the limit to be reached has flowed across the channel.

The value must be in the range 0 - 999999. The default value is 5000.

A value of zero in this attribute means that no data limit is applied to batches over this channel.

The batch is terminated when one of the following conditions is met:

- BATCHSZ messages have been sent.
- BATCHLIM bytes have been sent.
- The transmission queue is empty and BATCHINT is exceeded.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

This parameter is supported on all platforms.

**Batch size (BATCHSZ):**

This attribute is the maximum number of messages to be sent before a sync point is taken.

The batch size does not affect the way the channel transfers messages; messages are always transferred individually, but are committed or backed out as a batch.

To improve performance, you can set a batch size to define the maximum number of messages to be transferred between two *sync points*. The batch size to be used is negotiated when a channel starts, and the lower of the two channel definitions is taken. On some implementations, the batch size is calculated from the lowest of the two channel definitions and the two queue manager MAXUMSGS values. The actual size of a batch can be less; for example, a batch completes when there are no messages left on the transmission queue or the batch interval expires.

A large value for the batch size increases throughput, but recovery times are increased because there are more messages to back out and send again. The default BATCHSZ is 50, and you are advised to try that value first. You might choose a lower value for BATCHSZ if your communications are unreliable, making the need to recover more likely.

Sync point procedure needs a unique logical unit of work identifier to be exchanged across the link every time a sync point is taken, to coordinate batch commit procedures.

If the synchronized batch commit procedure is interrupted, an *in-doubt* situation might arise. In-doubt situations are resolved automatically when a message channel starts. If this resolution is not successful, manual intervention might be necessary, using the RESOLVE command.

Some considerations when choosing the number for batch size:

- If the number is too large, the amount of queue space taken up on both ends of the link becomes excessive. Messages take up queue space when they are not committed, and cannot be removed from queues until they are committed.

- If there is likely to be a steady flow of messages, you can improve the performance of a channel by increasing the batch size because fewer confirm flows are needed to transfer the same quantity of bytes.
- If message flow characteristics indicate that messages arrive intermittently, a batch size of 1 with a relatively large disconnect time interval might provide a better performance.
- The number can be in the range 1 through 9999. However, for data integrity reasons, channels connecting to any of the current platforms must specify a batch size greater than 1. A value of 1 is for use with Version 1 products, apart from IBM MQ for MVS.
- Even though nonpersistent messages on a fast channel do not wait for a sync point, they do contribute to the batch-size count.

This attribute is valid for channel types of:

- Sender
- Server
- Receiver
- Requester
- Cluster sender
- Cluster receiver

#### **Certificate label (CERTLABL):**

This attribute specifies the certificate label of the channel definition.

The label identifies which personal certificate in the key repository is sent to the remote peer. The certificate is defined as described in Digital certificate labels.

Inbound channels (including RCVR, CLUSRCVR, unqualified SERVER, and SVRCONN channels) will only send the configured certificate if the IBM MQ version of the remote peer fully supports certificate label configuration and the channel is using a TLS CipherSpec. If that is not the case, the queue manager **CERTLABL** attribute determines the certificate sent. This restriction is because the certificate label selection mechanism for inbound channels depends upon a TLS protocol extension that is not supported in all cases. In particular, Java™ clients, JMS clients, and all versions of IBM MQ prior to Version 8.0 do not support the required protocol extension and will only ever receive the certificate configured by the queue manager **CERTLABL** attribute, regardless of the channel-specific label setting.

None of the administrative interfaces allow this attribute to be inquired or set for CLUSSDR channels. You will receive an MQRCCF\_WRONG\_CHANNEL\_TYPE message. However, the attribute is present in CLUSSDR channel objects (including MQCD structures) and a CHAD exit can set it programmatically if required.

For more information about what the certificate label can contain, see Digital certificate labels, understanding the requirements.

This attribute is valid for all channel types.

### Channel name (CHANNEL):

This attribute specifies the name of the channel definition.

The name can contain up to 20 characters, although as both ends of a message channel must have the same name, and other implementations might have restrictions on the size, the actual number of characters might have to be smaller.

Where possible, channel names are unique to one channel between any two queue managers in a network of interconnected queue managers.

The name must contain characters from the following list:

Alphabetic	(A-Z, a-z; note that uppercase and lowercase are significant)
Numerics	(0-9)
Period	(.)
Forward slash	(/)
Underscore	(_)
Percentage sign	(%)

#### Note:

1. Embedded blanks are not allowed, and leading blanks are ignored.
2. On systems using EBCDIC Katakana, you cannot use lowercase characters.

This attribute is valid for all channel types.

### Channel statistics (STATCHL):

This attribute controls the collection of statistics data for channels.

The possible values are:

#### QMGR

Statistics data collection for this channel is based upon the setting of the queue manager attribute STATCHL. This value is the default value.

**OFF** Statistics data collection for this channel is disabled.

**LOW** Statistics data collection for this channel is enabled with a low ratio of data collection.

#### MEDIUM

Statistics data collection for this channel is enabled with a moderate ratio of data collection.

**HIGH** Statistics data collection for this channel is enabled with a high ratio of data collection.

For more information about channel statistics, see Monitoring reference.

On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

This attribute is valid for channel types of:

- Sender
- Server
- Receiver
- Requester
- Cluster sender

- Cluster receiver

### Channel type (CHLTYPE):

This attribute specifies the type of the channel being defined.

The possible channel types are:

#### Message channel types:

- Sender
- Server
- Receiver
- Requester
- Cluster-sender
- Cluster-receiver

#### MQI channel types:

- Client-connection ( IBM MQ for Windows systems, and UNIX systems only)

**Note:** Client-connection channels can also be defined on z/OS for use on other platforms.

- Server-connection
-  AMQP

The two ends of a channel must have the same name and have compatible types:

- Sender with receiver
- Requester with server
- Requester with sender (for callback)
- Server with receiver (server is used as a sender)
- Client-connection with server-connection
- Cluster-sender with cluster-receiver
-  AMQP with AMQP

### Client channel weight (CLNTWGHT):

This attribute specifies a weighting to influence which client-connection channel definition is used.

The client channel weighting attribute is used so that client channel definitions can be selected at random based on their weighting when more than one suitable definition is available.

When a client issues an MQCONN requesting connection to a queue manager group, by specifying a queue manager name starting with an asterisk, which enables client weight balancing across several queue managers, and more than one suitable channel definition is available in the client channel definition table (CCDT), the definition to use is randomly selected based on the weighting, with any applicable CLNTWGHT(0) definitions selected first in alphabetical order.

Specify a value in the range 0 - 99. The default is 0.

A value of 0 indicates that no load balancing is performed and applicable definitions are selected in alphabetical order. To enable load balancing choose a value in the range 1 - 99 where 1 is the lowest weighting and 99 is the highest. The distribution of connections between two or more channels with non-zero weightings is proportional to the ratio of those weightings. For example, three channels with CLNTWGHT values of 2, 4, and 14 are selected approximately 10%, 20%, and 70% of the time. This

distribution is not guaranteed. If the `AFFINITY` attribute of the connection is set to `PREFERRED`, the first connection chooses a channel definition according to client weightings, and then subsequent connections continue to use the same channel definition.

This attribute is valid for the client-connection channel type only.

#### **Cluster (CLUSTER):**

This attribute is the name of the cluster to which the channel belongs.

The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

Up to one of the resultant values of `CLUSTER` or `CLUSNL` can be non-blank. If one of the values is non-blank, the other must be blank.

This attribute is valid for channel types of:

- Cluster sender
- Cluster receiver

#### **Cluster namelist (CLUSNL):**

This attribute is the name of the namelist that specifies a list of clusters to which the channel belongs.

Up to one of the resultant values of `CLUSTER` or `CLUSNL` can be nonblank. If one of the values is nonblank, the other must be blank.

This attribute is valid for channel types of:

- Cluster sender
- Cluster receiver

#### **CLWLPRTY channel attribute:**

The `CLWLPRTY` channel attribute specifies the priority order for channels for cluster workload distribution. The value must be in the range 0-9, where 0 is the lowest priority and 9 is the highest.

Use the `CLWLPRTY` channel attribute to set a priority order for the available cluster destinations. IBM MQ selects the destinations with the highest priority before selecting destinations with the lowest cluster destination priority. If there are multiple destinations with the same priority, it selects the least recently used destination.

If there are two possible destinations, you can use this attribute to allow failover. Messages go to the queue manager with the highest priority channel. If it becomes unavailable then messages go to the next highest priority queue manager. Lower priority queue managers act as reserves.

IBM MQ checks channel status before prioritizing the channels. Only available queue managers are candidates for selection.

#### **Notes:**

- Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See Cluster channels.
- The availability of a remote queue manager is based on the status of the channel to that queue manager. When channels start, their state changes several times, with some of the states being less preferential to the cluster workload management algorithm. In practice this means that lower priority (backup) destinations can be chosen while the channels to higher priority (primary) destinations are starting.

- If you need to ensure that no messages go to a backup destination, do not use CLWLPRTY. Consider using separate queues, or CLWLRANK with a manual switch over from the primary to backup.

**CLWLRANK channel attribute:**

The CLWLRANK channel attribute specifies the rank of channels for cluster workload distribution. The value must be in the range 0-9, where 0 is the lowest rank and 9 is the highest.

Use the CLWLRANK channel attribute if you want control over the final destination for messages sent to a queue manager in another cluster. Control the choice of final destination by setting the rank of the channels connecting a queue manager to the gateway queue managers at the intersection of the clusters.

When you set CLWLRANK, messages take a specified route through the interconnected clusters towards a higher ranked destination. For example, messages arrive at a gateway queue manager that can send them to either of two queue managers using channels ranked 1 and 2. They are automatically sent to the queue manager connected by a channel with the highest rank, in this case the channel to the queue manager ranked 2.

IBM MQ gets the rank of channels before checking channel status. Getting the rank before checking channel status means that even non-accessible channels are available for selection. It allows messages to be routed through the network even if the final destination is unavailable.

**Notes:**

- Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See Cluster channels.
- If you also used the priority attribute CLWLPRTY, IBM MQ selects between available destinations. If a channel is not available to the destination with the highest rank, the message is held on the transmission queue. It is released when the channel becomes available. The message does not get sent to the next available destination in the rank order.

**CLWLWGHT channel attribute:**

The CLWLWGHT channel attribute specifies the weight applied to CLUSSDR and CLUSRCVR channels for cluster workload distribution. The value must be in the range 1-99, where 1 is the lowest weight and 99 is the highest.

Use CLWLWGHT to send servers with more processing power more messages. The higher the channel weight, the more messages are sent over that channel.

**Notes:**

- Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See Cluster channels.
- When CLWLWGHT is modified from the default of 50 on any channel, workload balancing becomes dependent on the total number of times each channel was chosen for a message sent to any clustered queue. For more information, see "The cluster workload management algorithm" on page 149.

### **Connection affinity (AFFINITY):**

This attribute specifies whether client applications that connect multiple times using the same queue manager name, use the same client channel.

Use this attribute when multiple applicable channel definitions are available.

The possible values are:

#### **PREFERRED**

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions based on the client channel weight, with any definitions having a weight of 0 first and in alphabetical order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful definitions with client channel weight values other than 0 are moved to the end of the list. Definitions with a client channel weight of 0 remain at the start of the list and are selected first for each connection.

Each client process with the same host name always creates the same list.

For client applications written in C, C++, or the .NET programming framework (including fully managed .NET), and for applications that use the IBM MQ classes for Java and IBM MQ classes for JMS, the list is updated if the CCDT has been modified since the list was created.

This value is the default value.

#### **NONE**

The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the client channel weight, with any definitions having a weight of 0 selected first in alphabetical order.

For client applications written in C, C++, or the .NET programming framework (including fully managed .NET), and for applications that use the IBM MQ classes for Java and IBM MQ classes for JMS, the list is updated if the CCDT has been modified since the list was created.

This attribute is valid for the client-connection channel type only.

### **Connection name (CONNNAME):**

This attribute is the communications connection identifier. It specifies the particular communications links to be used by this channel.

It is optional for server channels, unless the server channel is triggered, in which case it must specify a connection name.

Specify CONNNAME as a comma-separated list of names of machines for the stated TRPTYPE. Typically only one machine name is required. You can provide multiple machine names to configure multiple connections with the same properties. The connections are usually tried in the order they are specified in the connection list until a connection is successfully established. The order is modified for clients if the CLNTWGHT attribute is provided. If no connection is successful, the channel attempts the connection again, as determined by the attributes of the channel. With client channels, a connection-list provides an alternative to using queue manager groups to configure multiple connections. With message channels, a connection list is used to configure connections to the alternative addresses of a multi-instance queue manager.

Providing multiple connection names in a list was first supported in IBM WebSphere MQ Version 7.0.1. It changes the syntax of the CONNNAME parameter. Earlier clients and queue managers connect using the first connection name in the list, and do not read the rest of the connection names in the list. In order for the earlier clients and queue managers to parse the new syntax, you must specify a port number on the

first connection name in the list. Specifying a port number avoids problems when connecting to the channel from a client or queue manager that is running at a level earlier than IBM WebSphere MQ Version 7.0.1.

On AIX, HP-UX, IBM i, Linux, Solaris, and Windows platforms, the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example: (1415)

The generated CONNAME is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

The name is up to 48 characters (see note 1) for z/OS, 264 characters for other platforms, and:

**If the transport type is TCP**

CONNNAME is either the host name or the network address of the remote machine (or the local machine for cluster-receiver channels). For example, (ABC.EXAMPLE.COM), (2001:DB8:0:0:0:0:0:0) or (127.0.0.1). It can include the port number, for example (MACHINE(123)). It can include the IP\_name of a z/OS dynamic DNS group or a Network Dispatcher input port.

If you use an IPv6 address in a network that only supports IPv4, the connection name is not resolved. In a network which uses both IPv4 and IPv6, Connection name interacts with Local Address to determine which IP stack is used. See “Local Address ( LOCLADDR )” on page 114 for further information.

**If the transport type is LU 6.2**

For IBM MQ for IBM i, Windows systems, and UNIX systems, give the fully-qualified name of the partner LU if the TPNAME and MODENAME are specified. For other versions or if the TPNAME and MODENAME are blank, give the CPI-C side information object name for your specific platform.

On z/OS, there are two forms in which to specify the value:

- Logical unit name

The logical unit information for the queue manager, comprising the logical unit name, TP name, and optional mode name. This name can be specified in one of three forms:

Form	Example
luname	IGY12355
luname/TPname	IGY12345/APING
luname/TPname/modename	IGY12345/APINGD/#INTER

For the first form, the TP name and mode name must be specified for the TPNAME and MODENAME attributes; otherwise these attributes must be blank.

**Note:** For client-connection channels, only the first form is allowed.

- Symbolic name

The symbolic destination name for the logical unit information for the queue manager, as defined in the side information data set. The TPNAME and MODENAME attributes must be blank.

**Note:** For cluster-receiver channels, the side information is on the other queue managers in the cluster. Alternatively, in this case it can be a name that a channel auto-definition exit can resolve into the appropriate logical unit information for the local queue manager.

The specified or implied LU name can be that of a VTAM generic resources group.

**If the transmission protocol is NetBIOS**

CONNNAME is the NetBIOS name defined on the remote machine.

**If the transmission protocol is SPX**

CONNNAME is an SPX-style address consisting of a 4 byte network address, a 6 byte node address and a 2 byte socket number. Enter these values in hexadecimal, with the network and node addresses separated by a period and the socket number in brackets. For example:

```
CONNNAME('0a0b0c0d.804abcde23a1(5e86)')
```

If the socket number is omitted, the default IBM MQ SPX socket number is used. The default is X'5E86'.

This attribute is valid for channel types of:

- Sender
- Server
- Requester
- Client connection
- Cluster sender
- Cluster receiver

It is optional for server channels, unless the server channel is triggered, in which case it must specify a connection name.

**Note:**

1. A workaround to the 48 character limit might be one of the following suggestions:
  - Set up your DNS servers so that you use, for example, host name of "myserver" instead of "myserver.location.company.com", ensuring you can use the short host name.
  - Use IP addresses.
2. The definition of transmission protocol is contained in "Transport type (TRPTYPE)" on page 134.

**Convert message (CONVERT):**

This attribute specifies that the message must be converted into the format required by the receiving system before transmission.

Application message data is typically converted by the receiving application. However, if the remote queue manager is on a platform that does not support data conversion, use this channel attribute to specify that the message must be converted into the format required by the receiving system *before* transmission.

The possible values are yes and no. If you specify yes, the application data in the message is converted before sending if you have specified one of the built-in format names, or a data conversion exit is available for a user-defined format (See Writing data-conversion exits ). If you specify no, the application data in the message is not converted before sending.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

**Data compression (COMPMSG):**

This attribute is a list of message data compression techniques supported by the channel.

For sender, server, cluster-sender, cluster-receiver, and client-connection channels the values specified are in order of preference. The first compression technique supported by the remote end of the channel is used. The channels' mutually supported compression techniques are passed to the sending channel's message exit where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits. See "Header compression (COMPHDR)" on page 112 for compression of the message header.

The possible values are:

**NONE**

No message data compression is performed. This value is the default value.

**RLE** Message data compression is performed using run-length encoding.

**ZLIBFAST**

Message data compression is performed using the zlib compression technique. A fast compression time is preferred.

ZLIBFAST can optionally be offloaded to the zEnterprise® Data Compression facility. See zEDC Express facility for further information.

**ZLIBHIGH**

Message data compression is performed using the zlib compression technique. A high level of compression is preferred.

**ANY** Allows the channel to support any compression technique that the queue manager supports. Only supported for Receiver, Requester and Server-Connection channels.

This attribute is valid for all channel types.

**Description (DESCR):**

This attribute describes the channel definition and contains up to 64 bytes of text.

**Note:** The maximum number of characters is reduced if the system is using a double byte character set (DBCS).

Use characters from the character set identified by the coded character set identifier (CCSID) for the queue manager to ensure that the text is translated correctly if it is sent to another queue manager.

This attribute is valid for all channel types.

### **Disconnect interval (DISCINT):**

This attribute is the length of time after which a channel closes down, if no message arrives during that period.

This attribute is a time-out attribute, specified in seconds, for the server, cluster-sender, sender, and cluster-receiver channels. The interval is measured from the point at which a batch ends, that is when the batch size is reached or when the batch interval expires and the transmission queue becomes empty. If no messages arrive on the transmission queue during the specified time interval, the channel closes down. (The time is approximate.)

The close-down exchange of control data between the two ends of the channel includes an indication of the reason for closing. This ensures that the corresponding end of the channel remains available to start again.

You can specify any number of seconds from zero through 999 999 where a value of zero means no disconnect; wait indefinitely.

For server-connection channels using the TCP protocol, the interval represents the client inactivity disconnect value, specified in seconds. If a server-connection has received no communication from its partner client for this duration, it terminates the connection. The server-connection inactivity interval applies under the following circumstances:

- between IBM MQ API calls from a client
- between an MQGET call, only if:
  - client application executes an MQGET with WaitInterval
  - the DISCINT parameter is set on the server-connection channel and is smaller than the MQGET WaitInterval
  - the SHARECNV parameter of the server-connection channel is greater than 0.

This attribute is valid for channel types of:

- Sender
- Server
- Server connection
- Cluster sender
- Cluster receiver

This attribute is not applicable for server-connection channels using protocols other than TCP.

**Note:** Performance is affected by the value specified for the disconnect interval.

A low value (for example a few seconds) can be detrimental to system performance by constantly starting the channel. A large value (more than an hour) might mean that system resources are needlessly held up. You can also specify a heartbeat interval, so that when there are no messages on the transmission queue, the sending MCA sends a heartbeat flow to the receiving MCA, thus giving the receiving MCA an opportunity to quiesce the channel without waiting for the disconnect interval to expire. For these two values to work together effectively, the heartbeat interval value must be significantly lower than the disconnect interval value.

The default DISCINT value is set to 100 minutes. However, a value of a few minutes is often a reasonable value to use without impacting performance or keeping channels running for unnecessarily long periods of time. If it is appropriate for your environment you can change this value, either on each individual channel or through changing the value in the default channel definitions, for example SYSTEM.DEF.SENDER.

For more information, see Stopping and quiescing channels.

**Disposition (QSGDISP):**

This attribute specifies the disposition of the channel in a queue-sharing group. It is valid on z/OS only.

Values are:

**QMGR**

The channel is defined on the page set of the queue manager that executes the command. This value is the default.

**GROUP**

The channel is defined in the shared repository. This value is allowed only if there is a shared queue manager environment. When a channel is defined with QSGDISP(GROUP), the command DEFINE CHANNEL(name) NOREPLACE QSGDISP(COPY) is generated automatically and sent to all active queue managers to cause them to make local copies on page set 0. For queue managers which are not active, or which join the queue sharing group at a later date, the command is generated when the queue manager starts.

**COPY** The channel is defined on the page set of the queue manager that executes the command, copying its definition from the QSGDISP(GROUP) channel of the same name. This value is allowed only if there is a shared queue manager environment.

This attribute is valid for all channel types.

**Header compression (COMPHDR):**

This attribute is a list of header data compression techniques supported by the channel.

For sender, server, cluster-sender, cluster-receiver, and client-connection channels the values specified are in order of preference with the first compression technique supported by the remote end of the channel being used. The channels' mutually supported compression techniques are passed to the sending channel's message exit where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits.

Possible values are:

**NONE**

No header data compression is performed. This value is the default value.

**SYSTEM**

Header data compression is performed.

This attribute is valid for all channel types.

### **Heartbeat interval (HBINT):**

This attribute specifies the approximate time between heartbeat flows that are to be passed from a sending message channel agent (MCA) when there are no messages on the transmission queue.

Heartbeat flows unblock the receiving MCA, which is waiting for messages to arrive or for the disconnect interval to expire. When the receiving MCA is unblocked, it can disconnect the channel without waiting for the disconnect interval to expire. Heartbeat flows also free any storage buffers that have been allocated for large messages and close any queues that have been left open at the receiving end of the channel.

The value is in seconds and must be in the range 0 - 999 999. A value of zero means that no heartbeat flows are to be sent. The default value is 300. To be most useful, the value must be significantly less than the disconnect interval value.

With applications that use IBM MQ classes for Java, JMS or .NET APIs, the HBINT value is determined in one of the following ways:

- Either by the value on the SVRCONN channel that is used by the application.
- Or by the value on the CLNTCONN channel, if the application has been configured to use a CCDT.

For server-connection and client-connection channels, heartbeats can flow from both the server side as well as the client side independently. If no data has been transferred across the channel for the heartbeat interval, the client-connection MQI agent sends a heartbeat flow and the server-connection MQI agent responds to it with another heartbeat flow. This happens irrespective of the state of the channel, for example, irrespective of whether it is inactive while making an API call, or is inactive waiting for client user input. The server-connection MQI agent is also capable of initiating a heartbeat to the client, again irrespective of the state of the channel. To prevent both server-connection and client-connection MQI agents heart beating to each other at the same time, the server heartbeat is flowed after no data has been transferred across the channel for the heartbeat interval plus 5 seconds.

For server-connection and client-connection channels working in the channel mode before IBM WebSphere MQ Version 7.0, heartbeats flow only when a server MCA is waiting for an MQGET command with the WAIT option specified, which it has issued on behalf of a client application.

For more information about making MQI channels work in the two modes, see [SharingConversations \(MQLONG\)](#).

#### **Related information:**

DEFINE CHANNEL

Use the MQSC command **DEFINE CHANNEL** to define a new channel, and set its parameters.

ALTER CHANNEL

Use the MQSC command **ALTER CHANNEL** to alter the parameters of a channel.

### **Keepalive Interval (KAINT):**

This attribute is used to specify a timeout value for a channel.

The Keepalive Interval attribute is a value passed to the communications stack specifying the Keepalive timing for the channel. It allows you to specify a different keepalive value for each channel.

You can set the Keepalive Interval (KAINT) attribute for channels on a per-channel basis. On platforms other than z/OS, you can access and modify the parameter, but it is only stored and forwarded; there is no functional implementation of the parameter. If you need the functionality provided by the KAJNT parameter, use the Heartbeat Interval (HBINT) parameter, as described in "Heartbeat interval (HBINT)."

For this attribute to have any effect, TCP/IP keepalive must be enabled. On z/OS, you do enable keepalive by issuing the ALTER QMGR TCPKEEP(YES) MQSC command. On other platforms, it occurs when the KEEPALIVE=YES parameter is specified in the TCP stanza in the distributed queuing configuration file, qm.ini, or through the IBM MQ Explorer. Keepalive must also be switched on within TCP/IP itself, using the TCP profile configuration data set.

The value indicates a time, in seconds, and must be in the range 0 - 99999. A Keepalive Interval value of 0 indicates that channel-specific Keepalive is not enabled for the channel and only the system-wide Keepalive value set in TCP/IP is used. You can also set KAINTE to a value of AUTO (this value is the default). If KAINTE is set to AUTO, the Keepalive value is based on the value of the negotiated heartbeat interval (HBINT) as follows:

*Table 29. Negotiated HBINT value and the corresponding KAINTE value.*

The table has two columns. The first column lists the negotiated HBINT values and the second column lists the corresponding KAINTE value for each negotiated HBINT.

Negotiated HBINT	KAINTE
>0	Negotiated HBINT + 60 seconds
0	0

This attribute is valid for all channel types.

The value is ignored for all channels that have a TransportType (TRPTYPE) other than TCP or SPX

#### **Local Address ( LOCLADDR ):**

This attribute specifies the local communications address for the channel.

**Note:** AMQP channels do not support the same format of LOCLADDR as other IBM MQ channels. For more information, see “LOCLADDR for AMQP channels” on page 117.

#### **LOCLADDR for all channels except AMQP channels**

This attribute only applies if the transport type ( TRPTYPE ) is TCP/IP. For all other transport types, it is ignored.

This attribute is valid for channel types of:

- Sender
- Server
- Requester
- Client connection
- Cluster sender
- Cluster receiver

When a LOCLADDR value is specified, a channel that is stopped and then restarted continues to use the TCP/IP address specified in LOCLADDR. In recovery scenarios, this attribute might be useful when the channel is communicating through a firewall. It is useful because it removes problems caused by the channel restarting with the IP address of the TCP/IP stack to which it is connected. LOCLADDR can also force a channel to use an IPv4 or IPv6 stack on a dual stack system, or a dual-mode stack on a single stack system.

When LOCLADDR includes a network address, the address must be a network addresses belonging to a network interface on the system where the channel is run. For example, when defining a sender channel on queue manager ALPHA to queue manager BETA with the following MSQC command:

```
DEFINE CHANNEL(TO.BETA) CHLTYPE(SDR) CONNAME(192.0.2.0) XMITQ(BETA) LOCLADDR(192.0.2.1)
```

The LOCLADDR address is the IPv4 address 192.0.2.1. This sender channel runs on the system of queue manager ALPHA, so the IPv4 address must belong to one of the network interfaces its system.

The value is the optional IP address, and optional port or port range used for outbound TCP/IP communications. The format for this information is as follows:

```
LOCLADDR([ip-addr][(low-port[,high-port])][,[ip-addr][(low-port[,high-port])]])
```

The maximum length of LOCLADDR, including multiple addresses, is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

Note, that you can set LOCLADDR for a C client using the Client Channel Definition Table (CCDT).

All the parameters are optional. Omitting the ip-addr part of the address is useful to enable the configuration of a fixed port number for an IP firewall. Omitting the port number is useful to select a particular network adapter without having the identify a unique local port number. The TCP/IP stack generates a unique port number.

Specify `[,[ip-addr][(low-port[,high-port])]]` multiple times for each additional local address. Use multiple local addresses if you want to specify a specific subset of local network adapters. You can also use `[,[ip-addr][(low-port[,high-port])]]` to represent a particular local network address on different servers that are part of a multi-instance queue manager configuration.

#### ip-addr

ip-addr is specified in one of three forms:

##### IPv4 dotted decimal

For example 192.0.2.1

##### IPv6 hexadecimal notation

For example 2001:DB8:0:0:0:0:0:0

##### Alphanumeric host name form

For example WWW.EXAMPLE.COM

#### low-port and high-port

low-port and high-port are port numbers enclosed in parentheses.

The following table shows how the LOCLADDR parameter can be used:

*Table 30. Examples of how the LOCLADDR parameter can be used*

LOCLADDR	Meaning
9.20.4.98	Channel binds to this address locally
9.20.4.98, 9.20.4.99	Channel binds to either IP address. The address might be two network adapters on one server, or a different network adapter on two different servers in a multi-instance configuration.
9.20.4.98(1000)	Channel binds to this address and port 1000 locally
9.20.4.98(1000,2000)	Channel binds to this address and uses a port in the range 1000 - 2000 locally
(1000)	Channel binds to port 1000 locally
(1000,2000)	Channel binds to port in range 1000 - 2000 locally

When a channel is started the values specified for connection name ( CONNAME ) and local address ( LOCLADDR ) determine which IP stack is used for communication. The IP stack used is determined as follows:

- If the system has only an IPv4 stack configured, the IPv4 stack is always used. If a local address ( LOCLADDR ) or connection name ( CONNAME ) is specified as an IPv6 network address, an error is generated and the channel fails to start.
- If the system has only an IPv6 stack configured, the IPv6 stack is always used. If a local address ( LOCLADDR ) is specified as an IPv4 network address, an error is generated and the channel fails to start. On platforms supporting IPv6 mapped addressing, if a connection name ( CONNAME ) is specified as an IPv4 network address, the address is mapped to an IPv6 address. For example, xxx.xxx.xxx.xxx is mapped to ::ffff:xxx.xxx.xxx.xxx. The use of mapped addresses might require protocol translators. Avoid the use of mapped addresses where possible.
- If a local address ( LOCLADDR ) is specified as an IP address for a channel, the stack for that IP address is used. If the local address ( LOCLADDR ) is specified as a host name resolving to both IPv4 and IPv6 addresses, the connection name ( CONNAME ) determines which of the stacks is used. If both the local address ( LOCLADDR ) and connection name ( CONNAME ) are specified as host names resolving to both IPv4 and IPv6 addresses, the stack used is determined by the queue manager attribute IPADDRV.
- If the system has dual IPv4 and IPv6 stacks configured and a local address ( LOCLADDR ) is not specified for a channel, the connection name ( CONNAME ) specified for the channel determines which IP stack to use. If the connection name ( CONNAME ) is specified as a host name resolving to both IPv4 and IPv6 addresses, the stack used is determined by the queue manager attribute IPADDRV.

**distributed** On distributed platforms, it is possible to set a default local address value that will be used for all sender channels that do not have a local address defined. The default value is defined by setting the MQ\_LCLADDR environment variable prior to starting the queue manager. The format of the value matches that of MQSC attribute LOCLADDR.

### Local addresses with cluster sender channels

Cluster sender channels always inherit the configuration of the corresponding cluster receiver channel as defined on the target queue manager. This is true even if there is a locally defined cluster sender channel of the same name, in which case the manual definition is only used for initial communication.

For this reason, it is not possible to depend on the LOCLADDR defined in the cluster receiver channel as it is likely that the IP address is not owned by the system where the cluster senders are created. For this reason, the LOCLADDR on the cluster receiver should not be used unless there is a reason to restrict only the ports, but not the IP address, for all potential cluster senders, and it is known that those ports are available on all systems where a cluster sender channel may be created.

If a cluster must use LOCLADDR to get the outbound communication channels to bind to a specific IP address, either use a Channel Auto-Definition Exit, or use the default LOCLADDR for the queue manager when possible. When using a channel exit, it forces the LOCLADDR value from the exit into any of the automatically defined CLUSSDR channels.

If using a non-default LOCLADDR for cluster sender channels through the use of an exit or a default value, any matching manually defined cluster sender channel, for example to a full repository queue manager, must also have the LOCLADDR value set to enable initial communication over the channel.

**Note:** If the operating system returns a bind error for the port supplied in LOCLADDR (or all ports, if a port range is supplied), the channel does not start; the system issues an error message.

## LOCLADDR for AMQP channels

AMQP channels support a different format of LOCLADDR than other IBM MQ channels:

### LOCLADDR ( *ip-addr* )

LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of LOCLADDR is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

#### **ip-addr**

*ip-addr* is a single network address, specified in one of three forms:

##### **IPv4 dotted decimal**

For example 192.0.2.1

##### **IPv6 hexadecimal notation**

For example 2001:DB8:0:0:0:0:0:0

##### **Alphanumeric host name form**

For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

#### **Related information:**

Working with auto-defined cluster-sender channels

#### **Long retry count (LONGRTY):**

This attribute specifies the maximum number of times that the channel is to try allocating a session to its partner.

If the initial allocation attempt fails, the *short retry count* number is decremented and the channel retries the remaining number of times. If it still fails, it retries a *long retry count* number of times with an interval of *long retry interval* between each try. If it is still unsuccessful, the channel closes down. The channel must then be restarted with a command (it is not started automatically by the channel initiator).

(Retry is not attempted if the cause of failure is such that a retry is not likely to be successful.)

If the channel initiator (on z/OS ) or the channel (on distributed platforms) is stopped while the channel is retrying, the *short retry count* and *long retry count* are reset when the channel initiator or the channel is restarted, or when a message is successfully put at the sender channel. However, if the channel initiator (on z/OS ) or queue manager (on distributed platforms) is shut down and restarted, the *short retry count* and *long retry count* are not reset. The channel retains the retry count values it had before the queue manager restart or the message being put.

**Note:** For IBM i, UNIX systems, and Windows systems:

1. When a channel goes from RETRYING state to RUNNING state, the *short retry count* and *long retry count* are not reset immediately. They are reset only once the first message flows across the channel successfully after the channel went into RUNNING state, that is; once the local channel confirms the number of messages sent to the other end.
2. The *short retry count* and *long retry count* are reset when the channel is restarted.

The *long retry count* attribute can be set from zero through 999 999 999.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

**Note:** For  IBM i, UNIX systems, and Windows systems, in order for retry to be attempted a channel initiator must be running. The channel initiator must be monitoring the initiation queue specified in the definition of the transmission queue that the channel is using.

### **Long retry interval (LONGTMR):**

This attribute is the approximate interval in seconds that the channel is to wait before retrying to establish connection, during the long retry mode.

The interval between retries can be extended if the channel has to wait to become active.

The channel tries to connect *long retry count* number of times at this long interval, after trying the *short retry count* number of times at the short retry interval.

This attribute can be set from zero through 999 999.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

### **LU 6.2 mode name (MODENAME):**

This attribute is for use with LU 6.2 connections. It gives extra definition for the session characteristics of the connection when a communication session allocation is performed.

When using side information for SNA communications, the mode name is defined in the CPI-C Communications Side Object or APPC side information, and this attribute must be left blank; otherwise, it must be set to the SNA mode name.

The name must be one to eight alphanumeric characters long.

This attribute is valid for channel types of:

- Sender
- Server
- Requester
- Client connection
- Cluster sender
- Cluster receiver

It is not valid for receiver or server-connection channels.

## LU 6.2 transaction program name (TPNAME):

This attribute is for use with LU 6.2 connections. It is the name, or generic name, of the transaction program (MCA) to be run at the far end of the link.

When using side information for SNA communications, the transaction program name is defined in the CPI-C Communications Side Object or APPC side information and this attribute must be left blank. Otherwise, this name is required by sender channels and requester channels.

The name can be up to 64 characters long.

The name must be set to the SNA transaction program name, unless the CONNAME contains a side-object name in which case it must be set to blanks. The actual name is taken instead from the CPI-C Communications Side Object, or the APPC side information data set.

This information is set in different ways on different platforms; see *Configuring distributed queuing* for more information about setting up communication for your platform.

This attribute is valid for channel types of:

- Sender
- Server
- Requester
- Client connection
- Cluster sender
- Cluster receiver

## Maximum instances (MAXINST):

This attribute specifies the maximum number of simultaneous instances of a server-connection channel or AMQP channel that can be started.

See the child topics for information on how the attribute is used for each channel type.

### *Maximum instances of server-connection channel connections:*

This attribute specifies the maximum number of simultaneous instances of a sever-connection channel that can be started.

This attribute can be set from zero through 999 999 999. A value of zero indicates that no client connections are allowed on this channel. The default value is 999 999 999.

If the value is reduced so that it is less than the number of instances of the server-connection channel that are currently running, then the running channels are not affected. However, new instances are not able to start until sufficient existing ones have ceased to run.

Maximum instances of AMQP channel connections: **V8.0.0.4**

This attribute specifies the maximum number of simultaneous instances of an AMQP channel that can be started.

This attribute can be set from zero through 999 999 999. A value of zero indicates that no client connections are allowed on this channel. The default value is 999 999 999.

If a client attempts to connect, and the number of connected clients has reached MAXINST, the channel closes the connection with a close frame. The close frame contains the following message:

```
amqp:resource-limit-exceeded
```

If a client connects with an ID that is already connected (that is, it performs a client-takeover) the takeover will succeed regardless of whether the number of connected clients has reached MAXINST.

#### **Maximum instances per client (MAXINSTC):**

This attribute specifies the maximum number of simultaneous instances of a server-connection channel that can be started from a single client.

This attribute can be set from zero through 999 999 999. A value of zero indicates that no client connections are allowed on this channel. The default value is 999 999 999.

If the value is reduced so that it is less than the number of instances of the server-connection channel that are currently running from individual clients, then the running channels are not affected. However, new instances from those clients are not able to start until sufficient existing ones have ceased to run.

This attribute is valid for server-connection channels only.

#### **Maximum message length (MAXMSGL):**

This attribute specifies the maximum length of a message that can be transmitted on the channel.

On IBM MQ for IBM i, UNIX systems, and Windows systems, specify a value greater than or equal to zero, and less than or equal to the maximum message length for the queue manager. See the MAXMSGL parameter of the ALTER QMGR command in ALTER QMGR for more information. On IBM MQ for z/OS, specify a value greater than or equal to zero, and less than or equal to 104 857 600 bytes.

Because various implementations of IBM MQ systems exist on different platforms, the size available for message processing might be limited in some applications. This number must reflect a size that your system can handle without stress. When a channel starts, the lower of the two numbers at each end of the channel is taken.

By adding the digital signature and key to the message, IBM MQ Advanced Message Security increases the length of the message.

#### **Note:**

1. You can use a maximum message size of 0 which is taken to mean that the size is to be set to the local queue manager maximum value.

This attribute is valid for all channel types.

**Message channel agent name (MCANAME):**

This attribute is reserved and if specified must only be set to blanks.

Its maximum length is 20 characters.

**Message channel agent type (MCATYPE):**

This attribute can specify the message channel agent as a *process* or a *thread*.

On IBM MQ for z/OS, it is supported only for channels with a channel type of cluster-receiver.

Advantages of running as a process include:

- Isolation for each channel providing greater integrity
- Job authority specific for each channel
- Control over job scheduling

Advantages of threads include:

- Much reduced use of storage
- Easier configuration by typing on the command line
- Faster execution - it is quicker to start a thread than to instruct the operating system to start a process

For channel types of sender, server, and requester, the default is process. For channel types of cluster-sender and cluster-receiver, the default is thread. These defaults can change during your installation.

If you specify process on the channel definition, a RUNMQCHL process is started. If you specify thread, the MCA runs on a thread of the AMQRMPPA process, or of the RUNMQCHI process if MQNOREMPOOL is specified. On the machine that receives the inbound allocates, the MCA runs as a thread if you use RUNMQLSR. It runs as a process if you use **inetd**.

On IBM MQ for z/OS, this attribute is supported only for channels with a channel type of cluster-receiver. On other platforms, it is valid for channel types of:

- Sender
- Server
- Requester
- Cluster sender
- Cluster receiver

**Message channel agent user identifier (MCAUSER):**

This attribute is the user identifier (a string) to be used by the MCA for authorization to access IBM MQ resources.

**Note:** An alternative way of providing a user ID for a channel to run under is to use channel authentication records. With channel authentication records, different connections can use the same channel while using different credentials. If both MCAUSER on the channel is set and channel authentication records are used to apply to the same channel, the channel authentication records take precedence. The MCAUSER on the channel definition is only used if the channel authentication record uses USERSRC(CHANNEL).

This authorization includes (if PUT authority is DEF) putting the message to the destination queue for receiver or requester channels.

On IBM MQ for Windows, the user identifier can be domain-qualified by using the format, user@domain, where the domain must be either the Windows systems domain of the local system, or a trusted domain.

If this attribute is blank, the MCA uses its default user identifier. For more information, see DEFINE CHANNEL.

This attribute is valid for channel types of:

- Receiver
- Requester
- Server connection
- Cluster receiver

**Related information:**

Channel authentication records

**Message exit name (MSGEXIT):**

This attribute specifies the name of the user exit program to be run by the channel message exit.

This attribute can be a list of names of programs that are to be run in succession. Leave blank, if no channel message exit is in effect.

The format and maximum length of this attribute depend on the platform, as for "Receive exit name (RCVEXIT)" on page 128.

This attribute is valid for channel types of:

- Sender
- Server
- Receiver
- Requester
- Cluster sender
- Cluster receiver

**Message exit user data (MSGDATA):**

This attribute specifies user data that is passed to the channel message exits.

You can run a sequence of message exits. The limitations on the user data length and an example of how to specify MSGDATA for more than one exit are as shown for RCVDATA. See “Receive exit user data (RCVDATA)” on page 129.

This attribute is valid for channel types of:

- Sender
- Server
- Receiver
- Requester
- Cluster sender
- Cluster receiver

**Message-retry exit name (MREXIT):**

This attribute specifies the name of the user exit program to be run by the message-retry user exit.

Leave blank if no message-retry exit program is in effect.

The format and maximum length of the name depend on the platform, as for “Receive exit name (RCVEXIT)” on page 128. However, there can only be one message-retry exit specified

This attribute is valid for channel types of:

- Receiver
- Requester
- Cluster receiver

**Message-retry exit user data (MRDATA):**

This attribute specifies data passed to the channel message-retry exit when it is called.

This attribute is valid for channel types of:

- Receiver
- Requester
- Cluster receiver

### **Message retry count (MRRTY):**

This attribute specifies the number of times the channel tries to redeliver the message.

This attribute controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of MRRTY is passed to the exit, but the number of attempts made (if any) is controlled by the exit, and not by this attribute.

The value must be in the range 0 - 999 999 999. A value of zero means that no additional attempts are made. The default is 10.

This attribute is valid for channel types of:

- Receiver
- Requester
- Cluster receiver

### **Message retry interval (MRTMR):**

This attribute specifies the minimum interval of time that must pass before the channel can retry the MQPUT operation.

This time interval is in milliseconds.

This attribute controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of MRTMR is passed to the exit for use by the exit, but the retry interval is controlled by the exit, and not by this attribute.

The value must be in the range 0 - 999 999 999. A value of zero means that the retry is performed as soon as possible (if the value of MRRTY is greater than zero). The default is 1000.

This attribute is valid for the following channel types:

- Receiver
- Requester
- Cluster receiver

### **Monitoring (MONCHL):**

This attribute controls the collection of online Monitoring data.

Possible values are:

#### **QMGR**

The collection of Online Monitoring Data is inherited from the setting of the MONCHL attribute in the queue manager object. This value is the default value.

**OFF** Online Monitoring Data collection for this channel is switched off.

**LOW** A low ratio of data collection with a minimal effect on performance. However, the monitoring results shown might not be up to date.

#### **MEDIUM**

A moderate ratio of data collection with limited effect on the performance of the system.

**HIGH** A high ratio of data collection with the possibility of an effect on performance. However, the monitoring results shown are the most current.

This attribute is valid for channel types of:

- Sender
- Server
- Receiver
- Requester
- Server connection
- Cluster sender
- Cluster receiver

For more information about monitoring data, see [Displaying queue and channel monitoring data](#).

**NETPRTY channel attribute:**

The NETPRTY channel attribute specifies the priority for a CLUSRCVR channel. The value must be in the range 0-9, where 0 is the lowest priority and 9 is the highest.

Use the NETPRTY attribute to make one network the primary network, and another network the backup network. Given a set of equally ranked channels, clustering chooses the path with the highest priority when multiple paths are available.

A typical example of using the NETPRTY channel attribute is to differentiate between networks that have different costs or speeds and connect the same destinations.

**Note:** Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See [Cluster channels](#).

**Nonpersistent message speed (NPMSPEED):**

This attribute specifies the speed at which nonpersistent messages are to be sent.

Possible values are:

**NORMAL**

Nonpersistent messages on a channel are transferred within transactions.

**FAST** Nonpersistent messages on a channel are not transferred within transactions.

The default is FAST. The advantage of this is that nonpersistent messages become available for retrieval far more quickly. The disadvantage is that because they are not part of a transaction, messages might be lost if there is a transmission failure or if the channel stops when the messages are in transit. See [Safety of messages](#).

This attribute is valid for channel types of:

- Sender
- Server
- Receiver
- Requester
- Cluster sender
- Cluster receiver

**Password (PASSWORD):**

This attribute specifies a password that can be used by the MCA when attempting to initiate a secure LU 6.2 session with a remote MCA.

You can specify a password of maximum length 12 characters, although only the first 10 characters are used.

It is valid for channel types of sender, server, requester, or client-connection.

On IBM MQ for z/OS, this attribute is valid only for client connection channels. On other platforms, it is valid for channel types of:

- Sender
- Server
- Requester
- Client connection
- Cluster sender

**Port number (PORT):**

Specify the port number that is used to connect the AMQP client.

The default port for AMQP 1.0 connections is 5672. If you are already using port 5672, you can specify a different port.

**PUT authority (PUTAUT):**

This attribute specifies the type of security processing to be carried out by the MCA.

This attribute is valid for channel types of:

- Receiver
- Requester
- Server connection ( z/OS only)
- Cluster receiver

Use this attribute to choose the type of security processing to be carried out by the MCA when executing:

- An MQPUT command to the destination queue (for message channels), or
- An MQI call (for MQI channels).

**z/OS**

On z/OS, the user IDs that are checked, and how many user IDs are checked, depends on the setting of the MQADMIN RACF® class hlq.RESLEVEL profile. Depending on the level of access the user ID of the channel initiator has to hlq.RESLEVEL, zero, one or two user IDs are checked. To see how many user IDs are checked, see RESLEVEL and channel initiator connections. For more information about which user IDs are checked, see User IDs used by the channel initiator.

You can choose one of the following:

**Process security, also called default authority (DEF)**

The default user ID is used.

On platforms other than z/OS, the user ID used to check open authority on the queue is that of the process or user running the MCA at the receiving end of the message channel.

On z/OS, both the user ID received from the network, and the user ID derived from MCAUSER might be used, depending on the number of user IDs that are to be checked.

The queues are opened with this user ID and the open option MQOO\_SET\_ALL\_CONTEXT.

### **Context security (CTX)**

The user ID from the context information associated with the message is used as an alternate user ID.

The *UserIdentifier* in the message descriptor is moved into the *AlternateUserId* field in the object descriptor. The queue is opened with the open options MQOO\_SET\_ALL\_CONTEXT and MQOO\_ALTERNATE\_USER\_AUTHORITY.

On platforms other than z/OS, the user ID used to check open authority on the queue for MQOO\_SET\_ALL\_CONTEXT and MQOO\_ALTERNATE\_USER\_AUTHORITY is that of the process or user running the MCA at the receiving end of the message channel. The user ID used to check open authority on the queue for MQOO\_OUTPUT is the *UserIdentifier* in the message descriptor.

On z/OS, the user ID received from the network or that derived from MCAUSER might be used, as well as the user ID from the context information in the message descriptor, depending on the number of user IDs that are to be checked.

Context security (CTX) is not supported on server-connection channels.

### **Only Message Channel Agent security (ONLYMCA)**

The user ID derived from MCAUSER is used.

Queues are opened with the open option MQOO\_SET\_ALL\_CONTEXT.

This value only applies to z/OS.

### **Alternate Message Channel Agent security (ALTMCA)**

The user ID from the context information (the *UserIdentifier* field) in the message descriptor might be used, as well as the user ID derived from MCAUSER, depending on the number of user IDs that are to be checked.

This value only applies to z/OS.

Further details about context fields and open options can be found in Controlling context information.

More information about security can be found in:

- Security
- Setting up security on Windows, UNIX and Linux systems for IBM MQ UNIX systems and Windows systems,
-  Setting up security on IBM i for IBM MQ for IBM i
-  Setting up security on z/OS for IBM MQ for z/OS

**Queue manager name (QMNAME):**

This attribute specifies the name of the queue manager or queue manager group to which an IBM MQ MQI client application can request connection.

This attribute is valid for channel types of:

- Client connection

**Receive exit name (RCVEXIT):**

This attribute specifies the name of the user exit program to be run by the channel receive user exit.

This attribute can be a list of names of programs that are to be run in succession. Leave blank, if no channel receive user exit is in effect.

The format and maximum length of this attribute depend on the platform:

- On z/OS it is a load module name, maximum length 8 characters, except for client-connection channels where the maximum length is 128 characters.
- On IBM i, it is of the form:

*libname/progname*

when specified in CL commands.

When specified in IBM MQ Commands (MQSC) it has the form:

*progname libname*

where *progname* occupies the first 10 characters, and *libname* the second 10 characters (both blank-padded to the right if necessary). The maximum length of the string is 20 characters.

- On Windows, it is of the form:

*dllname(functionname)*

where *dllname* is specified without the suffix .DLL. The maximum length of the string is 40 characters.

- On UNIX systems, it is of the form:

*libraryname(functionname)*

The maximum length of the string is 40 characters.

During cluster sender channel auto-definition on z/OS, channel exit names are converted to z/OS format. If you want to control how exit names are converted, you can write a channel auto-definition exit. For more information, see Channel auto-definition exit program.

You can specify a list of receive, send, or message exit program names. The names must be separated by a comma, a space, or both. For example:

```
RCVEXIT(exit1 exit2)
MSGEXIT(exit1,exit2)
SENDEXIT(exit1, exit2)
```

The total length of the string of exit names and strings of user data for a particular type of exit is limited to 500 characters. In IBM MQ for IBM i, you can list up to 10 exit names. In IBM MQ for z/OS, you can list up to eight exit names.

This attribute is valid for all channel types.

**Receive exit user data (RCVDATA):**

This attribute specifies user data that is passed to the receive exit.

You can run a sequence of receive exits. The string of user data for a series of exits must be separated by a comma, spaces, or both. For example:

```
RCVDATA(exit1_data exit2_data)
MSGDATA(exit1_data,exit2_data)
SENDDATA(exit1_data, exit2_data)
```

In IBM MQ for UNIX systems, and Windows systems, the length of the string of exit names and strings of user data is limited to 500 characters. In IBM MQ for IBM i, you can specify up to 10 exit names and the length of user data for each is limited to 32 characters. In IBM MQ for z/OS, you can specify up to eight strings of user data each of length 32 characters.

This attribute is valid for all channel types.

**Security exit name (SCYEXIT):**

This attribute specifies the name of the exit program to be run by the channel security exit.

Leave blank if no channel security exit is in effect.

The format and maximum length of the name depend on the platform, as for “Receive exit name (RCVEXIT)” on page 128. However, you can only specify one security exit.

This attribute is valid for all channel types.

**Security exit user data (SCYDATA):**

This attribute specifies user data that is passed to the security exit.

The maximum length is 32 characters.

This attribute is valid for all channel types.

**Send exit name (SENDEXIT):**

This attribute specifies the name of the exit program to be run by the channel send exit.

This attribute can be a list of names of programs that are to be run in sequence. Leave blank if no channel send exit is in effect.

The format and maximum length of this attribute depend on the platform, as for “Receive exit name (RCVEXIT)” on page 128.

This attribute is valid for all channel types.

### Send exit user data (SENDDATA):

This attribute specifies user data that is passed to the send exit.

You can run a sequence of send exits. The limitations on the user data length and an example of how to specify SENDDATA for more than one exit, are as shown for RCVDATA. See “Receive exit user data (RCVDATA)” on page 129.

This attribute is valid for all channel types.

### Sequence number wrap (SEQWRAP):

This attribute specifies the highest number the message sequence number reaches before it restarts at 1.

The value of the number must be high enough to avoid a number being reissued while it is still being used by an earlier message. The two ends of a channel must have the same sequence number wrap value when a channel starts; otherwise, an error occurs.

The value can be set from 100 through 999 999 999.

This attribute is valid for channel types of:

- Sender
- Server
- Receiver
- Requester
- Cluster sender
- Cluster receiver

### Short retry count (SHORTRTY):

This attribute specifies the maximum number of times that the channel is to try allocating a session to its partner.

If the initial allocation attempt fails, the *short retry count* is decremented and the channel retries the remaining number of times with an interval, defined in the *short retry interval* attribute, between each attempt. If it still fails, it retries *long retry count* number of times with an interval of *long retry interval* between each attempt. If it is still unsuccessful, the channel terminates.

(Retry is not attempted if the cause of failure is such that a retry is not likely to be successful.)

If the channel initiator (on z/OS ) or the channel (on distributed platforms) is stopped while the channel is retrying, the *short retry count* and *long retry count* are reset when the channel initiator or the channel is restarted, or when a message is successfully put at the sender channel. However, if the channel initiator (on z/OS ) or queue manager (on distributed platforms) is shut down and restarted, the *short retry count* and *long retry count* are not reset. The channel retains the retry count values it had before the queue manager restart or the message being put.

**Note:** For  IBM i, UNIX systems, and Windows systems:

1. When a channel goes from RETRYING state to RUNNING state, the *short retry count* and *long retry count* are not reset immediately. They are reset only once the first message flows across the channel successfully after the channel went into RUNNING state, that is; once the local channel confirms the number of messages sent to the other end.
2. The *short retry count* and *long retry count* are reset when the channel is restarted.

This attribute can be set from zero through 999 999 999.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

**Note:** On  IBM i, UNIX systems, and Windows systems, in order for retry to be attempted a channel initiator must be running. The channel initiator must be monitoring the initiation queue specified in the definition of the transmission queue that the channel is using.

#### **Short retry interval (SHORTTMR):**

This attribute specifies the approximate interval in seconds that the channel is to wait before retrying to establish connection, during the short retry mode.

The interval between retries might be extended if the channel has to wait to become active.

This attribute can be set from zero through 999 999.

This attribute is valid for channel types of:

- Sender
- Server
- Cluster sender
- Cluster receiver

#### **SSL Cipher Specification (SSLCIPH):**

This attribute specifies a single CipherSpec for a TLS or SSL connection.

Every IBM MQ channel definition includes the SSLCIPH attribute. The value is a string with a maximum length of 32 characters.

Note the following:

- The SSLCIPH attribute can contain a blank value, meaning that you are not using SSL or TLS. If one end of the channel has a blank SSLCIPH attribute, the other end of the channel must also have a blank SSLCIPH attribute.
- Alternatively, if SSLCIPH contains a nonblank value, the channel attempts to use the specified cipher to utilize SSL or TLS. Again, in this case, both ends of the channel must specify the same SSLCIPH value.
- The only exception to the rule that SSLCIPH must be the same at both ends of a channel, is that a fully-managed .NET client can specify the special value **\*NEGOTIATE**. This option allows the channel to select the most recent protocol version supported by the .NET framework, and negotiate a CipherSpec that the server supports.

It is valid only for channels with a transport type (TRPTYPE) of TCP. If the TRPTYPE is not TCP, the data is ignored and no error message is issued.

For more information about SSLCIPH, see DEFINE CHANNEL and Specifying CipherSpecs.

### **SSL Client Authentication (SSLCAUTH):**

This attribute specifies whether the channel needs to receive and authenticate an SSL certificate from an SSL client.

Possible values are:

#### **OPTIONAL**

If the peer SSL client sends a certificate, the certificate is processed as normal but authentication does not fail if no certificate is sent.

#### **REQUIRED**

If the SSL client does not send a certificate, authentication fails.

The default value is REQUIRED.

You can specify a value for SSLCAUTH on a non-SSL channel definition, one on which SSLCIPH is missing or blank. You can use this to temporarily disable SSL for debugging without first having to clear and then reinput the SSL parameters.

SSLCAUTH is an optional attribute.

This attribute is valid on all channel types that can ever receive a channel initiation flow, except for sender channels.

This attribute is valid for channel types of:

- Server
- Receiver
- Requester
- Server connection
- Cluster receiver

For more information about SSLCAUTH, see DEFINE CHANNEL (MQTT) and Security.

### **SSL Peer (SSLPEER):**

This attribute is used to check the Distinguished Name (DN) of the certificate from the peer queue manager or client at the other end of an IBM MQ channel.

**Note:** An alternative way of restricting connections into channels by matching against the SSL or TLS Subject Distinguished Name, is to use channel authentication records. With channel authentication records, different SSL or TLS Subject Distinguished Name patterns can be applied to the same channel. If both SSLPEER on the channel and a channel authentication record are used to apply to the same channel, the inbound certificate must match both patterns in order to connect.

If the DN received from the peer does not match the SSLPEER value, the channel does not start.

SSLPEER is an optional attribute. If a value is not specified, the peer DN is not checked when the channel is started.

On z/OS, the maximum length of the attribute is 256 bytes. On all other platforms, it is 1024 bytes. Channel authentication records provide greater flexibility when using SSLPEER and support 1024 bytes on all platforms.

On z/OS, the attribute values used are not checked. If you enter incorrect values, the channel fails at startup, and error messages are written to the error log at both ends of the channel. A Channel SSL Error

event is also generated at both ends of the channel. On platforms that support SSLPEER, other than z/OS, the validity of the string is checked when it is first entered.

You can specify a value for SSLPEER on a non-SSL channel definition, one on which SSLCIPH is missing or blank. You can use this to temporarily disable SSL for debugging without having to clear and later reinput the SSL parameters.

For more information about using SSLPEER, see SET CHLAUTH and Security.

This attribute is valid for all channel types.

**Related information:**

Channel authentication records

**Topic root (TPROOT):** 

This attribute specifies the topic root for an AMQP channel.

You can use the TPROOT attribute to specify a topic root for an AMQP channel. Using this attribute ensures that an MQ Light application, when deployed to a queue manager, does not publish or subscribe to messages to or from areas of the topic tree that are being used by other applications.

The default value for TPROOT is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other MQ pub/sub applications. To have AMQP clients publish and subscribe under a topic prefix, first create an MQ topic object with a topic string set to the prefix you want, then change the value of the AMQP channel TPROOT attribute to the name of the MQ topic object you created. The following example shows the topic root being set to APPGROUP1.BASE.TOPIC for AMQP channel MYAMQP:

```
DEFINE CHANNEL(MYAMQP) CHLTYPE(AMQP) TPROOT(APPGROUP1.BASE.TOPIC) PORT(5673)
```

**Note:** If the TPROOT attribute value, or the topic string that underpins it, is changed, existing AMQP topics and their messages might be orphaned.

**Transmission queue name (XMITQ):**

This attribute specifies the name of the transmission queue from which messages are retrieved.

This attribute is required for channels of type sender or server, it is not valid for other channel types.

Provide the name of the transmission queue to be associated with this sender or server channel, that corresponds to the queue manager at the far side of the channel. You can give the transmission queue the same name as the queue manager at the remote end.

This attribute is valid for channel types of:

- Sender
- Server

**Transport type (TRPTYPE):**

This attribute specifies the transport type to be used.

The possible values are:

LU62	LU 6.2
TCP	TCP/IP
NETBIOS	NetBIOS ( 1 )
SPX	SPX ( 1 )
<b>Notes:</b>	
1. For use on Windows. Can also be used on z/OS for defining client-connection channels for use on Windows.	

This attribute is valid for all channel types.

**Use client ID (USECLTID):**

Use client ID for connection to AMQP channel.

Specify whether the client ID is used for connection on an AMQP channel. Set to Yes or No.

**Use Dead-Letter Queue (USEDLQ):**

This attribute determines whether the dead-letter queue (or undelivered message queue) is used when messages cannot be delivered by channels.

Possible values are:

**NO** Messages that cannot be delivered by a channel are treated as a failure. The channel either discards these messages, or the channel ends, in accordance with the setting of NPMSPEED.

**YES (default)**

If the queue manager DEADQ attribute provides the name of a dead-letter queue, then it is used, otherwise the behavior is as for NO.

**User ID (USERID):**

This attribute specifies the user ID to be used by the MCA when attempting to initiate a secure SNA session with a remote MCA.

You can specify a task user identifier of 20 characters.

It is valid for channel types of sender, server, requester, or client-connection.

This attribute does not apply to IBM MQ for z/OS except for client-connection channels.

On the receiving end, if passwords are kept in encrypted format and the LU 6.2 software is using a different encryption method, an attempt to start the channel fails with invalid security details. You can avoid this failure by modifying the receiving SNA configuration to either:

- Turn off password substitution, or
- Define a security user ID and password.

On IBM MQ for z/OS, this attribute is valid only for client connection channels. On other platforms, it is valid for channel types of:

- Sender
- Server
- Requester
- Client connection
- Cluster sender

## IBM MQ cluster commands

The IBM MQ Script commands **runmqsc** commands have special attributes and parameters that apply to clusters. There are other administrative interfaces you can use to manager clusters.

The MQSC commands are shown as they would be entered by the system administrator at the command console. Remember that you do not have to issue the commands in this way. There are a number of other methods, depending on your platform; for example:

- On IBM MQ for IBM i, you run MQSC commands interactively from option 26 of **WRKMQM**. You can also use CL commands or you can store MQSC commands in a file and use the **STRMQMMQSC** CL command.
-  On z/OS you can use the **COMMAND** function of the **CSQUTIL** utility, the operations and control panels or you can use the z/OS console.
- On all other platforms, you can store the commands in a file and use **runmqsc**.

In a MQSC command, a cluster name, specified using the **CLUSTER** attribute, can be up to 48 characters long.

A list of cluster names, specified using the **CLUSNL** attribute, can contain up to 256 names. To create a cluster namelist, use the **DEFINE NAMELIST** command.

## IBM MQ Explorer

The Explorer GUI can administer a cluster with repository queue managers on IBM MQ for z/OS Version 6 or later. You do not need to nominate an additional repository on a separate system. For earlier versions of IBM MQ for z/OS, the IBM MQ Explorer cannot administer a cluster with repository queue managers. You must therefore nominate an additional repository on a system that the IBM MQ Explorer can administer.

On IBM MQ for Windows and IBM MQ for Linux, you can also use IBM MQ Explorer to work with clusters. You can also use the stand-alone IBM MQ Explorer client.

Using the IBM MQ Explorer you can view cluster queues and inquire about the status of cluster-sender and cluster-receiver channels. IBM MQ Explorer includes two wizards, which you can use to guide you through the following tasks:

- Create a cluster
- Join an independent queue manager to a cluster

## Programmable command formats (PCF)

Table 31. PCF equivalents of MQSC commands specifically to work with clusters

runmqsc command	PCF equivalent
DISPLAY CLUSQMGR	MQCMD_INQUIRE_CLUSTER_Q_MGR
SUSPEND QMGR	MQCMD_SUSPEND_Q_MGR_CLUSTER
RESUME QMGR	MQCMD_RESUME_Q_MGR_CLUSTER
REFRESH CLUSTER	MQCMD_REFRESH_CLUSTER
RESET CLUSTER	MQCMD_RESET_CLUSTER

**Related information:**

Clustering: Using REFRESH CLUSTER best practices

**Queue-manager definition commands**

Cluster attributes that can be specified on queue manager definition commands.

To specify that a queue manager holds a full repository for a cluster, use the ALTER QMGR command specifying the attribute REPOS( *clustername* ). To specify a list of several cluster names, define a cluster namelist and then use the attribute REPOSNL( *namelist* ) on the ALTER QMGR command:

```
DEFINE NAMELIST(CLUSTERLIST)
  DESCR('List of clusters whose repositories I host')
  NAMES(CLUS1, CLUS2, CLUS3)
ALTER QMGR REPOSNL(CLUSTERLIST)
```

You can provide additional cluster attributes on the ALTER QMGR command

**CLWLEXIT( *name* )**

Specifies the name of a user exit to be called when a message is put to a cluster queue.

**CLWLDATA( *data* )**

Specifies the data to be passed to the cluster workload user exit.

**CLWLLEN( *length* )**

Specifies the maximum amount of message data to be passed to the cluster workload user exit

**CLWLMRUC( *channels* )**

Specifies the maximum number of outbound cluster channels.

CLWLMRUC is a local queue manager attribute that is not propagated around the cluster. It is made available to cluster workload exits and the cluster workload algorithm that chooses the destination for messages.

**CLWLUSEQ( LOCAL|ANY )**

Specifies the behavior of MQPUT when the target queue has both a local instance and at least one remote cluster instance. If the put originates from a cluster channel, this attribute does not apply. It is possible to specify CLWLUSEQ as both a queue attribute and a queue manager attribute.

If you specify ANY, both the local queue and the remote queues are possible targets of the MQPUT.

If you specify LOCAL, the local queue is the only target of the MQPUT.

The equivalent PCFs are MQCMD\_CHANGE\_Q\_MGR and MQCMD\_INQUIRE\_Q\_MGR.

## Channel definition commands

Cluster attributes that can be specified on channel definition commands.

The DEFINE CHANNEL, ALTER CHANNEL, and DISPLAY CHANNEL commands have two specific CHLTYPE parameters for clusters: CLUSRCVR and CLUSSDR. To define a cluster-receiver channel you use the DEFINE CHANNEL command, specifying CHLTYPE(CLUSRCVR). Many attributes on a cluster-receiver channel definition are the same as the attributes on a receiver or sender-channel definition. To define a cluster-sender channel you use the DEFINE CHANNEL command, specifying CHLTYPE(CLUSSDR), and many of the same attributes as you use to define a sender-channel.

It is no longer necessary to specify the name of the full repository queue manager when you define a cluster-sender channel. If you know the naming convention used for channels in your cluster, you can make a CLUSSDR definition using the +QMNAME+ construction. The +QMNAME+ construction is not supported on z/OS. After connection, IBM MQ changes the name of the channel and substitutes the correct full repository queue manager name in place of +QMNAME+. The resulting channel name is truncated to 20 characters.

For more information on naming conventions, see Cluster naming conventions.

The technique works only if your convention for naming channels includes the name of the queue manager. For example, you define a full repository queue manager called QM1 in a cluster called CLUSTER1 with a cluster-receiver channel called CLUSTER1.QM1.ALPHA. Every other queue manager can define a cluster-sender channel to this queue manager using the channel name, CLUSTER1.+QMNAME+.ALPHA.

If you use the same naming convention for all your channels, be aware that only one +QMNAME+ definition can exist at one time.

The following attributes on the DEFINE CHANNEL and ALTER CHANNEL commands are specific to cluster channels:

### **CLUSTER**

The CLUSTER attribute specifies the name of the cluster with which this channel is associated. Alternatively use the CLUSNL attribute.

### **CLUSNL**

The CLUSNL attribute specifies a namelist of cluster names.

### **NETPRTY**

Cluster-receivers only.

The NETPRTY attribute specifies a network priority for the channel. NETPRTY helps the workload management routines. If there is more than one possible route to a destination, the workload management routine selects the one with the highest priority.

### **CLWLPRTY**

The CLWLPRTY parameter applies a priority factor to channels to the same destination for workload management purposes. This parameter specifies the priority of the channel for the purposes of cluster workload distribution. The value must be in the range zero through 9, where zero is the lowest priority and 9 is the highest.

### **CLWLRANK**

The CLWLRANK parameter applies a ranking factor to a channel for workload management purposes. This parameter specifies the rank of a channel for the purposes of cluster workload distribution. The value must be in the range zero through 9, where zero is the lowest rank and 9 is the highest.

### **CLWLWGHT**

The CLWLWGHT parameter applies a weighting factor to a channel for workload management purposes. CLWLWGHT weights the channel so that the proportion of messages sent down that

channel can be controlled. The cluster workload algorithm uses CLWLWGHT to bias the destination choice so that more messages can be sent over a particular channel. By default all channel weight attributes are the same default value. The weight attribute allows you to allocate a channel on a powerful UNIX machine a larger weight than another channel on small desktop PC. The greater weight means that the cluster workload algorithm selects the UNIX machine more frequently than the PC as the destination for messages.

## CONNAME

The CONNAME specified on a cluster-receiver channel definition is used throughout the cluster to identify the network address of the queue manager. Take care to select a value for the CONNAME parameter that resolves throughout your IBM MQ cluster. Do not use a generic name. Remember that the value specified on the cluster-receiver channel takes precedence over any value specified in a corresponding cluster-sender channel.

These attributes on the DEFINE CHANNEL command and ALTER CHANNEL command also apply to the DISPLAY CHANNEL command.

**Note:** Auto-defined cluster-sender channels take their attributes from the corresponding cluster-receiver channel definition on the receiving queue manager. Even if there is a manually defined cluster-sender channel, its attributes are automatically modified to ensure that they match the attributes on the corresponding cluster-receiver definition. Beware that you can, for example, define a CLUSRCVR without specifying a port number in the CONNAME parameter, while manually defining a CLUSSDR that does specify a port number. When the auto-defined CLUSSDR replaces the manually defined one, the port number (taken from the CLUSRCVR ) becomes blank. The default port number would be used and the channel would fail.

**Note:** The DISPLAY CHANNEL command does not display auto-defined channels. However, you can use the DISPLAY CLUSQMGR command to examine the attributes of auto-defined cluster-sender channels.

Use the DISPLAY CHSTATUS command to display the status of a cluster-sender or cluster-receiver channel. This command gives the status of both manually defined channels and auto-defined channels.

The equivalent PCFs are MQCMD\_CHANGE\_CHANNEL, MQCMD\_COPY\_CHANNEL, MQCMD\_CREATE\_CHANNEL, and MQCMD\_INQUIRE\_CHANNEL.

## Omitting the CONNAME value on a CLUSRCVR definition

In some circumstances you can omit the CONNAME value on a CLUSRCVR definition. You must not omit the CONNAME value on z/OS.

On AIX, HP-UX, IBM i, Linux, Solaris, and Windows platforms, the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example:  
(1415)

The generated CONNAME is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

This facility is useful when you have machines using Dynamic Host Configuration Protocol (DHCP). If you do not supply a value for the CONNAME on a CLUSRCVR channel, you do not need to change the CLUSRCVR definition. DHCP allocates you a new IP address.

If you specify a blank for the CONNAME on the CLUSRCVR definition, IBM MQ generates a CONNAME from the IP address of the system. Only the generated CONNAME is stored in the repositories. Other queue managers in the cluster do not know that the CONNAME was originally blank.

If you issue the DISPLAY CLUSQMGR command you see the generated CONNAME. However, if you issue the DISPLAY CHANNEL command from the local queue manager, you see that the CONNAME is blank.

If the queue manager is stopped and restarted with a different IP address, because of DHCP, IBM MQ regenerates the CONNAME and updates the repositories accordingly.

## Queue definition commands

Cluster attributes that can be specified on the queue definition commands.

### The DEFINE QLOCAL, DEFINE QREMOTE, and DEFINE QALIAS commands

The cluster attributes on the DEFINE QLOCAL, DEFINE QREMOTE, and DEFINE QALIAS commands, and the three equivalent ALTER commands, are:

#### CLUSTER

Specifies the name of the cluster to which the queue belongs.

#### CLUSNL

Specifies a namelist of cluster names.

#### DEFBIND

Specifies the binding to be used when an application specifies MQOO\_BIND\_AS\_Q\_DEF on the MQOPEN call. The options for this attribute are:

- Specify DEFBIND(OPEN) to bind the queue handle to a specific instance of the cluster queue when the queue is opened. DEFBIND(OPEN) is the default for this attribute.
- Specify DEFBIND(NOTFIXED) so that the queue handle is not bound to any instance of the cluster queue.
- Specify DEFBIND(GROUP) to allow an application to request that a group of messages are all allocated to the same destination instance.

When multiple queues with the same name are advertised in a Queue Manager Cluster, applications can choose whether to send all messages from this application to a single instance (MQOO\_BIND\_ON\_OPEN), to allow the workload management algorithm to select the most suitable destination on a per message basis (MQOO\_BIND\_NOT\_FIXED), or allow an application to request that a 'group' of messages be all allocated to the same destination instance (MQOO\_BIND\_ON\_GROUP). The workload balancing is re-driven between groups of messages (without requiring an MQCLOSE and MQOPEN of the queue).

When you specify DEFBIND on a queue definition, the queue is defined with one of the attributes, MQBND\_BIND\_ON\_OPEN, MQBND\_BIND\_NOT\_FIXED, or MQBND\_BIND\_ON\_GROUP. Either MQBND\_BIND\_ON\_OPEN or MQBND\_BIND\_ON\_GROUP must be specified when using groups with clusters.

We recommend that you set the DEFBIND attribute to the same value on all instances of the same cluster queue. Because MQOO\_BIND\_ON\_GROUP is new in IBM WebSphere MQ Version 7.1, it must not be used if any of the applications opening this queue are connecting to IBM WebSphere MQ Version 7.0.1 or earlier queue managers.

#### CLWLRANK

Applies a ranking factor to a queue for workload management purposes. CLWLRANK parameter is not supported on model queues. The cluster workload algorithm selects a destination queue with the highest rank. By default CLWLRANK for all queues is set to zero.

If the final destination is a queue manager on a different cluster, you can set the rank of any intermediate gateway queue managers at the intersection of neighboring clusters. With the

intermediate queue managers ranked, the cluster workload algorithm correctly selects a destination queue manager nearer the final destination.

The same logic applies to alias queues. The rank selection is made before the channel status is checked, and therefore even non-accessible queue managers are available for selection. This has the effect of allowing a message to be routed through a network, rather than having it select between two possible destinations (as the priority would). So, if a channel is not started to the place where the rank has indicated, the message is not routed to the next highest rank, but waits until a channel is available to that destination (the message is held on the transmit queue).

#### **CLWLPRTY**

Applies a priority factor to a queue for workload management purposes. The cluster workload algorithm selects a destination queue with the highest priority. By default priority for all queues is set to zero.

If there are two possible destination queues, you can use this attribute to make one destination failover to the other destination. The priority selection is made after the channel status is checked. All messages are sent to the queue with the highest priority unless the status of the channel to that destination is not as favorable as the status of channels to other destinations. This means that only the most accessible destinations are available for selection. This has the effect of prioritizing between multiple destinations that are all available.

#### **CLWLUSEQ**

Specifies the behavior of an MQPUT operation for a queue. This parameter specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance (except where the MQPUT originates from a cluster channel). This parameter is only valid for local queues.

Possible values are: QMGR (the behavior is as specified by the CLWLUSEQ parameter of the queue manager definition), ANY (the queue manager treats the local queue as another instance of the cluster queue, for the purposes of workload distribution), LOCAL (the local queue is the only target of the MQPUT operation, providing the local queue is put enabled). The MQPUT behavior depends upon the cluster workload management algorithm.

### **The DISPLAY QUEUE and DISPLAY QCLUSTER commands**

The attributes on the DEFINE QLOCAL, DEFINE QREMOTE, and DEFINE QALIAS commands also apply to the DISPLAY QUEUE command.

To display information about cluster queues, specify a queue type of QCLUSTER or the keyword CLUSINFO on the DISPLAY QUEUE command, or use the command DISPLAY QCLUSTER.

The DISPLAY QUEUE or DISPLAY QCLUSTER command returns the name of the queue manager that hosts the queue (or the names of all queue managers if there is more than one instance of the queue). It also returns the system name for each queue manager that hosts the queue, the queue type represented, and the date and time at which the definition became available to the local queue manager. This information is returned using the CLUSQMGR, QMID, CLUSQT, CLUSDATE, and CLUSTIME attributes.

The system name for the queue manager ( QMID ), is a unique, system-generated name for the queue manager.

You can define a cluster queue that is also a shared queue. For example, on z/OS you can define:  
DEFINE QLOCAL(MYQUEUE) CLUSTER(MYCLUSTER) QSGDISP(SHARED) CFSTRUCT(STRUCTURE)

The equivalent PCFs are MQCMD\_CHANGE\_Q, MQCMD\_COPY\_Q, MQCMD\_CREATE\_Q, and MQCMD\_INQUIRE\_Q.

## **DISPLAY CLUSQMGR**

Use the DISPLAY CLUSQMGR command to display cluster information about queue managers in a cluster.

If you issue this command from a queue manager with a full repository, the information returned applies to every queue manager in the cluster. Otherwise the information returned applies only to the queue managers in which it has an interest. That is, every queue manager to which it has tried to send a message and every queue manager that holds a full repository.

The information includes most channel attributes that apply to cluster-sender and cluster-receiver channels. In addition, the following attributes can be displayed:

### **CHANNEL**

The cluster-receiver channel name for the queue manager.

### **CLUSDATE**

The date at which the definition became available to the local queue manager.

### **CLUSTER**

What clusters the queue manager is in.

### **CLUSTIME**

The time at which the definition became available to the local queue manager.

### **DEFTYPE**

How the queue manager was defined. DEFTYPE can be one of the following values:

#### **CLUSSDR**

A cluster sender-channel has been administratively defined on the local queue manager but not yet recognized by the target queue manager. To be in this state the local queue manager has defined a manual cluster-sender channel but the receiving queue manager has not accepted the cluster information. This may be due to the channel never having been established due to availability or to an error in the cluster-sender configuration, for example a mismatch in the CLUSTER property between the sender and receiver definitions. This is a transitory condition or error state and should be investigated.

#### **CLUSSDRA**

This value represents an automatically discovered cluster queue manager, no cluster-sender channel is defined locally. This is the DEFTYPE for cluster queue managers for which the local queue manager has no local configuration but has been informed of. For example

- If the local queue manager is a full repository queue manager it should be the DEFTYPE value for all partial repository queue managers in the cluster.
- If the local queue manager is a partial repository, this could be the host of a cluster queue that is being used from this local queue manager or from a second full repository queue manager that this queue manager has been told to work with.

If the DEFTYPE value is CLUSSDRA and the local and remote queue managers are both full repositories for the named cluster, the configuration is not correct as a locally defined cluster-sender channel must be defined to convert this to a DEFTYPE of CLUSSDRB.

#### **CLUSSDRB**

A cluster sender-channel has been administratively defined on the local queue manager and accepted as a valid cluster channel by the target queue manager. This is the expected DEFTYPE of a partial repository queue manager's manually configured full repository queue manager. It should also be the DEFTYPE of any CLUSQMGR from one full repository to another full repository in the cluster. Manual cluster-sender channels should not be configured to partial repositories or from a partial repository queue manager to more than one full repository. If a DEFTYPE of CLUSSDRB is seen in either of these situations it should be investigated and corrected.

**CLUSRCVR**

Administratively defined as a cluster-receiver channel on the local queue manager. This represents the local queue manager in the cluster.

**Note:** To identify which CLUSQMGRs are full repository queue managers for the cluster, see the QMTYPE property.

For more information on defining cluster channels, see Cluster channels.

**QMTYPE**

Whether it holds a full repository or only a partial repository.

**STATUS**

The status of the cluster-sender channel for this queue manager.

**SUSPEND**

Whether the queue manager is suspended.

**VERSION**

The version of the IBM MQ installation that the cluster queue manager is associated with.

The version has the format VVRRMMFF:

- VV: Version
- RR: Release
- MM: Maintenance level
- FF: Fix level

**XMITQ** The cluster transmission queue used by the queue manager.

See also the DISPLAY QCLUSTER command. This is briefly described in DISPLAY QUEUE and in the DISPLAY QUEUE and DISPLAY QCLUSTER commands section of "Queue definition commands" on page 139. For examples of using DISPLAY QCLUSTER, search the information set for "DISPLAY QCLUSTER" and "DISPLAY QCLUSTER".

**Related information:**

MQSC command **DISPLAY CLUSQMGR**

Use the MQSC command **DISPLAY CLUSQMGR** to display information about cluster channels for queue managers in a cluster.

**SUSPEND QMGR, RESUME QMGR and clusters**

Use the SUSPEND QMGR and RESUME QMGR command to temporarily reduce the inbound cluster activity to this queue manager, for example, before you perform maintenance on this queue manager, and then reinstate it.

While a queue manager is suspended from a cluster, it does not receive messages on cluster queues that it hosts if there is an available queue of the same name on an alternative queue manager in the cluster. However, messages that are explicitly targeted at this queue manager, or where the target queue is only available on this queue manager, are still directed to this queue manager.

Receiving further inbound messages while the queue manager is suspended can be prevented by stopping the cluster receiver channels for this cluster. To stop the cluster receiver channels for a cluster, use the FORCE mode of the SUSPEND QMGR command.

**Related information:****SUSPEND QMGR**

Use the MQSC command SUSPEND QMGR to advise other queue managers in a cluster to avoid sending messages to the local queue manager if possible.

**RESUME QMGR**

Use the MQSC command RESUME QMGR to inform other queue managers in a cluster that the local queue manager is available again for processing and can be sent messages. It reverses the action of the SUSPEND QMGR command.

Maintaining a queue manager

**REFRESH CLUSTER**

Issue the REFRESH CLUSTER command from a queue manager to discard all locally held information about a cluster. You are unlikely to need to use this command, except in exceptional circumstances.

There are three forms of this command:

**REFRESH CLUSTER(clustername) REPOS(NO)**

The default. The queue manager retains knowledge of all locally defined cluster queue manager and cluster queues and all cluster queue managers that are full repositories. In addition, if the queue manager is a full repository for the cluster it also retains knowledge of the other cluster queue managers in the cluster. Everything else is removed from the local copy of the repository and rebuilt from the other full repositories in the cluster. Cluster channels are not stopped if REPOS(NO) is used. A full repository uses its CLUSSDR channels to inform the rest of the cluster that it has completed its refresh.

**REFRESH CLUSTER(clustername) REPOS(YES)**

In addition to the default behavior, objects representing full repository cluster queue managers are also refreshed. It is not valid to use this option if the queue manager is a full repository, if used the command will fail with an error AMQ9406/CSQX406E logged. If it is a full repository, you must first alter it so that it is not a full repository for the cluster in question. The full repository location is recovered from the manually defined CLUSSDR definitions. After refreshing with REPOS(YES) has been issued the queue manager can be altered so that it is once again a full repository, if required.

**REFRESH CLUSTER(\*)**

Refreshes the queue manager in all the clusters it is a member of. If used with REPOS(YES) REFRESH CLUSTER(\*) has the additional effect of forcing the queue manager to restart its search for full repositories from the information in the local CLUSSDR definitions. The search takes place even if the CLUSSDR channel connects the queue manager to several clusters.

**Note:** For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

Clustering: Using REFRESH CLUSTER best practices

## RESET CLUSTER

Use the **RESET CLUSTER** command to forcibly remove a queue manager from a cluster in exceptional circumstances.

You are unlikely to need to use this command, except in exceptional circumstances.

You can issue the **RESET CLUSTER** command only from full repository queue managers. The command takes two forms, depending on whether you reference the queue manager by name or identifier.

1. **RESET CLUSTER**( *clustername*  
 ) QMNAME( *qmname* ) ACTION(FORCEREMOVE) QUEUES(NO)
2. **RESET CLUSTER**( *clustername*  
 ) QMID( *qmid* ) ACTION(FORCEREMOVE) QUEUES(NO)

You cannot specify both QMNAME and QMID. If you use QMNAME, and there is more than one queue manager in the cluster with that name, the command is not run. Use QMID instead of QMNAME to ensure the **RESET CLUSTER** command is run.

Specifying QUEUES(NO) on a **RESET CLUSTER** command is the default. Specifying QUEUES(YES) removes references to cluster queues owned by the queue manager from the cluster. The references are removed in addition to removing the queue manager from the cluster itself.

The references are removed even if the cluster queue manager is not visible in the cluster; perhaps because it was previously forcibly removed, without the QUEUES option.

You might use the **RESET CLUSTER** command if, for example, a queue manager has been deleted but still has cluster-receiver channels defined to the cluster. Instead of waiting for IBM MQ to remove these definitions (which it does automatically) you can issue the **RESET CLUSTER** command to tidy up sooner. All other queue managers in the cluster are then informed that the queue manager is no longer available.

If a queue manager is temporarily damaged, you might want to tell the other queue managers in the cluster before they try to send it messages. **RESET CLUSTER** removes the damaged queue manager. Later, when the damaged queue manager is working again, use the **REFRESH CLUSTER** command to reverse the effect of **RESET CLUSTER** and return the queue manager to the cluster. If the queue manager is in a publish/subscribe cluster, you then need to reinstate any required proxy subscriptions. See REFRESH CLUSTER considerations for publish/subscribe clusters.

**Note:** For large clusters, use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

Using the **RESET CLUSTER** command is the only way to delete auto-defined cluster-sender channels. You are unlikely to need this command in normal circumstances. The IBM Support Center might advise you to issue the command to tidy up the cluster information held by cluster queue managers. Do not use this command as a short cut to removing a queue manager from a cluster. The correct way to remove a queue manager from a cluster is described in Removing a queue manager from a cluster.

Because repositories retain information for only 90 days, after that time a queue manager that was forcibly removed can reconnect to a cluster. It reconnects automatically, unless it has been deleted. If you want to prevent a queue manager from rejoining a cluster, you need to take appropriate security measures.

All cluster commands, except **DISPLAY CLUSQMGR**, work asynchronously. Commands that change object attributes involving clustering update the object and send a request to the repository processor. Commands for working with clusters are checked for syntax, and a request is sent to the repository processor.

The requests sent to the repository processor are processed asynchronously, along with cluster requests received from other members of the cluster. Processing might take a considerable time if they have to be propagated around the whole cluster to determine if they are successful or not.

## **Workload balancing in clusters**

If a cluster contains more than one instance of the same queue, IBM MQ selects a queue manager to route a message to. It uses the cluster workload management algorithm, and a number of cluster workload-specific attributes, to determine the best queue manager to use.

Suitable destinations are chosen, by the cluster workload management algorithm, based on the availability of the queue manager and queue, and on a number of cluster workload-specific attributes associated with queue managers, queues, and channels. These attributes are described in the subtopics.

**Note:** Specify the cluster workload channel attributes on the cluster-receiver channels at the target queue managers. Any balancing you specify on the matching cluster-sender channels is likely to be ignored. See Cluster channels.

After you configure the cluster workload-specific attributes, if the configuration does not behave as you expected, explore the details of how the algorithm chooses a queue manager. See “The cluster workload management algorithm” on page 149. If the results of this algorithm do not meet your needs, you can write a cluster workload user exit program, and use this exit to route messages to the queue of your choice in the cluster. See Writing and compiling cluster workload exits.

### **CLWLPRTY queue attribute:**

The CLWLPRTY queue attribute specifies the priority of local, remote, or alias queues for cluster workload distribution. The value must be in the range 0-9, where 0 is the lowest priority and 9 is the highest.

Use the CLWLPRTY queue attribute to set a preference for destination queues. IBM MQ selects the destinations with the highest priority before selecting destinations with the lowest cluster destination priority. If there are multiple destinations with the same priority, it selects the least recently used destination.

If there are two possible destinations, you can use this attribute to allow failover. The highest priority queue manager receives requests, lower priority queue managers act as reserves. If the highest priority queue manager fails, then the next highest priority queue manager that is available, takes over.

IBM MQ obtains the priority of queue managers after checking channel status. Only available queue managers are candidates for selection.

### **Note:**

The availability of a remote queue manager is based on the status of the channel to that queue manager. When channels start, their state changes several times, with some of the states being less preferential to the cluster workload management algorithm. In practice this means that lower priority (backup) destinations can be chosen while the channels to higher priority (primary) destinations are starting.

If you need to ensure that no messages go to a backup destination, do not use CLWLPRTY. Consider using separate queues, or CLWLRANK with a manual switch over from the primary to backup.

### **CLWLRANK queue attribute:**

The CLWLRANK queue attribute specifies the rank of a local, remote, or alias queue for cluster workload distribution. The value must be in the range 0-9, where 0 is the lowest rank and 9 is the highest.

Use the CLWLRANK queue attribute if you want control over the final destination for messages sent to a queue manager in another cluster. When you set CLWLRANK, messages take a specified route through the interconnected clusters towards a higher ranked destination.

For example, you might have defined two identically configured gateway queue managers to improve the availability of a gateway. Suppose you have defined cluster alias queues at the gateways for a local queue defined in the cluster. If the local queue becomes unavailable, you intend the message to be held at one of the gateways pending the queue becoming available again. To hold the queue at a gateway, you must define the local queue with a higher rank than the cluster alias queues at the gateway.

If you define the local queue with the same rank as the queue aliases and the local queue is unavailable, the message travels between the gateways. On finding the local queue unavailable the first gateway queue manager routes the message to the other gateway. The other gateway tries to deliver the message to the target local queue again. If the local queue is still unavailable, it routes the message back to the first gateway. The message keeps being moved back and forth between the gateways until the target local queue became available again. By giving the local queue a higher rank, even if the queue is unavailable, the message is not rerouted to a destination of lower rank.

IBM MQ obtains the rank of queues before checking channel status. Obtaining the rank before checking channel status means that even non-accessible queues are available for selection. It allows messages to be routed through the network even if the final destination is unavailable.

If you used the priority attribute IBM MQ selects between available destinations. If a channel is not available to the destination with the highest rank, the message is held on the transmission queue. It is released when the channel becomes available. The message does not get sent to the next available destination in the rank order.

### **CLWLUSEQ queue attribute:**

The CLWLUSEQ queue attribute specifies whether a local instance of a queue is given preference as a destination over other instances in a cluster.

The CLWLUSEQ queue attribute is valid only for local queues. It only applies if the message is put by an application, or a channel that is not a cluster channel.

- LOCAL** The local queue is the only target of MQPUT, providing the local queue is put enabled. MQPUT behavior depends upon the cluster workload management.
- QMGR** The behavior is as specified by the CLWLUSEQ queue manager attribute.
- ANY** MQPUT treats the local queue the same as any other instance of the queue in the cluster for workload distribution.

**CLWLUSEQ queue manager attribute:**

The CLWLUSEQ queue manager attribute specifies whether a local instance of a queue is given preference as a destination over other instances of the queue in a cluster. The attribute applies if the CLWLUSEQ queue attribute is set to QMGR.

The CLWLUSEQ queue attribute is valid only for local queues. It only applies if the message is put by an application, or a channel that is not a cluster channel.

**LOCAL** The local queue is the only target of MQPUT. LOCAL is the default.

**ANY** MQPUT treats the local queue the same as any other instance of the queue in the cluster for workload distribution.

**CLWLMRUC queue manager attribute:**

The CLWLMRUC queue manager attribute sets the number of most recently chosen channels. The cluster workload management algorithm uses CLWLMRUC to restrict the number of active outbound cluster channels. The value must be in the range 1 - 999 999 999.

The initial default value is 999 999 999.

**CLWLPRTY channel attribute:**

The CLWLPRTY channel attribute specifies the priority order for channels for cluster workload distribution. The value must be in the range 0-9, where 0 is the lowest priority and 9 is the highest.

Use the CLWLPRTY channel attribute to set a priority order for the available cluster destinations. IBM MQ selects the destinations with the highest priority before selecting destinations with the lowest cluster destination priority. If there are multiple destinations with the same priority, it selects the least recently used destination.

If there are two possible destinations, you can use this attribute to allow failover. Messages go to the queue manager with the highest priority channel. If it becomes unavailable then messages go to the next highest priority queue manager. Lower priority queue managers act as reserves.

IBM MQ checks channel status before prioritizing the channels. Only available queue managers are candidates for selection.

**Notes:**

- Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See Cluster channels.
- The availability of a remote queue manager is based on the status of the channel to that queue manager. When channels start, their state changes several times, with some of the states being less preferential to the cluster workload management algorithm. In practice this means that lower priority (backup) destinations can be chosen while the channels to higher priority (primary) destinations are starting.
- If you need to ensure that no messages go to a backup destination, do not use CLWLPRTY. Consider using separate queues, or CLWLRANK with a manual switch over from the primary to backup.

**CLWLRANK channel attribute:**

The CLWLRANK channel attribute specifies the rank of channels for cluster workload distribution. The value must be in the range 0-9, where 0 is the lowest rank and 9 is the highest.

Use the CLWLRANK channel attribute if you want control over the final destination for messages sent to a queue manager in another cluster. Control the choice of final destination by setting the rank of the channels connecting a queue manager to the gateway queue managers at the intersection of the clusters.

When you set CLWLRANK, messages take a specified route through the interconnected clusters towards a higher ranked destination. For example, messages arrive at a gateway queue manager that can send them to either of two queue managers using channels ranked 1 and 2. They are automatically sent to the queue manager connected by a channel with the highest rank, in this case the channel to the queue manager ranked 2.

IBM MQ gets the rank of channels before checking channel status. Getting the rank before checking channel status means that even non-accessible channels are available for selection. It allows messages to be routed through the network even if the final destination is unavailable.

**Notes:**

- Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See Cluster channels.
- If you also used the priority attribute CLWLPRTY, IBM MQ selects between available destinations. If a channel is not available to the destination with the highest rank, the message is held on the transmission queue. It is released when the channel becomes available. The message does not get sent to the next available destination in the rank order.

**CLWLWGHT channel attribute:**

The CLWLWGHT channel attribute specifies the weight applied to CLUSSDR and CLUSRCVR channels for cluster workload distribution. The value must be in the range 1-99, where 1 is the lowest weight and 99 is the highest.

Use CLWLWGHT to send servers with more processing power more messages. The higher the channel weight, the more messages are sent over that channel.

**Notes:**

- Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See Cluster channels.
- When CLWLWGHT is modified from the default of 50 on any channel, workload balancing becomes dependent on the total number of times each channel was chosen for a message sent to any clustered queue. For more information, see "The cluster workload management algorithm" on page 149.

### NETPRTY channel attribute:

The NETPRTY channel attribute specifies the priority for a CLUSRCVR channel. The value must be in the range 0-9, where 0 is the lowest priority and 9 is the highest.

Use the NETPRTY attribute to make one network the primary network, and another network the backup network. Given a set of equally ranked channels, clustering chooses the path with the highest priority when multiple paths are available.

A typical example of using the NETPRTY channel attribute is to differentiate between networks that have different costs or speeds and connect the same destinations.

**Note:** Specify this attribute on the cluster-receiver channel at the target queue manager. Any balancing you specify on the matching cluster-sender channel is likely to be ignored. See Cluster channels.

### The cluster workload management algorithm:

The workload management algorithm uses workload balancing attributes and many rules to select the final destination for messages being put onto cluster queues.

The workload management algorithm is exercised every time a choice of destination is required:

- It is used at the point a cluster queue is opened, by using the MQOO\_BIND\_ON\_OPEN option.
- It is used each time a message is put to a cluster queue when it is opened with MQOO\_BIND\_NOT\_FIXED.
- It is used each time a new message group is started when MQOO\_BIND\_ON\_GROUP is used to open a cluster queue.
- For topic host routing, it is used each time a message is published to a clustered topic. If the local queue manager is not a host for this topic, the algorithm is used to choose a host queue manager to route the message through.

The following section describes the workload management algorithm used when determining the final destination for messages being put onto cluster queues. These rules are influenced by the settings applied to the following attributes for queues, queue managers, and channels:

Table 32. Attributes for cluster workload management

Queues	Queue managers	Channels
<ul style="list-style-type: none"><li>• CLWLPRTY (This attribute applies only when choosing a clustered queue, not when choosing a topic.)<sup>1</sup></li><li>• CLWLRANK<sup>1</sup></li><li>• CLWLUSEQ<sup>1</sup></li><li>• PUT / PUB</li></ul>	<ul style="list-style-type: none"><li>• CLWLUSEQ<sup>1</sup></li><li>• CLWLMRUC</li></ul>	<ul style="list-style-type: none"><li>• CLWLPRTY</li><li>• CLWLRANK</li><li>• CLWLWGHT</li><li>• NETPRTY</li></ul>

Initially, the queue manager builds a list of possible destinations from two procedures:

- Matching the target ObjectName and ObjectQmgrName with queue manager alias definitions that are shared in the same clusters as the queue manager.
- Finding unique routes (that is, channels) to a queue manager that hosts a queue with the name ObjectName and is in one of the clusters that the queue manager is a member of.

The algorithm steps through the following rules to eliminate destinations from the list of possible destinations.

1. If a queue or topic name is specified:

- a. Queues that are not put enabled are eliminated as possible destinations.
  - b. Administered topic definitions that are not pub enabled are eliminated as possible destinations.
  - c. Remote instances of queues or topics that do not share a cluster with the local queue manager are eliminated.
  - d. Remote CLUSRCVR channels that are not in the same cluster as the queue or topic are eliminated.
2. If a queue manager name is specified:
    - a. Queue manager aliases that are not put enabled are eliminated.
    - b. Remote CLUSRCVR channels that are not in the same cluster as the local queue manager are eliminated.
  3. When choosing a queue, if the resulting set of queues contains the local instance of the queue, the local instance is typically used. The local instance of the queue is used if one of these three conditions are true:
    - Either the use-queue attribute of the queue, CLWLUSEQ is set to LOCAL,
    - Or both the following statements are true:
      - a. The **use-queue** attribute of the queue, CLWLUSEQ is set to QMGR.
      - b. The **use-queue** attribute of the queue manager, CLWLUSEQ is set to LOCAL.
    - Or the message is received over a cluster channel rather than by being put by a local application.
  4. All channels to queue managers or queue manager aliases that have a CLWLRANK less than the maximum rank of all remaining channels or queue manager aliases are eliminated.
  5. All queues (not queue manager aliases) with a CLWLRANK less than the maximum rank of all remaining queues are eliminated.
  6. If only remote instances of a queue or topic remain, resumed queue managers are chosen in preference to suspended ones.
  7. If more than one remote instance of a queue or topic remains, all channels that are inactive or running are included. The state constants are listed:
    - MQCHS\_INACTIVE
    - MQCHS\_RUNNING
  8. If no remote instance of a queue or topic remains, all channels that are in binding, initializing, starting, or stopping state are included. The state constants are listed:
    - MQCHS\_BINDING
    - MQCHS\_INITIALIZING
    - MQCHS\_STARTING
    - MQCHS\_STOPPING
  9. If no remote instance of a queue or topic remains, all channels that are being tried again are included. The state constant is listed:
    - MQCHS\_RETRYING
  10. If no remote instance of a queue or topic remains, all channels in requesting, paused, or stopped state are included. The state constants are listed:
    - MQCHS\_REQUESTING
    - MQCHS\_PAUSED
    - MQCHS\_STOPPED
  11. If more than one remote instance of a queue or topic on any queue manager remains, channels with the highest NETPRTY value for each queue manager are chosen.
  12. If a queue manager is being chosen:
    - All remaining channels and queue manager aliases other than channels and aliases with the highest priority, CLWLPRTY, are eliminated. If any queue manager aliases remain, channels to the queue manager are kept.
  13. If a queue is being chosen:
    - All queues other than queues with the highest priority, CLWLPRTY, are eliminated, and channels are kept.

14. The remaining channels are then reduced to no more than the maximum allowed number of most recently-used channels, CLWLMRUC, by eliminating the channels with the lowest values of MQWDR.DestSeqNumber.

**Note:** Internal cluster control messages are sent using the same cluster workload algorithm where appropriate.

After the list of valid destinations has been calculated, messages are workload balanced across them, using the following logic:

- When more than one remote instance of a destination remains and all channels to those destination have CLWLWGHT set to the default setting of 50, then the least recently used channel is chosen. This approximately equates to a round-robin style of workload balancing when multiple remote instances exist.
- When more than one remote instance of a destination remains and one or more of the channels to those queues has CLWLWGHT set to a non-default setting (even if they all have a matching non-default value), then routing becomes dependent on the relative weightings of each channel and the total number of times each channel has previously been chosen when sending messages.
- When observing the distribution of messages for a single clustered queue with multiple instances, this can appear to lead to an unbalanced distribution across a subset of queue instances. This is because it is the historic use of each cluster sender channel from this queue manager that is being balanced, not just the message traffic for that queue. If this behavior is not desirable, do one of the following steps.
  - Either set CLWLWGHT to 50 on all cluster receiver channels if even distribution is required,
  - Or, if certain queue instances need to be weighted differently from others, define those queues in a dedicated cluster, with defined dedicated cluster receiver channels. This action isolates the workload balancing of these queues from others in the cluster.
- The historic data that is used to balance the channels is reset if any cluster workload attributes of available cluster receiver channels are altered or the status of a cluster receiver channel becomes available. Modification to the workload attributes of manually defined cluster sender channels does not reset the historic data.
- When you are considering cluster workload exit logic, the chosen channel is the one with the lowest MQWDR.DestSeqFactor. Each time a channel is chosen, this value is increased by approximately  $1000/CLWLWGHT$ . If there is more than one channel with the lowest value, one of the channels with the lowest MQWDR.DestSeqNumber value is chosen.

The distribution of user messages is not always exact because administration and maintenance of the cluster causes messages to flow across channels. The result is an uneven distribution of user messages that can take some time to stabilize. Because of the admixture of administration and user messages, place no reliance on the exact distribution of messages during workload balancing.

## Asynchronous behavior of CLUSTER commands on z/OS

The command issuer of a cluster command on z/OS receives confirmation a command has been sent, but not that it has completed successfully.

For both REFRESH CLUSTER and RESET CLUSTER, message CSQM130I is sent to the command issuer indicating that a request has been sent. This message is followed by message CSQ9022I to indicate that the command has completed successfully, in that a request has been sent. It does not indicate that the cluster request has been completed successfully.

Any errors are reported to the z/OS console on the system where the channel initiator is running, they are not sent to the command issuer.

The asynchronous behavior is in contrast to CHANNEL commands. A message indicating that a channel command has been accepted is issued immediately. At some later time, when the command has been completed, a message indicating either normal or abnormal completion is sent to the command issuer.

Checking that async commands for distributed networks have finished

## Channel programs

This section looks at the different types of channel programs (MCAs) available for use at the channels.

The names of the MCAs are shown in the following tables.

*Table 33. Channel programs for Windows, UNIX and Linux systems*

Program name	Direction of connection	Communication
amqrmppa		Any
runmqslr	Inbound	Any
amqcrs6a	Inbound	LU 6.2
amqcrsta	Inbound	TCP
runmqchl	Outbound	Any
runmqchi	Outbound	Any

runmqslr (Run IBM MQ listener), runmqchl (Run IBM MQ channel), and runmqchi (Run IBM MQ channel initiator) are control commands that you can enter at the command line.

amqcrsta is invoked for TCP channels on UNIX and Linux systems using inetd, where no listener is started.

amqcrs6a is invoked as a transaction program when using LU6.2

## Environment Variables

A list of all the server and client Environment Variables. Example of use, on UNIX and Linux systems use: `export [environment variable]=filename`. On Windows Systems, use: `Set [environment variable]=filename`. On IBM i systems use: `ADDENVVAR ENVVAR(environment variable) VALUE(xx)`

### AMQ\_MQS\_INI\_LOCATION

On UNIX and Linux systems, you can alter the location used for the `mqs.ini` file by setting the location of the `mqs.ini` file in this variable. This variable must be set at the system level.

### AMQ\_REVERSE\_COMMIT\_ORDER

This variable configures a queue manager so that in an XA transaction the IBM MQ queue manager change is committed after the corresponding database update is completed.

Do not set `AMQ_REVERSE_COMMIT_ORDER` without reading and understanding the scenario that is described in the following topic: Isolation level.

## ► V8.0.0.7

### AMQ\_SSL\_ALLOW\_DEFAULT\_CERT

From IBM MQ Version 8.0.0, Fix Pack 7, when this variable is not set, an application can connect to a queue manager with a personal certificate in the client keystore only when the certificate includes the label name of `ibmwebsphermq<userid>`. By using the `AMQ_SSL_ALLOW_DEFAULT_CERT` environment variable, the certificate does not require the label name of `ibmwebsphermq<userid>`. That is, the certificate that is used to connect to a queue manager can be a default certificate, provided that a default certificate is present in the queue repository, and the key repository does not contain a personal certificate with the prefix `ibmwebsphermq<userid>`. For more information, see the technote [Specifying the userid in the SSL certificate label for an MQ client](#).

A value of 1 enables the use of a default certificate.

From IBM MQ Version 8.0, instead of using the `AMQ_SSL_ALLOW_DEFAULT_CERT` environment variable, an application can use the **CertificateLabel** setting of the SSL stanza in the `mqclient.ini` file. For more information, see [Digital certificate labels, understanding the requirements and SSL stanza of the client configuration file](#).

## ► V8.0.0.8

### AMQ\_SSL\_LDAP\_SERVER\_VERSION

From IBM MQ Version 8.0.0, Fix Pack 8, this variable can be used to ensure that either LDAP v2 or LDAP v3 is used by IBM MQ cryptographic components in cases where CRL servers require that a specific version of the LDAP protocol be used.

Set the variable to appropriate value in the environment that is used to start the queue manager or channel. To request that LDAP v2 is used, set `AMQ_SSL_LDAP_SERVER_VERSION=2`. To request that LDAP v3 is used, set `AMQ_SSL_LDAP_SERVER_VERSION=3`.

This variable does not affect LDAP connections established by the IBM MQ queue manager for user authentication or user authorization.

### GMQ\_MQ\_LIB

When both the IBM MQ MQI client and IBM MQ server are installed on your system, MQAX applications run against the server by default. To run MQAX against the client, the client bindings library must be specified in the `GMQ_MQ_LIB` environment variable, for example, set `GMQ_MQ_LIB=mqic.dll`. For a client only installation, it is not necessary to set the `GMQ_MQ_LIB` environment variable. When this variable is not set, IBM MQ attempts to load `amqzst.dll`. If this DLL is not present (as is the case in a client only installation), IBM MQ attempts to load `mqic.dll`.

**HOME**

This variable contains the name of the directory which is searched for the `mqclient.ini` file. This file contains configuration information used by IBM MQ MQI clients on IBM i, UNIX and Linux systems.

**HOMEDRIVE and HOMEPATH**

To be used both of these variables must be set. They are used to contain the name of the directory which is searched for the `mqclient.ini` file. This file contains configuration information used by IBM MQ MQI clients on Windows systems.

**LDAP\_BASEDN**

The required environment variable for running an LDAP sample program. It specifies the base Distinguished Name for the directory search.

**LDAP\_HOST**

An optional variable for running an LDAP sample program. It specifies the name of the host where the LDAP server is running; it defaults to the local host if it is not specified

**LDAP\_VERSION**

An optional variable for running an LDAP sample program. It specifies the version of the LDAP protocol to be used, and can be either 2 or 3. Most LDAP servers now support version 3 of the protocol; they all support the older version 2. This sample works equally well with either version of the protocol, and if it is not specified it defaults to version 2.

**MQAPI\_TRACE\_LOGFILE**

The sample API exit program generates an MQI trace to a user-specified file with a prefix defined in the `MQAPI_TRACE_LOGFILE` environment variable.

**MQCCSID**

Specifies the coded character set number to be used and overrides the native CCSID of the application.

**MQCERTLABL**

Defines the certificate label.

**MQCERTVPOL**

Determines the type of certificate validation used:

**ANY** Use any certificate validation policy supported by the underlying secure sockets library. This setting is the default setting.

**RFC5280**

Use only certificate validation which complies with the RFC 5280 standard.

**MQCHLLIB**

Specifies the directory path to the file containing the client channel definition table (CCDT). The file is created on the server, but can be copied across to the IBM MQ MQI client workstation.

**MQCHLTAB**

`MQCHLTAB` specifies the name of the file containing the client channel definition table (`ccdt`). The default file name is `AMQCLCHL.TAB`.

**MQC\_IPC\_HOST**

When sharing IBM MQ files and the generated value of `myHostName` creates a problem set `myHostName` using the environment variable `MQC_IPC_HOST`

**MQCLNTCF**

Use this environment variable to modify the `mqclient.ini` file path.

**MQ\_CONNECT\_TYPE**

On IBM MQ for IBM i, Windows, UNIX and Linux systems, use this environment variable in combination with the type of binding specified in the Options field of the `MQCNO` structure used on an `MQCONN` call. See `MQCONN` environment variable

### **MQ\_CROSS\_QUEUE\_ORDER\_ALL**

When you set the MQ\_CROSS\_QUEUE\_ORDER\_ALL environment variable to a non-zero value, the message put order is maintained in a unit of work. This means that, if messages in a Unit of Work (UoW) are put onto multiple queues (for example, Q1, then Q2), when an MQCMIT is issued, the messages are delivered and made available in the same queue order in which they were PUT.

In a multi-queue manager environment, MQ\_CROSS\_QUEUE\_ORDER\_ALL must exist and have a non-empty value on both the sending and receiving side before each queue manager is started.

### **MQ\_FILE\_PATH**

During the installation of the runtime package on the Windows platform, a new environment variable called MQ\_FILE\_PATH is configured. This environment variable contains the same data as the following key in the Windows Registry:

```
HKEY_LOCAL_MACHINE\SOFTWARE\IBM\WebSphere MQ\Installation\<InstallationName>\FilePath
```

### **MQIPADDRV**

MQIPADDRV specifies which IP protocol to use for a channel connection. It has the possible string values of "MQIPADDR\_IPv4" or "MQIPADDR\_IPv6". These values have the same meanings as IPv4 and IPv6 in ALTER QMGR IPADDRV. If it is not set, "MQIPADDR\_IPv4" is assumed.

### **MQ\_JAVA\_DATA\_PATH**

Specifies the directory for log and trace output.

### **MQ\_JAVA\_INSTALL\_PATH**

Specifies the directory where IBM MQ classes for Java are installed, as shown in IBM MQ classes for Java installation directories.

### **MQ\_JAVA\_LIB\_PATH**

Specifies the directory where the IBM MQ classes for Java libraries are stored. Some scripts supplied with IBM MQ classes for Java, such as IVTRun, use this environment variable.

### **MQNAME**

MQNAME specifies the local NetBIOS name that the IBM MQ processes can use.

### **MQNOREMPOOL**

When you set this variable, it switches off channel pooling and causes channels to run as threads of the listener.

### **MQPSE\_TRACE\_LOGFILE**

Use when you Publish the Exit Sample Program. In the application process to be traced, this environment variable describes where the trace files must be written to. See The Publish Exit sample program

### **MQSERVER**

MQSERVER environment variable is used to define a minimal channel. You cannot use MQSERVER to define an SSL channel or a channel with channel exits. MQSERVER specifies the location of the IBM MQ server and the communication method to be used.

### **MQ\_SET\_NODELAYACK**

When you set this variable, it switches off TCP delayed acknowledgment

When you set this variable on AIX, the setting switches off TCP delayed acknowledgment by calling the operating system's setsockopt call with the TCP\_NODELAYACK option. Only AIX supports this function, so the MQ\_SET\_NODELAYACK environment variable only has an effect on AIX.

### **MQSNOAUT**

MQSNOAUT disables the object authority manager (OAM) and prevents any security checking. The MQSNOAUT variable only takes effect when a queue manager is created.

## **MQSPREFIX**

As an alternative to changing the default prefix, you can use the environment variable MQSPREFIX to override the DefaultPrefix for the **crtmqm** command.

## **MQSSLCRYP**

MQSSLCRYP holds a parameter string that you can use to configure the cryptographic hardware present on the system. The permitted values are the same as for the SSLCRYP parameter of the ALTER QMGR command.

## **MQSSLFIPS**

MQSSLFIPS specifies whether only FIPS-certified algorithms are to be used if cryptography is carried out in IBM MQ. The values are the same as for the SSLFIPS parameter of the ALTER QMGR command.

## **MQSSLKEYR**

MQSSLKEYR specifies the location of the key repository that holds the digital certificate belonging to the user, in stem format. Stem format means that it includes the full path and the file name without an extension. For full details, see the SSLKEYR parameter of the ALTER QMGR command.

## **MQSSLPROXY**

MQSSLPROXY specifies the host name and port number of the HTTP proxy server to be used by GSKit for OCSP checks.

## **MQSSLRESET**

MQSSLRESET represents the number of unencrypted bytes sent and received on an SSL channel before the SSL secret key is renegotiated.

## **MQS\_TRACE\_OPTIONS**

Use the environment variable MQS\_TRACE\_OPTIONS to activate the high detail and parameter tracing functions individually.

## **MQTCPTIMEOUT**

This variable specifies how long IBM MQ waits for a TCP connect call.

## **MQSUITEB**

This variable specifies whether Suite B compliant cryptography is to be used. In the instance that Suite B cryptography is used you can specify the strength of the cryptography by setting MQSUITEB to one of the following:

- NONE
- 128\_BIT, 192\_BIT
- 128\_BIT
- 192\_BIT

## **ODQ\_MSG**

If you use a dead-letter queue handler that is different from RUNMQDLQ the source of the sample is available for you to use as your base. The sample is like the dead-letter handler provided within the product but trace and error reporting are different. Use the ODQ\_MSG environment variable to set the name of the file containing error and information messages. The file provided is called amqsdlq.msg.

## **ODQ\_TRACE**

If you use a dead-letter queue handler that is different from RUNMQDLQ the source of the sample is available for you to use as your base. The sample is like the dead-letter handler provided within the product but trace and error reporting are different. Set the ODQ\_TRACE environment variable to YES or yes to switch on tracing

## **OMQ\_PATH**

This environment variable is where you can find the First Failure Symptom report if your IBM MQ automation classes for ActiveX script fails.

## OMQ\_TRACE

MQAX includes a trace facility to help the service organization identify what is happening when you have a problem. It shows the paths taken when you run your MQAX script. Unless you have a problem, run with tracing set off to avoid any unnecessary use of system resources.

OMQ\_TRACE is one of the three environment variables set to control trace. Specifying any value for OMQ\_TRACE switches the trace facility on. Even if you set OMQ\_TRACE to OFF, trace is still active. See Using trace

## OMQ\_TRACE\_PATH

One of the three environment variables set to control trace. See Using trace

## OMQ\_TRACE\_LEVEL

One of the three environment variables set to control trace. See Using trace

## ONCONFIG

The name of the Informix® server configuration file. For example, on UNIX and Linux systems, use:

```
export ONCONFIG=onconfig.hostname_1
```

On Windows systems, use:

```
set ONCONFIG=onconfig.hostname_1
```

## WCF\_TRACE\_ON

Two different trace methods are available for the WCF custom channel, the two trace methods are activated independently or together. Each method produces its own trace file, so when both trace methods have been activated, two trace output files are generated. There are four combinations for enabling and disabling the two different trace methods. As well as these combinations to enable WCF trace, the XMS .NET trace can also be enabled using the WCF\_TRACE\_ON environment variable. See WCF trace configuration and trace file names

## WMQSOAP\_HOME

Use when making additional configuration steps after the .NET SOAP over JMS service hosting environment is correctly installed and configured in IBM MQ. It is accessible from a local queue manager. See WCF client to a .NET service hosted by IBM MQ sample and WCF client to an Axis Java service hosted by IBM MQ sample

Also use when you install IBM MQ web transport for SOAP. See Installing IBM MQ Web transport for SOAP

## Intercommunication jobs

The following jobs are associated with Intercommunication on IBM i. The names are contained in the following table.

Table 34. Job names

Job name	Description
AMQCLMAA	Non-threaded Listener
AMQCRSTA	Non-threaded Responder Job
AMQRMPPA	Channel Pool Job
RUNMQCHI	Channel Initiator
RUNMQCHL	Channel Job
RUNMQLSR	Threaded Listener

## Channel states on IBM i

Channel states are displayed on the Work with Channels panel

Table 35. Channel states on IBM i

State name	Meaning
STARTING	Channel is ready to begin negotiation with target MCA
BINDING	Establishing a session and initial data exchange
REQUESTING	Requester channel initiating a connection
RUNNING	Transferring or ready to transfer
PAUSED	Waiting for message-retry interval
STOPPING	Establishing whether to retry or stop
RETRYING	Waiting until next retry attempt
STOPPED	Channel stopped because of an error or because an end-channel command is issued
INACTIVE	Channel ended processing normally or channel never started
*None	No state (for server-connection channels only)

## Message channel planning example for distributed platforms

This section provides a detailed example of how to connect two queue managers together so that messages can be sent between them.

The example illustrates the preparations required to enable an application using queue manager QM1 to put messages on a queue at queue manager QM2. An application running on QM2 can retrieve these messages, and send responses to a reply queue on QM1.

The example illustrates the use of TCP/IP connections. The example assumes that channels are to be triggered to start when the first message arrives on the transmission queue they are servicing. You must start the channel initiator in order for triggering to work.

This example uses SYSTEM.CHANNEL.INITQ as the initiation queue. This queue is already defined by IBM MQ. You can use a different initiation queue, but you must define it yourself and specify the name of the queue when you start the channel initiator.

### What the example shows

The example shows the IBM MQ commands (MQSC) that you can use.

In all the examples, the MQSC commands are shown as they would appear in a file of commands, and as they would be typed at the command line. The two methods look identical, but, to issue a command at the command line, you must first type `runmqsc`, for the default queue manager, or `runmqsc qmname` where *qmname* is the name of the required queue manager. Then type any number of commands, as shown in the examples.

An alternative method is to create a file containing these commands. Any errors in the commands are then easy to correct. If you called your file `mqsc.in` then to run it on queue manager QMNAME use:

```
runmqsc QMNAME < mqsc.in > mqsc.out
```

You could verify the commands in your file before running it using:

```
runmqsc -v QMNAME < mqsc.in > mqsc.out
```

For portability, you should restrict the line length of your commands to 72 characters. Use a concatenation character to continue over more than one line. On Windows use Ctrl-z to end the input at the command line. On UNIX and Linux systems use Ctrl-d. Alternatively, use the **end** command.

Figure 7 shows the example scenario.

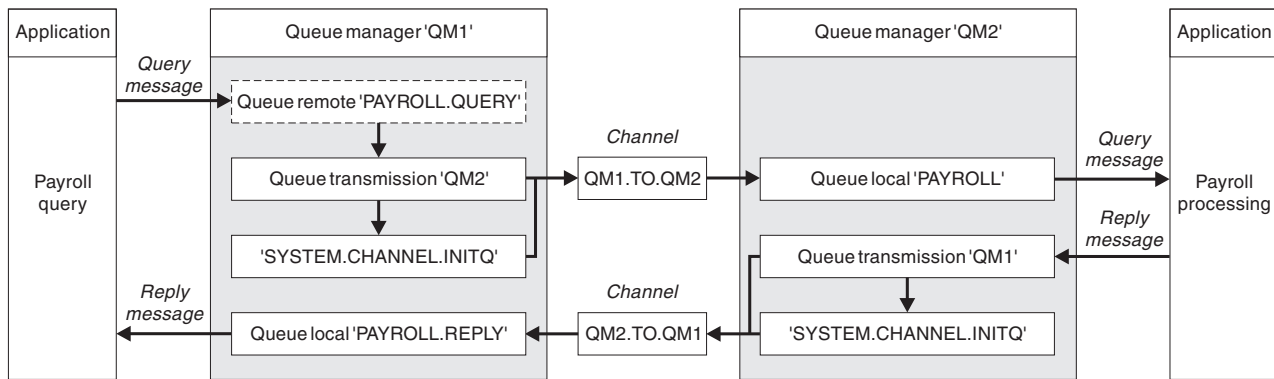

Figure 7. The message channel example for Windows, UNIX and Linux systems

The example involves a payroll query application connected to queue manager QM1 that sends payroll query messages to a payroll processing application running on queue manager QM2. The payroll query application needs the replies to its queries sent back to QM1. The payroll query messages are sent from QM1 to QM2 on a sender-receiver channel called QM1.TO.QM2, and the reply messages are sent back from QM2 to QM1 on another sender-receiver channel called QM2.TO.QM1. Both of these channels are triggered to start as soon as they have a message to send to the other queue manager.

The payroll query application puts a query message to the remote queue “PAYROLL.QUERY” defined on QM1. This remote queue definition resolves to the local queue “PAYROLL” on QM2. In addition, the payroll query application specifies that the reply to the query is sent to the local queue “PAYROLL.REPLY” on QM1. The payroll processing application gets messages from the local queue “PAYROLL” on QM2, and sends the replies to wherever they are required; in this case, local queue “PAYROLL.REPLY” on QM1.

In the example definitions for TCP/IP, QM1 has a host address of 192.0.2.0 and is listening on port 1411, and QM2 has a host address of 192.0.2.1 and is listening on port 1412. The example assumes that these are already defined on your system and available for use.

The object definitions that need to be created on QM1 are:

- Remote queue definition, PAYROLL.QUERY
- Transmission queue definition, QM2 (default=remote queue manager name)
- Sender channel definition, QM1.TO.QM2
- Receiver channel definition, QM2.TO.QM1
- Reply-to queue definition, PAYROLL.REPLY

The object definitions that need to be created on QM2 are:

- Local queue definition, PAYROLL
- Transmission queue definition, QM1 (default=remote queue manager name)
- Sender channel definition, QM2.TO.QM1
- Receiver channel definition, QM1.TO.QM2

The connection details are supplied in the CONNAME attribute of the sender channel definitions.

You can see a diagram of the arrangement in Figure 7.

## Queue manager QM1 example:

These object definitions allow applications connected to queue manager QM1 to send request messages to a queue called PAYROLL on QM2, and to receive replies on a queue called PAYROLL.REPLY on QM1.

All the object definitions have been provided with the DESCR and REPLACE attributes. The other attributes supplied are the minimum required to make the example work. The attributes that are not supplied take the default values for queue manager QM1.

Run the following commands on queue manager QM1.

### Remote queue definition

```
DEFINE QREMOTE(PAYROLL.QUERY) DESCR('Remote queue for QM2') REPLACE +  
PUT(ENABLED) XMITQ(QM2) RNAME(PAYROLL) RQMNAME(QM2)
```

**Note:** The remote queue definition is not a physical queue, but a means of directing messages to the transmission queue, QM2, so that they can be sent to queue manager QM2.

### Transmission queue definition

```
DEFINE QLOCAL(QM2) DESCR('Transmission queue to QM2') REPLACE +  
USAGE(XMITQ) PUT(ENABLED) GET(ENABLED) TRIGGER TRIGTYPE(FIRST) +  
INITQ(SYSTEM.CHANNEL.INITQ) PROCESS(QM1.TO.QM2.PROCESS)
```

When the first message is put on this transmission queue, a trigger message is sent to the initiation queue, SYSTEM.CHANNEL.INITQ. The channel initiator gets the message from the initiation queue and starts the channel identified in the named process.

### Sender channel definition

```
DEFINE CHANNEL(QM1.TO.QM2) CHLTYPE(SDR) TRPTYPE(TCP) +  
REPLACE DESCR('Sender channel to QM2') XMITQ(QM2) +  
CONNNAME('192.0.2.1(1412)')
```

### Receiver channel definition

```
DEFINE CHANNEL(QM2.TO.QM1) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QM2')
```

### Reply-to queue definition

```
DEFINE QLOCAL(PAYROLL.REPLY) REPLACE PUT(ENABLED) GET(ENABLED) +  
DESCR('Reply queue for replies to query messages sent to QM2')
```

The reply-to queue is defined as PUT(ENABLED). This ensures that reply messages can be put to the queue. If the replies cannot be put to the reply-to queue, they are sent to the dead-letter queue on QM1 or, if this queue is not available, remain on transmission queue QM1 on queue manager QM2. The queue has been defined as GET(ENABLED) to allow the reply messages to be retrieved.

## Queue manager QM2 example:

The following object definitions allow applications connected to queue manager QM2 to retrieve request messages from a local queue called PAYROLL, and to put replies to these request messages to a queue called PAYROLL.REPLY on queue manager QM1.

You do not need to provide a remote queue definition to enable the replies to be returned to QM1. The message descriptor of the message retrieved from local queue PAYROLL contains both the reply-to queue and the reply-to queue manager names. Therefore, as long as QM2 can resolve the reply-to queue manager name to that of a transmission queue on queue manager QM2, the reply message can be sent. In this example, the reply-to queue manager name is QM1 and so queue manager QM2 requires a transmission queue of the same name.

All the object definitions have been provided with the DESCR and REPLACE attributes and are the minimum required to make the example work. The attributes that are not supplied take the default values for queue manager QM2.

Run the following commands on queue manager QM2.

### Local queue definition

```
DEFINE QLOCAL(PAYROLL) REPLACE PUT(ENABLED) GET(ENABLED) +  
DESCR('Local queue for QM1 payroll details')
```

This queue is defined as PUT(ENABLED) and GET(ENABLED) for the same reason as the reply-to queue definition on queue manager QM1.

### Transmission queue definition

```
DEFINE QLOCAL(QM1) DESCR('Transmission queue to QM1') REPLACE +  
USAGE(XMITQ) PUT(ENABLED) GET(ENABLED) TRIGGER TRIGTYPE(FIRST) +  
INITQ(SYSTEM.CHANNEL.INITQ) PROCESS(QM2.TO.QM1.PROCESS)
```

When the first message is put on this transmission queue, a trigger message is sent to the initiation queue, SYSTEM.CHANNEL.INITQ. The channel initiator gets the message from the initiation queue and starts the channel identified in the named process.

### Sender channel definition

```
DEFINE CHANNEL(QM2.TO.QM1) CHLTYPE(SDR) TRPTYPE(TCP) +  
REPLACE DESCR('Sender channel to QM1') XMITQ(QM1) +  
CONNNAME('192.0.2.0(1411)')
```

### Receiver channel definition

```
DEFINE CHANNEL(QM1.TO.QM2) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QM1')
```

## Running the example

Information about starting the channel initiator and listener and suggestions for expanding on this scenario.

Once these definitions have been created, you need to:

- Start the channel initiator on each queue manager.
- Start the listener for each queue manager.

For information about starting the channel initiator and listener, see *Setting up communication for Windows* and *Setting up communication on UNIX and Linux systems*.

## Expanding this example

This simple example could be expanded with:

- The use of LU 6.2 communications for interconnection with CICS systems, and transaction processing.
- Adding more queue, process, and channel definitions to allow other applications to send messages between the two queue managers.
- Adding user-exit programs on the channels to allow for link encryption, security checking, or additional message processing.
- Using queue-manager aliases and reply-to queue aliases to understand more about how these can be used in the organization of your queue manager network.

## Message channel planning example for IBM MQ for IBM i

This section provides a detailed example of how to connect two IBM i queue managers together so that messages can be sent between them.

The example illustrates the preparations needed to allow an application using queue manager QM1 to put messages on a queue at queue manager QM2. An application running on QM2 can retrieve these messages, and send responses to a reply queue on QM1.

The example illustrates the use of TCP/IP connections. The example assumes that channels are to be triggered to start when the first message arrives on the transmission queue they are servicing.

This example uses `SYSTEM.CHANNEL.INITQ` as the initiation queue. This queue is already defined by IBM MQ. You can use a different initiation queue, but you have to define it yourself, start a new instance of the channel initiator using the `STRMQMCHLI` command, and provide it with the name of your initiation queue. For more information about triggering channels, see *Triggering channels*.

## What the example shows

This example involves a payroll query application connected to queue manager QM1 that sends payroll query messages to a payroll processing application running on queue manager QM2. The payroll query application needs the replies to its queries sent back to QM1.

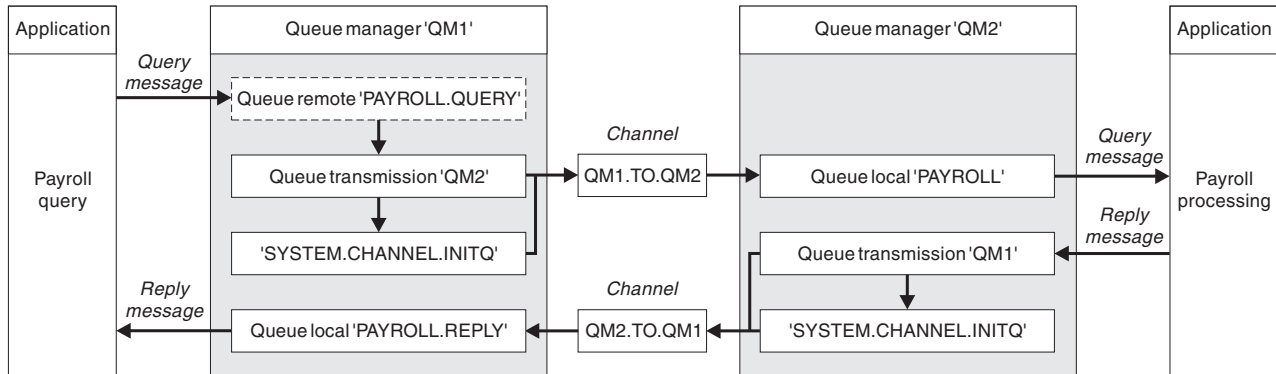

Figure 8. The message channel example for IBM MQ for IBM i

The payroll query messages are sent from QM1 to QM2 on a sender-receiver channel called QM1.TO.QM2, and the reply messages are sent back from QM2 to QM1 on another sender-receiver channel called QM2.TO.QM1. Both of these channels are triggered to start as soon as they have a message to send to the other queue manager.

The payroll query application puts a query message to the remote queue “PAYROLL.QUERY” defined on QM1. This remote queue definition resolves to the local queue “PAYROLL” on QM2. In addition, the payroll query application specifies that the reply to the query is sent to the local queue “PAYROLL.REPLY” on QM1. The payroll processing application gets messages from the local queue “PAYROLL” on QM2, and sends the replies to wherever they are required; in this case, local queue “PAYROLL.REPLY” on QM1.

Both queue managers are assumed to be running on IBM i. In the example definitions, QM1 has a host address of 192.0.2.0 and is listening on port 1411. QM2 has a host address of 192.0.2.1 and is listening on port 1412. The example assumes that these queue managers are already defined on your IBM i system, and are available for use.

The object definitions that need to be created on QM1 are:

- Remote queue definition, PAYROLL.QUERY
- Transmission queue definition, QM2 (default=remote queue manager name)
- Sender channel definition, QM1.TO.QM2
- Receiver channel definition, QM2.TO.QM1
- Reply-to queue definition, PAYROLL.REPLY

The object definitions that need to be created on QM2 are:

- Local queue definition, PAYROLL
- Transmission queue definition, QM1 (default=remote queue manager name)
- Sender channel definition, QM2.TO.QM1
- Receiver channel definition, QM1.TO.QM2

The connection details are supplied in the CONNAME attribute of the sender channel definitions.

You can see a diagram of the arrangement in Figure 8.

## Queue manager QM1 example:

The following object definitions allow applications connected to queue manager QM1 to send request messages to a queue called PAYROLL on QM2, and to receive replies on a queue called PAYROLL.REPLY on QM1.

All the object definitions have been provided with the TEXT attributes. The other attributes supplied are the minimum required to make the example work. The attributes that are not supplied take the default values for queue manager QM1.

Run the following commands on queue manager QM1:

### Remote queue definition

The CRTMQMQ command with the following attributes:

QNAME	'PAYROLL.QUERY'
QTYPE	*RMT
TEXT	'Remote queue for QM2'
PUTENBL	*YES
TMQNAME	'QM2' (default = remote queue manager name)
RMTQNAME	'PAYROLL'
RMTMQMNAME	'QM2'

**Note:** The remote queue definition is not a physical queue, but a means of directing messages to the transmission queue, QM2, so that they can be sent to queue manager QM2.

### Transmission queue definition

The CRTMQMQ command with the following attributes:

QNAME	QM2
QTYPE	*LCL
TEXT	'Transmission queue to QM2'
USAGE	*TMQ
PUTENBL	*YES
GETENBL	*YES
TRGENBL	*YES
TRGTYPE	*FIRST
INITQNAME	SYSTEM.CHANNEL.INITQ
TRIGDATA	QM1.TO.QM2

When the first message is put on this transmission queue, a trigger message is sent to the initiation queue, SYSTEM.CHANNEL.INITQ. The channel initiator gets the message from the initiation queue and starts the channel identified in the named process.

### Sender channel definition

The CRTMQMCHL command with the following attributes:

CHLNAME	QM1.TO.QM2
CHLTYPE	*SDR
TRPTYPE	*TCP
TEXT	'Sender channel to QM2'
TMQNAME	QM2
CONNNAME	'192.0.2.1(1412)'

### Receiver channel definition

The CRTMQMCHL command with the following attributes:

CHLNAME	QM2.TO.QM1
CHLTYPE	*RCVR
TRPTYPE	*TCP
TEXT	'Receiver channel from QM2'

### Reply-to queue definition

The CRTMQMQ command with the following attributes:

QNAME	PAYROLL.REPLY
QTYPE	*LCL
TEXT	'Reply queue for replies to query messages sent to QM2'
PUTENBL	*YES
GETENBL	*YES

The reply-to queue is defined as PUT(ENABLED). This definition ensures that reply messages can be put to the queue. If the replies cannot be put to the reply-to queue, they are sent to the dead-letter queue on QM1 or, if this queue is not available, remain on transmission queue QM1 on queue manager QM2. The queue has been defined as GET(ENABLED) to allow the reply messages to be retrieved.

### Queue manager QM2 example:

The following object definitions allow applications connected to queue manager QM2 to retrieve request messages from a local queue called PAYROLL, and to put replies to these request messages to a queue called PAYROLL.REPLY on queue manager QM1.

You do not need to provide a remote queue definition to enable the replies to be returned to QM1. The message descriptor of the message retrieved from local queue PAYROLL contains both the reply-to queue and the reply-to queue manager names. Therefore, as long as QM2 can resolve the reply-to queue manager name to that of a transmission queue on queue manager QM2, the reply message can be sent. In this example, the reply-to queue manager name is QM1 and so queue manager QM2 requires a transmission queue of the same name.

All the object definitions have been provided with the TEXT attribute and are the minimum required to make the example work. The attributes that are not supplied take the default values for queue manager QM2.

Run the following commands on queue manager QM2:

### Local queue definition

The CRTMQMQ command with the following attributes:

QNAME	PAYROLL
QTYPE	*LCL
TEXT	'Local queue for QM1 payroll details'
PUTENBL	*YES
GETENBL	*YES

This queue is defined as PUT(ENABLED) and GET(ENABLED) for the same reason as the reply-to queue definition on queue manager QM1.

### Transmission queue definition

The CRTMQMQ command with the following attributes:

QNAME	QM1
QTYPE	*LCL
TEXT	'Transmission queue to QM1'
USAGE	*TMQ
PUTENBL	*YES
GETENBL	*YES
TRGENBL	*YES
TRGTYPE	*FIRST
INITQNAME	SYSTEM.CHANNEL.INITQ
TRIGDATA	QM2.TO.QM1

When the first message is put on this transmission queue, a trigger message is sent to the initiation queue, SYSTEM.CHANNEL.INITQ. The channel initiator gets the message from the initiation queue and starts the channel identified in the trigger data.

### Sender channel definition

The CRTMQMCHL command with the following attributes:

CHLNAME	QM2.TO.QM1
CHLTYPE	*SDR
TRPTYPE	*TCP
TEXT	'Sender channel to QM1'
TMQNAME	QM1
CONNNAME	'192.0.2.0(1411)'

### Receiver channel definition

The CRTMQMCHL command with the following attributes:

CHLNAME	QM1.TO.QM2
CHLTYPE	*RCVR
TRPTYPE	*TCP
TEXT	'Receiver channel from QM1'

## Running the example

When you have created the required objects you must start the channel initiators and listeners for both queue managers.

The applications can then send messages to each other. The channels are triggered to start by the first message arriving on each transmission queue, so you do not need to issue the STRMQMCHL command.

For details about starting a channel initiator and a listener, see *Monitoring and controlling channels on IBM i*.

## Expanding this example

The example can be expanded in a number of ways.

This example can be expanded by:

- Adding more queue and channel definitions to allow other applications to send messages between the two queue managers.
- Adding user exit programs on the channels to allow for link encryption, security checking, or additional message processing.
- Using queue manager aliases and reply-to queue aliases to understand more about how these objects can be used in the organization of your queue manager network.

For a version of this example that uses MQSC commands, see “Message channel planning example for z/OS.”

## Message channel planning example for z/OS

This section provides a detailed example of how to connect z/OS or MVS queue managers together so that messages can be sent between them.

The example illustrates the preparations needed to allow an application using queue manager QM1 to put messages on a queue at queue manager QM2. An application running on QM2 can retrieve these messages, and send responses to a reply queue on QM1.

The example illustrates the use of both TCP/IP and LU 6.2 connections. The example assumes that channels are to be triggered to start when the first message arrives on the transmission queue they are servicing.

## What the example shows

This example involves a payroll query application connected to queue manager QM1 that sends payroll query messages to a payroll processing application running on queue manager QM2. The payroll query application needs the replies to its queries sent back to QM1.

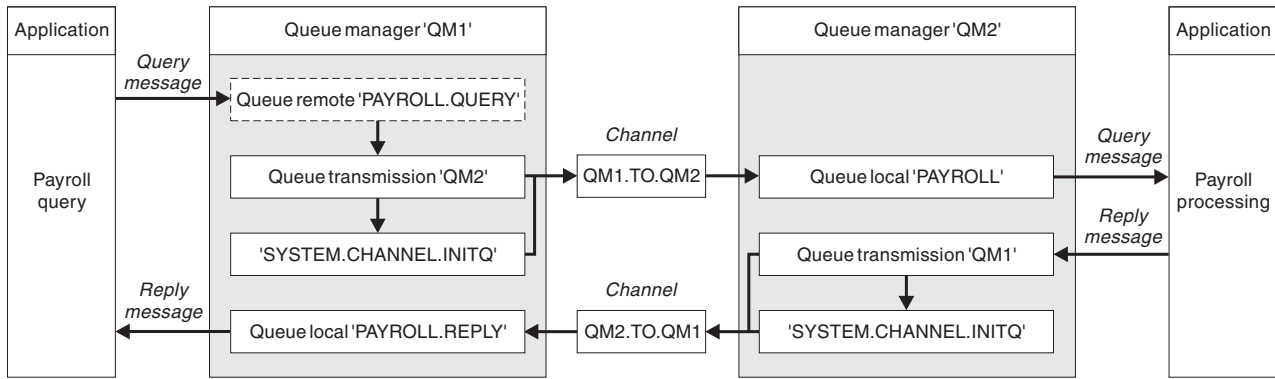

Figure 9. The first example for IBM MQ for z/OS

The payroll query messages are sent from QM1 to QM2 on a sender-receiver channel called QM1.TO.QM2, and the reply messages are sent back from QM2 to QM1 on another sender-receiver channel called QM2.TO.QM1. Both of these channels are triggered to start as soon as they have a message to send to the other queue manager.

The payroll query application puts a query message to the remote queue “PAYROLL.QUERY” defined on QM1. This remote queue definition resolves to the local queue “PAYROLL” on QM2. In addition, the payroll query application specifies that the reply to the query is sent to the local queue “PAYROLL.REPLY” on QM1. The payroll processing application gets messages from the local queue “PAYROLL” on QM2, and sends the replies to wherever they are required; in this case, local queue “PAYROLL.REPLY” on QM1.

Both queue managers are assumed to be running on z/OS. In the example definitions for TCP/IP, QM1 has a host address of 192.0.2.0 and is listening on port 1411, and QM2 has a host address of 192.0.2.1 and is listening on port 1412. In the definitions for LU 6.2, QM1 is listening on a symbolic luname called LUNAME1 and QM2 is listening on a symbolic luname called LUNAME2. The example assumes that these lunames are already defined on your z/OS system and available for use. To define them, see “Example configuration - IBM MQ for z/OS” on page 37.

The object definitions that need to be created on QM1 are:

- Remote queue definition, PAYROLL.QUERY
- Transmission queue definition, QM2 (default=remote queue manager name)
- Sender channel definition, QM1.TO.QM2
- Receiver channel definition, QM2.TO.QM1
- Reply-to queue definition, PAYROLL.REPLY

The object definitions that need to be created on QM2 are:

- Local queue definition, PAYROLL
- Transmission queue definition, QM1 (default=remote queue manager name)
- Sender channel definition, QM2.TO.QM1
- Receiver channel definition, QM1.TO.QM2

The example assumes that all the SYSTEM.COMMAND.\* and SYSTEM.CHANNEL.\* queues required to run DQM have been defined as shown in the supplied sample definitions, **CSQ4INSG** and **CSQ4INSX**.

The connection details are supplied in the CONNAME attribute of the sender channel definitions.

You can see a diagram of the arrangement in Figure 9.

## Queue manager QM1 example:

The following object definitions allow applications connected to queue manager QM1 to send request messages to a queue called PAYROLL on QM2. It also allows applications to receive replies on a queue called PAYROLL.REPLY on QM1.

All the object definitions have been provided with the DESCR and REPLACE attributes. The other attributes supplied are the minimum required to make the example work. The attributes that are not supplied take the default values for queue manager QM1.

Run the following commands on queue manager QM1.

### Remote queue definition

```
DEFINE QREMOTE(PAYROLL.QUERY) DESCR('Remote queue for QM2') REPLACE +  
PUT(ENABLED) XMITQ(QM2) RNAME(PAYROLL) RQMNAME(QM2)
```

**Note:** The remote queue definition is not a physical queue, but a means of directing messages to the transmission queue, QM2, so that they can be sent to queue manager QM2.

### Transmission queue definition

```
DEFINE QLOCAL(QM2) DESCR('Transmission queue to QM2') REPLACE +  
USAGE(XMITQ) PUT(ENABLED) GET(ENABLED) TRIGGER TRIGTYPE(FIRST) +  
TRIGDATA(QM1.TO.QM2) INITQ(SYSTEM.CHANNEL.INITQ)
```

When the first message is put on this transmission queue, a trigger message is sent to the initiation queue, SYSTEM.CHANNEL.INITQ. The channel initiator gets the message from the initiation queue and starts the channel identified in the trigger data. The channel initiator can only get trigger messages from the SYSTEM.CHANNEL.INITQ queue, so do not use any other queue as the initiation queue.

### Sender channel definition

For a TCP/IP connection:

```
DEFINE CHANNEL(QM1.TO.QM2) CHLTYPE(SDR) TRPTYPE(TCP) +  
REPLACE DESCR('Sender channel to QM2') XMITQ(QM2) +  
CONNNAME('192.0.2.1(1412)')
```

For an LU 6.2 connection:

```
DEFINE CHANNEL(QM1.TO.QM2) CHLTYPE(SDR) TRPTYPE(LU62) +  
REPLACE DESCR('Sender channel to QM2') XMITQ(QM2) +  
CONNNAME('LUNAME2')
```

### Receiver channel definition

For a TCP/IP connection:

```
DEFINE CHANNEL(QM2.TO.QM1) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QM2')
```

For an LU 6.2 connection:

```
DEFINE CHANNEL(QM2.TO.QM1) CHLTYPE(RCVR) TRPTYPE(LU62) +  
REPLACE DESCR('Receiver channel from QM2')
```

### Reply-to queue definition

```
DEFINE QLOCAL(PAYROLL.REPLY) REPLACE PUT(ENABLED) GET(ENABLED) +  
DESCR('Reply queue for replies to query messages sent to QM2')
```

The reply-to queue is defined as PUT(ENABLED) which ensures that reply messages can be put to the queue. If the replies cannot be put to the reply-to queue, they are sent to the dead-letter queue on QM1 or, if this queue is not available, remain on transmission queue QM1 on queue manager QM2. The queue has been defined as GET(ENABLED) to allow the reply messages to be retrieved.

### **QueueManager QM2 example:**

The following object definitions allow applications connected to queue manager QM2 to retrieve request messages from a local queue called PAYROLL and to put replies to these request messages to a queue called PAYROLL.REPLY on queue manager QM1.

You do not need to provide a remote queue definition to enable the replies to be returned to QM1. The message descriptor of the message retrieved from local queue PAYROLL contains both the reply-to queue and the reply-to queue manager names. Therefore, as long as QM2 can resolve the reply-to queue manager name to that of a transmission queue on queue manager QM2, the reply message can be sent. In this example, the reply-to queue manager name is QM1 and so queue manager QM2 requires a transmission queue of the same name.

All the object definitions have been provided with the DESCR and REPLACE attributes and are the minimum required to make the example work. The attributes that are not supplied take the default values for queue manager QM2.

Run the following commands on queue manager QM2.

#### **Local queue definition**

```
DEFINE QLOCAL(PAYROLL) REPLACE PUT(ENABLED) GET(ENABLED) +  
DESCR('Local queue for QM1 payroll details')
```

This queue is defined as PUT(ENABLED) and GET(ENABLED) for the same reason as the reply-to queue definition on queue manager QM1.

#### **Transmission queue definition**

```
DEFINE QLOCAL(QM1) DESCR('Transmission queue to QM1') REPLACE +  
USAGE(XMITQ) PUT(ENABLED) GET(ENABLED) TRIGGER TRIGTYPE(FIRST) +  
TRIGDATA(QM2.TO.QM1) INITQ(SYSTEM.CHANNEL.INITQ)
```

When the first message is put on this transmission queue, a trigger message is sent to the initiation queue, SYSTEM.CHANNEL.INITQ. The channel initiator gets the message from the initiation queue and starts the channel identified in the trigger data. The channel initiator can only get trigger messages from SYSTEM.CHANNEL.INITQ so do not use any other queue as the initiation queue.

#### **Sender channel definition**

For a TCP/IP connection:

```
DEFINE CHANNEL(QM2.TO.QM1) CHLTYPE(SDR) TRPTYPE(TCP) +  
REPLACE DESCR('Sender channel to QM1') XMITQ(QM1) +  
CONNNAME('192.0.2.0(1411)')
```

For an LU 6.2 connection:

```
DEFINE CHANNEL(QM2.TO.QM1) CHLTYPE(SDR) TRPTYPE(LU62) +  
REPLACE DESCR('Sender channel to QM1') XMITQ(QM1) +  
CONNNAME('LUNAME1')
```

#### **Receiver channel definition**

For a TCP/IP connection:

```
DEFINE CHANNEL(QM1.TO.QM2) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QM1')
```

For an LU 6.2 connection:

```
DEFINE CHANNEL(QM1.TO.QM2) CHLTYPE(RCVR) TRPTYPE(LU62) +  
REPLACE DESCR('Receiver channel from QM1')
```

## Running the example

When you have created the required objects, you must start the channel initiators and listeners for both queue managers.

The applications can then send messages to each other. Because the channels are triggered to start by the arrival of the first message on each transmission queue, you do not need to issue the START CHANNEL MQSC command.

For details about starting a channel initiator see Starting a channel initiator, and for details about starting a listener see Starting a channel listener.

## Expanding the example

The example can be expanded in a number of ways.

The example can be expanded by:

- Adding more queue, and channel definitions to allow other applications to send messages between the two queue managers.
- Adding user exit programs on the channels to allow for link encryption, security checking, or additional message processing.
- Using queue manager aliases and reply-to queue aliases to understand more about how these aliases can be used in the organization of your queue manager network.

## Message channel planning example for z/OS using queue-sharing groups

This example illustrates the preparations needed to allow an application using queue manager QM3 to put a message on a queue in a queue-sharing group that has queue members QM4 and QM5.

Ensure you are familiar with the example in “Message channel planning example for z/OS” on page 167 before trying this example.

### What this example shows

This example shows the IBM MQ commands (MQSC) that you can use in IBM MQ for z/OS for distributed queuing with queue-sharing groups.

This example expands the payroll query scenario of the example in “Message channel planning example for z/OS” on page 167 to show how to add higher availability of query processing by adding more serving applications to serve a shared queue.

The payroll query application is now connected to queue manager QM3 and puts a query to the remote queue 'PAYROLL QUERY' defined on QM3. This remote queue definition resolves to the shared queue 'PAYROLL' hosted by the queue managers in the queue-sharing group QSG1. The payroll processing application now has two instances running, one connected to QM4 and one connected to QM5.

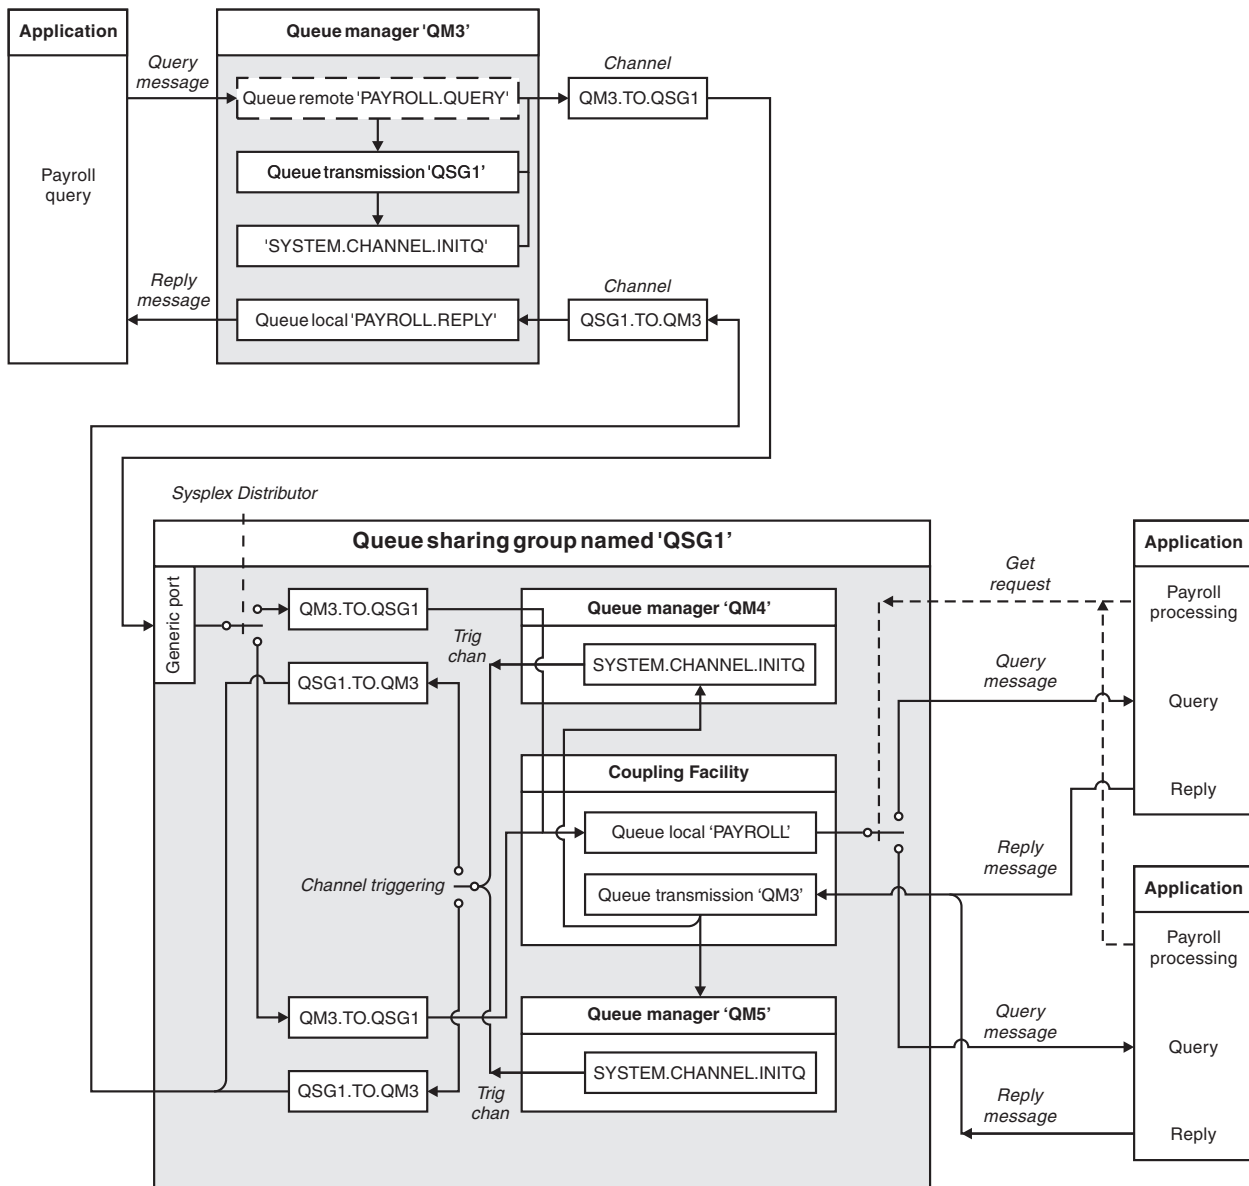

Figure 10. Message channel planning example for IBM MQ for z/OS using queue-sharing groups

All three queue managers are assumed to be running on z/OS. In the example definitions for TCP/IP, QM4 has a VIPA address of MVSIP01 and QM5 has a VIPA address of MVSIP02. Both queue managers are listening on port 1414. The generic address that Sysplex Distributor provides for this group is QSG1.MVSIP. QM3 has a host address of 192.0.2.0 and is listening on port 1411.

In the example definitions for LU6.2, QM3 is listening on a symbolic luname called LUNAME1. The name of the generic resource defined for VTAM for the lunames listened on by QM4 and QM5 is LUQSG1. The example assumes that they are already defined on your z/OS system and are available for use. To define them see “Defining yourself to the network using generic resources” on page 45.

In this example QSG1 is the name of a queue-sharing group, and queue managers QM4 and QM5 are the names of members of the group.

## Queue-sharing group definitions

Producing the following object definitions for one member of the queue-sharing group makes them available to all the other members.

Queue managers QM4 and QM5 are members of the queue sharing group. The definitions produced for QM4 are also available for QM5.

It is assumed that the coupling facility list structure is called 'APPLICATION1'. If it is not called 'APPLICATION1', you must use your own coupling facility list structure name for the example.

## Shared objects

The shared object definitions are stored in DB2® and their associated messages are stored within the coupling facility.

```
DEFINE QLOCAL(PAYROLL) QSGDISP(SHARED) REPLACE PUT(ENABLED) GET(ENABLED) +  
CFSTRUCT(APPLICATION1) +  
DESCR('Shared queue for payroll details')
```

```
DEFINE QLOCAL(QM3) QSGDISP(SHARED) REPLACE USAGE(XMITQ) PUT(ENABLED) +  
CFSTRUCT(APPLICATION1) +  
DESCR('Transmission queue to QM3') TRIGGER TRIGTYPE(FIRST) +  
TRIGDATA(QSG1.TO.QM3) GET(ENABLED) INITQ(SYSTEM.CHANNEL.INITQ)
```

## Group objects

The group object definitions are stored in Db2, and each queue manager in the queue-sharing group creates a local copy of the defined object.

Sender channel definition for a TCP/IP connection:

```
DEFINE CHANNEL(QSG1.TO.QM3) CHLTYPE(SDR) QSGDISP(GROUP) TRPTYPE(TCP) +  
REPLACE DESCR('Sender channel to QM3') XMITQ(QM3) +  
CONNNAME('192.0.2.0(1411)')
```

Sender channel definition for an LU 6.2 connection:

```
DEFINE CHANNEL(QSG1.TO.QM3) CHLTYPE(SDR) QSGDISP(GROUP) TRPTYPE(LU62) +  
REPLACE DESCR('Sender channel to QM3') XMITQ(QM3) +  
CONNNAME('LUNAME1')
```

Receiver channel definition for a TCP/IP connection:

```
DEFINE CHANNEL(QM3.TO.QSG1) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QM3') QSGDISP(GROUP)
```

Receiver channel definition for an LU 6.2 connection:

```
DEFINE CHANNEL(QM3.TO.QSG1) CHLTYPE(RCVR) TRPTYPE(LU62) +  
REPLACE DESCR('Receiver channel from QM3') QSGDISP(GROUP)
```

### Related reference:

“Disposition (QSGDISP)” on page 112

This attribute specifies the disposition of the channel in a queue-sharing group. It is valid on z/OS only.

### Queue manager QM3 example

QM3 is not a member of the queue-sharing group. The following object definitions allow it to put messages to a queue in the queue-sharing group.

The CONNAME for this channel is the generic address of the queue-sharing group, which varies according to transport type.

For a TCP/IP connection:

```
DEFINE CHANNEL(QM3.TO.QSG1) CHLTYPE(SDR) TRPTYPE(TCP) +  
REPLACE DESCR('Sender channel to QSG1') XMITQ(QSG1) +  
CONNAME('QSG1.MVSIP(1414)')
```

For an LU 6.2 connection:

```
DEFINE CHANNEL(QM3.TO.QSG1) CHLTYPE(SDR) TRPTYPE(LU62) +  
REPLACE DESCR('Sender channel to QSG1') XMITQ(QSG1) +  
CONNAME('LUQSG1') TPNAME('MQSERIES') MODENAME('#INTER')
```

### Other definitions

These definitions are required for the same purposes as the definitions in the first example.

```
DEFINE QREMOTE(PAYROLL.QUERY) DESCR('Remote queue for QSG1') REPLACE +  
PUT(ENABLED) XMITQ(QSG1) RNAME(APPL) RQMNAME(QSG1)
```

```
DEFINE QLOCAL(QSG1) DESCR('Transmission queue to QSG1') REPLACE +  
USAGE(XMITQ) PUT(ENABLED) GET(ENABLED) TRIGGER TRIGTYPE(FIRST) +  
TRIGDATA(QM3.TO.QSG1) INITQ(SYSTEM.CHANNEL.INITQ)
```

```
DEFINE CHANNEL(QSG1.TO.QM3) CHLTYPE(RCVR) TRPTYPE(TCP) +  
REPLACE DESCR('Receiver channel from QSG1')
```

```
DEFINE CHANNEL(QSG1.TO.QM3) CHLTYPE(RCVR) TRPTYPE(LU62) +  
REPLACE DESCR('Receiver channel from QSG1')
```

```
DEFINE QLOCAL(PAYROLL.REPLY) REPLACE PUT(ENABLED) GET(ENABLED) +  
DESCR('Reply queue for replies to query messages sent to QSG1')
```

### Running the example

When you have created the required objects you need to start the channel initiators for all three queue managers. You also need to start the listeners for both queue managers in the queue-sharing group.

For a TCP/IP connection, each member of the group must have a group listener started that is listening on port 1414.

```
STA LSTR PORT(1414) IPADDR(MVSIP01) INDISP(GROUP)
```

The previous entry starts the listener on QM4, for example.

For an LU6.2 connection, each member of the group must have a group listener started that is listening on a symbolic luname. This luname must correspond to the generic resource LUQSG1.

- Start the listener on QM3

```
STA LSTR PORT(1411)
```

## Using an alias to refer to an MQ library

You can define an alias to refer to an MQ library in your JCL, rather than use the name of the MQ library directly. Then, if the name of the MQ library changes, you have only to delete and redefine the alias.

### Example

The following example defines an alias MQM.SCSQANLE to refer to the MQ library MQM.V600.SCSQANLE:

```
//STEP1 EXEC PGM=IDCAMS
//SYSPRINT DD SYSOUT=*
//SYSIN DD *
DELETE (MQM.SCSQANLE)
DEFINE ALIAS (NAME(MQM.SCSQANLE) RELATE(MQM.V600.SCSQANLE))
/*
```

Then, to refer to the MQM.V600.SCSQANLE library in your JCL, use the alias MQM.SCSQANLE.

**Note:** The library and alias names must be in the same catalog, so use the same high level qualifier for both; in this example, the high level qualifier is MQM.

---

### Related information:

Queue names

Use this information to understand the restrictions of queue names and reserved queue names.

 IBM MQ for IBM i system and default objects

When you create a queue manager using the **CRTMQM** command, the system objects and the default objects are created automatically.

## Syntax diagrams

The syntax for a command and its options is presented in the form of a syntax diagram called a railroad diagram.

Railroad diagrams are a visual format suitable for sighted users; see, “How to read railroad diagrams” on page 176. It tells you what options you can supply with the command, how to enter them, indicates relationships between different options, and sometimes different values of an option.

## How to read railroad diagrams

Each railroad diagram begins with a double right arrow and ends with a right and left arrow pair. Lines beginning with a single right arrow are continuation lines. You read a railroad diagram from left to right and from top to bottom, following the direction of the arrows.

Other conventions used in railroad diagrams are:

Table 36. How to read railroad diagrams

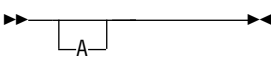

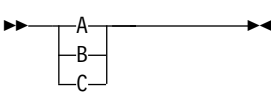

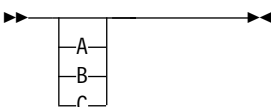

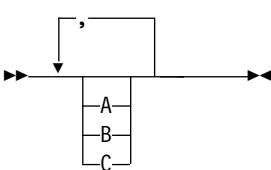

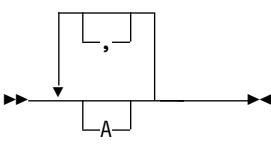

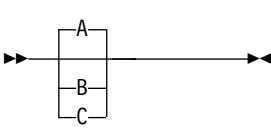

Convention	Meaning
	You must specify values A, B, and C. Required values are shown on the main line of a railroad diagram.
	You may specify value A. Optional values are shown below the main line of a railroad diagram.
	Values A, B, and C are alternatives, one of which you must specify.
	Values A, B, and C are alternatives, one of which you might specify.
	You might specify one or more of the values A, B, and C. Any required separator for multiple or repeated values (in this example, the comma (,)) is shown on the arrow.
	You might specify value A multiple times. The separator in this example is optional.
	Values A, B, and C are alternatives, one of which you might specify. If you specify none of the values shown, the default A (the value shown above the main line) is used.

Table 36. How to read railroad diagrams (continued)

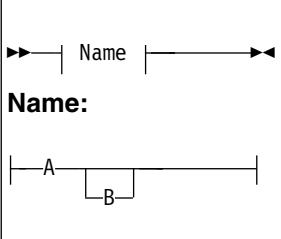

Convention	Meaning
 <p>▶—  Name  —▶</p> <p><b>Name:</b></p> <p> —A—┐ └—B—┘</p>	<p>The railroad fragment Name is shown separately from the main railroad diagram.</p>

Table 36. How to read railroad diagrams (continued)

Convention	Meaning
Punctuation and uppercase values	Specify exactly as shown.

## IBM MQ Control commands

Find out how to use the IBM MQ control commands.

If you want to issue control commands, your user ID must be a member of the mqm group. For more information, see *Authority to administer IBM MQ on UNIX, Linux, and Windows systems*.

When using control commands that operate on a queue manager configured to use connection authentication with `CHCKLOCL(REQUIRED)`, and a failure to connect is observed, either

- Supply a user id and password if the control command allows this.
- Use MQSC equivalents of the control commands where those exist.
- Start the queue manager using the `-ns` option, while control commands that cannot connect need to be run.

When using control commands that operate on a queue manager, you must use the command from the installation associated with the queue manager you are working with.

In addition, note the following environment-specific information:

- On Windows, all control commands can be issued from a command line. Command names and their flags are not case-sensitive: you can enter them in uppercase, lowercase, or a combination of uppercase and lowercase. However, arguments to control commands (such as queue names) are case-sensitive. In the syntax descriptions, the hyphen (-) is used as a flag indicator. You can use the forward slash (/) instead of the hyphen.
- On UNIX and Linux systems, all IBM MQ control commands can be issued from a shell. All commands are case-sensitive.
- A subset of the control commands can be issued using the IBM MQ Explorer.

For a list of the control commands see, “The control commands” on page 180.

For a comparison of the different administration command sets, see “Comparing command sets” on page 313.

For information about commands for managing keys and certificates, see “Managing keys and certificates” on page 319.

### Related concepts:

“MQSC reference” on page 340

Use MQSC commands to manage queue manager objects, including the queue manager itself, queues, process definitions, channels, client connection channels, listeners, services, namelists, clusters, and authentication information objects.

“Programmable command formats reference” on page 1044

Programmable Command Formats (PCFs) define command and reply messages that can be exchanged between a program and any queue manager (that supports PCFs) in a network. PCFs simplify queue manager administration and other network administration.

### Related reference:

 “IBM MQ for IBM i CL commands” on page 337

A list of IBM MQ for IBM i CL commands grouped according to command type:

## Using control commands

The table in this topic shows the three categories of control commands: queue manager commands, channel commands, and utility commands.

Control commands can be divided into three categories, as shown in Table 37.

Table 37. Categories of control commands

Category	Description
Queue manager commands	Queue manager control commands include commands for creating, starting, stopping, and deleting queue managers and command servers
Channel commands	Channel commands include commands for starting and ending channels and channel initiators
Utility commands	Utility commands include commands associated with: <ul style="list-style-type: none"><li>• Running MQSC commands</li><li>• Conversion exits</li><li>• Authority management</li><li>• Recording and recovering media images of queue manager resources</li><li>• Displaying and resolving transactions</li><li>• Trigger monitors</li><li>• Displaying the file names of IBM MQ objects</li></ul>

For more information, see “IBM MQ Control commands” on page 178

### Using control commands on Windows systems:

In IBM MQ for Windows, you enter control commands at a command prompt.

In Windows environments, control commands and their flags are not case-sensitive, but arguments to those commands (such as queue names and queue-manager names) are case-sensitive.

For example, in the command:

```
crtmqm /u SYSTEM.DEAD.LETTER.QUEUE jupiter.queue.manager
```

- The command name can be entered in uppercase or lowercase, or a mixture of the two. These are all valid: `crtmqm`, `CRTMQM`, and `CRTmqm`.
- The flag can be entered as `-u`, `-U`, `/u`, or `/U`.
- `SYSTEM.DEAD.LETTER.QUEUE` and `jupiter.queue.manager` must be entered exactly as shown.

For more information, see IBM MQ control commands.

## Using control commands on UNIX and Linux systems:

In IBM MQ for UNIX and Linux systems, you enter control commands in a shell window.

In UNIX environments, control commands, including the command name itself, the flags, and any arguments, are case-sensitive. For example, in the command:

```
crtmqm -u SYSTEM.DEAD.LETTER.QUEUE jupiter.queue.manager
```

- The command name must be `crtmqm`, not `CRTMQM`.
- The flag must be `-u`, not `-U`.
- The dead-letter queue is called `SYSTEM.DEAD.LETTER.QUEUE`.
- The argument is specified as `jupiter.queue.manager`, which is different from `JUPITER.queue.manager`.

Take care to type the commands exactly as you see them in the examples.

For more information about the `crtmqm` command, see “`crtmqm`” on page 194.

For more information on control commands, see “IBM MQ Control commands” on page 178

## The control commands

This collection of topics provides reference information for each of the IBM MQ control commands.

For information about running these commands refer to “IBM MQ Control commands” on page 178.

### **addmqinf:**

Add IBM MQ configuration information ( Windows and UNIX platforms only).

#### **Purpose**

Use the `addmqinf` command to add information to the IBM MQ configuration data.

For example, use `dspmqinf` and `addmqinf` to copy configuration data from the system where a queue manager was created, to other systems where the same multi-instance queue manager is also to be started.

#### **Syntax**

#### **Required parameters**

`-v Attribute = Value`

The name and value of the stanza attributes to be placed in the stanza specified in the command.

Table 38 on page 181 lists the QueueManager stanza attribute values. The queue manager stanza is the only stanza that is currently supported.

Table 38. QueueManager stanza attributes

Attribute	Value	Required or optional
<b>Name</b>	The name of the queue manager.  You must provide a different name from any other queue manager stanza on the system.	Required
<b>Prefix</b>	The directory path <i>under</i> which this queue manager data directory is stored by default.  You can use <b>Prefix</b> to modify the location of the queue manager data directories. The value of <b>Directory</b> is automatically appended to this path.	Required
<b>Directory</b>	The name of the queue manager data directory.  Sometimes the name must be provided (as in "Example" ), because it is different from the queue manager name. Copy the directory name from the value returned by <b>dspmqinf</b> .  The rules for transforming queue manager names into directory names are described in Understanding IBM MQ file names.	Required
<b>DataPath</b>	The directory path where the queue manager data files are placed. The value of <b>Directory</b> is <i>not</i> automatically appended to this path - you must provide the transformed queue manager name as part of <b>DataPath</b> .  If the <b>DataPath</b> attribute is omitted on UNIX, the queue manager data directory path is defined as <b>Prefix / Directory</b> .	UNIX: Optional Windows: Required

### Optional parameters

#### -s *StanzaType*

A stanza of the type *StanzaType* is added to the IBM MQ configuration.

The default value of *StanzaType* is QueueManager.

The only supported value of *StanzaType* is QueueManager.

### Return codes

Return code	Description
0	Successful operation
1	Queue manager location is invalid (either <b>Prefix</b> or <b>DataPath</b> )
39	Bad command-line parameters
45	Stanza already exists
46	Required configuration attribute is missing
58	Inconsistent use of installations detected
69	Storage is not available
71	Unexpected error
72	Queue manager name error
100	Log location is invalid

### Example

```
addmqinf -v DataPath=/MQHA/qmgrs/QM!NAME +
-v Prefix=/var/mqm +
-v Directory=QM!NAME +
-v Name=QM.NAME
```

Creates the following stanza in mqs.ini:

QueueManager:  
Name=QM.NAME  
Prefix=/var/mqm  
Directory=QM!NAME  
DataPath=/MQHA/qmgrs/QM!NAME

## Usage notes

Use **dspmqlnf** with **addmqinf** to create an instance of a multi-instance queue manager on a different server.

To use this command you must be an IBM MQ administrator and a member of the mqm group.

## Related commands

Command	Description
"dspmqlnf" on page 226	Display IBM MQ configuration information
"rmvmlnf" on page 259	Remove IBM MQ configuration information

## amqmdain:

**amqmdain** is used to configure or control some Windows specific administrative tasks.

## Purpose

The **amqmdain** command applies to IBM MQ for Windows only.

Use **amqmdain** to perform some Windows specific administrative tasks.

Starting a queue manager with **amqmdain** is equivalent to using the **strmqm** command with the option **-ss**. **amqmdain** makes the queue manager run in a non-interactive session under a different user account. However, to ensure that all queue manager startup feedback is returned to the command line, use the **strmqm -ss** command rather than **amqmdain**.

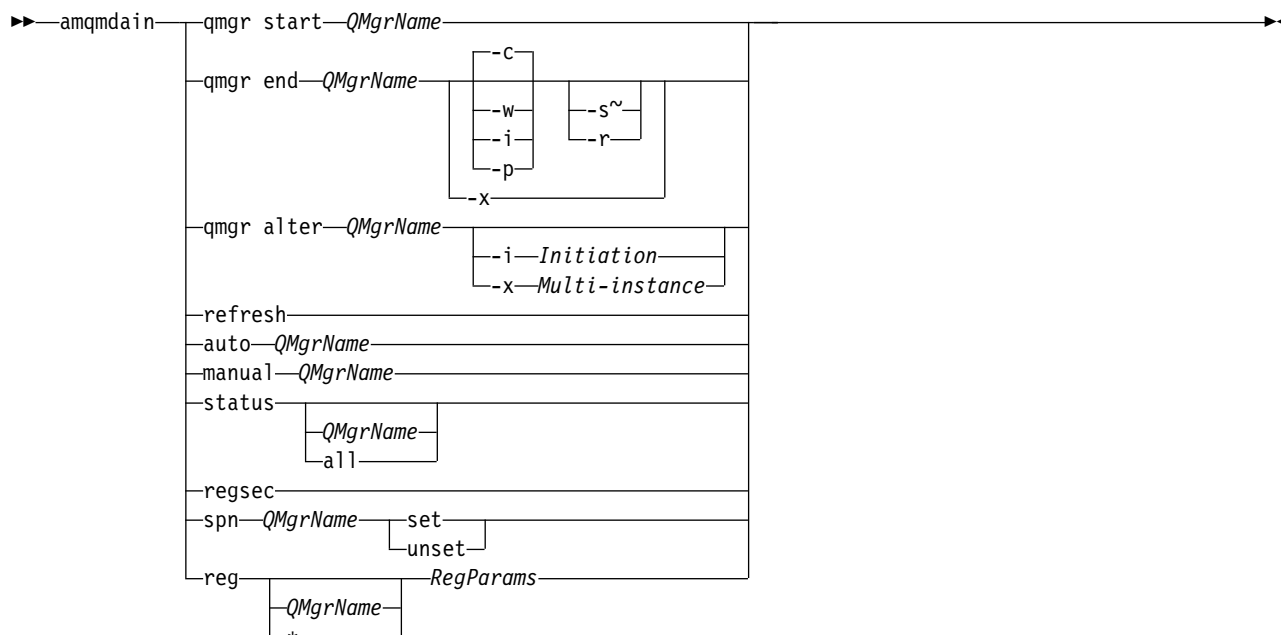

You must use the **amqmdain** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmql -o** installation command.

To administer and define IBM MQ service and listener objects, use MQSC commands, PCF commands, or the MQ Explorer.

The **amqmdain** command has been updated to modify either the **.ini** files or the registry as appropriate.

## Syntax

## Keywords and parameters

All parameters are required unless the description states they are optional.

In every case, *QMgrName* is the name of the queue manager to which the command applies.

### **qmgr start** *QMgrName*

Starts a queue manager.

This parameter can also be written in the form *start QMgrName*.

If you start your queue manager as a service and need the queue manager to continue to run after logoff, use `strmqm -ss qmgr` instead of `amqmdain start qmgr`.

### **qmgr end** *QMgrName*

Ends a queue manager.

This parameter can also be written in the form *end QMgrName*.

For consistency across platforms, use `endmqm qmgr` instead of `amqmdain end qmgr`.

For fuller descriptions of the options, see “*endmqm*” on page 244.

- c** Controlled (or quiesced) shutdown.
- w** Wait shutdown.
- i** Immediate shut down.
- p** Pre-emptive shut down.
- r** Reconnect clients.
- s** Switch over to a standby queue manager instance.
- x** End the standby instance of the queue manager without ending the active instance.

### **qmgr alter** *QMgrName*

Alters a queue manager.

#### **-i** *Initiation*

Specifies the initiation type. Possible values are:

Table 39. Initiation command parameters.

Value	Description
<b>auto</b>	Sets the queue manager to automatic startup (when the machine starts, or more precisely when the IBM MQ service starts). The syntax is: amqmdain qmgr alter QmgrName -i auto
<b>interactive</b>	Sets the queue manager to manual startup that then runs under the logged on (interactive) user. The syntax is: amqmdain qmgr alter QmgrName -i interactive
<b>service</b>	Sets the queue manager to manual startup that then runs as a service. The syntax is: amqmdain qmgr alter QmgrName -i service

**-x Multi-instance**

Specifies if **auto** queue manager start by the IBM MQ service permits multiple instances. Equivalent to the **-sax** option on the **crtmqm** command. Also specifies if the **amqmdain start qmgr** command permits standby instances. Possible values are:

Table 40. Multi-instance command parameters.

Value	Description
<b>set</b>	Sets automatic queue manager startup to permit multiple instances. Issues <b>strmqm -x</b> . The set option is ignored for queue managers that are initiated interactively or as a manual service startup. The syntax of the command is: amqmdain qmgr alter QmgrName -x set
<b>unset</b>	Sets automatic queue manager startup to single instance. Issues <b>strmqm</b> . The unset option is ignored for queue managers that are initiated interactively or as a manual service startup. The syntax of the command is: amqmdain qmgr alter QmgrName -x unset

**refresh**

Refreshes or checks the status of a queue manager. You will not see anything returned on the screen after executing this command.

**auto QMgrName**

Sets a queue manager to automatic startup.

**manual QMgrName**

Sets a queue manager to manual startup.

**status QMgrName | all**

These parameters are optional.

Table 41. Status command parameters.

Header	Header
If no parameter is supplied:	Displays the status of the IBM MQ services.
If a <i>QMgrName</i> is supplied:	Displays the status of the named queue manager.
If the parameter <i>all</i> is supplied:	Displays the status of the IBM MQ services and all queue managers.

## regsec

Ensures that the security permissions assigned to the Registry keys containing installation information are correct.

## spn *QMgrName* set | unset

You can set or unset the service principal name for a queue manager.

## reg *QMgrName* | \* *RegParams*

Parameters *QMgrName*, and \* are optional.

Table 42. Reg command parameters.

Value	Description
If <i>RegParams</i> is specified alone:	Modifies <b>queue manager</b> configuration information related to the default queue manager.
If <i>QMgrName</i> and <i>RegParams</i> are specified:	Modifies <b>queue manager</b> configuration information related to the queue manager specified by <i>QMgrName</i> .
If * and <i>RegParams</i> are specified:	Modifies <b>IBM MQ</b> configuration information.

The parameter, *RegParams*, specifies the stanzas to change, and the changes that are to be made. *RegParams* takes one of the following forms:

- -c add -s *stanza* -v attribute= *value*
- -c remove -s *stanza* -v [attribute|\*]
- -c display -s *stanza* -v [attribute|\*]

If you are specifying queue manager configuration information, the valid values for *stanza* are:

XAResourceManager\*name*  
ApiExitLocal\*name*  
Channels  
ExitPath  
InstanceData  
Log  
QueueManagerStartup  
TCP  
LU62  
SPX  
NetBios  
Connection  
QMErrorLog  
Broker

ExitPropertiesLocal  
SSL

If you are modifying IBM MQ configuration information, the valid values for *stanza* are:

ApiExitCommon\*name*  
ApiExitTemplate\*name*  
ACPI  
AllQueueManagers  
Channels  
DefaultQueueManager  
LogDefaults  
ExitProperties

The following are usage considerations:

- **amqmdain** does not validate the values you specify for *name*, *attribute*, or *value*.
- When you specify add, and an attribute exists, it is modified.
- If a stanza does not exist, **amqmdain** creates it.
- When you specify remove, you can use the value \* to remove all attributes.

- When you specify display, you can use the value \* to display all attributes which have been defined. This value only displays the attributes which have been defined and not the complete list of valid attributes.
- If you use remove to delete the only attribute in a stanza, the stanza itself is deleted.
- Any modification you make to the Registry re-secures all IBM MQ Registry entries.

## Examples

The following example adds an XAResourceManager to queue manager TEST. The commands issued are:

```
amqmdain reg TEST -c add -s XAResourceManager\Sample -v SwitchFile=sf1
amqmdain reg TEST -c add -s XAResourceManager\Sample -v ThreadOfControl=THREAD
amqmdain reg TEST -c add -s XAResourceManager\Sample -v XAOpenString=openit
amqmdain reg TEST -c add -s XAResourceManager\Sample -v XACloseString=closeit
```

To display the values set by the commands, use:

```
amqmdain reg TEST -c display -s XAResourceManager\Sample -v *
```

The display would look something like the following:

```
0784726, 5639-B43 (C) Copyright IBM Corp. 1994, 2002. ALL RIGHTS RESERVED.
Displaying registry value for Queue Manager 'TEST'
Attribute = Name, Value = Sample
Attribute = SwitchFile, Value = sf1
Attribute = ThreadOfControl, Value = THREAD
Attribute = XAOpenString, Value = openit
Attribute = XACloseString, Value = closeit
```

To remove the XAResourceManager from queue manager TEST, use:

```
amqmdain reg TEST -c remove -s XAResourceManager\Sample -v *
```

## Return codes

Return code	Description
0	Command completed normally
-2	Syntax error
-3	Failed to initialize MFC
-6	Feature no longer supported
-7	Configuration failed
-9	Unexpected Registry error
-16	Failed to configure service principal name
-29	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
71	Unexpected error
119	Permission denied ( Windows only)

### Note:

1. If the *qmgr start QMgrName* command is issued, all return codes that can be returned with **strmqm**, can be returned here also. For a list of these return codes, see “strmqm” on page 303.
2. If the *qmgr end QMgrName* command is issued, all return codes that can be returned with **endmqm**, can be returned here also. For a list of these return codes, see “endmqm” on page 244.

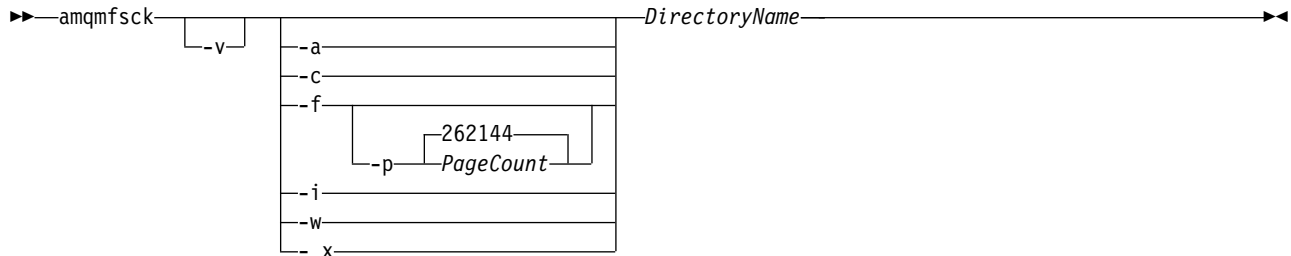

### amqmfsc (file system check):

**amqmfsc** checks whether a shared file system on UNIX and IBM i systems meets the requirements for storing the queue manager data of a multi-instance queue manager.

## Purpose

The **amqmfscck** command applies only to UNIX and IBM i systems. You do not need to check the network drive on Windows. **amqmfscck** tests that a file system correctly handles concurrent writes to a file and the waiting for and releasing of locks.

## Syntax

## Required parameters

*DirectoryName*

The name of the directory to check.

## Optional parameters

- a** Perform the second phase of the data integrity test.  
Run this on two machines at the same time. You must have formatted the test file using the **-f** option previously
- c** Test writing to a file in the directory concurrently.
- f** Perform the first phase of the data integrity test.  
Formats a file in the directory in preparation for data integrity testing.
- i** Perform the third phase of the data integrity test.  
Checks the integrity of the file after the failure to discover whether the test worked.
- p** Specifies the size of the test file used in the data integrity test in pages. .  
The size is rounded up to the nearest multiple of 16 pages. The file is formatted with *PageCount* pages of 4 KB.  
The optimum size of the file depends on the speed of the filesystem and the nature of the test you perform. If this parameter is omitted, the test file is 262144 pages, or 1 GB.  
The size is automatically reduced so that the formatting completes in about 60 seconds even on a very slow filesystem.
- v** Verbose output.
- w** Test waiting for and releasing locks.
- x** Deletes any files created by **amqmfscck** during the testing of the directory.  
Do not use this option until you have completed the testing, or if you need to change the number of pages used in the integrity test.

## Usage

You must be an IBM MQ Administrator to run the command. You must have read/write access to the directory being checked.

On IBM i, use QSH to run the program. There is no CL command.

The command returns an exit code of zero if the tests complete successfully.

The task, Verifying shared file system behavior, describes how to use **amqmfsc** to check the whether of a file system is suitable for multi-instance queue managers.

### Interpreting your results

If the check fails, the file system is not capable of being used by IBM MQ queue managers. If the tests fail, choose verbose mode to help you to interpret the errors. The output from the verbose option helps you understand why the command failed, and if the problem can be solved by reconfiguring the file system.

Sometimes the failure might be an access control problem that can be fixed by changing directory ownership or permissions. Sometimes the failure can be fixed by reconfiguring the file system to behave in a different way. For example, some file systems have performance options that might need to be changed. It is also possible that the file system protocol does not support concurrency sufficiently robustly, and you must use a different file system. For example, you must use NFSv4 rather than NFSv3.

If the check succeeds, the command reports The tests on the directory completed successfully. If your environment is not listed as supported in the Testing and support statement for IBM MQ multi-instance queue managers, this result does not necessarily mean that you can run IBM MQ multi-instance queue managers successfully.

You must plan and run a variety of tests to satisfy yourself that you have covered all foreseeable circumstances. Some failures are intermittent, and there is a better chance of discovering them if you run the tests more than once.

#### Related information:

Verifying shared file system behavior

#### **crtmqcvx:**

Create data conversion code from data type structures.

#### **Purpose**

Use the **crtmqcvx** command to create a fragment of code that performs data conversion on data type structures. The command generates a C function that can be used in an exit to convert C structures.

The command reads an input file containing structures to be converted, and writes an output file containing code fragments to convert those structures.

For information about using this command, see Utility for creating conversion-exit code.

#### **Syntax**

## Required parameters

### *SourceFile*

The input file containing the C structures to convert.

### *TargetFile*

The output file containing the code fragments generated to convert the structures.

## Return codes

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

## Examples

The following example shows the results of using the data conversion command against a source C structure. The command issued is:

```
crtmqcvx source.tmp target.c
```

The input file, `source.tmp`, looks like this:

```
/* This is a test C structure which can be converted by the */
/* crtmqcvx utility                                         */

struct my_structure
{
    int    code;
    MQLONG value;
};
```

The output file, `target.c`, produced by the command, looks like this:

```

MQLONG Convertmy_structure(
    PMQDXP  pExitParms,
    PMQBYTE *in_cursor,
    PMQBYTE *out_cursor,
    PMQBYTE in_lastbyte,
    PMQBYTE out_lastbyte,
    MQHCONN hConn,
    MQLONG  opts,
    MQLONG  MsgEncoding,
    MQLONG  ReqEncoding,
    MQLONG  MsgCCSID,
    MQLONG  ReqCCSID,
    MQLONG  CompCode,
    MQLONG  Reason)
{
    MQLONG ReturnCode = MQRC_NONE;

    ConvertLong(1); /* code */

    AlignLong();
    ConvertLong(1); /* value */

Fail:
    return(ReturnCode);
}

```

You can use these code fragments in your applications to convert data structures. However, if you do so, the fragment uses macros supplied in the header file `amqsvmha.h`.

### **crtmqenv:**

Create a list of environment variables for an installation of IBM MQ, on UNIX, Linux, and Windows.

#### **Purpose**

You can use the **crtmqenv** command to create a list of environment variables with the appropriate values for an installation of IBM MQ. The list of environment variables is displayed on the command line, and any variables that exist on the system have the IBM MQ values added to them. This command does not set the environment variables for you, but gives you the appropriate strings to set the variables yourself, for example, within your own scripts.

If you want the environment variables set for you in a shell environment, you can use the **setmqenv** command instead of using the **crtmqenv** command.

You can specify which installation the environment is created for by specifying a queue manager name, an installation name, or an installation path. You can also create the environment for the installation that issues the **crtmqenv** command by issuing the command with the **-s** parameter.

This command lists the following environment variables, and their values, appropriate to your system:

- CLASSPATH
- INCLUDE
- LIB
- MANPATH
- MQ\_DATA\_PATH
- MQ\_ENV\_MODE
- MQ\_FILE\_PATH

- MQ\_JAVA\_INSTALL\_PATH
- MQ\_JAVA\_DATA\_PATH
- MQ\_JAVA\_LIB\_PATH
- MQ\_JAVA\_JVM\_FLAG
- MQ\_JRE\_PATH
- PATH

On UNIX and Linux systems, if the **-l** or **-k** flag is specified, the *LIBPATH* environment variable is set on AIX, and the *LD\_LIBRARY\_PATH* environment variable is set on HP-UX, Linux, and Solaris.

### Usage notes

The **crtmqenv** command removes all directories for all IBM MQ installations from the environment variables before adding new references to the installation for which you are setting up the environment. Therefore, if you want to set any additional environment variables that reference IBM MQ, set the variables after issuing the **crtmqenv** command. For example, if you want to add *MQ\_INSTALLATION\_PATH/java/lib* to *LD\_LIBRARY\_PATH*, you must do so after running **crtmqenv**.

### Syntax

### Required Parameters

- m QMgrName**  
Create the environment for the installation associated with the queue manager *QMgrName*.
- n InstallationName**  
Create the environment for the installation named *InstallationName*.
- p InstallationPath**  
Create the environment for the installation in the path *InstallationPath*.
- r** Remove all installations from the environment.
- s** Create the environment for the installation that issued the command.

### Optional Parameters

- k** UNIX and Linux only.  
Include the *LD\_LIBRARY\_PATH*, or *LIBPATH*, environment variable in the environment, adding the path to the IBM MQ libraries at the start of the current *LD\_LIBRARY\_PATH*, or *LIBPATH*, variable.
- l** UNIX and Linux only.  
Include the *LD\_LIBRARY\_PATH*, or *LIBPATH*, environment variable in the environment, adding the path to the IBM MQ libraries at the end of the current *LD\_LIBRARY\_PATH*, or *LIBPATH*, variable.
- x Mode**  
*Mode* can take the value 32, or 64.  
Create a 32-bit or 64-bit environment. If this parameter is not specified, the environment matches that of the queue manager or installation specified in the command.  
Any attempt to display a 64-bit environment with a 32-bit installation fails.

**-i** List only the additions to the environment.

When this parameter is specified, the environment variables set for previous installations remain in the environment variable path and must be manually removed.

## Return codes

Return code	Description
0	Command completed normally.
10	Command completed with unexpected results.
20	An error occurred during processing.

## Examples

The following examples assume that a copy of IBM MQ is installed in `/opt/mqm` on a UNIX or Linux system.

1. This command creates a list of environment variables for an installation installed in `/opt/mqm`:  
`/opt/mqm/bin/crtmqenv -s`
2. This command creates a list of environment variables for an installation installed in `/opt/mqm2`, and includes the path to the installation at the end of the current value of the `LD_LIBRARY_PATH` variable:  
`/opt/mqm/bin/crtmqenv -p /opt/mqm2 -l`
3. This command creates a list of environment variables for the queue manager QM1, in a 32-bit environment:  
`/opt/mqm/bin/crtmqenv -m QM1 -x 32`

The following example assumes that a copy of IBM MQ is installed in `C:\Program Files\IBM\WebSphere MQ` on a Windows system.

1. This command creates a list of environment variables for an installation called `installation1`:  
`"C:\Program Files\IBM\WebSphere MQ\crtmqenv" -n installation1`

### Related reference:

“`setmqenv`” on page 290

Use the **setmqenv** command to set up the IBM MQ environment on UNIX, Linux, and Windows.

### Related information:

Choosing a primary installation

Multiple installations

### **crtmqinst:**

Create installation entries in `mqinst.ini` on UNIX and Linux systems.

## Purpose

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see Installation configuration file, `mqinst.ini`.

The first IBM MQ installation is automatically given an installation name of `Installation1` because the **crtmqinst** command is not available until an installation of IBM MQ is on the system. Subsequent installations can have an installation name set before installation occurs, by using the **crtmqinst** command. The installation name cannot be changed after installation. For more information about installation names, see Choosing an installation name.

## Syntax

### Notes:

- 1 When specified together, the installation name and installation path must refer to the same installation.

### Parameters

**-d** Text that describes the installation.

The text can be up to 64 single-byte characters, or 32 double-byte characters. The default value is all blanks. You must use quotation marks around the text if it contains spaces.

**-n** *InstallationName*

The name of the installation.

The name can contain up to 16 single-byte characters and must be a combination of alphabetic and numeric characters in the ranges a-z, A-Z, and 0-9. The installation name must be unique, regardless of whether uppercase or lowercase characters are used. For example, the names INSTALLATIONNAME and InstallationName are not unique. If you do not supply the installation name, the next available name in the series Installation1, Installation2... is used.

**-p** *InstallationPath*

The installation path. If you do not supply the installation path, /opt/mqm is used on UNIX and Linux systems, and /usr/mqm is used on AIX.

### Return codes

Return code	Description
0	Entry created without error
10	Invalid installation level
36	Invalid arguments supplied
37	Descriptive text was in error
45	Entry already exists
59	Invalid installation specified
71	Unexpected error
89	.ini file error
96	Could not lock .ini file
98	Insufficient authority to access .ini file
131	Resource problem

### Example

1. This command creates an entry with an installation name of myInstallation, an installation path of /opt/myInstallation, and a description "My IBM MQ installation":

```
crtmqinst -n MyInstallation -p /opt/myInstallation -d "My IBM MQ installation"
```

Quotation marks are needed because the descriptive text contains spaces.

**Note:** On UNIX systems, the **crtmqinst** command must be run by the root user because full access permissions are required to write to the mqinst.ini configuration file.

## crtmqm:

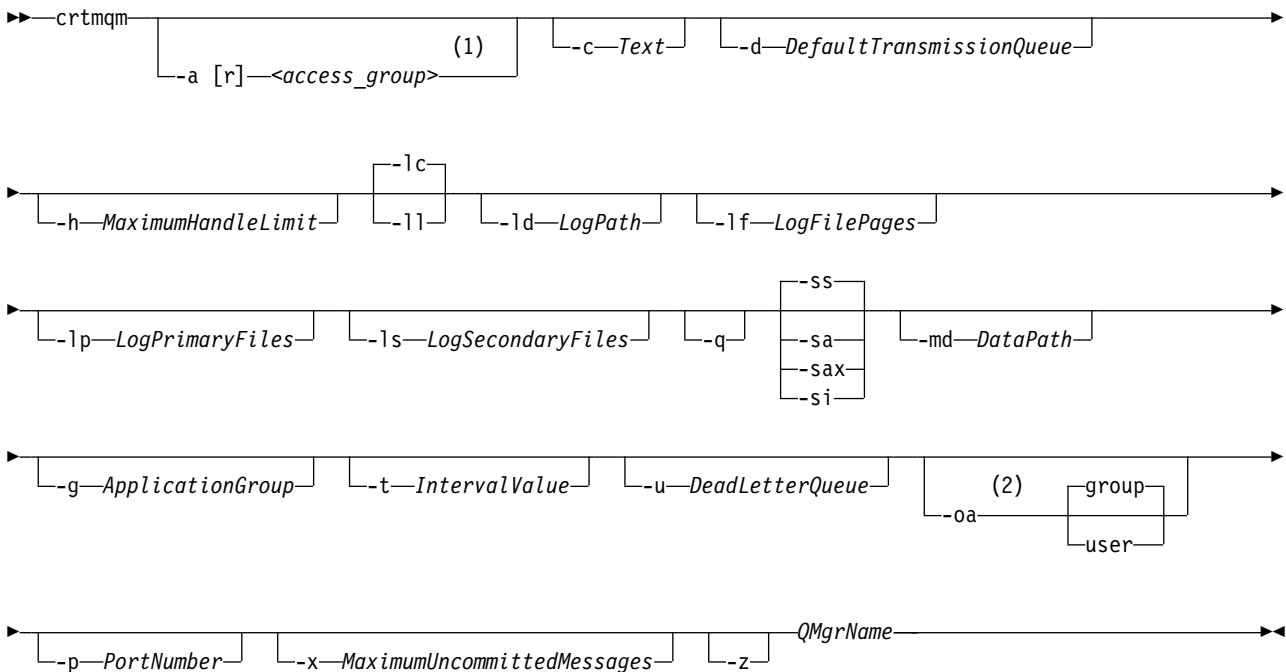

Create a queue manager.

### Purpose

Use the **crtmqm** command to create a queue manager and define the default and system objects. The objects created by the **crtmqm** command are listed in System and default objects. When you have created a queue manager, use the **strmqm** command to start it.

The queue manager is automatically associated with the installation from which the **crtmqm** command was issued. To change the associated installation, use the **setmqm** command. Note that the Windows installer does not automatically add the user that performs the installation to the mqm group. For more details, see Authority to administer IBM MQ on UNIX, Linux and Windows systems.

### Syntax

### Notes:

- 1 Windows only
- 2 UNIX and Linux only

### Required parameters

#### QMgrName

The name of the queue manager that you want to create. The name can contain up to 48 characters. This parameter must be the last item in the command.

**Note:** The *QMgrName* is used by IBM MQ applications, other IBM MQ queue managers, and IBM MQ control commands to identify this queue manager.

No other queue manager with the same name can exist on this machine. Where this queue manager is going to connect to other queue managers you must ensure that queue manager names are unique within that group of queue managers.

The *QMgrName* is also used to name the directories created on disk for the queue manager. Due to filesystem limitations the name of the directories created might not be identical to the *QMgrName* supplied on the **crtmqm** command.

In these cases the directories created will be based upon the supplied *QMgrName*, but might be modified, or have a suffix such as .000 or .001, and so on, added to the queue manager name.

## Optional parameters

**Windows** **-a[r]** *access\_group*

Use the access group parameter to specify a Windows security group, members of which will be granted full access to all queue manager data files. The group can either be a local or global group, depending on the syntax used.

Valid syntax for the group name is as follows:

*LocalGroup*

*Domain name\GlobalGroup name*

*GlobalGroup name @ Domain name*

You must define the additional access group before running the **crtmqm** command with the **-a [r]** option.

If you specify the group using **-ar** instead of **-a**, the local **mqm** group is not granted access to the queue manager data files. Use this option if the file system hosting the queue manager data files does not support access control entries for locally defined groups.

The group is typically a global security group, which is used to provide multi-instance queue managers with access to a shared queue manager data and logs folder. Use the additional security access group to set read and write permissions on the folder or to share containing queue manager data and log files.

The additional security access group is an alternative to using the local group named **mqm** to set permissions on the folder containing queue manager data and logs. Unlike the local group **mqm**, you can make the additional security access group a local or a global group. It must be a global group to set permissions on the shared folders that contain the data and log files used by multi-instance queue managers.

The Windows operating system checks the access permissions to read and write queue manager data and log files. It checks the permissions of the user ID that is running queue manager processes. The user ID that is checked depends on whether you started the queue manager as a service or you started it interactively. If you started the queue manager as a service, the user ID checked by the Windows system is the user ID you configured with the Prepare IBM MQ wizard. If you started the queue manager interactively, the user ID checked by the Windows system is the user ID that ran the **strmqm** command.

The user ID must be a member of the local **mqm** group to start the queue manager. If the user ID is a member of the additional security access group, the queue manager can read and write files that are given permissions by using the group.

**Restriction:** You can specify an additional security access group only on Windows operating system. If you specify an additional security access group on other operating systems, the **crtmqm** command returns an error.

**-c** *Text*

Descriptive text for this queue manager. You can use up to 64 characters; the default is all blanks.

If you include special characters, enclose the description in single quotation marks. The maximum number of characters is reduced if the system is using a double-byte character set (DBCS).

**-d** *DefaultTransmissionQueue*

The name of the local transmission queue where remote messages are put if a transmission queue is not explicitly defined for their destination. There is no default.

**-g** *ApplicationGroup*

The name of the group that contains members that are allowed to perform the following actions:

- Run MQI applications
- Update all IPCC resources
- Change the contents of some queue manager directories

This option applies to IBM MQ for AIX, Solaris, HP-UX, and Linux.

The default value is **-g all**, which allows unrestricted access.

The **-g ApplicationGroup** value is recorded in the queue manager configuration file named, *qm.ini*.

The *mqm* user ID and the user running the command must belong to the specified Application Group. For further details of the operation of restricted mode, see Restricted mode.

**-h** *MaximumHandleLimit*

The maximum number of handles that an application can open at the same time.

Specify a value in the range 1 - 999999999. The default value is 256.

The next set of parameter descriptions relate to logging, which is described in Using the log for recovery.

**Note:** Choose the logging arrangements with care, because some cannot be changed after they are committed.

**-lc**

Use circular logging. This method is the default logging method.

**-ld** *LogPath*

The directory used to store log files. The default directory to store log paths is defined when you install IBM MQ.

If the volume containing the log file directory supports file security, the log file directory must have access permissions. The permissions allow the user IDs, under whose authority the queue manager runs, read and write access to the directory and its subdirectories. When you install IBM MQ, you grant permissions to the user IDs and to the *mqm* group on the default log directory. If you set the *LogPath* parameter to write the log file to a different directory, you must grant the user IDs permission to read and write to the directory. The user ID and permissions for UNIX and Linux are different from those for the Windows system:

**UNIX and Linux**

The directory and its subdirectories must be owned by the user *mqm* in the group *mqm*.

If the log file is shared between different instances of the queue manager, the security identifiers (*sid*) that are used must be the same for the different instances. You must have set the user *mqm* to the same *sid* on the different servers running instances of the queue manager. Likewise for the group *mqm*.

**Windows**

If the directory is accessed by only one instance of the queue manager, you must give read and write access permission to the directory for the following groups and users:

- The local group *mqm*
- The local group Administrators
- The SYSTEM user ID

To give different instances of a queue manager access to the shared log directory, the queue manager must access the log directory using a global user. Give the global group, which contains the global user, read and write access permission to the log directory. The global group is the additional security access group specified in the **-a** parameter.

In IBM MQ for Windows systems, the default directory is C:\ProgramData\IBM\MQ\log (assuming that C is your data drive). If the volume supports file security, the SYSTEM ID, Administrators, and mqm group must be granted read/write access to the directory.

In IBM MQ for UNIX and Linux systems, the default directory is /var/mqm/log. User ID mqm and group mqm must have full authorities to the log files.

If you change the locations of these files, you must give these authorities yourself. If these authorities are set automatically, then the log files are in their default locations.

#### **-1f** *LogFilePages*

The log data is held in a series of files called log files. The log file size is specified in units of 4 KB pages.

In IBM MQ for UNIX and Linux systems, the default number of log file pages is 4096, giving a log file size of 16 MB. The minimum number of log file pages is 64 and the maximum is 65535.

In IBM MQ for Windows systems, the default number of log file pages is 4096, giving a log file size of 16 MB. The minimum number of log file pages is 32 and the maximum is 65535.

**Note:** The size of the log files for a queue manager specified during creation of that queue manager cannot be changed.

#### **-11** *LinearLogging*

Use linear logging.

#### **-1p** *LogPrimaryFiles*

The log files allocated when the queue manager is created.

On a Windows system, the minimum number of primary log files you can have is 2 and the maximum is 254. On UNIX and Linux systems, the minimum number of primary log files you can have is 2 and the maximum is 510. The default is 3.

On a Windows system, the total number of primary and secondary log files must not exceed 255 and must not be less than 3. On UNIX and Linux systems the total number of primary and secondary log files must not exceed 511 and must not be less than 3.

Operating system limits can reduce the maximum log size.

The value is examined when the queue manager is created or started. You can change it after the queue manager has been created. However, a change in the value is not effective until the queue manager is restarted, and the effect might not be immediate.

For more information about primary log files, see What logs look like.

To calculate the size of the primary log files, see Calculating the size of the log.

#### **-1s** *LogSecondaryFiles*

The log files allocated when the primary files are exhausted.

On a Windows system, the minimum number of secondary log files you can have is 1 and the maximum is 253. On UNIX and Linux systems, the minimum number of secondary log files you can have is 2 and the maximum is 509. The default is 2.

On a Windows system, the total number of primary and secondary log files must not exceed 255 and must not be less than 3. On UNIX and Linux systems the total number of primary and secondary log files must not exceed 511 and must not be less than 3.

Operating system limits can reduce the maximum log size.

The value is examined when the queue manager is started. You can change this value, but changes do not become effective until the queue manager is restarted, and even then the effect might not be immediate.

For more information about the use of secondary log files, see [What logs look like](#).

To calculate the size of the secondary log files, see [Calculating the size of the log](#).

#### **-md** *DataPath*

The directory used to hold the data files for a queue manager.

In IBM MQ for Windows systems, the default is `C:\ProgramData\IBM\MQ\qmgrs` (assuming that **C:** is your data drive). If the volume supports file security, the SYSTEM ID, Administrators, and mqm group must be granted read/write access to the directory.

In IBM MQ for UNIX and Linux systems, the default is `/var/mqm/qmgrs`. User ID mqm and group mqm must have full authorities to the log files.

The `DataPath` parameter is provided to assist in the configuration of multi-instance queue managers. For example, on UNIX and Linux systems: if the `/var/mqm` directory is located on a local file system, use the `DataPath` parameter and the `LogPath` parameter to point to the shared file systems accessible to multiple queue managers.

**Note:** A queue manager created using `DataPath` parameter runs on versions of IBM MQ earlier than Version 7.0.1, but the queue manager must be reconfigured to remove the `DataPath` parameter. You have two options to restore the queue manager to a pre-Version 7.0.1 configuration and run without the `DataPath` parameter: If you are confident about editing queue manager configurations, you can manually configure the queue manager using the `Prefix` queue manager configuration parameter. Alternatively, complete the following steps to edit the queue manager:

1. Stop the queue manager.
2. Save the queue manager data and log directories.
3. Delete the queue manager.
4. Backout IBM MQ to the pre-v7.0.1 fix level.
5. Create the queue manager with the same name.
6. Replace the new queue manager data and log directories with the ones you saved.

#### **-oa** *group* | *user*

  On UNIX and Linux systems, you can specify whether group or user authorization is to be used. If you do not set this parameter, group authorization is used. You can change the authorization model later by setting the **SecurityPolicy** parameter in the Service stanza of the `qm.ini` file (see [Service stanza format](#)).

For further information, see [Object authority manager \(OAM\)](#).

#### **-p** *PortNumber*

Create a managed TCP listener on the specified port.

Specify a valid port value in the range 1-65535, to create a TCP listener object that uses the specified port. The new listener is called `SYSTEM.LISTENER.TCP.1`. This listener is under queue manager control, and is started and stopped along with the queue manager.

- q** Makes this queue manager the default queue manager. The new queue manager replaces any existing default queue manager.

If you accidentally use this flag and you want to revert to an existing queue manager as the default queue manager, change the default queue manager as described in [Making an existing queue manager the default](#).

#### **-sa**

Automatic queue manager startup. For Windows systems only.

The queue manager is configured to start automatically when the IBM MQ Service starts.

This is the default option if you create a queue manager from MQ Explorer.

Queue managers created in IBM MQ releases earlier than Version 7 retain their existing startup type.

**-sax**

Automatic queue manager startup, permitting multiple instances. For Windows systems only.

The queue manager is configured to start automatically when the IBM MQ Service starts.

If an instance of the queue manager is not already running the queue manager starts, the instance becomes active, and standby instances are permitted elsewhere. If a queue manager instance that permits standbys is already active on a different server, the new instance becomes a standby instance.

Only one instance of a queue manager can run on a server.

Queue managers created in IBM MQ versions earlier than Version 7.0.1 retain their existing startup type.

**-si**

Interactive (manual) queue manager startup.

The queue manager is configured to start only when you manually request startup by using the **strmqm** command. The queue manager runs under the (interactive) user when that user is logged-on. Queue managers configured with interactive startup end when the user who started them logs off.

**-ss**

Service (manual) queue manager startup.

A queue manager configured to start only when manually requested by using the **strmqm** command. The queue manager then runs as a child process of the service when the IBM MQ Service starts.

Queue managers configured with service startup continue to run even after the interactive user has logged off.

This is the default option if you create a queue manager from the command line.

**-t** *IntervalValue*

The trigger time interval in milliseconds for all queues controlled by this queue manager. This value specifies the length of time triggering is suspended, after the queue manager receives a trigger-generating message. That is, if the arrival of a message on a queue causes a trigger message to be put on the initiation queue, any message arriving on the same queue within the specified interval does not generate another trigger message.

You can use the trigger time interval to ensure that your application is allowed sufficient time to deal with a trigger condition before it is alerted to deal with another trigger condition on the same queue. You might choose to see all trigger events that happen; if so, set a low or zero value in this field.

Specify a value in the range 0 - 999999999. The default is 999999999 milliseconds; a time of more than 11 days. Allowing the default to be used effectively means that triggering is disabled after the first trigger message. However, an application can enable triggering again by servicing the queue using a command to alter the queue to reset the trigger attribute.

**-u** *DeadLetterQueue*

The name of the local queue that is to be used as the dead-letter (undelivered-message) queue. Messages are put on this queue if they cannot be routed to their correct destination.

The default is no dead-letter queue.

**-x** *MaximumUncommittedMessages*

The maximum number of uncommitted messages under any one sync point. The uncommitted messages are the sum of:

- The number of messages that can be retrieved from queues
- The number of messages that can be put on queues

- Any trigger messages generated within this unit of work

This limit does not apply to messages that are retrieved or put outside a sync point.

Specify a value in the range 1 - 999999999. The default value is 10000 uncommitted messages.

- z Suppresses error messages.

This flag is used within IBM MQ to suppress unwanted error messages. Do not use this flag when using a command line. Using this flag can result in a loss of information.

## Return codes

Return code	Description
0	Queue manager created
8	Queue manager exists
39	Invalid parameter specified
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage unavailable
70	Queue space unavailable
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started.
100	Log location invalid
111	Queue manager created. However, there was a problem processing the default queue manager definition in the product configuration file. The default queue manager specification might be incorrect.
115	Invalid log size
119	Permission denied ( Windows only)

## Examples

- The following command creates a default queue manager called `Paint.queue.manager`, with a description of `Paint shop`, and creates the system and default objects. It also specifies that linear logging is to be used:

```
crtmqm -c "Paint shop" -ll -q Paint.queue.manager
```

- The following command creates a default queue manager called `Paint.queue.manager`, creates the system and default objects, and requests two primary and three secondary log files:

```
crtmqm -c "Paint shop" -ll -lp 2 -ls 3 -q Paint.queue.manager
```

- The following command creates a queue manager called `travel`, creates the system and default objects, sets the trigger interval to 5000 milliseconds (5 seconds), and specifies `SYSTEM.DEAD.LETTER.QUEUE` as its dead-letter queue.

```
crtmqm -t 5000 -u SYSTEM.DEAD.LETTER.QUEUE travel
```

- The following command creates a queue manager called `QM1` on UNIX and Linux systems, which has log and queue manager data folders in a common parent directory. The parent directory is to be shared on highly available networked storage to create a multi-instance queue manager. Before issuing the command, create other parameters `/MQHA`, `/MQHA/logs` and `/MQHA/qmgrs` owned by the user and group `mqm`, and with permissions `rwxrwxr-x`.

```
crtmqm -ld /MQHA/logs -md /MQHA/qmgrs QM1
```

## Related commands

Command	Description
"strmqm" on page 303	Start queue manager
"endmqm" on page 244	End queue manager
"dlmqm" on page 202	Delete queue manager
"setmqm" on page 294	Set associated installation

### dlmqinst:

Delete installation entries from mqinst.ini on UNIX and Linux systems.

### Purpose

File mqinst.ini contains information about all IBM MQ installations on a system. For more information about mqinst.ini, see Installation configuration file, mqinst.ini.

### Syntax

### Notes:

- 1 When specified together, the installation name and installation path must refer to the same installation.

### Parameters

- n *InstallationName*  
The name of the installation.
- p *InstallationPath*  
The installation path is the location where IBM MQ is installed.

### Return codes

Return code	Description
0	Entry deleted without error
5	Entry still active
36	Invalid arguments supplied
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	ini file error
96	Could not lock ini file
98	Insufficient authority to access ini file
131	Resource problem

### Example

1. This command deletes an entry with an installation name of myInstallation, and an installation path of /opt/myInstallation:  
dlmqinst -n MyInstallation -p /opt/myInstallation

**Note:** You can only use the **dltmqinst** command on another installation from the one it runs from. If you only have one IBM MQ installation, the command will not work.

**Note:** On a Solaris 10 MQ Client installation, only the root user has permissions to edit the mqinst.ini file.

### **dltmqm:**

Delete a queue manager.

#### **Purpose**

Use the **dltmqm** command to delete a specified queue manager and all objects associated with it. Before you can delete a queue manager, you must end it using the **endmqm** command.

You must use the **dltmqm** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmqr -o** installation command.

In IBM MQ for Windows, it is an error to delete a queue manager when queue manager files are open. If you get this error, close the files and reissue the command.

#### **Syntax**

```
▶▶ dltmqm [ -z ] QMgrName ▶▶
```

#### **Required parameters**

*QMgrName*

The name of the queue manager to delete.

#### **Optional parameters**

**-z** Suppresses error messages.

#### **Return codes**

<b>Return code</b>	<b>Description</b>
0	Queue manager deleted
3	Queue manager being created
5	Queue manager running
16	Queue manager does not exist
24	A process that was using the previous instance of the queue manager has not yet disconnected.
25	An error occurred while creating or checking the directory structure for the queue manager.
26	Queue manager running as a standby instance.
27	Queue manager could not obtain data lock.
29	Queue manager deleted, however there was a problem removing it from Active Directory.
33	An error occurred while deleting the directory structure for the queue manager.
49	Queue manager stopping
58	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started.

Return code	Description
100	Log location invalid.
112	Queue manager deleted. However, there was a problem processing the default queue manager definition in the product configuration file. The default queue manager specification might be incorrect.
119	Permission denied ( Windows only).

## Examples

- The following command deletes the queue manager saturn.queue.manager.  

```
dltmqm saturn.queue.manager
```
- The following command deletes the queue manager travel and also suppresses any messages caused by the command.  

```
dltmqm -z travel
```

## Usage notes

In IBM MQ for Windows, it is an error to delete a queue manager when queue manager files are open. If you get this error, close the files and reissue the command.

Deleting a cluster queue manager does not remove it from the cluster. To check whether the queue manager you want to delete is part of a cluster, issue the command **DIS CLUSQMGR(\*)**. Then check whether this queue manager is listed in the output. If it is listed as a cluster queue manager you must remove the queue manager from the cluster before deleting it. See the related link for instructions.

If you do delete a cluster queue manager without first removing it from the cluster, the cluster continues to regard the deleted queue manager as a member of the cluster for at least 30 days. You can remove it from the cluster using the command **RESET CLUSTER** on a full repository queue manager. Re-creating a queue manager with an identical name and then trying to remove that queue manager from the cluster does not result in the cluster queue manager being removed from the cluster. This is because the newly created queue manager, although having the same name, does not have the same queue manager ID (QMID). Therefore it is treated as a different queue manager by the cluster.

## Related commands

Command	Description
crtmqm	Create queue manager
strmqm	Start queue manager
endmqm	End queue manager

## dmpmqaut:

Dump a list of current authorizations for a range of IBM MQ object types and profiles.

## Purpose

Use the **dmpmqaut** command to dump the current authorizations to a specified object.

## Syntax

## Optional parameters

### -m *QMgrName*

Dump authority records only for the queue manager specified. If you omit this parameter, only authority records for the default queue manager are dumped.

### -n *Profile*

The name of the profile for which to dump authorizations. The profile name can be generic, using wildcard characters to specify a range of names as explained in Using OAM generic profiles on UNIX, Linux, and Windows systems.

-l Dump only the profile name and type. Use this option to generate a *terse* list of all defined profile names and types.

-a Generate set authority commands.

### -t *ObjectType*

The type of object for which to dump authorizations. Possible values are:

Value	Description
<b>authinfo</b>	An authentication information object, for use with Secure Sockets Layer (SSL) channel security
<b>channel</b> or <b>chl</b>	A channel
<b>clntconn</b> or <b>clcn</b>	A client connection channel
<b>listener</b> or <b>lstr</b>	A listener
<b>namelist</b> or <b>nl</b>	A namelist
<b>process</b> or <b>prcs</b>	A process
<b>queue</b> or <b>q</b>	A queue or queues matching the object name parameter
<b>qmgr</b>	A queue manager
<b>rqmname</b> or <b>rqmn</b>	A remote queue manager name
<b>service</b> or <b>srvc</b>	A service
<b>topic</b> or <b>top</b>	A topic

### -s *ServiceComponent*

If installable authorization services are supported, specifies the name of the authorization service for which to dump authorizations. This parameter is optional; if you omit it, the authorization inquiry is made to the first installable component for the service.

### -p *PrincipalName*

This parameter applies to IBM MQ for Windows only; UNIX systems keep only group authority records.

The name of a user for whom to dump authorizations to the specified object. The name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see Principals and groups.

**-g** *GroupName*

The name of the user group for which to dump authorizations. You can specify only one name, which must be the name of an existing user group.

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain  
domain\GroupName
```

**-e** Display all profiles used to calculate the cumulative authority that the entity has to the object specified in **-n** *Profile*. The variable *Profile* must not contain any wildcard characters.

The following parameters must also be specified:

- **-m** *QMgrName*
- **-n** *Profile*
- **-t** *ObjectType*

and either **-p** *PrincipalName*, or **-g** *GroupName*.

**-x** Display all profiles with the same name as specified in **-n** *Profile*. This option does not apply to the **QMGR** object, so a dump request of the form `dmpmqaut -m QM -t QMGR ... -x` is not valid.

## Examples

The following examples show the use of `dmpmqaut` to dump authority records for generic profiles:

1. This example dumps all authority records with a profile that matches queue a.b.c for principal user1.

```
dmpmqaut -m qm1 -n a.b.c -t q -p user1
```

The resulting dump would look something like this:

```
profile:      a.b.*  
object type: queue  
entity:       user1  
type:         principal  
authority:    get, browse, put, inq
```

**Note:** UNIX users cannot use the **-p** option; they must use **-g** *groupname* instead.

2. This example dumps all authority records with a profile that matches queue a.b.c.

```
dmpmqaut -m qmgr1 -n a.b.c -t q
```

The resulting dump would look something like this:

```
profile:      a.b.c  
object type: queue  
entity:       Administrator  
type:         principal  
authority:    all  
-----  
profile:      a.b.*  
object type: queue  
entity:       user1  
type:         principal  
authority:    get, browse, put, inq  
-----  
profile:      a.**  
object type: queue  
entity:       group1  
type:         group  
authority:    get
```

3. This example dumps all authority records for profile a.b.\*, of type queue.

```
dmpmqaut -m qmgr1 -n a.b.* -t q
```

The resulting dump would look something like this:

```
profile:    a.b.*
object type: queue
entity:     user1
type:       principal
authority:  get, browse, put, inq
```

4. This example dumps all authority records for queue manager qmX.

```
dmpmqaut -m qmX
```

The resulting dump would look something like this:

```
profile:    q1
object type: queue
entity:     Administrator
type:       principal
authority:  all
-----
profile:    q*
object type: queue
entity:     user1
type:       principal
authority:  get, browse
-----
profile:    name.*
object type: namelist
entity:     user2
type:       principal
authority:  get
-----
profile:    pr1
object type: process
entity:     group1
type:       group
authority:  get
```

5. This example dumps all profile names and object types for queue manager qmX.

```
dmpmqaut -m qmX -l
```

The resulting dump would look something like this:

```
profile: q1, type: queue
profile: q*, type: queue
profile: name.*, type: namelist
profile: pr1, type: process
```

#### Note:

1. For IBM MQ for Windows only, all principals displayed include domain information, for example:

```
profile:    a.b.*
object type: queue
entity:     user1@domain1
type:       principal
authority:  get, browse, put, inq
```

2. Each class of object has authority records for each group or principal. These records have the profile name @CLASS and track the crt (create) authority common to all objects of that class. If the crt authority for any object of that class is changed then this record is updated. For example:

```
profile:    @class
object type: queue
entity:     test
entity type: principal
authority:  crt
```

This shows that members of the group test have crt authority to the class queue.

- For IBM MQ for Windows only, members of the “Administrators” group are by default given full authority. This authority, however, is given automatically by the OAM, and is not defined by the authority records. The **dmpmqaut** command displays authority defined only by the authority records. Unless an authority record has been explicitly defined, therefore, running the **dmpmqaut** command against the “Administrators” group displays no authority record for that group.

### dmpmqcfg:

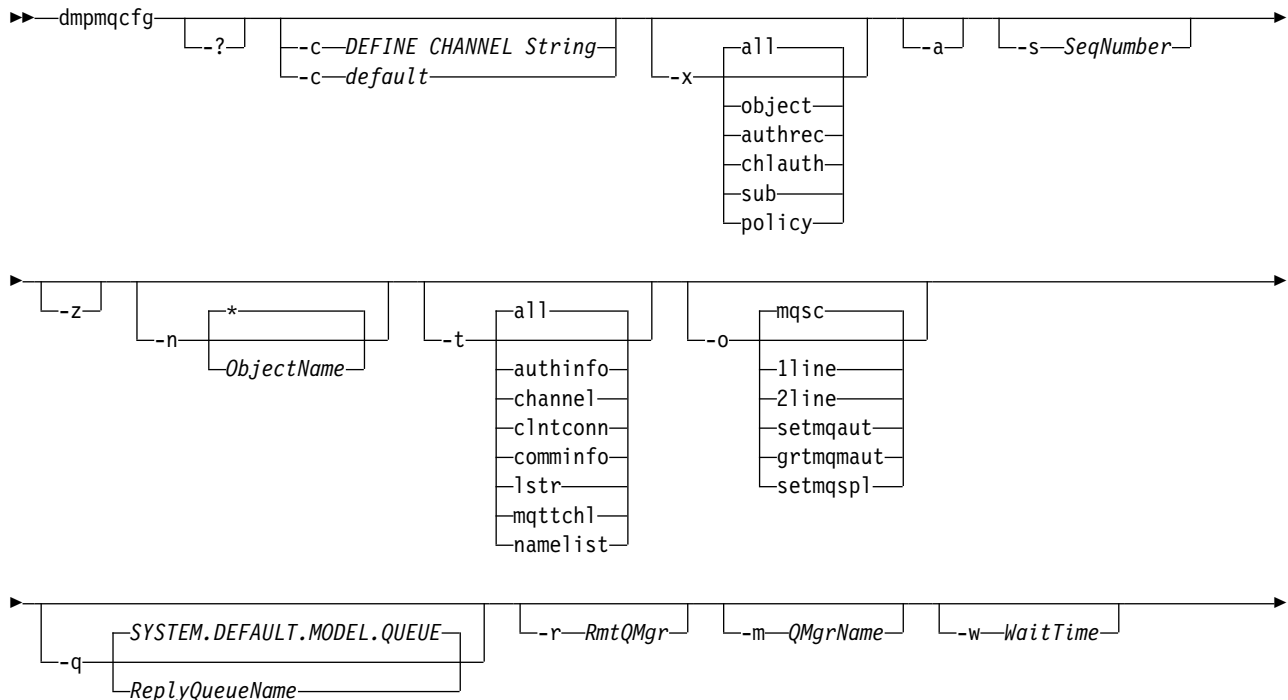

Use the **dmpmqcfg** command to dump the configuration of an IBM MQ queue manager.

#### Purpose

Use the **dmpmqcfg** command to dump the configuration of IBM MQ queue managers. If any default object has been edited, the -a option must be used if the dumped configuration will be used to restore the configuration.

The **dmpmqcfg** utility dumps only subscriptions of type MQSUBTYPE\_ADMIN, that is, only subscriptions that are created using the MQSC command **DEFINE SUB** or its PCF equivalent. The output from **dmpmqcfg** is a **runmqsc** command to enable the administration subscription to be re-created. Subscriptions that are created by applications using the MQSUB MQI call of type MQSUBTYPE\_API are not part of the queue manager configuration, even if durable, and so are not dumped by **dmpmqcfg**. MQTT channels will only be returned for types -t all and -t mqttchl if the telemetry (MQXR) service is running. For instructions on how to start the telemetry service, see Administering IBM MQ Telemetry.

**Note:** The **dmpmqcfg** command does not make a backup of the IBM MQ Advanced Message Security policies. If you want to export the IBM MQ Advanced Message Security policies, ensure that you run **dspmqspl** with the -export flag. This command exports the policies for IBM MQ Advanced Message Security into a text file, which can be used for restoration purposes. For more information see “dspmqspl” on page 236.

—*UserId*—

## Optional Parameters

- ? Inquire the usage message for dmpmqcfg.
- c Force a client mode connection. If the **-c** parameter is qualified with the option `default`, the default client connection process is used. If **-c** is omitted, the default is to attempt to connect to the queue manager first by using server bindings and then if this fails by using client bindings.  
  
If the option is qualified with an MQSC DEFINE CHANNEL CHLTYPE(CLNTCONN) string then this is parsed and if successful, used to create a temporary connection to the queue manager.
- x [ *all* | *object* | *authrec* | *chlauth* | *sub* | *policy* ]  
Filter the definition procedure to show object definitions, authority records, channel authentication records, durable subscriptions or policy. The default value `all` is that all types are returned.  
  
Note that when you specify an export type of `policy`, the security policies for the queue manager are reported in the configuration information dumped.
- a Return object definitions to show all attributes. The default is to return only attributes which differ from the defaults for the object type.
- s *SeqNumber*  
Reset channel sequence number for sender, server and cluster sender channel types to the numeric value specified. The value `SeqNumber` must be in the range 1 - 999999999.
- z  
Activate silent mode in which warnings, such as those which appear when inquiring attributes from a queue manager of a higher command level are suppressed.
- n [ \* | *ObjectName* ]  
Filter the definitions produced by object or profile name, the object/profile name can contain a single asterisk. The `*` option can be placed only at the end of the entered filter string.
- t  
Choose a single type of object to export. Possible values are:

Value	Description
<code>all</code>	All object types
<code>authinfo</code>	An authentication information object
<code>channel</code> or <code>chl</code>	A channel
<code>comminfo</code>	A communications information object
<code>lstr</code> or <code>listener</code>	A listener
<code>mqttchl</code>	An MQTT channel
<code>namelist</code> or <code>nl</code>	A namelist
<code>process</code> or <code>prcs</code>	A process
<code>queue</code> or <code>q</code>	A queue
<code>qmgr</code>	A queue manager
<code>svrc</code> or <code>service</code>	A service
<code>topic</code> or <code>top</code>	A topic

- o [ *mqsc* | *1line* | *2line* | *setmqaut* | *grtmqaut* | *setmqspl* ]  
Possible values are:

Value	Description
mqsc	Multi-line MQSC that can be used as direct input to <b>runmqsc</b>
1line	MQSC with all attributes on a single line for line diffing
2line	MQSC with output on two lines. The first line is an MQSC command string and the second is a commented version with immutable values.
setmqaut	setmqaut statements for UNIX and Windows queue managers; valid only when <b>-x authrec</b> is specified
grtmqaut	Linux only; generates iSeries syntax for granting access to the objects.
setmqspl	<p>The security policies for the queue manager are reported in the format of <b>setmqspl</b> command lines. This format can be used to generate scripts to restore policy configuration to a queue manager.</p> <p>Note that the <b>setmqspl</b> command lines produced by this format includes parameters (-m) that specify the queue manager from which the definition was backed up. This implies that the definitions need to be replayed against the same queue manager.</p> <p>If you need to backup policy definitions from one queue manager, and restore them to a different queue manager, consider using the default MQSC format where the queue manager name is not explicitly specified.</p>

- q** The name of the reply-to queue used when getting configuration information.
- r** The name of the remote queue manager/transmit queue when using queued mode. If this parameter is omitted the configuration for the directly connected queue manager (specified with the **-m** parameter) is dumped.
- m** The name of the queue manager to connect to. If omitted the default queue manager name is used.

#### **V 8.0.0.8** **-w** *WaitTime*

The time, in seconds, that **dmpmqcfcg** waits for replies to its commands.

Any replies received after a timeout are discarded, but the MQSC commands still run.

The check for timeout is performed once for each command reply.

Specify a time in the range 1 through 999999; the default value is 60 seconds.

Timed-out failure is indicated by:

- Nonzero return code to the calling shell or environment.
- Error message to stdout or stderr.

#### **-u** *UserId*

The ID of the user authorized to dump the configuration of queue managers.

### Authorizations

The user must have MQZAO\_OUTPUT (+put) authority to access the command input queue (SYSTEM.ADMIN.COMMAND.QUEUE) and MQZAO\_DISPLAY (+dsp) authority to access the default model queue (SYSTEM.DEFAULT.MODEL.QUEUE), to be able to create a temporary dynamic queue if using the default reply queue.

The user must also have MQZAO\_CONNECT (+connect) and MQZAO\_INQUIRE (+inq) authority for the queue manager, and MQZAO\_DISPLAY (+dsp) authority for every object that is requested.

### Return code

If a failure occurs **dmpmqcfcg** returns an error code. Otherwise, the command outputs a footer, an example of which follows:

```

*****
* Script ended on 2016-01-05 at 05.10.09
* Number of Inquiry commands issued: 14
* Number of Inquiry commands completed: 14
* Number of Inquiry responses processed: 273
* QueueManager count: 1
* Queue count: 55
* NameList count: 3
* Process count: 1
* Channel count: 10
* AuthInfo count: 4
* Listener count: 1
* Service count: 1
* CommInfo count: 1
* Topic count: 5
* Subscription count: 1
* ChlAuthRec count: 3
* Policy count: 1
* AuthRec count: 186
* Number of objects/records: 273
*****

```

## Examples

To make these examples work you need to ensure that your system is set up for remote MQSC operation. See *Preparing queue managers for remote administration* and *Preparing channels and transmission queues for remote administration*.

```
dmpmqcfcfg -m MYQMGR -c "DEFINE CHANNEL(SYSTEM.ADMIN.SVRCONN) CHLTYPE(CLNTCONN)
CONNAME('myhost.mycorp.com(1414)')"
```

dumps all the configuration information from remote queue manager *MYQMGR* in MQSC format and creates an ad-hoc client connection to the queue manager using a client channel called *SYSTEM.ADMIN.SVRCONN*.

**Note:** You need to ensure that a server-connection channel with the same name exists.

```
dmpmqcfcfg -m LOCALQM -r MYQMGR
```

dumps all configuration information from remote queue manager *MYQMGR*, in MQSC format, connects initially to local queue manager *LOCALQM*, and sends inquiry messages through this local queue manager.

**Note:** You need to ensure that the local queue manager has a transmission queue named *MYQMGR*, with channel pairings defined in both directions, to send and receive replies between queue managers.

### Related information:

Restoring queue manager configuration

### dmpmqlog:

Display and format a portion of the IBM MQ system log.

### Purpose

Use the **dmpmqlog** command to dump a formatted version of the IBM MQ system log to standard out.

The log to be dumped must have been created on the same type of operating system as that being used to issue the command.

### Syntax

## Optional parameters

### Dump start point

Use one of the following parameters to specify the log sequence number (LSN) at which the dump should start. If you omit this, dumping starts by default from the LSN of the first record in the active portion of the log.

**-b** Start dumping from the base LSN. The base LSN identifies the start of the log extent that contains the start of the active portion of the log.

**-s** *StartLSN*

Start dumping from the specified LSN. The LSN is specified in the format `nnnn:nnnn:nnnn:nnnn`.

If you are using a circular log, the LSN value must be equal to or greater than the base LSN value of the log.

**-n** *ExtentNumber*

Start dumping from the specified extent number. The extent number must be in the range 0 - 9999999.

This parameter is valid only for queue managers using linear logging.

**-e** *EndLSN*

End dumping at the specified LSN. The LSN is specified in the format `nnnn:nnnn:nnnn:nnnn`.

**-f** *LogFilePath*

The absolute (rather than relative) directory path name to the log files. The specified directory must contain the log header file (`amqh1ctl.lfh`) and a subdirectory called `active`. The `active` subdirectory must contain the log files. By default, log files are assumed to be in the directories specified in the IBM MQ configuration information. If you use this option, queue names associated with queue identifiers are shown in the dump only if you use the `-m` option to name a queue manager name that has the object catalog file in its directory path.

On a system that supports long file names this file is called `qmqmobjcat` and, to map the queue identifiers to queue names, it must be the file used when the log files were created. For example, for a queue manager named `qm1`, the object catalog file is located in the directory `..\qmgrs\qm1\qmanager\`. To achieve this mapping, you might need to create a temporary queue manager, for example named `tmpq`, replace its object catalog with the one associated with the specific log files, and then start `dmpmqlog`, specifying `-m tmpq` and `-f` with the absolute directory path name to the log files.

**-m** *QMgrName*

The name of the queue manager. If you omit this parameter, the name of the default queue manager is used.

**Note:** Do not dump the log while the queue manager is running, and do not start the queue manager while `dmpmqlog` is running.

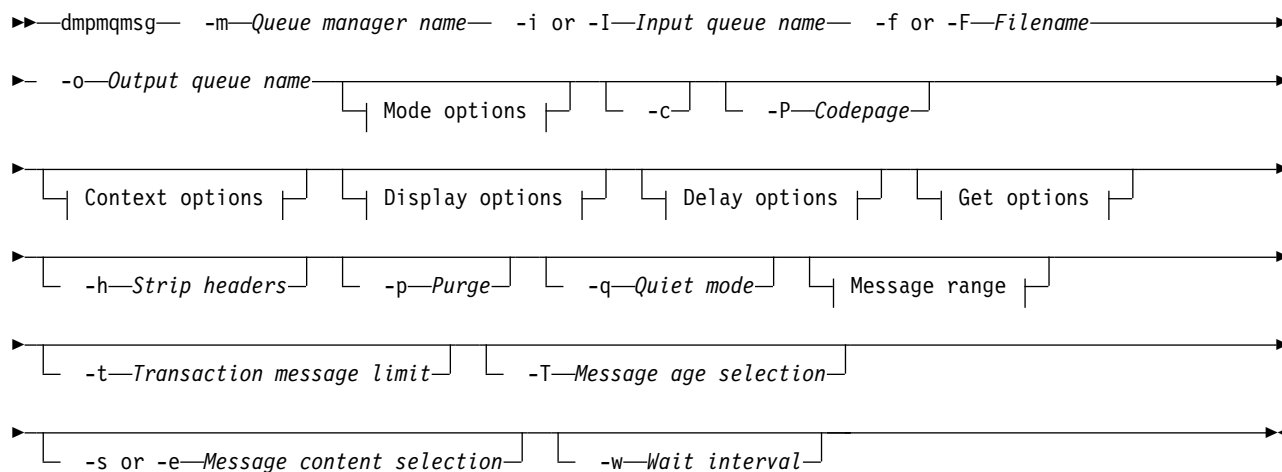

### dmpmqmsg:

Formerly the IBM MQ queue load and unload utility.

### Purpose

Use the `dmpmqmsg` utility to copy or move the contents of a queue, or its messages, to a file.

## Syntax

### Mode options:

### Context options:

### Display options:

### Delay options:

## Get options:

## Message range options:

## Required parameters

- m** *QueueManagerName*  
The name of the queue manager on which the queue, or queues, exist.
- i** or **-I** *Input queue name*  
The name of the input queue.

**Note:** Using *-i* browses the queue, whereas using *-I* gets messages from the queue.

## Optional parameters

- f** or **-F** *Filename*  
Specifies either the source or target file name.  
  
**Note:** Using *-F* on a target file forces output to a file if it already exists. The program does not ask you if the file should be overwritten.
- o** *Output queue name*  
Specifies the name of the output queue.
- a** Controls whether the file is opened in append or binary mode, by adding one of the following values to the keyword:
  - a** Append mode
  - b** Binary mode
- c** Connect in client mode.  
If you do not select this flag, the utility runs in local mode, which is the default.  
This option is not available on z/OS.
- P** Controls whether messages taken from a queue are converted.  
Use the command  
`-P <CCSID> [ : X 'Encoding' ]`  
For example `-P850:111`
- C** Controls the context option, by adding one of the following values to the keyword:
  - A** Set all context. This is the default value.
  - I** Set identity context.

- a Pass all context.
  - p Pass identity context.
- Use of the *pass* options is not applicable if the source messages are browsed on a queue.
- d Default context.
  - n No context.
- d** Controls the display option or options, by adding one or more of the following values to the keyword. For example `-dsCM`:
- a Add ASCII columns to the hexadecimal output in the file to aid readability.
  - A Write ASCII lines of data wherever possible.
  - c Output *ApplicationOriginData* and *ApplicationIdentityData* as characters
  - C Display the *Correlation Identifier* in the queue summary.
  - H Do not write the file header.
- Files created with this option are not loadable by the program as the program does not recognize the file format. However, if necessary you can use an editor to add an appropriate header manually, to make the file loadable.
- i Include the message index in the output.
  - p Printable character output format.
- This format is not codepage safe. Loading a file written in this format, while running in a new codepage does not guarantee to produce the same message.
- s Write a simple summary of the messages found on input.
  - M Display the *Message Identifier* in the queue summary.
  - N Do not write out the message descriptor content, only the message payload.
  - t text line output format.
- This format is not codepage safe. Loading a file written in this format, while running in a new codepage does not guarantee to produce the same message.
- T Display the time the message has been on the queue.
- w** *<Length>*  
Set the data width for the output.
- D** Add a delay, expressed in milliseconds, before writing a message to the output destination, by adding one of the following values to the keyword. For example.
- <positive value>**  
Add a fixed delay before putting a message. For example, `-D500` puts each message half a second apart.
- <negative value>**  
Add a random delay, up to the specified value before putting a message. For example, `-D-10000` adds a random delay of up to 10 seconds before putting a message.
- r** *<value>*  
Replays the messages at a percentage of their original put speed. For example:
- r Replays messages at their original speed.
  - r50 Replays messages at half their original speed.
  - r200 Replays messages at twice their original speed.

**-g** Filter by Message identifier, Correlation identifier, or Group identifier, by adding one of the following values to the keyword.

**c<value>**

Get by character Correlation identifier.

**m<value>**

Get by character Message identifier.

**g<value>**

Get by character Group identifier.

**xc<value>**

Get by hexadecimal Correlation identifier.

**xm<value>**

Get by hexadecimal Message identifier.

**xg<value>**

Get by hexadecimal Group identifier.

**-h** Strip headers.

Any Dead Letter Queue header (MQDLH) or Transmission Queue header (MQXQH) is removed from the message before the message is written.

**-o** Output queue name.

**-p** Causes the source queue to be purged of messages as they are copied to the target destination.

**-q** Sets quiet mode. When set, the program does not output its usual summary of activity.

**-r** Sets the applicable message range by adding one of the following values to the keyword.

**x** Only message x. For example, `-r10`.

**x..y** From message x to message y. For example, `-r 10..20`.

**x#y** Output y messages starting at message x. For example, `-r 100#10`.

**#x** Output the first x messages. For example, `-r #100`.

**-t** Set the transaction message limit. If the optional `-n` flag is not set, all the messages are done in a single transaction.

**n** The message operations are split into groups of n messages. For example `-t 1000` deals with 1000 messages in a single transaction.

**-T** Allows message selection based on message age.

See "Using message age" on page 216 for information on selection using message age.

**-s or -e**

Allows message selection based on message content.

On ASCII platforms ( Windows and UNIX and Linux ) use the `-s` option to search for a natively encoded string; on EBCDIC platforms ( z/OS ) use the `-e` option to search for a natively encoded string.

See "Using message content" on page 216 for information on selection using message content.

**-w** Wait interval, in seconds, for consuming messages. If specified the program waits for messages to arrive, for the specified period, before ending.

See Examples of using the `dmpmqmsg` utility for examples on using the utility.

### *Message selection:*

The following information describes how message selection occurs using message age and message content.

#### **Using message age**

You can choose to process only messages older than a certain time interval using the `-T` flag.

Time interval can be specified in Days, Hours and Minutes. The general format being `[days:]hours:]minutes`.

The parameter can take one or two times, `-T [OlderThanTime] [,YoungerThanTime]`.

For example:

- Display messages older than five minutes  
`dmpmqmsg -m QM1 -i Q1 -fstdout -T5`
- Display messages younger than five minutes  
`dmpmqmsg -m QM1 -i Q1 -fstdout -T,5`
- Display messages older than one day but younger than two days.  
`dmpmqmsg -m QM1 -i Q1 -fstdout -T1440,2880`
- The following command copies messages older than one hour from Q1 to Q2.  
`dmpmqmsg -m QM1 -i Q1 -o Q2 -T1:0`
- The following command moves messages older than one week from Q1 to Q2  
`dmpmqmsg -m QM1 -I Q1 -o Q2 -T7:0:0`

#### **Using message content**

You can specify a maximum of three of each search string. If multiple strings are used, they are treated as follows:

##### **Positive search strings**

When multiple positive strings are used, then all the strings must be present for the search to match. For example, the command

```
dmpmqmsg -iMATCH -s LIVERPOOL -s CHELSEA
```

only returns messages that contain both strings.

##### **Negative search strings**

When multiple negative strings are used, then none of the strings must be present for the search to match. For example, the command

```
dmpmqmsg -IMATCH -S HOME -S DRAW
```

only returns messages that contain neither string.

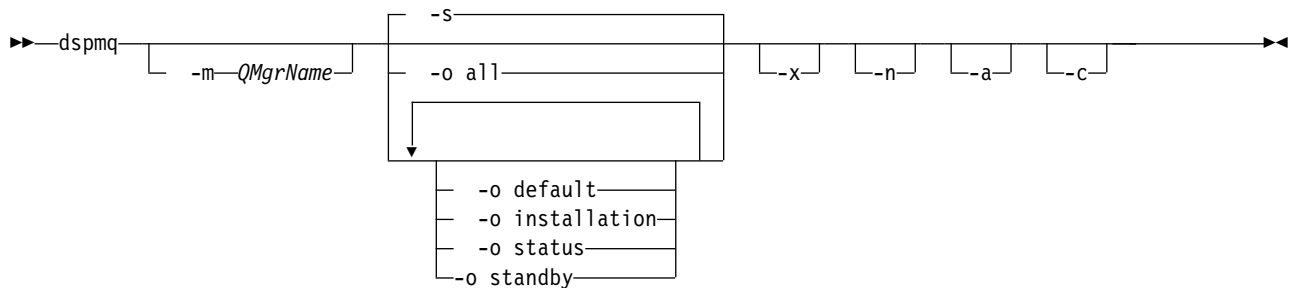

## dspmqr

Display information about queue managers.

### Purpose

Use the **dspmqr** command to display names and details of the queue managers on a system.

### Syntax

### Required parameters

None

### Optional parameters

**-a** Displays information about the active queue managers only.

A queue manager is active if it is associated with the installation from which the **dspmqr** command was issued and one or more of the following statements are true:

- The queue manager is running
- A listener for the queue manager is running
- A process is connected to the queue manager

**-m** *QMGrName*

The queue manager for which to display details. If you give no name, all queue manager names are displayed.

**-n** Suppresses translation of output strings.

**-s** The operational status of the queue managers is displayed. This parameter is the default status setting.

The parameter *-o status* is equivalent to *-s*.

**-o all**

The operational status of the queue managers is displayed, and whether any are the default queue manager.

On Windows, UNIX and Linux, the installation name (INSTNAME), installation path (INSTPATH), and installation version (INSTVER) of the installation that the queue manager is associated with is also displayed.

**-o default**

Displays whether any of the queue managers are the default queue manager.

**-o installation**

Windows, UNIX and Linux only.

Displays the installation name (INSTNAME), installation path (INSTPATH), and installation version (INSTVER) of the installation that the queue manager is associated with.

**-o status**

The operational status of the queue managers is displayed.

**-o standby**

Displays whether a queue manager currently permits starting a standby instance. The possible values are shown in Table 43.

*Table 43. Standby values*

Value	Description
Permitted	The queue manager is running and is permitting standby instances.
Not permitted	The queue manager is running and is not permitting standby instances.
Not applicable	The queue manager is not running. You can start the queue manager and this instance becomes active if it starts successfully.

**-x** Information about queue manager instances are displayed. The possible values are shown in Table 44.

*Table 44. Instance values*

Value	Description
Active	The instance is the active instance.
Standby	The instance is a standby instance.

**-c** Shows the list of processes currently connected to the IPCC, QMGR, and PERSISTENT sub pools for a queue manager.

For example, this list typically includes:

- Queue manager processes
- Applications, including those that are inhibiting shutdown
- Listeners

**Queue Manager States**

The following is a list of the different states a queue manager can be in:

*Table 45. Queue manager states.*

Queue Manager States
Starting
Running
Running as standby
Running elsewhere
Quiescing
Ending immediately
Ending pre-emptively
Ended normally
Ended immediately
Ended unexpectedly
Ended pre-emptively
Status not available

## Return codes

Return code	Description
0	Command completed normally
36	Invalid arguments supplied
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error

## Examples

1. The following command displays queue managers on this server:  
`dspmq -o all`
2. The following command displays standby information for queue managers on this server that have ended immediately:  
`dspmq -o standby`
3. The following command displays standby information and instance information for queue managers on this server:  
`dspmq -o standby -x`

## dspmqaut:

dspmqaut displays the authorizations of a specific IBM MQ object.

## Purpose

Use the **dspmqaut** command to display the current authorizations to a specified object.

If a user ID is a member of more than one group, this command displays the combined authorizations of all the groups.

Only one group or principal can be specified.

For more information about authorization service components, see Installable services, Service components, and Authorization service interface.

## Syntax

```
▶▶ dspmqaut [-m QMgrName] [-n Profile] [-t ObjectType] [-g GroupName] [-p PrincipalName]
▶ [-s ServiceComponent]
```

## Required parameters

### -n Profile

The name of the profile for which to display authorizations. The authorizations apply to all IBM MQ objects with names that match the profile name specified.

This parameter is required, unless you are displaying the authorizations of a queue manager. In this case you must not include it and instead specify the queue manager name using the `-m` parameter.

### -t ObjectType

The type of object on which to make the inquiry. Possible values are:

Table 46. The object type on which to make the inquiry.

Object Type	Description
<b>authinfo</b>	An authentication information object, for use with Secure Sockets Layer (SSL) channel security
<b>channel</b> or <b>chl</b>	A channel
<b>clntconn</b> or <b>clcn</b>	A client connection channel
<b>listener</b> or <b>lstr</b>	A Listener
<b>namelist</b> or <b>nl</b>	A namelist
<b>process</b> or <b>prcs</b>	A process
<b>queue</b> or <b>q</b>	A queue or queues matching the object name parameter
<b>qmgr</b>	A queue manager
<b>rqmname</b> or <b>rqmn</b>	A remote queue manager name
<b>service</b> or <b>srvc</b>	A service
<b>topic</b> or <b>top</b>	A topic

### Optional parameters

**-m** *QMgrName*

The name of the queue manager on which to make the inquiry. This parameter is optional if you are displaying the authorizations of your default queue manager.

**-g** *GroupName*

The name of the user group on which to make the inquiry. You can specify only one name, which must be the name of an existing user group.

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

**-p** *PrincipalName*

The name of a user for whom to display authorizations to the specified object.

For IBM MQ for Windows only, the name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see Principals and groups.

**-s** *ServiceComponent*

If installable authorization services are supported, specifies the name of the authorization service to which the authorizations apply. This parameter is optional; if you omit it, the authorization inquiry is made to the first installable component for the service.

### Returned parameters

Returns an authorization list, which can contain none, one, or more authorization values. Each authorization value returned means that any user ID in the specified group or principal has the authority to perform the operation defined by that value.

Table 47 on page 221 shows the authorities that can be given to the different object types.

Table 47. Specifying authorities for different object types

Authority	Queue	Process	Queue manager	Remote queue manager name	Namelist	Topic	Auth info	Clntconn	Channel	Listener	Service
all	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
alladm	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
allmqi	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No	No	No	No
none	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
altusr	No	No	Yes	No	No	No	No	No	No	No	No
browse	Yes	No	No	No	No	No	No	No	No	No	No
chg	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
clr	Yes	No	No	No	No	Yes	No	No	No	No	No
connect	No	No	Yes	No	No	No	No	No	No	No	No
crt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
ctrl	No	No	No	No	No	Yes	No	No	Yes	Yes	Yes
ctrlx	No	No	No	No	No	No	No	No	Yes	No	No
dlt	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
dsp	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
get	Yes	No	No	No	No	No	No	No	No	No	No
pub	No	No	No	No	No	Yes	No	No	No	No	No
put	Yes	No	No	Yes	No	Yes	No	No	No	No	No
inq	Yes	Yes	Yes	No	Yes	No	Yes	No	No	No	No
passall	Yes	No	No	No	No	Yes	No	No	No	No	No
passid	Yes	No	No	No	No	Yes	No	No	No	No	No
resume	No	No	No	No	No	Yes	No	No	No	No	No
set	Yes	Yes	Yes	No	No	No	No	No	No	No	No
setall	Yes	No	Yes	No	No	Yes	No	No	No	No	No
setid	Yes	No	Yes	No	No	Yes	No	No	No	No	No
sub	No	No	No	No	No	Yes	No	No	No	No	No
system	No	No	Yes	No	No	No	No	No	No	No	No

The following list defines the authorizations associated with each value:

Table 48. Authorizations associated with each value.

Value	Description
all	Use all operations relevant to the object. all authority is equivalent to the union of the authorities alladm, allmqi, and system appropriate to the object type.
alladm	Perform all administration operations relevant to the object
allmqi	Use all MQI calls relevant to the object
altusr	Specify an alternative user ID on an MQI call
browse	Retrieve a message from a queue by issuing an MQGET call with the BROWSE option

Table 48. Authorizations associated with each value. (continued)

Value	Description
chg	Change the attributes of the specified object, using the appropriate command set
clr	Clear a queue (PCF command Clear queue only) or a topic
ctrl	Start, and stop the specified channel, listener, or service, and ping the specified channel.
ctrlx	Reset or resolve the specified channel
connect	Connect the application to the specified queue manager by issuing an <b>MQCONN</b> call
crt	Create objects of the specified type using the appropriate command set
dlt	Delete the specified object using the appropriate command set
dsp	Display the attributes of the specified object using the appropriate command set
get	Retrieve a message from a queue by issuing an <b>MQGET</b> call
inq	Make an inquiry on a specific queue by issuing an <b>MQINQ</b> call
passall	Pass all context
passid	Pass the identity context
pub	Publish a message on a topic using the <b>MQPUT</b> call.
put	Put a message on a specific queue by issuing an <b>MQPUT</b> call
resume	Resume a subscription using the <b>MQSUB</b> call.
set	Set attributes on a queue from the MQI by issuing an <b>MQSET</b> call
setall	Set all context
setid	Set the identity context
sub	Create, alter, or resume a subscription to a topic using the <b>MQSUB</b> call.
system	Use queue manager for internal system operations

The authorizations for administration operations, where supported, apply to these command sets:

- Control commands
- MQSC commands
- PCF commands

#### Return codes

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
133	Unknown object name
145	Unexpected object name
146	Object name missing
147	Object type missing
148	Invalid object type
149	Entity name missing

### Examples

- The following example shows a command to display the authorizations on queue manager saturn.queue.manager associated with user group staff:

```
dspmqaout -m saturn.queue.manager -t qmgr -g staff
```

The results from this command are:

Entity staff has the following authorizations for object:

```
get
browse
put
inq
set
connect
altusr
passid
passall
setid
```

- The following example displays the authorities user1 has for queue a.b.c:

```
dspmqaout -m qmgr1 -n a.b.c -t q -p user1
```

The results from this command are:

Entity user1 has the following authorizations for object:

```
get
put
```

### dspmqcsv:

The status of a command server is displayed

### Purpose

Use the **dspmqcsv** command to display the status of the command server for the specified queue manager.

The status can be one of the following:

- Starting
- Running
- Running with SYSTEM.ADMIN.COMMAND.QUEUE not enabled for gets
- Ending
- Stopped

You must use the **dspmqcsv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmqr -o` installation command.

## Syntax

```
▶▶ dspmqcsv QMGrName ▶▶
```

## Required parameters

None

## Optional parameters

*QMGrName*

The name of the local queue manager for which the command server status is being requested.

## Return codes

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

## Examples

The following command displays the status of the command server associated with `venus.q.mgr`:

```
dspmqcsv venus.q.mgr
```

## Related commands

Command	Description
<code>strmqcsv</code>	Start a command server
<code>endmqcsv</code>	End a command server

## dspmqrfls:

Display the file names corresponding to IBM MQ objects.

## Purpose

Use the **dspmqrfls** command to display the real file system name for all IBM MQ objects that match a specified criterion. You can use this command to identify the files associated with a particular object. This command is useful for backing up specific objects. See [Understanding IBM MQ file names for information about name transformation](#).

## Syntax

```

▶▶ dspmqls [-m QMgrName] [-t ObjType] GenericObjName ▶▶

```

## Required parameters

### *GenericObjName*

The name of the object. The name is a string with no flag and is a required parameter. Omitting the name returns an error.

This parameter supports an asterisk (\*) as a wildcard at the end of the string.

## Optional parameters

### **-m** *QMGrName*

The name of the queue manager for which to examine files. If you omit this name, the command operates on the default queue manager.

### **-t** *ObjType*

The object type. The following list shows the valid object types. The abbreviated name is shown first followed by the full name.

Table 49. Valid object types.

Object Type	Description
* or all	All object types; this parameter is the default
authinfo	Authentication information object, for use with Secure Sockets Layer (SSL) channel security
channel or chl	A channel
clntconn or clcn	A client connection channel
catalog or ctlg	An object catalog
namelist or nl	A namelist
listener or lstr	A listener
process or prcs	A process
queue or q	A queue or queues matching the object name parameter
qalias or qa	An alias queue
qlocal or ql	A local queue
qmodel or qm	A model queue
qremote or qr	A remote queue
qmgr	A queue manager object
service or srvc	A service

## Note:

1. The **dspmqls** command displays the name of the directory containing the queue, *not* the name of the queue itself.
2. In IBM MQ for UNIX systems, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (\*). The way you do this depends on the shell you are using. It may involve the use of single quotation marks, double quotation marks, or a backslash.

## Return codes

Return code	Description
0	Command completed normally
10	Command completed but not entirely as expected
20	An error occurred during processing

## Examples

- The following command displays the details of all objects with names beginning SYSTEM.ADMIN defined on the default queue manager.  

```
dspmqls SYSTEM.ADMIN*
```
- The following command displays file details for all processes with names beginning PROC defined on queue manager RADIUS.  

```
dspmqls -m RADIUS -t prcs PROC*
```

## dspmqlf:

Display IBM MQ configuration information ( Windows and UNIX platforms only).

## Purpose

Use the **dspmqlf** command to display IBM MQ configuration information.

## Syntax

## Required parameters

### *StanzaName*

The name of the stanza. That is, the value of the key attribute that distinguishes between multiple stanzas of the same type.

## Optional parameters

### **-s** *StanzaType*

The type of stanza to display. If omitted, the QueueManager stanza is displayed.

The only supported value of *StanzaType* is QueueManager.

### **-o stanza**

Displays the configuration information in stanza format as it is shown in the .ini files. This format is the default output format.

Use this format to display stanza information in a format that is easy to read.

### **-o command**

Displays the configuration information as an **addmqinf** command.

Information about the installation associated with the queue manager is not displayed using this parameter. The **addmqinf** command does not require information about the installation.

Use this format to paste into a command shell.

## Return codes

Return code	Description
0	Successful operation
39	Bad command-line parameters
44	Stanza does not exist
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error

## Examples

```
dspmqlnf QM.NAME
```

The command defaults to searching for a QueueManager stanza named QM.NAME and displays it in stanza format.

```
QueueManager:
  Name=QM.NAME
  Prefix=/var/mqm
  Directory=QM!NAME
  DataPath=/MQHA/qmgrs/QM!NAME
  InstallationName=Installation1
```

The following command gives the same result:

```
dspmqlnf -s QueueManager -o stanza QM.NAME
```

The next example displays the output in **addmqinf** format.

```
dspmqlnf -o command QM.NAME
```

The output is on one line:

```
addmqinf -s QueueManager -v Name=QM.NAME -v Prefix=/var/mqm -v Directory=QM!NAME
-v DataPath=/MQHA/qmgrs/QM!NAME
```

## Usage notes

Use **dspmqlnf** with **addmqinf** to create an instance of a multi-instance queue manager on a different server.

To use this command you must be an IBM MQ administrator and a member of the `mqm` group.

## Related commands

Command	Description
"addmqinf" on page 180	Add queue manager configuration information
"rmvmqlnf" on page 259	Remove queue manager configuration information

## dspmqlnst:

Display installation entries from `mqinst.ini` on UNIX, Linux, and Windows.

## Purpose

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see Installation configuration file, `mqinst.ini`.

## Syntax

### Notes:

- 1 When specified together, the installation name and installation path must refer to the same installation.

### Required parameters

None

### Optional parameters

- `-n InstallationName`  
The name of the installation.
- `-p InstallationPath`  
The installation path.
- `?` Display usage information.

### Return codes

Return code	Description
0	Entry displayed without error
36	Invalid arguments supplied
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	.ini file error
96	Could not lock .ini file
131	Resource problem

### Examples

1. Display details of all IBM MQ installations on the system:  
`dspmqinst`
2. Query the entry for the installation named *Installation3*:  
`dspmqinst -n Installation3`
3. Query the entry with an installation path of */opt/mqm*:  
`dspmqinst -p /opt/mqm`
4. Query the entry for the installation named *Installation3*. Its expected installation path is */opt/mqm*:  
`dspmqinst -n Installation3 -p /opt/mqm`

### dspmqrte:

Determine the route that a message has taken through a queue manager network.

## Purpose

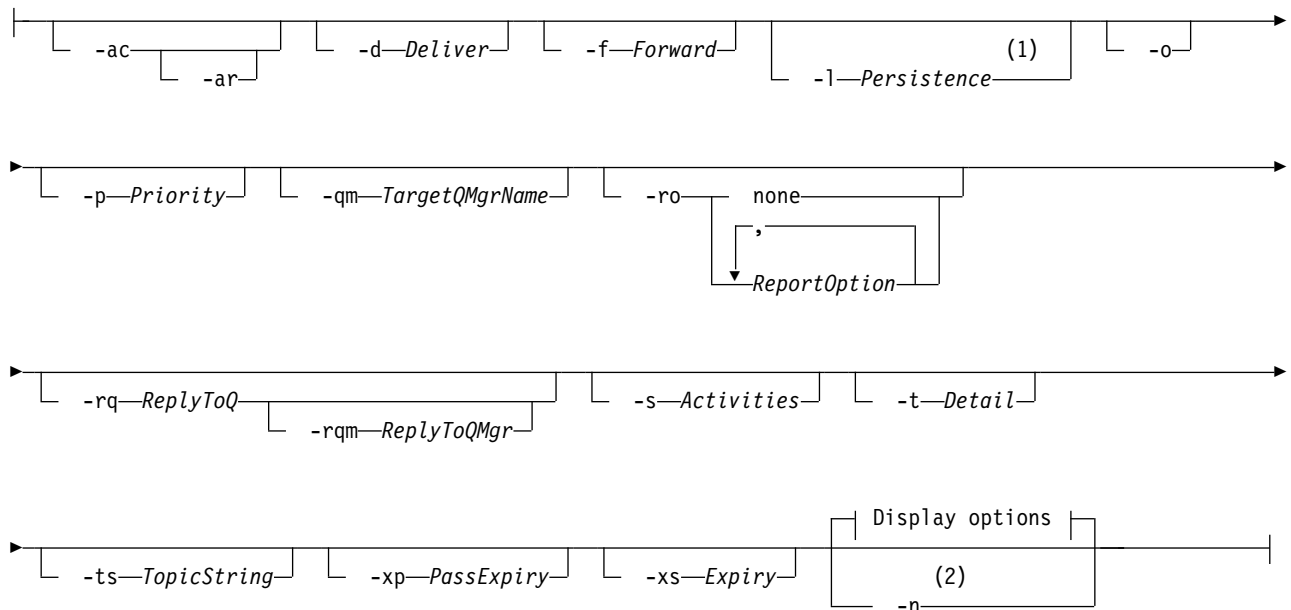

**z/OS** The IBM MQ display route application (dspmqrte) can be run on all platforms except z/OS. You can run the IBM MQ display route application as a client to an IBM MQ for z/OS queue manager by specifying the `-c` parameter when issuing the `dspmqrte` command.

The IBM MQ display route application generates and puts a trace-route message into a queue manager network. As the trace-route message travels through the queue manager network, activity information is recorded. When the trace-route message reaches its target queue, the activity information is collected by the IBM MQ display route application and displayed. For more information, and examples of using the IBM MQ display route application, see [IBM MQ display route application](#).

## Syntax

### Generation options:

### Display options:

## Notes:

- 1 If *Persistence* is specified as *yes*, and is accompanied by a request for a trace-route reply message ( *-ar* ), or any report generating options ( *-ro ReportOption* ), then you must specify the parameter *-rq ReplyToQ*. The reply-to queue must not resolve to a temporary dynamic queue.
- 2 If this parameter is accompanied by a request for a trace-route reply message ( *-ar* ), or any of the report generating options ( *-ro ReportOption* ), then a specific (non-model) reply-to queue must be specified using *-rq ReplyToQ*. By default, activity report messages are requested.

## Required parameters

### **-q** *TargetQName*

If the IBM MQ display route application is being used to send a trace-route message into a queue manager network, *TargetQName* specifies the name of the target queue.

If the IBM MQ display route application is being used to view previously gathered activity information, *TargetQName* specifies the name of the queue where the activity information is stored.

## Optional parameters

- c** Specifies that the IBM MQ display route application connects as a client application. For more information about how to set up client machines, see *Installing an IBM MQ client*.

This parameter can be used only if the client component is installed.

### **-i** *CorrelId*

This parameter is used when the IBM MQ display route application is used to display previously accumulated activity information only. There can be many activity reports and trace-route reply messages on the queue specified by *-q TargetQName*. *CorrelId* is used to identify the activity reports, or a trace-route reply message, related to a trace-route message. Specify the message identifier of the original trace-route message in *CorrelId*.

The format of *CorrelId* is a 48 character hexadecimal string.

### **-m** *QMgrName*

The name of the queue manager to which the IBM MQ display route application connects. The name can contain up to 48 characters.

If you do not specify this parameter, the default queue manager is used.

## Generation options

**The following parameters are used when the IBM MQ display route application is used to put a trace-route message into a queue manager network.**

### **-ac**

Specifies that activity information is to be accumulated within the trace-route message.

If you do not specify this parameter, activity information is not accumulated within the trace-route message.

### **-ar**

Requests that a trace-route reply message containing all accumulated activity information is generated in the following circumstances:

- The trace-route message is discarded by a IBM WebSphere MQ Version 7.0 queue manager.
- The trace-route message is put to a local queue (target queue or dead-letter queue) by a IBM WebSphere MQ Version 7.0 queue manager.
- The number of activities performed on the trace-route message exceeds the value of specified in *-s Activities*.

For more information about trace-route reply messages, see *Trace-route reply message reference*.

If you do not specify this parameter, a trace-route reply message is not requested.

**-d Deliver**

Specifies whether the trace-route message is to be delivered to the target queue on arrival. Possible values for *Deliver* are:

Table 50. Delivery parameter values.

Value	Description
yes	On arrival, the trace-route message is put to the target queue, even if the queue manager does not support trace-route messaging.
no	On arrival, the trace-route message is <b>not</b> put to the target queue.

If you do not specify this parameter, the trace-route message is **not** put to the target queue.

**-f Forward**

Specifies the type of queue manager that the trace-route message can be forwarded to. Queue managers use an algorithm when determining whether to forward a message to a remote queue manager. For details of this algorithm, see The cluster workload management algorithm. The possible values for *Forward* are:

Table 51. Forward parameter values.

Value	Description
all	The trace-route message is forwarded to any queue manager. <b>Warning:</b> If forwarded to an IBM MQ queue manager before Version 6.0, the trace-route message is not recognized and can be delivered to a local queue despite the value of the <i>-d Deliver</i> parameter.
supported	The trace-route message is only forwarded to a queue manager that honors the <i>Deliver</i> parameter from the <i>TraceRoute</i> PCF group.

If you do not specify this parameter, the trace-route message is only forwarded to a queue manager that honors the *Deliver* parameter.

**-l Persistence**

Specifies the persistence of the generated trace-route message. Possible values for *Persistence* are:

Table 52. Persistence parameter values.

Value	Description
yes	The generated trace-route message is persistent. (MQPER_PERSISTENT).
no	The generated trace-route message is not persistent. (MQPER_NOT_PERSISTENT).
q	The generated trace-route message inherits its persistence value from the queue specified by <i>-q TargetQName</i> . (MQPER_PERSISTENCE_AS_Q_DEF).

A trace-route reply message, or any report messages, returned shares the same persistence value as the original trace-route message.

If *Persistence* is specified as **yes**, you must specify the parameter *-rq ReplyToQ*. The reply-to queue must not resolve to a temporary dynamic queue.

If you do not specify this parameter, the generated trace-route message is not persistent.

- o Specifies that the target queue is not bound to a specific destination. Typically this parameter is used when the trace-route message is to be put across a cluster. The target queue is opened with option MQOO\_BIND\_NOT\_FIXED.

If you do not specify this parameter, the target queue is bound to a specific destination.

**-p Priority**

Specifies the priority of the trace-route message. The value of *Priority* is either greater than or equal to 0, or MQPRI\_PRIORITY\_AS\_Q\_DEF. MQPRI\_PRIORITY\_AS\_Q\_DEF specifies that the priority value is taken from the queue specified by -q *TargetQName*.

If you do not specify this parameter, the priority value is taken from the queue specified by -q *TargetQName*.

**-qmq TargetQMgrName**

Qualifies the target queue name; normal queue manager name resolution applies. The target queue is specified with -q *TargetQName* .

If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the reply-to queue manager.

**-ro none | ReportOption**

Table 53. ReportOption parameter values.

Value	Description
<b>none</b>	Specifies no report options are set.
<b>ReportOption</b>	<p>Specifies report options for the trace-route message. Multiple report options can be specified using a comma as a separator. Possible values for <i>ReportOption</i> are:</p> <p><b>activity</b> The report option MQRO_ACTIVITY is set.</p> <p><b>coa</b> The report option MQRO_COA_WITH_FULL_DATA is set.</p> <p><b>cod</b> The report option MQRO_COD_WITH_FULL_DATA is set.</p> <p><b>exception</b> The report option MQRO_EXCEPTION_WITH_FULL_DATA is set.</p> <p><b>expiration</b> The report option MQRO_EXPIRATION_WITH_FULL_DATA is set.</p> <p><b>discard</b> The report option MQRO_DISCARD_MSG is set.</p>

If -ro *ReportOption* or -ro *none* are not specified, then the MQRO\_ACTIVITY and MQRO\_DISCARD\_MSG report options are specified.

**-rq ReplyToQ**

Specifies the name of the reply-to queue that all responses to the trace-route message are sent to. If the trace-route message is persistent, or if the -n parameter is specified, a reply-to queue must be specified that is not a temporary dynamic queue.

If you do not specify this parameter, the system default model queue, SYSTEM.DEFAULT.MODEL.QUEUE is used as the reply-to queue. Using this model queue causes a temporary dynamic queue, for the IBM MQ display route application, to be created.

**-rqm ReplyToQMgr**

Specifies the name of the queue manager where the reply-to queue is located. The name can contain up to 48 characters.

If you do not specify this parameter, the queue manager to which the IBM MQ display route application is connected is used as the reply-to queue manager.

**-s Activities**

Specifies the maximum number of recorded activities that can be performed on behalf of the trace-route message before it is discarded. This parameter prevents the trace-route message from being forwarded indefinitely if caught in an infinite loop. The value of *Activities* is either greater than or equal to 1, or MQROUTE\_UNLIMITED\_ACTIVITIES. MQROUTE\_UNLIMITED\_ACTIVITIES specifies that an unlimited number of activities can be performed on behalf of the trace-route message.

If you do not specify this parameter, an unlimited number of activities can be performed on behalf of the trace-route message.

**-t Detail**

Specifies the activities that are recorded. The possible values for *Detail* are:

Table 54. Detail parameter values.

Value	Description
low	Activities performed by user-defined application are recorded only.
medium	Activities specified in <b>low</b> are recorded. Additionally, activities performed by MCAs are recorded.
high	Activities specified in <b>low</b> , and <b>medium</b> are recorded. MCAs do not expose any further activity information at this level of detail. This option is available to user-defined applications that are to expose further activity information only. For example, if a user-defined application determines the route a message takes by considering certain message characteristics, the routing logic can be included with this level of detail.

If you do not specify this parameter, medium level activities are recorded.

**-ts TopicString**

Specifies a topic string to which the IBM MQ display route application is to publish a trace-route message, and puts this application into topic mode. In this mode, the application traces all of the messages that result from the publish request.

**-xp PassExpiry**

Specifies whether the report option MQRO\_DISCARD\_MSG and the remaining expiry time from the trace-route message is passed on to the trace-route reply message. Possible values for *PassExpiry* are:

Table 55. PassExpiry parameter values.

Value	Description
yes	The report option MQRO_PASS_DISCARD_AND_EXPIRY is specified in the message descriptor of the trace-route message.  If a trace-route reply message, or activity reports, are generated for the trace-route message, the MQRO_DISCARD_MSG report option (if specified), and the remaining expiry time are passed on.  This parameter is the default value.

Table 55. PassExpiry parameter values. (continued)

Value	Description
no	The report option MQRO_PASS_DISCARD_AND_EXPIRY is <b>not</b> specified.  If a trace-route reply message is generated for the trace-route message, the discard option and remaining expiry time from the trace-route message are <b>not</b> passed on.

If you do not specify this parameter, the MQRO\_PASS\_DISCARD\_AND\_EXPIRY report option is not specified in the trace-route message.

**-xs Expiry**

Specifies the expiry time for the trace-route message, in seconds.

If you do not specify this parameter, the expiry time is specified as 60 seconds.

**-n** Specifies that activity information returned for the trace-route message is not to be displayed.

If this parameter is accompanied by a request for a trace-route reply message ( *-ar* ), or any of the report generating options from ( *-ro ReportOption* ), then a specific (non-model) reply-to queue must be specified using *-rq ReplyToQ* . By default, activity report messages are requested.

After the trace-route message is put to the specified target queue, a 48 character hexadecimal string is returned containing the message identifier of the trace-route message. The message identifier can be used by the IBM MQ display route application to display the activity information for the trace-route message at a later time. This can be done using the *-i CorrelId* parameter.

If you do not specify this parameter, activity information returned for the trace-route message is displayed in the form specified by the *-v* parameter.

**Display options**

The following parameters are used when the IBM MQ display route application is used to display collected activity information.

**-b** Specifies that the IBM MQ display route application only browses activity reports or a trace-route reply message related to a message. This parameter allows activity information to be displayed again at a later time.

If you do not specify this parameter, the IBM MQ display route application gets activity reports and deletes them, or a trace-route reply message related to a message.

**-v summary | all | none | outline** *DisplayOption*

Table 56. DisplayOption parameter values.

Value	Description
summary	The queues that the trace-route message was routed through are displayed.
all	All available information is displayed.
none	No information is displayed.

Table 56. *DisplayOption* parameter values. (continued)

Value	Description
<b>outline <i>DisplayOption</i></b>	<p>Specifies display options for the trace-route message. Multiple display options can be specified using a comma as a separator.</p> <p>If no values are supplied the subsequent information is displayed:</p> <ul style="list-style-type: none"> <li>• The application name</li> <li>• The type of each operation</li> <li>• Any operation-specific parameters</li> </ul> <p>Possible values for <i>DisplayOption</i> are:</p> <p><b>activity</b> All non-PCF group parameters in <i>Activity</i> PCF groups are displayed.</p> <p><b>identifiers</b> Values with parameter identifiers MQBACF_MSG_ID or MQBACF_CORREL_ID are displayed. This overrides <i>msgdelta</i>.</p> <p><b>message</b> All non-PCF group parameters in <i>Message</i> PCF groups are displayed. When this value is specified, you cannot specify <i>msgdelta</i>.</p> <p><b>msgdelta</b> All non-PCF group parameters in <i>Message</i> PCF groups, that have changed since the last operation, are displayed. When this value is specified, you cannot specify <i>message</i>.</p> <p><b>operation</b> All non-PCF group parameters in <i>Operation</i> PCF groups are displayed.</p> <p><b>traceroute</b> All non-PCF group parameters in <i>TraceRoute</i> PCF groups are displayed.</p>

If you do not specify this parameter, a summary of the message route is displayed.

**-w *WaitTime***

Specifies the time, in seconds, that the IBM MQ display route application waits for activity reports, or a trace-route reply message, to return to the specified reply-to queue.

If you do not specify this parameter, the wait time is specified as the expiry time of the trace-route message, plus 60 seconds.

**-u *UserId***

The ID of the user authorized to determine the route that a message has taken through a queue manager network.

**Return codes**

Return code	Description
0	Command completed normally
10	Invalid arguments supplied
20	An error occurred during processing

## Examples

1. The following command puts a trace-route message into a queue manager network with the target queue specified as TARGET.Q. Providing queue managers on route are enabled for activity recording, activity reports are generated. Depending on the queue manager attribute, ACTIVREC, activity reports are either delivered to the reply-to queue ACT.REPORT.REPLY.Q, or are delivered to a system queue. The trace-route message is discarded on arrival at the target queue.

```
dspmqrtc -q TARGET.Q -rq ACT.REPORT.REPLY.Q
```

Providing one or more activity reports are delivered to the reply-to queue, ACT.REPORT.REPLY.Q, the IBM MQ display route application orders and displays the activity information.

2. The following command puts a trace-route message into a queue manager network with the target queue specified as TARGET.Q. Activity information is accumulated within the trace-route message, but activity reports are not generated. On arrival at the target queue, the trace-route message is discarded. Depending on the value of the target queue manager attribute, ROUTEREC, a trace-route reply message can be generated and delivered to either the reply-to queue, TRR.REPLY.TO.Q, or to a system queue.

```
dspmqrtc -ac -ar -ro discard -rq TRR.REPLY.TO.Q -q TARGET.Q
```

Providing a trace-route reply message is generated, and delivered to the reply-to queue TRR.REPLY.TO.Q, the IBM MQ display route application orders and displays the activity information that was accumulated in the trace-route message.

For more examples of using the IBM MQ display route application and its output, see IBM MQ display route application examples.

## dspmqspl:

Use the **dspmqspl** command to display a list of all policies and details of a named policy.

### Syntax

```

▶▶ dspmqspl --m QMgrName [ -p PolicyName ] [ -export ]

```

Table 57. dspmqspl command flags.

Command flag	Explanation
-m	Queue manager name ( <b>mandatory</b> ).
-p	Policy name.
-export	Adding this flag generates output which can easily be applied to a different queue manager.

## dspmqtrc:

Format and display IBM MQ trace.

## Purpose

The **dspmqrtrc** command is supported on UNIX and HP Integrity NonStop Server systems only. Use the **dspmqrtrc** command to display IBM MQ formatted trace output.

The runtime SSL trace files have the names AMQ.SSL.TRC and AMQ.SSL.TRC.1. You cannot format any of the SSL trace files. The SSL trace files are binary files and, if they are transferred to IBM support by FTP, they must be transferred in binary transfer mode.

## Syntax

```
►► dspmqrtrc [ -t FormatTemplate ] [ -h ] [ -s ] [ -o OutputFilename ] InputFileName ►►
```

## Required parameters

### *InputFileName*

The name of the file containing the unformatted trace, for example:

```
/var/mqm/trace/AMQ12345.01.TRC
```

If you provide one input file, **dspmqrtrc** formats it to the output file you name. If you provide more than one input file, any output file you name is ignored, and formatted files are named AMQ *yyyyy*. *zz*.FMT, based on the PID of the trace file.

## Optional parameters

### **-t** *FormatTemplate*

The name of the template file containing details of how to display the trace. If this parameter is not supplied, the default template file location is used:

For AIX systems, the default value is as follows:

```
MQ_INSTALLATION_PATH/lib/amqtrc2.fmt
```

For all HP Integrity NonStop Server, and UNIX systems other than AIX systems, the default value is as follows:

```
MQ_INSTALLATION_PATH/lib/amqtrc.fmt
```

*MQ\_INSTALLATION\_PATH* represents the high-level directory in which IBM MQ is installed.

**-h** Omit header information from the report.

**-s** Extract trace header and put to stdout.

### **-o** *output\_filename*

The name of the file into which to write formatted data.

## Related commands

Command	Description
endmqtrc	End trace
"strmqtrc" on page 307	Start trace

## **dspmqrtrn:**

Display in-doubt and heuristically completed transactions.

## Purpose

Use the **dspmqrn** command to display details of transactions. This command includes transactions coordinated by IBM MQ and by an external transaction manager.

## Syntax

```
▶▶ dspmqrn [-e] [-h] [-i] [-a] [-q] [-m QMgrName] ▶▶
```

## Optional parameters

- e** Requests details of externally coordinated, in-doubt transactions. Such transactions are those for which IBM MQ has been asked to prepare to commit, but has not yet been informed of the transaction outcome.
- h** Requests details of externally coordinated transactions that were resolved by the `rsvmqtrn` command, and the external transaction coordinator has yet to acknowledge with an `xa-forget` command. This transaction state is termed *heuristically completed* by X/Open.

**Note:** If you do not specify `-e`, `-h`, or `-i`, details of both internally and externally coordinated in-doubt transactions are displayed, but details of externally coordinated, heuristically completed transactions are not displayed.

- i** Requests details of internally coordinated, in-doubt transactions. Such transactions are those for which each resource manager has been asked to prepare to commit, but IBM MQ has yet to inform the resource managers of the transaction outcome.

Information about the state of the transaction in each of its participating resource managers is displayed. This information can help you assess the affects of failure in a particular resource manager.

**Note:** If you do not specify `-e` or `-i`, details of both internally and externally coordinated in-doubt transactions are displayed.

- a** Requests a list of all transactions known to the queue manager . The returned data includes transaction details for all transactions known to the queue manager. If a transaction is currently associated with an IBM MQ application connection, information related to that IBM MQ application connection is also returned. The data returned by this command might typically be correlated with the output of a `runmqsc "DISPLAY CONN"` on page 800 command, and the output fields have the same meaning as in that command.

Not all of the fields are appropriate for all transactions. When the fields are not meaningful, they are displayed as blank. For example: The `UOWLOG` value when the command is issued against a circular logging queue manager.

- q** Specifying this parameter on its own is the same as specifying `-a -q`.

Displays all the data from the `-a` parameter and a list of up to 100 unique objects updated within the transaction. If more than 100 objects are updated in the same transaction, only the first 100 distinct objects are listed for each transaction.

### **-m QMgrName**

The name of the queue manager for which to display transactions. If you omit the name, the transaction of the default queue manager are displayed.

## Return codes

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
102	No transactions found

## Related commands

Command	Description
rsvmqtrn	Resolve transaction

## dspmqver:

Display IBM MQ version and build information.

## Purpose

Use the **dspmqver** command to display IBM MQ version and build information.

By default, the **dspmqver** command displays details of the installation from which it was invoked. A note is displayed if other installations exist; use the **-i** parameter to display their details.

## Syntax

```

▶▶ dspmqver [-a] [-p components] [-f fields] [-b] [-v] [-i]

```

## Optional parameters

**-a** Display information about all fields and components.

**-p** *Components*

Display information for the components specified by *component*. Either a single component or multiple components can be specified. Enter either the value of a single component or the sum of the values of all the required components. Available components and related values follow:

Value	Description
1	IBM MQ server, or client.
2	IBM MQ classes for Java.
4	IBM MQ classes for Java Message Service.
8	WebScale Distribution Hub
16 <sup>1</sup>	IBM MQ custom channel for Windows Communication Foundation
32	IBM Message Service Client for .NET (XMS .NET) - this component is only available on Windows

Value	Description
64	GSKit , or for HP Integrity NonStop Server, SSL
128	IBM MQ Advanced Message Security
V 8.0.0.4 256	IBM MQ AMQP Service
512	IBM MQ Telemetry Service

**Notes:**

1. Supported by IBM MQ for Windows only. If you have not installed Microsoft.NET 3 or later, the following error message is displayed:

Title: WMQWCFCustomChannelLevel.exe - Application Error The application failed to initialize properly (0x0000135).

The default value is 1.

**-f Fields**

Display information for the fields specified by *field*. Specify either a single field or multiple fields. Enter either the value of a single field or the sum of the values of all the required fields. Available fields and related values follow:

Value	Description
1	Name
2	Version, in the form V.R.M.F: Where V =Version, R =Release, M =Modification, and F =Fix pack
4	Level
8	Build type
16	Platform
32	Addressing mode
64	Operating system
128	Installation path
256 <sup>1</sup>	Installation description
512 <sup>1</sup>	Installation name
1024 <sup>1</sup>	Maximum command level
2048 <sup>1</sup>	Primary installation
4096	Data Path
8192	License type

**Note:**

1. Not applicable to HP Integrity NonStop Server.

Information for each selected field is displayed on a separate line when the dspmqver command is run.

The default value is 8191. This displays information for all fields.

- b Omit header information from the report.
- v Display verbose output.
- i Display information about all installations. You cannot use this option with other options. The installation from which the dspmqver command was issued is displayed first. For any other

installations, only the following fields are displayed: Name, Version, Installation name, Installation description, Installation path, and Primary installation. Not applicable to HP Integrity NonStop Server.

## Return codes

Return code	Description
0	Command completed normally.
10	Command completed with unexpected results.
20	An error occurred during processing.

## Examples

The following command displays IBM MQ version and build information, using the default settings for **-p** and **-f**:

```
dspmqr
```

The following command displays information about all fields and components and is the equivalent of specifying `dspmqr -p 63 -f 4095`:

```
dspmqr -a
```

The following command displays version and build information for the IBM MQ classes for Java:

```
dspmqr -p 2
```

The following command displays the Common Services for Java Platform Standard Edition, IBM MQ, Java Message Service Client, and IBM MQ classes for Java Message Service:

```
dspmqr -p 4
```

The following command displays the build level of the WebScale Distribution Hub:

```
dspmqr -p 8 -f 4
```

The following command displays the name and build type for IBM MQ custom channel for Windows Communication Foundation:

```
dspmqr -p 16 -f 9
```

The following command displays information about installations of IBM MQ.

```
dspmqr -i
```

## Command Failure

The **dspmqr** command can fail if you try to view version or build information for the IBM MQ classes for Java, and you have not correctly configured your environment. For example, you might see the following message:

```
[root@blade883 ~]# dspmqr -p2  
AMQ8351: IBM MQ Java environment has not been configured correctly.
```

To resolve this problem, ensure that the path is configured to include the JRE, and that the correct environment variables are set; for example, by using `setjmsenv` or `setjmsenv64`. For example:

```
export PATH=$PATH:/opt/mqm/java/jre/bin  
cd /opt/mqm/java/bin/  
./setjmsenv64
```

```
[root@blade883 bin]# dspmqr -p2
```

Name: WebSphere MQ classes for Java  
Version: 8.0.0.0  
Level: k000-L110908  
Build Type: Production

**UNIX** Note that the **setjmsenv** and **setjmsenv64** commands apply to UNIX platforms only.

**Windows** On Windows you need to issue the **setmqenv** command to resolve error AMQ8351.

### endmqcsv:

Stop the command server for a queue manager.

### Purpose

Use the **endmqscv** command to stop the command server on the specified queue manager.

You must use the **endmqscv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmqr -o` installation command.

If the queue manager attribute, SCMDSERV, is specified as QMGR then changing the state of the command server using **endmqscv** does not effect how the queue manager acts upon the SCMDSERV attribute at the next restart.

### Syntax

►► endmqscv [ -c ] [ -i ] QMgrName

### Required parameters

*QMgrName*

The name of the queue manager for which to end the command server.

### Optional parameters

**-c** Stops the command server in a controlled manner. The command server can complete the processing of any command message that it has already started. No new message is read from the command queue.

This parameter is the default.

**-i** Stops the command server immediately. Actions associated with a command message currently being processed might not complete.

### Return codes

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

### Examples

1. The following command stops the command server on queue manager saturn.queue.manager:

```
endmqcsv -c saturn.queue.manager
```

The command server can complete processing any command it has already started before it stops.

Any new commands received remain unprocessed in the command queue until the command server is restarted.

2. The following command stops the command server on queue manager pluto immediately:

```
endmqcsv -i pluto
```

### Related commands

Command	Description
strmqcsv	Start a command server
dspmqcsv	Display the status of a command server

### endmq1sr:

End all listener process for a queue manager.

### Purpose

The **endmq1sr** command ends all listener processes for the specified queue manager.

You must use the **endmq1sr** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmq -o installation` command.

You do not have to stop the queue manager before issuing the **endmq1sr** command. If any of the listeners are configured to have inbound channels running within the **runmq1sr** listener process, rather than within a pool process, the request to end that listener might fail if channels are still active. In this case a message is written indicating how many listeners were successfully ended and how many listeners are still running.

If the listener attribute, CONTROL, is specified as QMGR then changing the state of the listener using **endmq1sr** does not effect how the queue manager acts upon the CONTROL attribute at the next restart.

### Syntax

```

▶▶ endmq1sr [-w] [-m QMgrName]

```

### Optional parameters

**-m** *QMGrName*

The name of the queue manager. If you omit this parameter, the command operates on the default queue manager.

**-w** Wait before returning control.

Control is returned to you only after all listeners for the specified queue manager have stopped.

### Return codes

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

### endmqdnm:

Stop the .NET monitor for a queue ( Windows only).

### Purpose

**Note:** The endmqdnm command applies to IBM MQ for Windows only.

Use the **endmqdnm** control command to stop a .NET monitor.

### Syntax

```
►►—endmqdnm— -q—QueueName— [ -m—QMgrName— ]
```

### Required parameters

**-q** *QueueName*  
The name of the application queue that the .NET monitor is monitoring.

### Optional parameters

**-m** *QMgrName*  
The name of the queue manager that hosts the application queue.  
If omitted, the default queue manager is used.

### Return codes

Return code	Description
0	Successful operation
36	Invalid arguments supplied
40	Queue manager not available
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error
133	Unknown object name error

### endmqm:

Stop a queue manager or switch to a standby queue manager.

### Purpose

Use the **endmqm** command to end (stop) a specified queue manager. This command stops a queue manager in one of three modes:

- Controlled or quiesced shutdown
- Immediate shutdown
- Pre-emptive shut down

The **endmqm** command stops all instances of a multi-instance queue manager in the same way as it stops a single instance queue manager. You can issue the **endmqm** on either the active instance, or one of the standby instances of a multi-instance queue manager. You must issue **endmqm** on the active instance to end the queue manager.

If you issue the **endmqm** command on the active instance of a multi-instance queue manager, you can permit a standby instance to switch over to being the new active instance when the current active instance completes its shutdown.

If you issue the **endmqm** command on a standby instance of a multi-instance queue manager, you can end the standby instance by adding the **-x** option, and leave the active instance running. The queue manager reports an error if you issue **endmqm** on the standby instance without the **-x** option.

Issuing the **endmqm** command will affect any client application connected through a server-connection channel. The effect varies depending on the parameter used, but it is as though a STOP CHANNEL command was issued in one of the three possible modes. See Stopping MQI channels, for information about the effects of STOP CHANNEL modes on server-connection channels. The **endmqm** optional parameter descriptions state which STOP CHANNEL mode they will be equivalent to.

If you issue **endmqm** to stop a queue manager, reconnectable clients do not try to reconnect. To override this behavior, specify either the **-r** or **-s** option to enable clients to start trying to reconnect.

**Note:** If a queue manager or a channel ends unexpectedly, reconnectable clients start trying to reconnect.

**Note:** The client might not reconnect to this queue manager. Depending on the MQCONNX reconnect option the client has used, and the definition of the queue manager group in the client connection table, the client might reconnect to a different queue manager. You can configure the client to force it to reconnect to the same queue manager.

You must use the **endmqm** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmqr -o** installation command.

The attributes of the queue manager and the objects associated with it are not affected by the **endmqm** command. You can restart the queue manager using the **strmqm** (Start queue manager) command.

To delete a queue manager, stop it and then use the **dlmqm** (Delete queue manager) command.

## Syntax

## Required parameters

*QMgrName*

The name of the message queue manager to be stopped.

## Optional parameters

- c Controlled (or quiesced) shutdown. This parameter is the default.

The queue manager stops, but only after all applications have disconnected. Any MQI calls currently being processed are completed. In the unlikely event that a “dspmq” on page 217 command is issued in the small timeframe between the applications disconnecting and the queue manager actually stopping, the “dspmq” on page 217 command might transiently report the status as Ending immediately, even though a controlled shutdown was requested.

Control is returned to you immediately and you are not notified of when the queue manager has stopped.

The effect on any client applications connected through a server-connection channel is equivalent to a STOP CHANNEL command issued in QUIESCE mode.

- i Immediate shutdown. The queue manager stops after it has completed all the MQI calls currently being processed. Any MQI requests issued after the command has been issued fail. Any incomplete units of work are rolled back when the queue manager is next started.

Control is returned after the queue manager has ended.

The effect on any client applications connected through a server-connection channel is equivalent to a STOP CHANNEL command issued in FORCE mode.

- p Pre-emptive shutdown.

*Use this type of shutdown only in exceptional circumstances.* For example, when a queue manager does not stop as a result of a normal **endmqm** command.

The queue manager might stop without waiting for applications to disconnect or for MQI calls to complete. This can give unpredictable results for IBM MQ applications. The shutdown mode is set to *immediate shutdown*. If the queue manager has not stopped after a few seconds, the shutdown mode is escalated, and all remaining queue manager processes are stopped.

The effect on any client applications connected through a server-connection channel is equivalent to a STOP CHANNEL command issued in TERMINATE mode.

- r Start trying to reconnect reconnectable clients. This parameter has the effect of reestablishing the connectivity of clients to other queue managers in their queue manager group.
- s Switch over to a standby queue manager instance after shutting down. The command checks that there is a standby instance running before ending the active instance. It does not wait for the standby instance to start before ending.

Connections to the queue manager are broken by the active instance shutting down. Reconnectable clients start trying to reconnect.

You can configure the reconnection options of a client to reconnect only to another instance of the same queue manager, or to reconnect to other queue managers in the queue manager group.

- w Wait shutdown.

This type of shutdown is equivalent to a controlled shutdown except that control is returned to you only after the queue manager has stopped. You receive the message Waiting for queue manager *qmName* to end while shutdown progresses. In the unlikely event that a “dspmq” on page 217 command is issued in the small timeframe between the applications disconnecting and the queue manager actually stopping, the “dspmq” on page 217 command might transiently report the status as Ending immediately, even though a controlled shutdown was requested.

The effect on any client applications connected through a server-connection channel is equivalent to a STOP CHANNEL command issued in QUIESCE mode.

- x End a standby instance of the queue manager, without ending the active instance of the queue manager.

**-z** Suppresses error messages on the command.

## Return codes

Return code	Description
0	Queue manager ended
3	Queue manager being created
16	Queue manager does not exist
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
72	Queue manager name error
77	IBM MQ queue manager cannot switch over
79	Active instance of IBM MQ queue manager <i>QmgrName</i> not ended
90	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended
119	Permission denied

## Examples

The following examples show commands that stop the specified queue managers.

1. This command ends the queue manager named `mercury.queue.manager` in a controlled way. All applications currently connected are allowed to disconnect.  

```
endmqm mercury.queue.manager
```
2. This command ends the queue manager named `saturn.queue.manager` immediately. All current MQI calls complete, but no new ones are allowed.  

```
endmqm -i saturn.queue.manager
```

The results of issuing **endmqm** to the local instance of a multi-instance queue manager are shown in Table 58. The results of the command depend on whether the `-s` or `-x` switch is used, and the running status of local and remote instances of the queue manager.

Table 58. *endmqm* actions.

endmqm option	Local machine	Remote machine	RC	Message	Result
	Active	None	0	-	Queue manager ended.
		Standby			Queue manager ended, including the standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended.
-s	Active	None	77	AMQ7276	IBM MQ queue manager cannot switch over.
		Standby	0	-	Queue manager QMNAME ended, permitting switchover to a standby instance.
	Standby	Active	90	AMQ8368	Standby instance of IBM MQ queue manager <i>QmgrName</i> not ended.
-x	Active	None	79	AMQ8367	Active instance of IBM MQ queue manager <i>QmgrName</i> not ended.
		Standby			
	Standby	Active	0	-	Standby instance of queue manager QMNAME ended.

## Related commands

Command	Description
" <b>crtmqm</b> " on page 194	Create queue manager
" <b>endmqm</b> " on page 244	End queue manager
" <b>dltmqm</b> " on page 202	Delete queue manager

### **endmqsvc:**

End the IBM MQ service on Windows.

### **Purpose**

The command ends the IBM MQ service on Windows. Run the command on Windows only.

Run the command to end the service, if the service is running.

Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

### **Syntax**

**endmqsvc**

### **Parameters**

The **endmqsvc** command has no parameters.

You must set the path to the installation that contains the service. Either make the installation primary, run the **setmqenv** command, or run the command from the directory containing the **endmqsvc** binary file.

### **Related reference:**

"**strmqsvc**" on page 302

Start the IBM MQ service on Windows.

### **endmqtrc:**

End trace for some or all of the entities that are being traced.

### **Purpose**

Use the **endmqtrc** command to end tracing for the specified entity or all entities. The **endmqtrc** command ends only the trace that is described by its parameters. Using **endmqtrc** with no parameters ends early tracing of all processes.

**Attention:** There can be a slight delay between the **endmqtrc** command ending, and all trace operations actually completing. This is because IBM MQ processes are accessing their own trace files. As each process becomes active at different times, their trace files close independently of one another.

### **Syntax**

The syntax of this command is as follows:

►► endmqtrc [ -m *QMgrName* ] [ -i *PidTids* ] [ -p *Apps* ] [ -e ] [ -a ] ►►

## Optional parameters

### -m *QMgrName*

The name of the queue manager for which to end tracing. This parameter applies to server products only.

The *QMgrName* supplied must match exactly the *QMgrName* supplied on the `strmqtrc` command. If the `strmqtrc` command used wildcards, the `endmqtrc` command must use the same wildcard specification including the escaping of any wildcard characters to prevent them being processed by the command environment.

A maximum of one `-m` flag and associated queue manager name can be supplied on the command.

### -i *PidTids*

Process identifier (PID) and thread identifier (TID) for which to end tracing. You cannot use the `-i` flag with the `-e` flag. If you try to use the `-i` flag with the `-e` flag, then an error message is issued. This parameter must only be used under the guidance of IBM Service personnel.

### -p *Apps*

The named processes for which to end tracing. *Apps* is a comma-separated list. You must specify each name in the list exactly as the program name would be displayed in the "Program Name" FDC header. Asterisk (\*) or question mark (?) wildcards are allowed. You cannot use the `-p` flag with the `-e` flag. If you try to use the `-p` flag with the `-e` flag, then an error message is issued.

### -e Ends early tracing of all processes.

Using `endmqtrc` with no parameters has the same effect as `endmqtrc -e`. You cannot specify the `-e` flag with the `-m` flag, the `-i` flag, or the `-p` flag.

### -a Ends all tracing.

This flag *must* be specified alone.

## Return codes

Return code	Description
AMQ5611	This message is issued if you supply invalid arguments to the command.
58	Inconsistent use of installations detected

## Examples

This command ends tracing of data for a queue manager called QM1.

```
endmqtrc -m QM1
```

The following examples are a sequence that shows how the `endmqtrc` command ends only the trace that is described by its parameters.

1. The following command enables tracing for queue manager QM1 and process `amqxxx.exe`:

```
strmqtrc -m QM1 -p amqxxx.exe
```

2. The following command enables tracing for queue manager QM2:

```
strmqtrc -m QM2
```

3. The following command ends tracing for queue manager QM2 only. Tracing of queue manager QM1 and process `amqxxx.exe` continues:

```
endmqtrc -m QM2
```

## Related commands

Command	Description
dspmqttrc	Display formatted trace output
"strmqtrc" on page 307	Start trace

### mqcertck (certify TLS setup): V8.0.0.4

Use the **mqcertck** command to diagnose potential SSL or TLS problems with your queue managers.

#### Purpose

The command can be used as a first check to determine why a connection using SSL or TLS has been unable to successfully connect on queue managers within your enterprise, and works with multiple certificates.

#### Syntax

```

mqcertck QmgrName [-clientkeyr client_key_repository] -clientchannel channel_name
[-clientuser client_username] [-clientlabel client_certlabl] [-clientport client_port]

```

#### Required parameters

*QmgrName*

Name of the queue manager to check for SSL or TLS errors.

**-clientchannel** *channel\_name*

Name of the channel on the referenced queue manager to check for SSL or TLS errors.

#### Optional parameters

**-clientkeyr** *client\_key\_repository*

Required if you supplied the **-clientuser**, **-clientlabel**, or **-clientport** parameters.

Location of the client key repository that would be used by a client application connecting to the referenced queue manager.

**Important:** You must supply the name without the .kdb extension.

**-clientuser** *client\_username*

Cannot be used if you supplied the **-clientlabel** parameter.

User running the client application, connecting to the referenced queue manager, if the client application is not using the client CERTLABL attribute to supply a certificate label.

**-clientlabel** *client\_certlabl*

Cannot be used if you supplied the **-clientuser** parameter.

Certificate label that is given to the client, connecting to the referenced queue manager, using one of the IBM MQ MQI client CERTLABL methods.

**-clientport** *client\_port*

Specify a specific port to use when testing the client.

The value must be:

- An integer value between 1 and 65535 inclusive.
- A port number, which must be a free port that **mqcertck** can use during its client checks.

- Not be a port that is in use by the queue manager, or any other process on the machine running **mqcertck**.

If you do not specify a value, port 5857 is used.

## Examples

### Example 1

After configuring an IBM MQ queue manager for TLS connections, you can use **mqcertck** to verify that no mistakes have been made, prior to attempting to start your channels.

To do this, run the command:

```
mqcertck <QmgrName>
```

where Qmgrname is the name of your queue manager, and check the output for any problems identified with your configuration.

### Example 2

After creating a key repository, certificate, and exchanging certificates for a client application, you can use **mqcertck** to verify that a client application is able to connect to a queue manager.

To do this, you need to run **mqcertck** on the machine where the IBM MQ queue manager is running, and have access to the client key repository.

You can do this in a variety of ways, for example, a file system mount. After you have set up your machine, run the command:

```
mqcertck <QMGR Name> -clientkeyr <Location of Client Key Repository>  
-clientlabel <Client certificate label>
```

and check the output for any problems identified with your configuration.

Note, that if you are planning on having your clients connect anonymously, you can run the preceding command without the **-clientlabel** parameter.

## **mqconfig:**

Checks that the system configuration meets the requirements to run IBM MQ ( UNIX and Linux platforms only).

## **Purpose**

The **mqconfig** command is run to verify the system configuration matches or exceeds that which is required by IBM MQ. The configuration values are minimum values, and large installations might require values greater than those checked by this command.

For further information about configuring your system for IBM MQ, see Operating System configuration and tuning for IBM MQ on UNIX and Linux systems, and IBM i .

## **Syntax**

## Optional parameters

### -v *Version*

The system requirements vary between different versions of IBM MQ. Specify the version of IBM MQ for which you need to verify the current system configuration.

The default value, if **-v** is not specified, is the current version.

## Example

The following output is an example of what the command produces on a Linux system:

```
# mqconfig -v 8.0
mqconfig: V3.7 analyzing Red Hat Enterprise Linux Server release 6.5
(Santiago) settings for IBM MQ V8.0

System V Semaphores
semmsl (sem:1) 500 semaphores          IBM>=32      PASS
semnms (sem:2) 35 of 256000 semaphores (0%) IBM>=4096  PASS
semopm (sem:3) 250 operations          IBM>=32      PASS
semnmi (sem:4) 3 of 1024 sets          (0%) IBM>=128  PASS

System V Shared Memory
shmmax 68719476736 bytes              IBM>=268435456 PASS
shmnmi 1549 of 4096 sets              (37%) IBM>=4096  PASS
shmll 7464 of 2097152 pages           (0%) IBM>=2097152 PASS

System Settings
file-max 4416 of 524288 files          (1%) IBM>=524288  PASS

Current User Limits (root)
nofile (-Hn) 10240 files                IBM>=10240  PASS
nofile (-Sn) 10240 files                IBM>=10240  PASS
nproc (-Hu) 11 of 30501 processes       (0%) IBM>=4096  PASS
nproc (-Su) 11 of 4096 processes        (1%) IBM>=4096  PASS
```

**Note:** Any values listed in the Current User Limits section are resource limits for the user who ran **mqconfig**. If you normally start your queue managers as the **mqm** user, you should switch to **mqm** and run **mqconfig** there.

If other members of the **mqm** group (and perhaps root) also start queue managers, all those members should all run **mqconfig**, to ensure that their limits are suitable for IBM MQ.

## MQExplorer (launch MQ Explorer):

Start MQ Explorer ( Windows and Linux x86-64 platforms only).

### Purpose

To launch MQ Explorer by using the system menu on Linux, or the start menu on Windows, you must left-click on the installation that you want to launch.

On Windows, open the start menu, and select the MQ Explorer installation entry under the **IBM MQ** folder that corresponds to the installation that you want to launch. Each instance of MQ Explorer listed is identified by the name that you chose for its installation.

On Linux, the system menu entry for MQ Explorer is added to the **Development** category. Where it appears within the system menu is dependent on your Linux distribution (SUSE or Red Hat), and your desktop environment (GNOME or KDE).

- On SUSE
  - Left-click **Computer > More Applications...**, and find the installation of MQ Explorer that you want to launch under the **Development** category.
- On Red Hat
  - The installation of MQ Explorer that you want to launch can be found under **Applications > Programming**.

## Syntax

The **MQExplorer** command is stored in `MQ_INSTALLATION_PATH/bin`. **MQExplorer.exe** (the `MQExplorer` command) supports standard Eclipse runtime options. The syntax of this command is as follows:

## Optional parameters

### -clean

Is passed to Eclipse. This parameter causes Eclipse to delete any cached data used by the Eclipse runtime.

### -initialize

Is passed to Eclipse. This parameter causes Eclipse to discard configuration information used by the Eclipse runtime.

The graphical user interface (GUI) does not start.

## mqr (MQ return code):

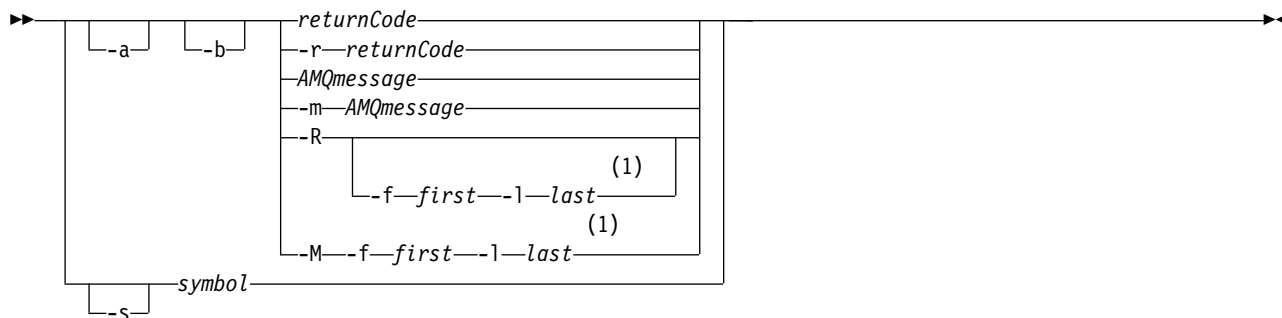

Display information about return codes.

## Purpose

You can use the **mqr** command to display information about symbols, return codes, and AMQ messages. You can specify a range of return codes or AMQ messages, as well as specifying specific return codes or AMQ messages.

Numeric arguments are interpreted as decimal if they start with a digit 1 - 9, or hex if prefixed with 0x.

## Syntax

## Notes:

- 1 If there is a problem with a message within a range, an indication is displayed before the message

text. ? is displayed if there are no matching return codes for the message. ! is displayed if the message severity is different to the return code severity.

## Parameters

### **returnCode**

The return code to display

### **AMQmessage**

The AMQ message to display

### **symbol**

The symbol to display

**-a** Try all severities to find message text

**-b** Display messages without extended information

### **-f first**

First number in a range

### **-l last**

Last number in a range

### **-m AMQmessage**

The AMQ message to list

**-M** Display AMQ messages in a range

### **-r returnCode**

The return code to display

**-R** Display all return codes. If used with the **-f** and **-l** parameters, **-R** displays the return codes within a range.

### **-s symbol**

The symbol to display

## Examples

1. This command displays AMQ message 5005:

```
mqr c AMQ5005
```

2. This command displays return codes in the range 2505 - 2530:

```
mqr c -R -f 2505 -l 2530
```

## **rcdmqimg:**

Write the image of an object or group of objects to the log for media recovery.

## **Purpose**

Use the **rcdmqimg** command to write an image of an object, or group of objects, to the log for use in media recovery. This command can be used only when using linear logging. See Types of logging for more information about linear logging. Use the associated command **rcrmqobj** to recreate the object from the image.

**rcdmqimg** must be run manually or from an automated task you have created. The command does not run automatically as it must be run in accordance with, and as determined by, the usage of each individual customer of IBM MQ .

Running **rcdmqimg** moves the log sequence number (LSN) forwards and frees up old log files for archival or deletion.

When determining when and how often to run **rcdmqimg**, consider these factors:

### Disk space

If disk space is limited, regular running of **rcdmqimg** releases log files for archive or deletion.

### Impact on normal system performance

**rcdmqimg** activity can take a long time if the queues on the system are deep. At this time, other system usage is slower and disk utilization increases because data is being copied from the queue files to the logs. Therefore, the ideal time to run **rcdmqimg** is when the queues are empty and the system is not being heavily used.

You use this command with an active queue manager. Further activity on the queue manager is logged so that, although the image becomes out of date, the log records reflect any changes to the object.

### Syntax

```
►► rcdmqimg [-m QMgrName] [-z] [-l] -t ObjectType GenericObjName ◀◀
```

### Required parameters

#### *GenericObjName*

The name of the object to record. This parameter can have a trailing asterisk to record that any objects with names matching the portion of the name before the asterisk.

This parameter is required unless you are recording a queue manager object or the channel synchronization file. Any object name you specify for the channel synchronization file is ignored.

#### **-t** *ObjectType*

The types of object for which to record images. Valid object types are:

Table 59. Valid object types

Object Type	Description
<b>all</b> and <b>*</b>	All the object types; <b>ALL</b> for objtype and <b>*</b> for <i>GenericObjName</i>
<b>authinfo</b>	Authentication information object, for use with Secure Sockets Layer (SSL) channel security
<b>channel</b> or <b>chl</b>	Channels
<b>clntconn</b> or <b>clcn</b>	Client connection channels
<b>catalog</b> or <b>ctlg</b>	An object catalog
<b>listener</b> or <b>lstr</b>	Listeners
<b>namelist</b> or <b>nl</b>	Namelists
<b>process</b> or <b>prcs</b>	Processes
<b>queue</b> or <b>q</b>	All types of queue
<b>qalias</b> or <b>qa</b>	Alias queues
<b>qlocal</b> or <b>ql</b>	Local queues
<b>qmodel</b> or <b>qm</b>	Model queues
<b>qremote</b> or <b>qr</b>	Remote queues
<b>qmgr</b>	Queue manager object
<b>service</b> or <b>srvc</b>	Service
<b>syncfile</b>	Channel synchronization file.
<b>topic</b> or <b>top</b>	Topics

**Note:** When using IBM MQ for UNIX systems, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (\*). How you do this depends on the shell you are using, but might involve the use of single quotation marks ('), double quotation marks ("), or a backslash (\).

### Optional parameters

**-m** *QMgrName*

The name of the queue manager for which to record images. If you omit this parameter, the command operates on the default queue manager.

**-z** Suppresses error messages.

**-l** Writes messages containing the names of the oldest log files required to restart the queue manager and to perform media recovery. The messages are written to the error log and the standard error destination. (If you specify both the **-z** and **-l** parameters, the messages are sent to the error log, but not to the standard error destination.)

When issuing a sequence of **rcdmqimg** commands, include the **-l** parameter only on the last command in the sequence, so that the log file information is gathered only once.

### Return codes

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
68	Media recovery not supported
69	Storage not available
71	Unexpected error
72	Queue manager name error
119	User not authorized
128	No objects processed
131	Resource problem
132	Object damaged
135	Temporary object cannot be recorded

### Examples

The following command records an image of the queue manager object `saturn.queue.manager` in the log.  
`rcdmqimg -t qmgr -m saturn.queue.manager`

### Related commands

Command	Description
<b>rcrmqobj</b>	Recreate a queue manager object

#### **rcrmqobj:**

Re-create an object, or group of objects, from their images contained in the log.

## Purpose

Use this command to re-create an object, or group of objects, from their images.

- With `ObjectType` argument of `clchltab` or `syncfile`, this command recreates the object files from the internal queue manager state.
- For other `ObjectType` arguments, the command can only be used when the queue manager is configured to use linear logging. Use the associated command, `rcdmqimg`, to record the object images to the log. The object is recreated from images in the log.

Use this command on a running queue manager. All activity on the queue manager after the image was recorded is logged. To re-create an object, replay the log to re-create events that occurred after the object image was captured.

## Syntax

```
►► rcrmqobj [-m QMgrName] [-z] -t ObjectType GenericObjName ◀◀
```

## Required parameters

### *GenericObjName*

The name of the object to re-create. This parameter can have a trailing asterisk to re-create any objects with names matching the portion of the name before the asterisk.

This parameter is required *unless* the object type is the channel synchronization file; any object name supplied for this object type is ignored.

### *-t ObjectType*

The types of object to re-create. Valid object types are:

Table 60. Valid object types.

Object Type	Description
* or all	All object types
authinfo	Authentication information object, for use with Secure Sockets Layer (SSL) channel security
channel or chl	Channels
clntconn or clcn	Client connection channels
clchltab	Client channel table
listener or lstr	Listener
namelist or nl	Namelists
process or prcs	Processes
queue or q	All types of queue
qalias or qa	Alias queues
qlocal or ql	Local queues
qmodel or qm	Model queues
qremote or qr	Remote queues
service or srvc	Service

Table 60. Valid object types. (continued)

Object Type	Description
<b>syncfile</b>	Channel synchronization file.  You can use this option when circular logs are configured but the <code>syncfile</code> fails if the channel scratchpad files, which are used to rebuild <code>syncfile</code> , are damaged or missing. You might want to do this if your system has reported the error message AMQ7353 ( <code>krcE_SYNCFILE_UPDATE_FAILED</code> ).
<b>topic or top</b>	Topics

**Note:** When using IBM MQ for UNIX systems, you must prevent the shell from interpreting the meaning of special characters, for example, an asterisk (\*). How you do this depends on the shell you are using, but might involve the use of single quotation marks ('), double quotation marks ("), or a backslash (\).

### Optional parameters

**-m** *QMgrName*

The name of the queue manager for which to re-create objects. If omitted, the command operates on the default queue manager.

**-z** Suppresses error messages.

### Return codes

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
66	Media image not available
68	Media recovery not supported
69	Storage not available
71	Unexpected error
72	Queue manager name error
119	User not authorized
128	No objects processed
135	Temporary object cannot be recovered
136	Object in use

### Examples

1. The following command re-creates all local queues for the default queue manager:

```
rcrmqobj -t ql *
```

2. The following command re-creates all remote queues associated with queue manager store:

```
rcrmqobj -m store -t qr *
```

### Related commands

Command	Description
rctmqimg	Record an object in the log

### rmvmqinf:

Remove IBM MQ configuration information ( Windows and UNIX platforms only).

### Purpose

Use the **rmvmqinf** command to remove IBM MQ configuration information.

You must use the **rmvmqinf** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmqs -o` installation command.

### Syntax

### Required parameters

#### *StanzaName*

The name of the stanza. That is, the value of the key attribute that distinguishes between multiple stanzas of the same type.

### Optional parameters

#### **-s** *StanzaType*

The type of stanza to remove. If omitted, a QueueManager stanza is removed.

The only supported value of *StanzaType* is QueueManager.

### Return codes

Return code	Description
0	Successful operation
5	Queue manager is running
26	Queue manager is running as a standby instance
39	Bad command line parameters
44	Stanza does not exist
49	Queue manager is stopping
58	Inconsistent use of installations detected
69	Storage is not available
71	Unexpected error
72	Queue manager name error

### Example

```
rmvmqinf QM.NAME
```

## Usage notes

Use **rmvmqinf** to remove an instance of a multi-instance queue manager.

To use this command you must be an IBM MQ administrator and a member of the `mqm` group.

## Related commands

Command	Description
"addmqinf" on page 180	Add queue manager configuration information
"dspmqinf" on page 226	Display queue manager configuration information

## rsvmqtrn:

Resolve in-doubt and heuristically completed transactions

## Purpose

The **rsvmqtrn** command is used to resolve two different transaction states.

### in-doubt transactions

Use the **rsvmqtrn** command to commit or back out internally or externally coordinated in-doubt transactions.

**Note:** Use this command only when you are certain that transactions cannot be resolved by the normal protocols. Issuing this command might result in the loss of transactional integrity between resource managers for a distributed transaction.

### heuristically completed transactions

Use the **rsvmqtrn** command with the `-f` option for IBM MQ to remove all information about externally coordinated transactions that were previously resolved manually using the **rsvmqtrn** command, but the resolution has not been acknowledged by the transaction coordinator using the `xa-forget` command. Transactions that are manually resolved by a resource manager and unacknowledged by the transaction manager, are known as *heuristically completed* transactions by X/Open.

**Note:** Only use the `-f` option if the external transaction coordinator is permanently unavailable. The queue manager, as a resource manager, remembers the transactions that are committed or backed out manually by the **rsvmqtrn** command.

## Syntax

## Required parameters

**-m QMgrName**  
The name of the queue manager.

## Optional parameters

**-a** The queue manager resolves all internally coordinated, in-doubt transactions (that is, all global units of work).

- b Backs out the named transaction. This flag is valid for externally coordinated transactions (that is, for external units of work) only.
- c Commits the named transaction. This flag is valid for externally coordinated transactions (that is, external units of work) only.
- f Forgets the named heuristically completed transaction. This flag is valid only for externally coordinated transactions (that is, external units of work) that are resolved, but unacknowledged by the transaction coordinator.

**Note:** Use only if the external transaction coordinator is never going to be able to acknowledge the heuristically completed transaction. For example, if the transaction coordinator has been deleted.

**-r *RMID***

The participation of the resource manager in the in-doubt transaction can be ignored. This flag is valid for internally coordinated transactions only, and for resource managers that have had their resource manager configuration entries removed from the queue manager configuration information.

**Note:** The queue manager does not call the resource manager. Instead, it marks the participation of the resource manager in the transaction as being complete.

*Transaction*

The transaction number of the transaction being committed or backed out. Use the **dspmqrn** command to find the relevant transaction number. This parameter is required with the -b, -c, and -r *RMID* parameters and if used it must be the last parameter.

**Return codes**

Return code	Description
0	Successful operation
26	Queue manager running as a standby instance.
32	Transactions could not be resolved
34	Resource manager not recognized
35	Resource manager not permanently unavailable
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
85	Transactions not known

**Related commands**

Command	Description
dspmqrn	Display list of prepared transactions

**runmqccred (obfuscate passwords for mqccred exit):**

Obfuscate passwords in the .ini file used by the **mqccred** security exit.

**Purpose**

Use the **runmqccred** command to process the **mqccred** exit .ini file to change all plain text passwords into an obfuscated form. This command should be run before using the .ini with the exit to ensure the exit runs successfully.

## Syntax

► runmqccred [ -f ] [ -p ]

### Optional Parameters

**-f** Specify a specific file to edit, other than the default file.

By default, the program locates the `.ini` file in the same way as the channel exit.

**-p** By default the program fails with an error, if the filemode enables others to access the file you edited.

Use the **-p** flag to continue processing even when the error appears.

This might be necessary in situations where you might, for example, have mounted a UNIX filesystem onto your Windows machine using NFS, or some other protocol, and are trying to use the `.ini` file from there (perhaps to share the same `.ini` file across multiple accounts).

Since NFS doesn't support the Windows NTFS Access Control Lists, the exit would fail unless you bypass the permissions check.

### Usage notes

The **runmqccred** program locates the ini file in the same way as the channel exit. The program also writes console messages saying which file is being modified, and any success or failure status.

Note that the channel exit can work with either **Password** or **OPW** attributes, but the expectation is that you will protect passwords.

**Important:** The **runmqccred** program works only from IBM MQ Version 8.0, You must run the program on a Version 8.0 system and then transfer the output `.ini` file manually to a system running a previous version if you want to use clients there.

By default the exit only works when there are no plain text passwords in the file. You can override this by using the **NOCHECKS SCYDATA** option.

The **runmqccred** program also checks that the `.ini` file does not have excessive permissions set that allow other users to access it. By default the program fails with an error if the filemode enables others to access it. Use the **-p** flag to continue processing even when the error appears.

The **runmqccred** program is installed in the following folder:

#### Windows platforms

The <installation directory>\Tools\c\Samples\mqccred\

#### UNIX platforms

The <installation directory>/usr/mqm/samp/mqccred/

If the file permissions are not secure enough **runmqccred** produces this message:

```
Configuration file 'C:\Users\User1\mqm\mqccred.ini' is not secure.  
Other users may be able to read it. No changes have been made to the file.  
Use the -p option for runmqccred to bypass this error.
```

You can bypass this issue with the **-p** flag, but the exit will fail to run when put into production if you have not resolved this issue. When **runmqccred** runs successfully it informs you how many passwords have been obfuscated.

```
File 'C:\Users\User1\mqm\mqccred.in' processed successfully.  
Plaintext passwords found: 3
```

## runmqchi:

Run a channel initiator process to automate starting channels.

### Purpose

Use the **runmqchi** command to run a channel initiator process.

You must use the **runmqchi** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmqr -o` installation command.

The channel initiator is started by default as part of the queue manager.

### Syntax

```
►►—runmqchi— [ -q—InitiationQName— ] [ -m—QMgrName— ] ►►
```

### Optional parameters

#### -q *InitiationQName*

The name of the initiation queue to be processed by this channel initiator. If you omit it, SYSTEM.CHANNEL.INITQ is used.

#### -m *QMgrName*

The name of the queue manager on which the initiation queue exists. If you omit the name, the default queue manager is used.

### Return codes

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

If errors occur that result in return codes of either 10 or 20, review the queue manager error log that the channel is associated with for the error messages, and the system error log for records of problems that occur before the channel is associated with the queue manager. For more information about error logs, see Error log directories.

## runmqchl:

Start a sender or requester channel

### Purpose

Use the **runmqchl** command to run either a sender (SDR) or a requester (RQSTR) channel.

The channel runs synchronously. To stop the channel, issue the MQSC command STOP CHANNEL.

### Syntax

```

▶▶ runmqchl -c ChannelName -m QMgrName

```

### Required parameters

**-c ChannelName**  
The name of the channel to run.

### Optional parameters

**-m QMgrName**  
The name of the queue manager with which this channel is associated. If you omit the name, the default queue manager is used.

### Return codes

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

If return codes 10 or 20 are generated, review the error log of the associated queue manager for the error messages, and the system error log for records of problems that occur before the channel is associated with the queue manager.

### runmqdlq:

Start the dead-letter queue handler to monitor and process messages on the dead-letter queue.

### Purpose

Use the **runmqdlq** command to start the dead-letter queue (DLQ) handler, which monitors and handles messages on a dead-letter queue.

### Syntax

```

▶▶ runmqdlq QName QMgrName

```

### Description

Use the dead-letter queue handler to perform various actions on selected messages by specifying a set of rules that can both select a message and define the action to be performed on that message.

The **runmqdlq** command takes its input from stdin. When the command is processed, the results and a summary are put into a report that is sent to stdout.

By taking stdin from the keyboard, you can enter **runmqdlq** rules interactively.

By redirecting the input from a file, you can apply a rules table to the specified queue. The rules table must contain at least one rule.

If you use the DLQ handler without redirecting stdin from a file (the rules table), the DLQ handler reads its input from the keyboard. In IBM MQ for AIX, Solaris, HP-UX, and Linux, the DLQ handler does not

start to process the named queue until it receives an end\_of\_file (Ctrl+D) character. In IBM MQ for Windows, it does not start to process the named queue until you press the following sequence of keys: Ctrl+Z, Enter, Ctrl+Z, Enter.

For more information about rules tables and how to construct them, see The DLQ handler rules table.

### Optional parameters

The MQSC command rules for comment lines and for joining lines also apply to the DLQ handler input parameters.

#### *QName*

The name of the queue to be processed.

If you omit the name, the dead-letter queue defined for the local queue manager is used. If you enter one or more blanks (' '), the dead-letter queue of the local queue manager is explicitly assigned.

#### *QMgrName*

The name of the queue manager that owns the queue to be processed.

If you omit the name, the default queue manager for the installation is used. If you enter one or more blanks (' '), the default queue manager for this installation is explicitly assigned.

### runmqdnm:

Start processing messages on a queue using the .NET monitor ( Windows only).

### Purpose

**Note:** The runmqdnm command applies to IBM MQ for Windows only.

**runmqdnm** can be run from the command line, or as a triggered application.

Use the **runmqdnm** control command to start processing messages on an application queue with a .NET monitor.

### Syntax

```
runmqdnm -q-QueueName -a-AssemblyName [-m-QMgrName] [-c-ClassName]
[-u-UserParameter] [-s-Syncpoint] [-d-Conversion] [-n-MaxThreads]
[-t-Timeout] [-b-BackoutThreshold] [-r-QueueName] [-p-ContextOption]
```

### Required parameters

#### **-q** *QueueName*

The name of the application queue to monitor.

#### **-a** *AssemblyName*

The name of the .NET assembly.

### Optional parameters

#### **-m** *QMgrName*

The name of the queue manager that hosts the application queue.

If omitted, the default queue manager is used.

**-c** *ClassName*

The name of the .NET class that implements the IMQObjectTrigger interface. This class must reside in the specified assembly.

If omitted, the specified assembly is searched to identify classes that implement the IMQObjectTrigger interface:

- If one class is found, then *ClassName* takes the name of this class.
- If no classes or multiple classes are found, then the .NET monitor is not started and a message is written to the console.

**-u** *UserData*

User-defined data. This data is passed to the Execute method when the .NET monitor calls it. User data must contain ASCII characters only, with no double quotation marks, NULLs, or carriage returns.

If omitted, null is passed to the Execute method.

**-s** *Syncpoint*

Specifies whether sync point control is required when messages are retrieved from the application queue. Possible values are:

Table 61. Syncpoint parameter values.

Value	Description
YES	Messages are retrieved under sync point control (MQGMO_SYNCPOINT).
NO	Messages are not retrieved under sync point control (MQGMO_NO_SYNCPOINT).
PERSISTENT	Persistent messages are retrieved under sync point control (MQGMO_SYNCPOINT_IF_PERSISTENT).

If omitted, the value of *Syncpoint* is dependent on your transactional model:

- If distributed transaction coordination (DTC) is being used, then *Syncpoint* is specified as YES.
- If distributed transaction coordination (DTC) is not being used, then *Syncpoint* is specified as PERSISTENT.

**-d** *Conversion*

Specifies whether data conversion is required when messages are retrieved from the application queue. Possible values are:

Table 62. Conversion parameter values.

Value	Description
YES	Data conversion is required (MQGMO_CONVERT).
NO	Data conversion is not required (no get message option specified).

If omitted, *Conversion* is specified as NO.

**-n** *MaxThreads*

The maximum number of active worker threads.

If omitted, *MaxThreads* is specified as 20.

**-t** *Timeout*

The time, in seconds, that the .NET monitor waits for further messages to arrive on the application queue. If you specify -1, the .NET monitor waits indefinitely.

If omitted when run from the command line, the .NET monitor waits indefinitely.

If omitted when run as a triggered application, the .NET monitor waits for 10 seconds.

**-b** *BackoutThreshold*

Specifies the backout threshold for messages retrieved from the application queue. Possible values are:

Table 63. *BackoutThreshold* parameter values.

Value	Description
-1	The backout threshold is taken from the application queue attribute, BOTHRESH.
0	The backout threshold is not set.
1 or more	Explicitly sets the backout threshold.

If omitted, *BackoutThreshold* is specified as -1.

**-r** *QueueName*

The queue to which messages, with a backout count exceeding the backout threshold, are put.

If omitted, the value of *QueueName* is dependent on the value of the BOQNAME attribute from the application queue:

- If BOQNAME is non-blank, then *QueueName* takes the value of BOQNAME.
- If BOQNAME is blank, then *QueueName* is specified as the queue manager dead letter queue. If a dead letter queue has not been assigned to the queue manager, then backout processing is not available.

**-p** *ContextOption*

Specifies whether context information from a message that is being backed out is passed to the backed out message. Possible values are:

Table 64. *ContextOption* parameter values.

Value	Description
NONE	No context information is passed.
IDENTITY	Identity context information is passed only.
ALL	All context information is passed.

If omitted, *ContextOption* is specified as ALL.

## Return codes

Return code	Description
0	Successful operation
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
71	Unexpected error
72	Queue manager name error
133	Unknown object name error

## runmqtsr:

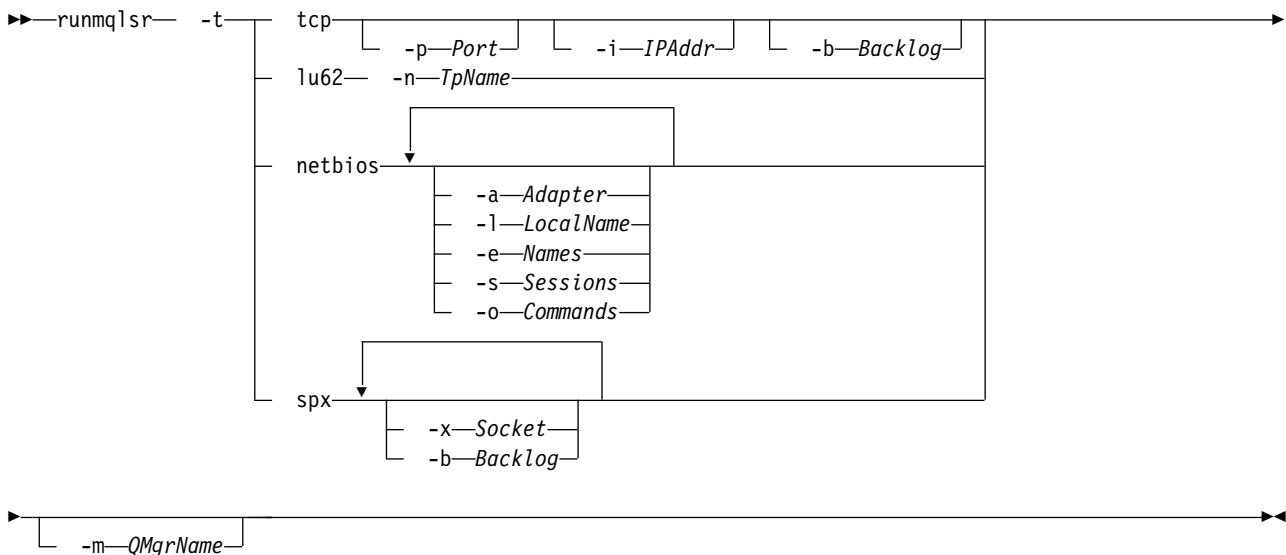

Run a listener process to listen for remote requests on various communication protocols.

## Purpose

Use the **runmqtsr** command to start a listener process.

This command is run synchronously and waits until the listener process has finished before returning to the caller.

### Syntax

### Required parameters

**-t** The transmission protocol to be used:

Table 65. Transmission protocol values.

Header	Header
tcp	Transmission Control Protocol / Internet Protocol (TCP/IP)
lu62	SNA LU 6.2 ( Windows only)
netbios	NetBIOS ( Windows only)
spx	SPX ( Windows only)

### Optional parameters

#### **-p** *Port*

The port number for TCP/IP. This flag is valid for TCP only. If you omit the port number, it is taken from the queue manager configuration information, or from defaults in the program. The default value is 1414. It must not exceed 65535.

#### **-i** *IPAddr*

The IP address for the listener, specified in one of the following formats:

- IPv4 dotted decimal
- IPv6 hexadecimal notation
- Alphanumeric format

This flag is valid for TCP/IP only.

On systems that are both IPv4 and IPv6 capable you can split the traffic by running two separate listeners. One listening on all IPv4 addresses and one listening on all IPv6 addresses. If you omit this parameter, the listener listens on all configured IPv4 and IPv6 addresses.

- n** *TpName*  
The LU 6.2 transaction program name. This flag is valid only for the LU 6.2 transmission protocol. If you omit the name, it is taken from the queue manager configuration information.
- a** *Adapter*  
The adapter number on which NetBIOS listens. By default the listener uses adapter 0.
- l** *LocalName*  
The NetBIOS local name that the listener uses. The default is specified in the queue manager configuration information.
- e** *Names*  
The number of names that the listener can use. The default value is specified in the queue manager configuration information.
- s** *Sessions*  
The number of sessions that the listener can use. The default value is specified in the queue manager configuration information.
- o** *Commands*  
The number of commands that the listener can use. The default value is specified in the queue manager configuration information.
- x** *Socket*  
The SPX socket on which SPX listens. The default value is hexadecimal 5E86.
- m** *QMGrName*  
The name of the queue manager. By default the command operates on the default queue manager.
- b** *Backlog*  
The number of concurrent connection requests that the listener supports. See TCP, LU62, NETBIOS, and SPX for a list of default values and further information.

## Return codes

Return code	Description
0	Command completed normally
4	Command completed after being ended by the <b>endmq1sr</b> command
10	Command completed with unexpected results
20	An error occurred during processing: the AMQMSRVN process did not start.

## Examples

The following command runs a listener on the default queue manager using the NetBIOS protocol. The listener can use a maximum of five names, five commands, and five sessions. These resources must be within the limits set in the queue manager configuration information.

```
runmq1sr -t netbios -e 5 -s 5 -o 5
```

### **runmqras:**

Use the **runmqras** command to gather IBM MQ diagnostic information together into a single archive, for example to submit to IBM Support.

## Purpose

The **runmqras** command is used to gather diagnostic information from a machine, into a single archive. You can use this command to gather information about an application or IBM MQ failure, possibly for submitting to IBM when you report a problem.

By default, **runmqras** gathers information such as:

- IBM MQ FDC files
- Error logs (from all queue managers as well as the machine-wide IBM MQ error logs)
- Product versioning, status information, and output from various other operating system commands.

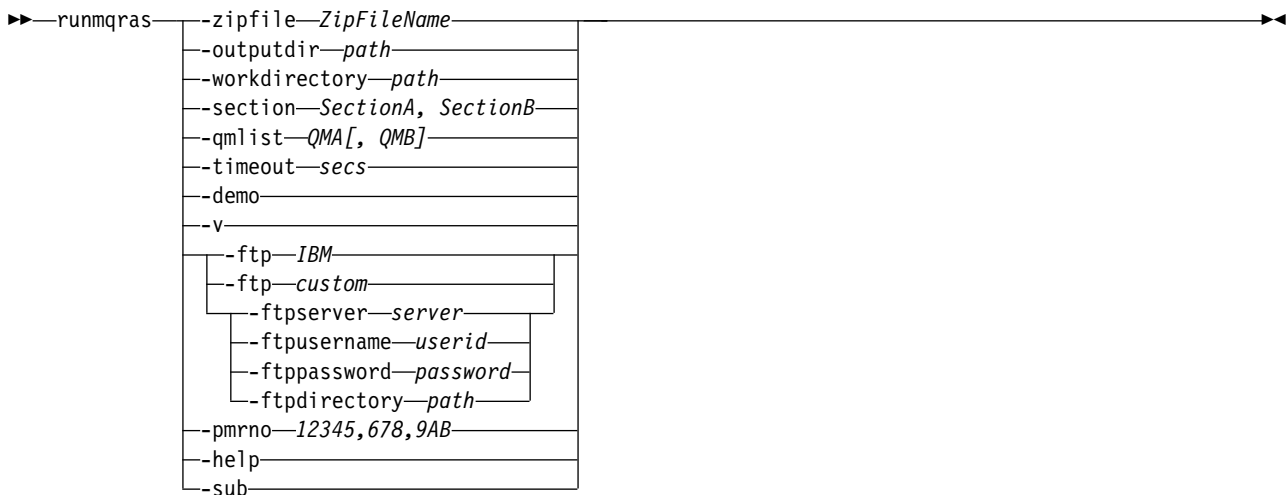

Note, for example, the **runmqras** command does not gather user information that is contained in messages on queues.

Running without requesting more sections is intended as a starting point for general problem diagnosis, however, you can request more *sections* through the command line.

These additional *sections* gather more detailed information, depending on the type of problem being diagnosed. If non-default sections are needed by IBM support personnel, they will tell you.

The **runmqras** command can be run under any user ID, but the command gathers only information that the user ID can gather manually. In general, when debugging IBM MQ problems, run the command under the mqm user ID to allow the command to gather queue manager files and command outputs.

## Syntax

## Keywords and parameters

All parameters are required unless the description states they are optional.

In every case, *QMgrName* is the name of the queue manager to which the command applies.

### **-zipfile** *ZipFileName*

Supply the file name of the resulting archive.

By default, the name of the output archive is runmqras.zip.

### **-outputdir** *path*

The directory in which the resulting output file is placed.

By default, the output directory is the same as the work directory.

### **-workdirectory** *path*

The directory that is used for storing the output from commands that are run during the processing of the tool. If supplied, this directory must either not exist, in which case it is created, or must be empty.

If you do not supply the path, a directory under /tmp is used on UNIX systems, and under %temp% is used on Windows, whose name starts with **runmqras** and is suffixed by the date and time.

**-section** *SectionA, SectionB*

The optional sections about which to gather more specific information.

By default, a generic section of documentation is collected, whereas more specific information can be gathered for a specified problem type; for example, a section name of *trace* gathers all of the contents of the trace directory.

The default collections can be avoided by supplying a section name of *nodefault*.

IBM support generally supplies you with the sections to use. Example available sections are:

**all** Gathers all possible information, including all trace files, and diagnostics for many different types of problems. You must use this option only in certain circumstances and this option is not intended for general use.

**default**

IBM MQ logs, FDC files, basic configuration, and status.

**Note:** Always gathered unless you use the section name **nodefault**.

**nodefault**

Prevents the default collections from occurring, but other explicitly requested sections are still collected.

**trace** Gathers all the trace file information plus the default information.

**Note:** Does not enable tracing.

**defs** Gathers the queue manager definitions and status information.

**cluster**

Gathers cluster configuration and queue information.

**dap** Gathers transaction and persistence information.

**kernel** Gathers queue manager kernel information.

**logger** Gathers recovery logging information.

**topic** Gathers topic tree information.

**QMGR**

Gathers all queue manager files: queues, logs, and configuration files.

For more information, see Section names and descriptions, in the IBM technote on using the IBM MQ **runmqras** command to collect data.

**-qm1ist** *QMA[,QMB]*

A list of queue manager names on which the **runmqras** command is to be run. This parameter does not apply to a client product (for example, HP Integrity NonStop Server ) because there are no queue managers from which to request direct output.

By supplying a comma-separated list, you can restrict the iteration across queue managers to a specific list of queue managers. By default, iteration of commands is across all queue managers.

**-timeout** *secs*

The default timeout to give an individual command before the command stops waiting for completion.

By default, a timeout of 10 seconds is used. A value of zero means wait indefinitely.

**-demo**

Run in demonstration mode where no commands are processed, and no files gathered.

By running in demonstration mode, you can see exactly which commands would have been processed, and what files would have been gathered. The output zip file contains a `console.log` file that documents exactly what would have been processed and gathered, should the command be run normally.

**-v** Extends the amount of information that is logged in the `console.log` file, contained in the output zip file.

**-ftp *ibm/custom***

Allows the collected archive to be sent through basic FTP to a remote destination.

At the end of processing, the resultant archive can be sent through basic FTP, either directly into IBM, or to a site of your choosing. If you select the *ibm* option, anonymous FTP is used to deliver the archive into the IBM ECuRep server. This process is identical to submitting the file manually using FTP.

Note if you select the *ibm* option, you must also provide the *pmrno* option, and all other FTP\* options are ignored.

**-ftpserver *server***

An FTP server name to connect to, when an FTP custom option is used.

**-ftpusername *userid***

The user ID to log in to the FTP server with, when an FTP custom option is used.

**-ftppassword *password***

The password to log in to the FTP server with, when an FTP custom option is used.

**-ftpdirectory *path***

The directory on the FTP server to place the resulting zip file into, used when an FTP custom option is used.

**-pmrno *12345,678,9AB***

A valid IBM PMR number (problem record number) against which to associate the documentation.

Use this option to ensure that the output is prefixed with your PMR Number, so that when the information is sent to IBM, the information is automatically associated with that problem record.

**-help**

Provide simple help.

**-sub**

Shows the keywords that will be substituted in the xml.

## Examples

This command gathers the default documentation from the IBM MQ installation, and all queue managers on a machine:

```
runmqras
```

This command gathers the default documentation from the IBM MQ installation on a machine, and sends it directly into IBM to be associated with PMR number 11111,222,333 using the basic FTP capability:

```
runmqras -ftp ibm -pmrno 11111,222,333
```

This command gathers the default documentation from a machine, plus all trace files, the queue manager definitions, and status for all queue managers on the machine:

```
runmqras -section trace,defs
```

## Return codes

A non zero return code indicates failure.

## runmqsc:

Run IBM MQ commands on a queue manager.

### Purpose

Use the **runmqsc** command to issue MQSC commands to a queue manager. MQSC commands enable you to perform administration tasks. For example, you can define, alter, or delete a local queue object. MQSC commands and their syntax are described in MQSC commands.

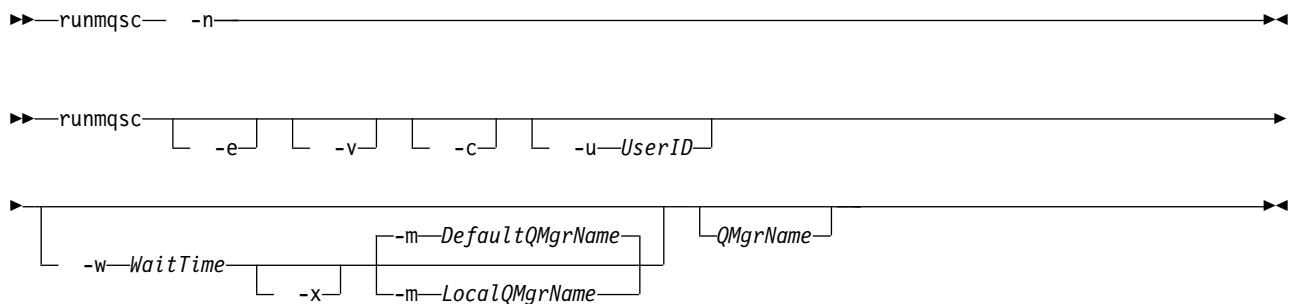

You must use the **runmqsc** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with by using the `dspmqr -o` installation command.

To stop the **runmqsc** command, use the **end** command. You can also use the **exit** or the **quit** command.

From IBM MQ Version 8.0, you can make it easier to see that you are in an MQSC environment and see some details of the current environment by setting a prompt of your choice by using the `MQPROMPT` environment variable. For more information, see [Performing local administration tasks using MQSC commands](#).

### Syntax

You can use the **-n** parameter on its own, or you can use a number of other parameters in combination:

### Description

You can start the **runmqsc** command in three ways:

#### Verify command

Verify MQSC commands but do not run them. An output report is generated indicating the success or failure of each command. This mode is available on a local queue manager only.

#### Run command directly

Send MQSC commands directly to a local queue manager.

#### Run command indirectly

Run MQSC commands on a remote queue manager. These commands are put on the command queue of a remote queue manager and run in the order in which they were queued. Reports from the commands are returned to the local queue manager.

The **runmqsc** command takes its input from `stdin`. When the commands are processed, the results and a summary are put into a report that is sent to `stdout`.

By taking `stdin` from the keyboard, you can enter MQSC commands interactively.

By redirecting the input from a file, you can run a sequence of frequently used commands contained in the file. You can also redirect the output report to a file.

### Optional parameters

- c Modifies the **runmqsc** command to connect to a queue manager by using a client connection. The client channel definitions used to connect to the queue manager are located using the following environment variables in this order of precedence: **MQSERVER** , **MQCHLLIB** , and **MQCHLTAB** .

This option requires the client to be installed. If it is not installed an error message reporting the missing client libraries is issued.

- e Prevents source text for the MQSC commands from being copied into a report. This parameter is useful when you enter commands interactively.

- m **LocalQMgrName**

The local queue manager that you want to use to submit commands to the remote queue manager. If you omit this parameter the local default queue manager is used to submit commands to the remote queue manager. The **-w** parameter must also be specified.

- n Modifies the **runmqsc** command to not connect to a queue manager. If this parameter is specified, all other command parameters must be omitted, otherwise an error message is issued.

This option requires the client libraries to be installed. If they are not installed an error message is issued.

MQSC commands entered in this mode are limited to managing the local channel definition file, which is located through the **MQCHLLIB** and **MQCHLTAB** environment variables, or the default values if not defined.

**Note:** If you add new entries into the local channel definition file, or alter existing entries, these changes are not reflected inside the queue manager. The queue manager does not read the contents of the local channel definition file. The CCDT file is a write-only file from the perspective of the queue manager. The queue manager does not read the contents of the CCDT file.

Only the following MQSC commands are recognised:

**ALTER, DEFINE, DELETE, DISPLAY AUTHINFO** (Only of type CRLLDAP or OCSP)

**ALTER, DEFINE, DELETE, DISPLAY CHANNEL** (Only of type CLNTCONN)

For the AUTHINFO management commands, the names of existing AUTHINFO definitions are mapped and addressed using the names CRLLDAP

or OCSP *n* (according to type), where *n* is the numeric order in which

they appear in the channel definition file. New AUTHINFO definitions are appended to the client channel table in order. For example, the the following commands are issued:

```
DEFINE AUTHINFO(XYZ) AUTHTYPE(CRLLDAP) CONNAME('xyz')
```

```
DEFINE AUTHINFO(ABC) AUTHTYPE(CRLLDAP) CONNAME('abc')
```

This results in the 'xyz' LDAP server being checked for a CRL first, if that CRL server is unavailable then the 'abc' server is checked.

issuing the DISPLAY AUTHINFO(\*) CONNAME command shows this:

```
AMQ8566: Display authentication information details.
AUTHINFO(CRLLDAP1)
AUTHTYPE(CRLLDAP)          CONNAME(xyz)
AMQ8566: Display authentication information details.
AUTHINFO(CRLLDAP2)
AUTHTYPE(CRLLDAP)          CONNAME(abc)
```

**Note:** The client mode only supports inserting new entries at the end of the client channel table. If you want to change the order of precedence of the CRL LDAP servers, you must remove the existing objects from the list and reinsert them in the correct order at the end.

**-u *UserID***

If you use the **-u** parameter to supply a user ID, you are prompted for a matching password.

If you have configured the CONNAUTH AUTHINFO record with CHCKLOCL(REQUIRED) or CHCKLOCL(REQDADM), you must use the **-u** parameter otherwise you will not be able to administer your queue manager with **runmqsc**.

- v** Verifies the specified commands without performing the actions. This mode is only available locally. The **-w** and **-x** parameters are ignored if they are specified at the same time as **-v**.

**Important:** The **-v** flag checks the syntax of the command only. Setting the flag does not check if any objects mentioned in the command actually exist.

For example, if the queue Q1 does not exist in the queue manager, the following command is syntactically correct and does not generate any syntax errors: `runmqsc -v Qmgr display ql(Q1)`.

However, if you omit the **-v** flag, you receive error message AMQ8147.

**-w *WaitTime***

Run the MQSC commands on another queue manager. You must have the required channel and transmission queues set up for this. See Preparing channels and transmission queues for remote administration for more information.

This parameter is ignored if the **-v** parameter is specified.

***WaitTime***

The time, in seconds, that **runmqsc** waits for replies. Any replies received after this are discarded, but the MQSC commands still run. Specify a time in the range 1 through 999999.

Each command is sent as an Escape PCF to the command queue (SYSTEM.ADMIN.COMMAND.QUEUE) of the target queue manager.

The replies are received on queue SYSTEM.MQSC.REPLY.QUEUE and the outcome is added to the report. This can be defined as either a local queue or a model queue.

- x** The target queue manager is running under z/OS. This parameter applies only in indirect mode. The **-w** parameter must also be specified. In indirect mode, the MQSC commands are written in a form suitable for the IBM MQ for z/OS command queue.

***QMgrName***

The name of the target queue manager on which to run the MQSC commands. If not specified, the default queue manager is used.

**Return codes**

**Return code Description**

00	MQSC command file processed successfully
10	MQSC command file processed with errors; report contains reasons for failing commands
20	Error; MQSC command file not run

**Examples**

1. Enter this command at a command prompt:

```
runmqsc
```

Now you can enter MQSC commands directly at the command prompt. No queue manager name is specified, so the MQSC commands are processed on the default queue manager.

2. Use one of these commands, as appropriate in your environment, to specify that MQSC commands are to be verified only:

```
runmqsc -v BANK < "/u/users/commfile.in"
```

```
runmqsc -v BANK < "c:\users\commfile.in"
```

The queue manager name is BANK. The command verifies the MQSC commands in file commfile.in and displays the output in the current window.

3. These commands run the MQSC command file mqscfile.in against the default queue manager.

```
runmqsc < "/var/mqm/mqsc/mqscfile.in" > "/var/mqm/mqsc/mqscfile.out"
```

```
runmqsc < "C:\Program Files\IBM\WebSphere MQ\mqsc\mqscfile.in" >  
"C:\Program Files\IBM\WebSphere MQ\mqsc\mqscfile.out"
```

In this example, the output is directed to file mqscfile.out.

4. This command submits commands to the QMREMOTE queue manager, using QMLOCAL to submit the commands.

```
runmqsc -w 30 -m QMLOCAL QMREMOTE
```

### Related information:

Performing local administration tasks using MQSC commands

### runmqtmc:

Start the trigger monitor on a client.

### Purpose

Use the **runmqtmc** command to start a trigger monitor for a client. For further information about using trigger monitors, see Trigger monitors.

When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends, see "endmqm" on page 244. While the client trigger monitor is running it keeps the dead letter queue open.

### Syntax

```
runmqtmc [-m QMGrName] [-q InitiationQName] [-r] [-u UserId]
```

### Optional parameters

#### -m *QMGrName*

The name of the queue manager on which the client trigger monitor operates, by default the default queue manager.

#### -q *InitiationQName*

The name of the initiation queue to be processed, by default SYSTEM.DEFAULT.INITIATION.QUEUE.

-r Specifies that the client trigger monitor automatically reconnects.

#### -u *UserId*

The ID of the user authorized to get the triggered message.

Note that using this option does not affect the authority of the triggered program, that might have its own authentication options.

## Return codes

### Return code Description

0	Not used. The client trigger monitor is designed to run continuously and therefore not to end. The value is reserved.
10	Client trigger monitor interrupted by an error.
20	Error; client trigger monitor not run.

## Examples

For examples of using this command, see The Triggering sample programs.

### **runmqtrm:**

Start the trigger monitor on a server.

### Purpose

Use the **runmqtrm** command to start a trigger monitor. For further information about using trigger monitors, see Trigger monitors.

When a trigger monitor starts, it continuously monitors the specified initiation queue. The trigger monitor does not stop until the queue manager ends, see “endmqm” on page 244. While the trigger monitor is running it keeps the dead letter queue open.

### Syntax

```
▶▶ runmqtrm [-m QMgrName] [-q InitiationQName] [-u UserId]
```

### Optional parameters

#### **-m** *QMgrName*

The name of the queue manager on which the trigger monitor operates, by default the default queue manager.

#### **-q** *InitiationQName*

Specifies the name of the initiation queue to be processed, by default SYSTEM.DEFAULT.INITIATION.QUEUE.

#### **-u** *UserId*

The ID of the user authorized to read the initiation queue, and get the triggered message.

Note that using this option does not affect the authority of the triggered program, that might have its own authentication options.

### Return codes

**Return code Description**

0	Not used. The trigger monitor is designed to run continuously and therefore not to end. Hence a value of 0 would not be seen. The value is reserved.
10	Trigger monitor interrupted by an error.
20	Error; trigger monitor not run.

**runswchl:**

runswchl (switch cluster channel) on UNIX, Linux, and Windows.

**Purpose**

The command switches or queries the cluster transmission queues associated with cluster-sender channels.

**Usage notes**

You must log on as an Administrator to run this command.

The command switches all the stopped or inactive cluster-sender channels that match the **-c** parameter, require switching, and can be switched. The command reports back on the channels that are switched, the channels that do not require switching, and the channels it cannot switch because they are not stopped or inactive.

If you set the **-q** parameter, the command does not perform the switch, but it provides the list of channels that would be switched.

**Syntax**

```

▶▶ runswchl -m QmgrName -c * -c GenericChannelName -c ChannelName [-q] [-n]

```

**Required parameters**

**-m** *QmgrName*  
The queue manager to run the command against. The queue manager must be started.

**-c** \*  
All the cluster-sender channels

**-c** *GenericChannelName*  
All matching cluster-sender channels

**-c** *ChannelName*  
Single cluster-sender channel.

**Optional parameters**

**-q** Display the state of one or more channels. If you omit this parameter, the commands switches any stopped or inactive channels that require switching.

**-n** When switching transmission queues, do not transfer messages from the old queue to the new transmission queue.

**Note:** Take care with the **-n** option: messages on the old transmission queue are not transferred unless you associate the transmission queue with another cluster-sender channel.

## Return codes

- 0 The command completed successfully
- 10 The command completed with warnings.
- 20 The command completed with errors.

## Examples

To display the configuration state of cluster-sender channel T0.QM2:

```
RUNSWCHL -m QM1 -c T0.QM2 -q
```

To switch the transmission queue for cluster-sender channel T0.QM3 without moving the messages on it:

```
RUNSWCHL -m QM1 -c T0.QM3 -n
```

To switch the transmission queue for cluster-sender channel T0.QM3 and move the messages on it:

```
RUNSWCHL -m QM1 -c T0.QM3
```

To display the configuration state of all cluster-sender channels on QM1:

```
RUNSWCHL -m QM1 -c * -q
```

To display the configuration state of all cluster-sender channels with a generic name of T0.\*:

```
RUNSWCHL -m QM1 -c T0.* -q
```

## Related information:

Clustering: Switching cluster transmission queues

## setmqaut:

Change the authorizations to a profile, object, or class of objects. Authorizations can be granted to, or revoked from, any number of principals or groups.

From IBM MQ Version 8.0, on UNIX and Linux systems, the object authority manager (OAM) can use user-based authorization as well as group-based authorization.

For more information about authorization service components, see Installable services, Service components, and Authorization service interface.

For more information about how authorizations work, see How authorizations work.

For more information about how user-based authorizations, see User-based permissions on Unix and Linux systems.

## Syntax

```
►► setmqaut [ -m QMGrName ] -n Profile -t ObjectType [ -s ServiceComponent ]
```

**MQI authorizations:**

**Context authorizations:**

**Administration authorizations:**

### Generic authorizations:

### Description

Use **setmqaut** both to *grant* an authorization, that is, give a principal or user group permission to perform an operation, and to *revoke* an authorization, that is, remove the permission to perform an operation. You can specify a number of parameters:

- Queue manager name
- Principals and user groups
- Object type
- Profile name
- Service component

The authorizations that can be given are categorized as follows:

- Authorizations for issuing MQI calls
- Authorizations for MQI context
- Authorizations for issuing commands for administration tasks
- Generic authorizations

Each authorization to be changed is specified in an authorization list as part of the command. Each item in the list is a string prefixed by a plus sign (+) or a minus sign (-). For example, if you include +put in the authorization list, you grant authority to issue MQPUT calls against a queue. Alternatively, if you include -put in the authorization list, you revoke the authority to issue MQPUT calls.

You can specify any number of principals, user groups, and authorizations in a single command, but you must specify at least one principal or user group.

On UNIX, Linux, and Windows, you can use the installable services to control the queue manager authorization. For more information about the **SecurityPolicy** attribute that must be set to control the queue manager authorization, see Installable services. If the **SecurityPolicy** attribute is set to group or default, or if the **SecurityPolicy** attribute is not set, the following information is true:

- If a principal is a member of more than one user group, the principal effectively has the combined authorities of all those user groups. On Windows systems, the principal also has all the authorities that are granted to it explicitly using the **setmqaut** command.
- On UNIX systems, all authorities are held by user groups internally, not by principals. Granting authorities to groups has the following implications:
  - If you use the **setmqaut** command to grant an authority to a principal, the authority is granted to the primary user group of the principal. This means that the authority is effectively granted to all members of that user group.
  - If you use the **setmqaut** command to revoke an authority from a principal, the authority is revoked from the primary user group of the principal. This means that the authority is effectively revoked from all members of that user group.

To alter authorizations for a cluster sender channel that has been automatically generated by a repository, see Channel definition commands.

### Required parameters

#### **-t** *ObjectType*

The type of object for which to change authorizations.

Possible values are as follows:

Table 66. *ObjectType* values.

Value	Description
<b>authinfo</b>	An authentication information object
<b>channel</b> or <b>chl</b>	A channel
<b>clntconn</b> or <b>clcn</b>	A client connection channel
<b>comminfo</b>	A communication information object
<b>listener</b> or <b>lstr</b>	A listener
<b>namelist</b> or <b>nl</b>	A namelist
<b>process</b> or <b>prcs</b>	A process
<b>queue</b> or <b>q</b>	A queue
<b>qmgr</b>	A queue manager
<b>rqmname</b> or <b>rqmn</b>	A remote queue manager name
<b>service</b> or <b>srvc</b>	A service
<b>topic</b> or <b>top</b>	A topic

#### **-n** *Profile*

The name of the profile for which to change authorizations. The authorizations apply to all IBM MQ objects with names that match the profile name specified. The profile name can be generic, using wildcard characters to specify a range of names as explained in Using OAM generic profiles on UNIX, Linux, and Windows systems.

This parameter is required, unless you are changing the authorizations of a queue manager, in which case you must *not* include it. To change the authorizations of a queue manager use the queue manager name, for example

```
setmqaut -m QMGR -t qmgr -p user1 +connect
```

where *QMGR* is the name of the queue manager and *user1* is the user requesting the change.

Each class of object has authority records for each group or principal. These records have the profile name @CLASS and track the crt (create) authority common to all objects of that class. If the crt authority for any object of that class is changed then this record is updated. For example:

```
profile: @class
object type: queue
entity: test
entity type: principal
authority: crt
```

This shows that members of the group test have crt authority to the class queue.

### Optional parameters

#### **-m** *QMGrName*

The name of the queue manager of the object for which to change authorizations. The name can contain up to 48 characters.

This parameter is optional if you are changing the authorizations of your default queue manager.

#### **-p** *PrincipalName*

The name of the principal for which to change authorizations.

 For IBM MQ for Windows only, the name of the principal can optionally include a domain name, specified in the following format:

```
userid@domain
```

For more information about including domain names on the name of a principal, see Principals and groups.

You must have at least one principal or group.

#### **-g** *GroupName*

The name of the user group for which to change authorizations. You can specify more than one group name, but each name must be prefixed by the -g flag.

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

The IBM MQ Object Authority Manager validates the users and groups at the domain level, only if you set the **GroupMode1** attribute to *GlobalGroups* in the Security stanza of the queue manager.

#### **-u** *SID*

The SID for which authorities are to be removed. You can specify more than one SID, but each name must be prefixed by the -u flag.

This option must be used with either **+remove** or **-remove** .

This parameter is only valid on IBM MQ for Windows.

#### **-s** *ServiceComponent*

The name of the authorization service to which the authorizations apply (if your system supports installable authorization services). This parameter is optional; if you omit it, the authorization update is made to the first installable component for the service.

**+remove or -remove**

Remove all the authorities from IBM MQ objects that match the specified profile.

*Authorizations*

The authorizations to be granted or revoked. Each item in the list is prefixed by a plus sign (+) or a minus sign (-). The plus sign indicates that authority is to be granted. The minus sign indicates that authority is to be revoked.

For example, to grant authority to issue MQPUT calls, specify +put in the list. To revoke the authority to issue MQPUT calls, specify -put.

Table 67 shows the authorities that can be given to the different object types.

*Table 67. Specifying authorities for different object types*

Authority	Queue	Process	Queue manager	Remote queue manager name	Namespace	Topic	Auth info	Clntconn	Channel	Listener	Service	Comm info
all <sup>1</sup>	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

system	No	No	Yes	No	No	No	No	No	No	No	No	No

Table 67. Specifying authorities for different object types (continued)

Authority	Queue	Process	Queue manager	Remote queue manager name	Namelist	Topic	Auth info	Clntconn	Channel	Listener	Service	Comm info
<p><b>Notes:</b></p> <ol style="list-style-type: none"> <li>1. all authority is equivalent to the union of the authorities alladm, allmqi, and system appropriate to the object type.</li> <li>2. alladm authority is equivalent to the union of the individual authorities chg, clr, dlt, dsp, ctrl, and ctrlx appropriate to the object type. crt authority is not included in the subset alladm.</li> <li>3. allmqi authority is equivalent to the union of the individual authorities altusr, browse, connect, get, inq, pub, put, resume, set, and sub appropriate to the object type.</li> <li>4. To use setid or setall authority, authorizations must be granted on both the appropriate queue object and also on the queue manager object.</li> </ol>												

### Description of specific authorities

You should not grant a user an authority (for example, set authority on a queue manager, or system authority) that allows the user to access IBM MQ privileged options, unless the required authority is specifically documented, and required to run any IBM MQ command, or IBM MQ API call.

For example, a user requires system authority to run the **setmqaut** command.

#### chg

A user needs chg authority to make any authorization changes on the queue manager. The authorization changes include:

- Changing the authorizations to a profile, object, or class of objects
- Creating and modifying channel authentication records, and so on

A user also needs chg authority to change or set the attributes of an IBM MQ object, using PCF or MQSC commands.

#### crt

If you grant an entity +crt authority to the queue manager, then that entity also gains +crt authority for each object class.

However, when you remove +crt authority against the queue manager object that only removes the authority on the queue manager object class; crt authority for other objects classes are not removed.

Note that crt authority on the queue manager object has no functional use, and is available for backwards-compatibility purposes only.

#### dlt

Note that the dlt authority against the queue manager object has no functional use, and is available for backwards-compatibility purposes only.

#### set

A user needs set authority against the queue to change or set the attributes of a queue using the MQSET API call.

set authority on the queue manager is not required for any administrative purpose, or for any application connecting to the queue manager.

However, a user needs set authority against the queue manager to set privileged connection options.

Note that set authority on the process object has no functional use, and is available for backwards-compatibility purposes only.

**Important:** Privileged connection options are internal to the queue manager and are not available in IBM MQ API calls used by IBM MQ applications.

## system

The **setmqaut** command makes a privileged IBM MQ connection to the queue manager.

Any user who runs IBM MQ commands that makes a privileged IBM MQ connection needs system authority on the queue manager.

## Return codes

Return code	Explanation
0	Successful operation
26	Queue manager running as a standby instance.
36	Invalid arguments supplied
40	Queue manager not available
49	Queue manager stopping
58	Inconsistent use of installations detected
69	Storage not available
71	Unexpected error
72	Queue manager name error
133	Unknown object name
145	Unexpected object name
146	Object name missing
147	Object type missing
148	Invalid object type
149	Entity name missing
150	Authorization specification missing
151	Invalid authorization specification

## Examples

1. This example shows a command that specifies that the object on which authorizations are being given is the queue orange.queue on queue manager saturn.queue.manager.

```
setmqaut -m saturn.queue.manager -n orange.queue -t queue  
-g tango +inq +alladm
```

The authorizations are given to a user group called tango, and the associated authorization list specifies that the user group can:

- Issue MQINQ calls
- Perform all administration operations on that object

2. In this example, the authorization list specifies that a user group called foxy:

- Cannot issue any MQI calls to the specified queue
- Can perform all administration operations on the specified queue

```
setmqaut -m saturn.queue.manager -n orange.queue -t queue  
-g foxy -allmqi +alladm
```

3. This example gives user1 full access to all queues with names beginning a.b. on queue manager qmgr1. The profile applies to any object with a name that matches the profile.

```
setmqaut -m qmgr1 -n a.b.* -t q -p user1 +all
```

4. This example deletes the specified profile.

```
setmqaut -m qmgr1 -n a.b.* -t q -p user1 -remove
```

5. This example creates a profile with no authority.

```
setmqaut -m qmgr1 -n a.b.* -t q -p user1 +none
```

**Related reference:**

“SET AUTHREC” on page 986

Use the MQSC command SET AUTHREC to set authority records associated with a profile name.

*Authorizations for MQI calls:*

*Table 68. Authorizations for MQI calls.*

Value	Description
altusr	Use another user's authority for the queue manager. Also required for channel operations where the asserting userid is different from the one associated with the connection handle. (For example, an assigned dedicated profile on the receiver MCA end, or when processing a RESET CHL SEQNUM() request from remote systems.)  If you are using IBM MQ prior to Version 7.0.1.4, you must set +altusr for the group containing the user ID specified in MCAUSER on a receiver channel. This action prevents error message AMQ2035 appearing if you reset the sequence number of the corresponding sender channel.
browse	Retrieve a message from a queue using an MQGET call with the BROWSE option.
connect	Connect the application to the specified queue manager using an MQCONN call.
get	Retrieve a message from a queue using an MQGET call.
inq	Make an inquiry on a specific queue using an MQINQ call.
pub	Publish a message on a topic using the MQPUT call.
put	Put a message on a specific queue using an MQPUT call.
resume	Resume a subscription using the MQSUB call.
set	Set attributes on a queue from the MQI using an MQSET call.
sub	Create, alter or resume a subscription to a topic using the MQSUB call.

**Note:** If you open a queue for multiple options, you must be authorized for each option.

*Authorizations for context:*

Table 69. Authorizations for context.

Value	Description
passall	Pass all context on the specified queue. All the context fields are copied from the original request.
passid	Pass identity context on the specified queue. The identity context is the same as that of the request.
setall	Set all context on the specified queue. This is used by special system utilities.
setid	Set identity context on the specified queue. This is used by special system utilities.  In order to modify any of the message context options, you must have the appropriate authorizations to issue the call. For example, in order to use MQOO_SET_IDENTITY_CONTEXT or MQPMO_SET_IDENTITY_CONTEXT, you must have +setid permission.

**Note:** To use setid or setall authority authorizations must be granted on both the appropriate queue object and also on the queue manager object.

Authorizations for commands:

Table 70. Authorizations for commands.

Value	Description
chg	Change the attributes of the specified object.
clr	Clear the specified queue or a topic.
crt	Create objects of the specified type.
dlt	Delete the specified object.  Note, that the dlt authority has no effect on a queue manager object.
dsp	Display the attributes of the specified object.
ctrl	For listeners and services, start and stop the specified channel, listener, or service.  For channels, start, stop, and ping the specified channel.  For topics, define, alter, or delete subscriptions.
ctrlx	Reset or resolve the specified channel.

Authorizations for generic operations:

Table 71. Authorizations for generic operations.

Value	Description
all	Use all operations applicable to the object. all authority is equivalent to the union of the authorities alladm, allmqi, and system appropriate to the object type.
alladm	Use all administration operations applicable to the object.
allmqi	Use all MQI calls applicable to the object.
none	No authority. Use this authorization to create profiles without authority. When an authority is given to an object or group that was previously showing "none", then the authorization changes to the authority just applied. However, when the "none" authorization is added to an object or group with an existing alternative authority, the authority does not change.
system	Use queue manager for internal system operations.

### setmqcrl:

Administer CRL (certificate revocation list) LDAP definitions in an Active Directory ( Windows only).

### Purpose

**Note:** The **setmqcrl** command applies to IBM MQ for Windows only.

Use the **setmqcrl** command to configure and administer support for publishing CRL (certificate revocation list) LDAP definitions in an Active Directory.

A domain administrator must use this command, or **setmqscp** , initially to prepare the Active Directory for IBM MQ usage and to grant IBM MQ users and administrators the relevant authorities to access and update the IBM MQ Active Directory objects. You can also use the **setmqcrl** command to display all the currently configured CRL server definitions available on the Active Directory, that is, those definitions referred to by the queue manager's CRL namelist.

The only types of CRL servers supported are LDAP servers.

### Syntax

### Optional parameters

You must specify one of -a (add), -r (remove) or -d (display).

- a Adds the IBM MQ MQI client connections Active Directory container, if it does not already exist. You must be a user with the appropriate privileges to create subcontainers in the *System* container of your domain. The IBM MQ folder is called CN=IBM-MQClientConnections. Do not delete this folder in any other way than by using the **setmqscp** command.
- d Displays the IBM MQ CRL server definitions.
- r Removes the IBM MQ CRL server definitions.

**-m [ \* | qmgr ]**

Modifies the specified parameter ( -a or -r) so that only the specified queue manager is affected. You must include this option with the -a parameter.

**\* | qmgr**

\* specifies that all queue managers are affected. This enables you to migrate a specific IBM MQ CRL server definitions file from one queue manager alone.

## Examples

The following command creates the IBM-MQClientConnections folder and allocates the required permissions to IBM MQ administrators for the folder, and to child objects created subsequently. (In this, it is functionally equivalent to setmqscp -a.)

```
setmqcrl -a
```

The following command migrates existing CRL server definitions from a local queue manager, Paint.queue.manager, to the Active Directory, **deleting any other CRL definitions from the Active Directory first**:

```
setmqcrl -a -m Paint.queue.manager
```

## setmqenv:

Use the **setmqenv** command to set up the IBM MQ environment on UNIX, Linux, and Windows.

## Purpose

You can use the **setmqenv** command to automatically set up the environment for use with an installation of IBM MQ. Alternatively, you can use the **crtmqenv** command to create a list of environment variables and values to manually set each environment variable for your system; see “crtmqenv” on page 190 for more information.

**Note:** Any changes you make to the environment are not persistent. If you log out, and log in again, your changes are lost.

You can specify which installation the environment is set up for by specifying a queue manager name, an installation name, or an installation path. You can also set up the environment for the installation that issues the **setmqenv** command by issuing the command with the **-s** parameter.

The **setmqenv** command sets the following environment variables, appropriate to your system:

- CLASSPATH
- INCLUDE
- LIB
- MANPATH
- MQ\_DATA\_PATH
- MQ\_ENV\_MODE
- MQ\_FILE\_PATH
- MQ\_JAVA\_INSTALL\_PATH
- MQ\_JAVA\_DATA\_PATH
- MQ\_JAVA\_LIB\_PATH
- MQ\_JAVA\_JVM\_FLAG
- MQ\_JRE\_PATH
- PATH

On UNIX and Linux systems, if the **-l** or **-k** flag is specified, the *LIBPATH* environment variable is set on AIX, and the *LD\_LIBRARY\_PATH* environment variable is set on HP-UX, Linux, and Solaris.

### Usage notes

- If you have installed IBM MQ V 7.0.1, do not use the **setmqenv** command. Some of the components of IBM MQ V 7.0.1, such as Explorer, reference the environment variables for their library paths and therefore will not work if the **setmqenv** command has been used to alter the environment variables to point to an IBM MQ V 7.0.1 installation path.
- The **setmqenv** command removes all directories for all IBM MQ installations from the environment variables before adding new references to the installation for which you are setting up the environment for. Therefore, if you want to set any additional environment variables that reference IBM MQ, set the variables after issuing the **setmqenv** command. For example, if you want to add *MQ\_INSTALLATION\_PATH/java/lib* to *LD\_LIBRARY\_PATH*, you must do so after running the **setmqenv** command.
- In some shells, command-line parameters cannot be used with **setmqenv** and any **setmqenv** command issued is assumed to be a **setmqenv -s** command. The command produces an informational message that the command has been run as if a **setmqenv -s** command had been issued. Therefore, in these shells you must ensure that you issue the command from the installation for which you want to set the environment for. In these shells, you must set the *LD\_LIBRARY\_PATH* variable manually. Use the **crtmqenv** command with the **-l** or **-k** parameter to list the *LD\_LIBRARY\_PATH* variable and value. Then use this value to set the *LD\_LIBRARY\_PATH*.

### Syntax

### Optional Parameters

#### **-m QMgrName**

Set the environment for the installation associated with the queue manager *QMgrName*.

#### **-n InstallationName**

Set the environment for the installation named *InstallationName*.

#### **-p InstallationPath**

Set the environment for the installation in the path *InstallationPath*.

**-r** Remove all installations from the environment.

**-s** Set the environment for the installation that issued the **setmqenv** command.

**-k** UNIX and Linux only.

Include the *LD\_LIBRARY\_PATH* or *LIBPATH* environment variable in the environment, adding the path to the IBM MQ libraries at the start of the current *LD\_LIBRARY\_PATH* or *LIBPATH* variable.

**-l** UNIX and Linux only.

Include the *LD\_LIBRARY\_PATH* or *LIBPATH* environment variable in the environment, adding the path to the IBM MQ libraries at the end of the current *LD\_LIBRARY\_PATH* or *LIBPATH* variable.

#### **-x Mode**

*Mode* can take the value 32 or 64.

Create a 32-bit or 64-bit environment. If this parameter is not specified, the environment matches that of the queue manager or installation specified in the command.

Any attempt to display a 64-bit environment with a 32-bit installation fails.

### Return codes

Return code	Description
0	Command completed normally.
10	Command completed with unexpected results.
20	An error occurred during processing.

### Examples

The following examples assume that a copy of IBM MQ is installed in the `/opt/mqm` directory on a UNIX or Linux system.

**Note:** The period character (`.`) character used at the beginning of each command makes the `setmqenv` script run in the current shell. Therefore, the environment changes made by the `setmqenv` script are applied to the current shell. Without the period character (`.`), the environment variables are changed in another shell, and the changes are not applied to the shell from which the command is issued.

- The following command sets up the environment for an installation installed in the `/opt/mqm` directory:

```
. /opt/mqm/bin/setmqenv -s
```

- The following command sets up the environment for an installation installed in the `/opt/mqm2` directory, and includes the path to the installation at the end of the current value of the `LD_LIBRARY_PATH` variable:

```
. /opt/mqm/bin/setmqenv -p /opt/mqm2 -l
```

- The following command sets up the environment for queue manager QM1 in a 32-bit environment:

```
. /opt/mqm/bin/setmqenv -m QM1 -x 32
```

The following example assumes that a copy of IBM MQ is installed in `C:\Program Files\IBM\WebSphere MQ` on a Windows system.

This command sets up the environment for an installation called `Installation1`:

```
"C:\Program Files\IBM\WebSphere MQ\bin\setmqenv.cmd" -n Installation1
```

### Related reference:

"`crtmqenv`" on page 190

Create a list of environment variables for an installation of IBM MQ, on UNIX, Linux, and Windows.

### Related information:

Choosing a primary installation

Multiple installations

### setmqinst:

Set IBM MQ installations, on UNIX, Linux, and Windows.

### Purpose

You can use the `setmqinst` command to change the installation description of an installation, or to set or unset an installation as the primary installation. To change the primary installation, you must unset the current primary installation before you can set a new primary installation. This command updates information contained in the `mqinst.ini` file.

After unsetting the primary installation, the `setmqinst` command will not be available unless you specify the full path or have an appropriate installation directory on your `PATH` (or equivalent). The default path in a system standard location will have been deleted.

On UNIX platforms you should not assume that the current directory is in the path. If you are in `/opt/mqm/bin` and want to run, for example, `/opt/mqm/bin/dspmqrver` you need to enter `"/opt/mqm/bin/dspmqrver"` or `"/dspmqrver"`.

File `mqinst.ini` contains information about all IBM MQ installations on a system. For more information about `mqinst.ini`, see Installation configuration file, `mqinst.ini`.

On UNIX or Linux systems, you must run this command as root. On Windows systems, you must run this command as a member of the Administrators group. The command does not have to be run from the installation you are modifying.

### Syntax

```
►► setmqinst | Action | Installation |
```

### Action:

```
|
| -i
| -x
| -d DescriptiveText
|
```

### Installation:

```
|
| -p InstallationPath
| -n InstallationName
| -p InstallationPath -n InstallationName (1)
| -n InstallationName -p InstallationPath (1)
|
```

### Notes:

- 1 When specified together, the installation name and installation path must refer to the same installation.

### Parameters

**-d** *DescriptiveText*

Text that describes the installation.

The text can be up to 64 single-byte characters, or 32 double-byte characters. The default value is all blanks. You must use double quotation marks around the text if it contains spaces.

**-i** Set this installation as the primary installation.

**-x** Unset this installation as the primary installation.

**-n** *InstallationName*

The name of the installation to modify.

**-p** *InstallationPath*

The path of the installation to modify. You must use double quotation marks around the path if it contains spaces

### Return codes

Return code	Description
0	Entry set without error
36	Invalid arguments supplied
37	Descriptive text was in error
44	Entry does not exist
59	Invalid installation specified
71	Unexpected error
89	ini file error
96	Could not lock ini file
98	Insufficient authority to access ini file
131	Resource problem

### Examples

1. This command sets the installation with the name of myInstallation as the primary installation:  

```
setmqinst -i -n myInstallation
```
2. This command sets the installation with an installation path of /opt/myInstallation as the primary installation:  

```
setmqinst -i -p /opt/myInstallation
```
3. This command unsets the installation named myInstallation as the primary installation:  

```
setmqinst -x -n myInstallation
```
4. This command unsets the installation with an installation path of /opt/myInstallation as the primary installation:  

```
setmqinst -x -p /opt/myInstallation
```
5. This command sets the descriptive text for the installation named myInstallation:  

```
setmqinst -d "My installation" -n myInstallation
```

The descriptive text is enclosed in quotation marks as it contains spaces.

### Related information:

Choosing a primary installation

Changing the primary installation

### setmqm:

Set the associated installation of a queue manager.

### Purpose

Use the **setmqm** command to set the associated IBM MQ installation of a queue manager. The queue manager can then be administered using only the commands of the associated installation. For example, when a queue manager is started with **strmqm**, it must be the **strmqm** command of the installation that was specified by the **setmqm** command.

For more information about using this command, including information about when to use it, see [Associating a queue manager with an installation](#).

This command is only applicable to UNIX, Linux and Windows.

### Usage notes

- You must use the **setmqm** command from the installation you want to associate the queue manager with.
- The installation name specified by the **setmqm** command must match the installation from which the **setmqm** command is issued.

- You must stop the queue manager before executing the **setmqm** command. The command fails if the queue manager is still running.
- Once you have set the associated installation of a queue manager using the **setmqm** command, migration of the queue manager's data occurs when you start the queue manager using the **strmqm** command.
- Once you have started the queue manager on an installation, you cannot then use **setmqm** to set the associated installation to an earlier version of IBM MQ, as it is not possible to migrate back to earlier versions of IBM MQ.
- You can find out which installation is associated with a queue manager by using the **dspmqr** command. See “dspmqr” on page 217 for more information.

## Syntax

```
►► setmqm -m QMGrName -n InstallationName ◀◀
```

## Required Parameters

**-m** *QMGrName*

The name of the queue manager to set the associated installation for.

**-n** *InstallationName*

The name of the installation that the queue manager is to be associated with. The installation name is not case-sensitive.

## Return codes

Return code	Description
0	Queue manager set to an installation without error
5	Queue manager running
36	Invalid arguments supplied
59	Invalid installation specified
60	Command not executed from the installation named by the -n parameter
61	Invalid installation name for this queue manager
69	Resource problem
71	Unexpected error
72	Queue manager name error
119	User not authorized

## Examples

1. This command associates a queue manager QMGR1, with an installation with the installation name of myInstallation.

```
MQ_INSTALLATION_PATH/bin/setmqm -m QMGR1 -n myInstallation
```

## setmqprd:

Enroll an IBM MQ production license.

A license is normally enrolled as part of the installation process.

**Note:** You must have the appropriate privileges to run this command on your system. UNIX requires root access, and Windows with UAC (User Account Control) requires Administrator access to run this command.

## Syntax

## Required parameters

### *LicenseFile*

Specifies the fully-qualified name of the production license certificate file.

The full license file is **amqpcert.lic**:

- On UNIX and Linux, it is in the */MediaRoot/licenses* directory on the installation media.
- On Windows it is in the *\MediaRoot\licenses* directory on the installation media. It is installed into the *bin* directory on the IBM MQ installation path.
- On IBM i, issue the command

```
CALL PGM(QMQM/SETMQPRD) PARM('/QOPT/OPT01/amqpcert.lic')
```

## Trial license conversion

A trial license installation is identical to a production license installation, except for the “count-down” message that is displayed when you start a queue manager on an installation with a trial license. Parts of IBM MQ that are not installed on the server, such as the IBM MQ MQI client, continue to work after the expiry of the trial license. You do not need to run **setmqprd** to enroll them with a production license.

When a trial license expires, you can still uninstall IBM MQ. You can also reinstall IBM MQ with a full production license.

Run **setmqprd** to enroll a production license after installing and using a installation with a trial license.

### Related information:

Converting a trial license on UNIX, Linux, and Windows

### setmqscp:

Publish client connection channel definitions in an Active Directory ( Windows only).

### Purpose

**Note:** The **setmqscp** command applies to IBM MQ for Windows only.

Use the **setmqscp** command to configure and administer support for publishing client connection channel definitions in an Active Directory.

Initially, this command is used by a domain administrator to:

- Prepare the Active Directory for IBM MQ use
- Grant IBM MQ users and administrators the relevant authorities to access and update the IBM MQ Active Directory objects

You can also use the **setmqscp** command to display all the currently configured client connection channel definitions available on the Active Directory.

### Syntax

## Optional parameters

You must specify one of `-a` (add), `-r` (remove) or `-d` (display).

- a** Adds the IBM MQ MQI client connections Active Directory container, if it does not already exist. You must be a user with the appropriate privileges to create subcontainers in the *System* container of your domain. The IBM MQ folder is called CN=IBM-MQClientConnections. Do not delete this folder in any other way than by using the `setmqscp -r` command.
- d** Displays the service connection points.
- r** Removes the service connection points. If you omit `-m`, and no client connection definitions exist in the IBM-MQClientConnections folder, the folder itself is removed from the Active Directory.
- m [ \* | qmgr ]**  
Modifies the specified parameter (`-a` or `-r`) so that only the specified queue manager is affected.
  - \* | qmgr**  
\* specifies that all queue managers are affected. This enables you to migrate a specific client connection table file from one queue manager alone, if required.

## Examples

The following command creates the IBM-MQClientConnections folder and allocates the required permissions to IBM MQ administrators for the folder, and to child objects created subsequently:

```
setmqscp -a
```

The following command migrates existing client connection definitions from a local queue manager, Paint.queue.manager, to the Active Directory:

```
setmqscp -a -m Paint.queue.manager
```

The following command migrates all client connection definitions on the local server to the Active Directory:

```
setmqscp -a -m *
```

## setmqspl:

Use the **setmqspl** command to define a new security policy, alter an already existing one, or remove an existing policy.

## Syntax

## Policy definition:

**Notes:**

- 1 If an encryption algorithm is selected, a recipient DN must also be provided.
- 2 If an author DN is provided, a signing algorithm must also be selected.

Table 72. setmqspl command flags.

Command flag	Explanation
-m	Queue manager name.  This flag is mandatory for all actions on security policies.
-p	Policy name.  Set the policy name to the name of the queue you want the policy to apply to.
-s	Digital signature algorithm.  IBM MQ Advanced Message Security supports the following values: MD5, SHA1, SHA256, SHA384, and SHA512. All must be in uppercase. The default value is NONE <b>Important:</b> <ul style="list-style-type: none"> <li>• For the SHA384 and SHA512 cryptographic hash functions, keys used for signing must be longer than 768 bits.</li> <li>• The name, or names, of the encryption algorithms must be in uppercase.</li> <li>• The signature algorithm cannot be NONE if the encryption algorithm is different from NONE.</li> </ul>
-e	Digital encryption algorithm.  IBM MQ Advanced Message Security supports the following encryption algorithms: RC2, DES, 3DES, AES128, AES256. The default value is NONE. <b>Important:</b> The name, or names, of the encryption algorithms must be in uppercase

Table 72. *setmqspl* command flags. (continued)

Command flag	Explanation
-r	<p>The distinguished name (DN) of the message recipient (certificate of a DN provided is used to encrypt a given message). Recipients can be specified only if encryption algorithm is different from NONE. Multiple recipients can be included for a message. Each DN must be provided with a separate -r flag.</p> <p><b>Important:</b></p> <ul style="list-style-type: none"> <li>• DN attribute names must be in uppercase.</li> <li>• Commas must be used as a name separators.</li> <li>• To avoid command interpreter errors, place quotation marks around the DNs.</li> </ul> <p>For example: -r "CN=alice, O=ibm, C=US"</p>
-a	<p>Signature DN that is validated during message retrieval. Only messages signed by a user with a DN provided are accepted during the retrieval. Signature DNs can be specified only if the signature algorithm is different from NONE. Multiple authors can be included. Each author needs to have a separate -a flag.</p> <p><b>Important:</b> DN attribute name must be in uppercase.</p>
-t	<p>Toleration flag that indicates whether a policy that is associated with a queue can be ignored when an attempt to retrieve a message from the queue involves a message with no security policy set. Valid values include:</p> <ul style="list-style-type: none"> <li>• <b>0 (default)</b> Toleration flag off.</li> <li>• <b>1</b> Toleration flag on.</li> </ul> <p>Toleration is optional and facilitates staged implementation, where policies were applied to queues but those queues may already contain messages that have no policy, or still receive messages from remote systems that do not have the security policy set.</p>
-remove	<p>Delete policy.</p> <p>If specified, only the -p flag remains valid.</p>

**setmqxacred (add XA credentials):** 

Use the **setmqxacred** command to add or modify credentials in the IBM MQ XA credentials store.

**Purpose**

The command adds new credentials to the IBM MQ XA credentials store, or modifies or deletes existing credentials.

**Syntax**

## Required parameters

**-m** *QmgrName*  
The queue manager for which authentication details are stored.

## Optional parameters

**-x** *ResourceMgrName*  
Specifies the resource manager name as defined in the `qm.ini` file.

**-u** *user*  
Specifies the user name to use to connect to the database.

**-p** *password*  
Specifies the password for the user.

**-d**  
Deletes the credentials for the named resource manager.

**-l**  
Lists the credentials in the queue manager store.

## Examples

To add credentials for the queue manager QM1 for the resource mqdb2:

```
# setmqxacred -m QM1 -x mydb2 -u user1 -p Password1
Successfully added credentials for XA Resource Manager mydb2
```

To delete the credentials for the queue manager QM1 for the resource mqdb2:

```
# setmqxacred -m QM1 -x mydb2 -d
Successfully removed credentials for XA Resource Manager mydb2
```

To list details about the credentials stored in the credentials store.

```
# setmqxacred -m QM1 -l
ResourceName(mydb2) UserName(user1)
ResourceName(myora) UserName(user2)
```

## **strmqcfg:**

Start MQ Explorer ( Windows and Linux x86-64 platforms only).

### **Purpose**

For IBM MQ for Windows only, note that if you use **runas** to execute this command, you must define the Environment Variable *APPDATA* to set a path to a directory that the user you are running as has access. For example:

```
set APPDATA=C:\Users\user_name\AppData\Roaming
```

You can use the following command to identify the path that *APPDATA* is set to:

```
set APPDATA
```

On Linux, to start MQ Explorer successfully, you must be able to write a file to your home directory, and the home directory must exist.

**Note:** The preferred way to start MQ Explorer on Windows and Linux systems is by using the system menu, or the MQExplorer executable file.

### **Syntax**

The syntax of this command follows:

```
►► strmqcfg [ -c ] [ -i ] [ -x ]
```

### **Optional parameters**

- c** `-clean` is passed to Eclipse. This parameter causes Eclipse to delete any cached data used by the Eclipse runtime.
- i** `-clean -initialize` is passed to Eclipse. This parameter causes Eclipse to delete any cached data as well as discard configuration information used by the Eclipse runtime.  
MQ Explorer starts briefly and then ends without displaying the user interface.
- x** Output debug messages to the console.

## **strmqcsv:**

Start the command server for a queue manager.

### **Purpose**

Use the **strmqcsv** command to start the command server for the specified queue manager. This enables IBM MQ to process commands sent to the command queue.

You must use the **strmqcsv** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmqr -o` installation command.

If the queue manager attribute, *SCMDSERV*, is specified as *QMGR* then changing the state of the command server using **strmqcsv** does not effect how the queue manager acts upon the *SCMDSERV* attribute at the next restart.

### **Syntax**

## Required parameters

None

## Optional parameters

**-a** Blocks the following PCF commands from modifying or displaying authority information:

- Inquire authority records ( `MQCMD_INQUIRE_AUTH_RECS` )
- Inquire entity authority ( `MQCMD_INQUIRE_ENTITY_AUTH` )
- Set authority record ( `MQCMD_SET_AUTH_REC` ).
- Delete authority record ( `MQCMD_DELETE_AUTH_REC` ).

### *QMgrName*

The name of the queue manager on which to start the command server. If omitted, the default queue manager is used.

## Return codes

Return code	Description
0	Command completed normally
10	Command completed with unexpected results
20	An error occurred during processing

## Examples

The following command starts a command server for queue manager earth:

```
strmqcsv earth
```

## Related commands

Command	Description
endmqcsv	End a command server
dspmqcsv	Display the status of a command server

## strmqsvc:

Start the IBM MQ service on Windows.

## Purpose

The command starts the IBM MQ service on Windows. Run the command on Windows only.

Run the command to start the service, if it has not been started automatically, or if the service has ended.

Restart the service for IBM MQ processes to pick up a new environment, including new security definitions.

## Syntax

```
strmqsvc
```

## Parameters

The **strmqsvc** command has no parameters.

You must set the path to the installation that contains the service. Either make the installation primary, run the **setmqenv** command, or run the command from the directory containing the **strmqsvc** binary file.

### Related reference:

“endmqsvc” on page 248

End the IBM MQ service on Windows.

### strmqm:

Start a queue manager or ready it for standby operation.

## Purpose

Use the **strmqm** command to start a queue manager.

You must use the **strmqm** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the **dspmqs** installation command.

If a queue manager has no associated installation and there is no installation of IBM WebSphere MQ Version 7.0.1 on the system, the **strmqm** command will associate the queue manager with the installation that issued the **strmqm** command.

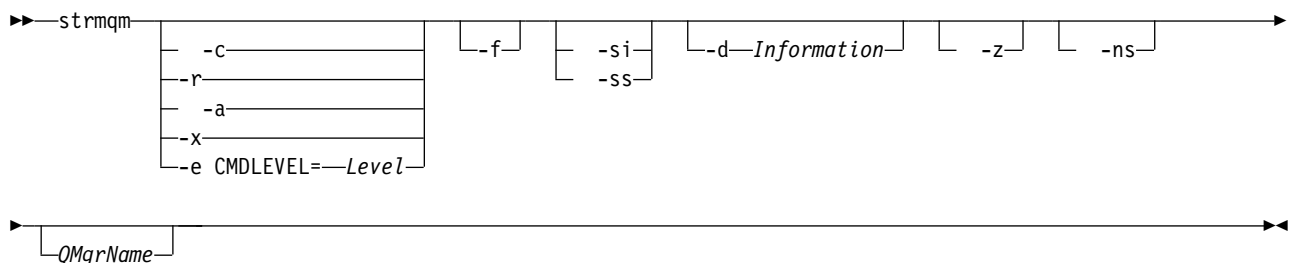

If the queue manager startup takes more than a few seconds IBM MQ shows intermittent messages detailing the startup progress.

## V8.0.0.8

### Usage notes

From IBM MQ Version 8.0.0, Fix Pack 8, the **strmqm** command checks the syntax of the CHANNELS and SSL stanzas in the `qm.ini` file early on, before starting the queue manager fully. If the `qm.ini` file contains any errors, this check makes it much easier to see what is wrong, and correct it quickly. If an error is found, **strmqm** outputs an AMQ9224 error message, describing the full details of the position of the error in the `qm.ini` file. It also ends immediately without starting the queue manager.

## Syntax

## Optional parameters

**-a** Activate the specified backup queue manager. The backup queue manager is not started.

When activated, a backup queue manager can be started using the control command `strmqm QMgrName`. The requirement to activate a backup queue manager prevents accidental startup.

When activated, a backup queue manager can no longer be updated.

For more information about using backup queue managers, see Backing up and restoring IBM MQ queue manager data.

- c Starts the queue manager, redefines the default and system objects, then stops the queue manager. Any existing system and default objects belonging to the queue manager are replaced if you specify this flag, and any non-default system object values are reset (for example, the value of MCAUSER is set to blank).

Use the **strmqm** command to create the default and system objects for a queue manager.

**Note:** If you run **strmqm -c** on a queue manager that is being used as an IBM MQ Managed File Transfer coordination queue manager you must re-run the MQSC script that defines the coordination queue manager objects. This script is in a file called *queue\_manager\_name.mqsc*, which is in the IBM MQ Managed File Transfer configuration directory.

**-d Information**

Specifies whether information messages are displayed. Possible values for *Information* follow:

Value	Description
all	All information messages are displayed. This value is the default value.
minimal	The minimal number of information messages are displayed.
none	No information messages are displayed. This parameter is equivalent to <b>-z</b> .

The **-z** parameter takes precedence over this parameter.

**-e CMDLEVEL = Level**

Enables a command level for this queue manager, and then stops the queue manager.

The queue manager is now able to use all functions provided by the specified command level. You can start the queue manager only with an installation that supports the new command level.

This option is only valid if the current command level used by the queue manager is lower than the maximum command level supported by the installation. Specify a command level that is greater than the current command level of the queue manager and less than or equal to the maximum command level supported by the installation.

Use exactly the command level as a value for *Level* that is associated with the function you want to enable.

This flag cannot be specified with **-a**, **-c**, **-r** or **-x**.

- f Use this option if you *know* a queue manager is not starting because its data directories are missing or corrupted.

The **strmqm -f qmname** command attempts to re-create the queue manager data directory and reset file permissions. If it is successful, the queue manager starts, unless the queue manager configuration information is missing. If the queue manager fails to start because the configuration information is missing, re-create the configuration information, and restart the queue manager.

In releases of IBM MQ earlier than 7.0.1, **strmqm**, with no **-f** option, automatically repaired missing data directories and then tried to start. This behavior has changed.

From IBM WebSphere MQ Version 7.0.1 onwards, the default behavior of **strmqm**, with no **-f** option, is *not* to recover missing or corrupted data directories automatically, but to report an error, such as AMQ6235 or AMQ7001, and *not* start the queue manager.

You can think of the `-f` option as performing the recover actions that used to be performed automatically by **strmqm**.

The reason for the change to the behavior of **strmqm** is that with the support for networked file storage in IBM WebSphere MQ Version 7.0.1, the most likely cause of missing or corrupted queue manager data directories is a configuration error that can be rectified, rather than the data directories are corrupted or irretrievably unavailable.

You must *not* use **strmqm -f** to re-create the queue manager data directories if you can restore the directories by correcting the configuration.

Possible solutions to problems with **strmqm** are to make the networked file storage location accessible to the queue manager, or to ensure the gid and uid of the mqm group and user ID on the server hosting the queue manager match the gid and uid of the mqm group and user ID on the server hosting the queue manager data directory.

From IBM WebSphere MQ Version 7.0.1, if you are performing media recovery for a queue manager, then you must use the `-f` option to re-create the queue manager data directory.

#### **-ns**

Prevents any of the following processes from starting automatically when the queue manager starts:

- The channel initiator
- The command server
- Listeners
- Services

This parameter also runs the queue manager as if the `CONNAUTH` attribute is blank, regardless of its current value. This allows unauthenticated access to the queue manager for locally bound applications; client applications cannot connect because there are no listeners. Administrative changes must be made by using **runmqsc** because the command server is not running.

#### **-r**

Updates the backup queue manager. The backup queue manager is not started. IBM MQ updates the objects of the backup queue manager by reading the queue manager log and replaying updates to the object files.

For more information about using backup queue managers, see *Backing up and restoring IBM MQ queue manager data*.

#### **-si**

Interactive (manual) queue manager startup type. This option is available on IBM MQ for Windows only.

The queue manager runs under the logged on (interactive) user. Queue managers configured with interactive startup end when the user who started them logs off.

If you set this parameter, it overrides any startup type set previously by the **crtmqm** command, the **amqmdain** command, or the IBM MQ Explorer.

If you do not specify a startup type of either `-si` or `-ss`, the queue manager startup type specified on the **crtmqm** command is used.

#### **-ss**

Service (manual) queue manager startup type. This option is available on IBM MQ for Windows only.

The queue manager runs as a service. Queue managers configured with service startup continue to run even after the interactive user has logged off.

If you set this parameter, it overrides any startup type set previously by the **crtmqm** command, the **amqmdain** command, or the IBM MQ Explorer.

#### **-x**

Start an instance of a multi-instance queue manager on the local server, permitting it to be highly available. If an instance of the queue manager is not already running elsewhere, the queue manager starts and the instance becomes active. The active instance is ready to accept local and remote connections to the queue manager on the local server.

If a multi-instance queue manager instance is already active on a *different* server the new instance becomes a standby, permitting it to takeover from the active queue manager instance. While it is in standby, it cannot accept local or remote connections.

You must not start a second instance of a queue manager on the *same* server.

The default behavior, omitting the `-x` optional parameter, is to start the instance as a single instance queue manager, forbidding standby instances from being started.

**-z** Suppresses error messages.

This flag is used within IBM MQ to suppress unwanted information messages. Because using this flag can result in loss of information, do not use it when entering commands on a command line.

This parameter takes precedence over the `-d` parameter.

#### *QMGrName*

The name of a local queue manager. If omitted, the default queue manager is used.

### Return codes

#### Return

code	Description
0	Queue manager started
3	Queue manager being created
5	Queue manager running
16	Queue manager does not exist
23	Log not available
24	A process that was using the previous instance of the queue manager has not yet disconnected.
30	A standby instance of the queue manager started. The active instance is running elsewhere
31	The queue manager already has an active instance. The queue manager permits standby instances.
39	Invalid parameter specified
43	The queue manager already has an active instance. The queue manager does not permit standby instances.
47	The queue manager already has the maximum number of standby instances
49	Queue manager stopping
58	Inconsistent use of installations detected
62	The queue manager is associated with a different installation
69	Storage not available
71	Unexpected error
72	Queue manager name error
74	The IBM MQ service is not started.
91	The command level is outside the range of acceptable values.
92	The queue manager's command level is greater or equal to the specified value.
100	Log location invalid
119	User not authorized to start the queue manager

### Examples

The following command starts the queue manager account:

```
strmqm account
```

### Related commands

Command	Description
" <b>crtmqm</b> " on page 194	Create a queue manager
" <b>dltmqm</b> " on page 202	Delete a queue manager
" <b>dspmqr</b> " on page 239	Display MQ version information
" <b>endmqm</b> " on page 244	End a queue manager

### strmqtrc:

Enable trace at a specified level of detail, or report the level of tracing in effect.

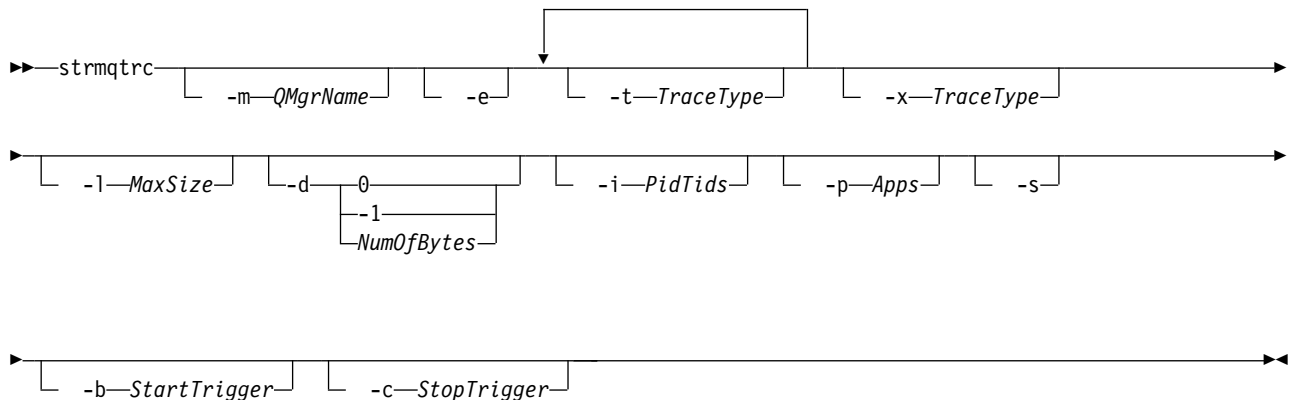

### Purpose

Use the **strmqtrc** command to enable tracing.

You must use the **strmqtrc** command from the installation associated with the queue manager that you are working with. You can find out which installation a queue manager is associated with using the `dspmqr -o` installation command. This does not apply to a client product (for example, HP Integrity NonStop Server ) because there are no queue managers from which to request direct output.

### Syntax

The syntax of this command is as follows:

### Description

The **strmqtrc** command enables tracing. The command has optional parameters that specify the level of tracing you want:

- One or more queue managers
- Levels of trace detail
- One or more IBM MQ processes. The processes can be either part of the IBM MQ product or customer applications that use the IBM MQ API
- Specific threads within customer applications, either by IBM MQ thread number or by operating system thread number
- Events. These can be either the entry or exit from internal IBM MQ functions or the occurrence of a first failure data capture (FDC).

Each combination of parameters on an individual invocation of the command are interpreted by IBM MQ as having a logical AND between them. You can start the `strmqtrc` command multiple times, regardless of whether tracing is already enabled. If tracing is already enabled, the trace options that are in effect are modified to those specified on the most recent invocation of the command. Multiple invocations of the command, without an intervening `enmqtrc` command, are interpreted by IBM MQ as having a logical OR between them. The maximum number of concurrent `strmqtrc` commands that can be in effect at one time is 16.

For the IBM MQ client on HP Integrity NonStop Server, you must direct your trace commands to specific processors. For example, if your client is running on processor 2 and your shell is on processor 1, initiating trace with `strmqtrc <options>` does not trace the client. In this case, run `-cpu=2 strmqtrc` is required.

### Optional parameters

#### **-m** *QMgrName*

The name of the queue manager to trace. This parameter applies to server products only.

The following wildcards are allowed: asterisk (\*), replacing zero or more characters, and question mark (?), replacing any single character. In command environments such as the UNIX shell, where the asterisk (\*) and question mark (?) characters have special meaning, you must either escape the wildcard character or enclose it in quotation marks to prevent the command environment from operating on the wildcard character.

- e** Requests early tracing of all processes, making it possible to trace the creation or startup of a queue manager. If you include this flag, any process belonging to any component of any queue manager traces its early processing. The default is not to perform early tracing.

Use the following command to trace a client:

```
strmqtrc -e
```

You cannot use the `-e` flag with the `-m` flag, `-i` flag, the `-p` flag, the `-c` flag, or the `-b` flag. If you try to use the `-e` flag with the `-m` flag, the `-i` flag, the `-p` flag, the `-c` flag, or the `-b` flag, then an error message is issued.

#### **-t** *TraceType*

The points to trace and the amount of trace detail to record. By default **all** trace points are enabled and a default-detail trace is generated.

Alternatively, you can supply one or more of the options in the following list. For each *tracetype* value you specify, including `-t all`, specify either `-t parms` or `-t detail` to obtain the appropriate level of trace detail. If you do not specify either `-t parms` or `-t detail` for any particular trace type, only a default-detail trace is generated for that trace type.

If you supply multiple trace types, each must have its own `-t` flag. You can include any number of `-t` flags, if each has a valid trace type associated with it.

It is not an error to specify the same trace type on multiple `-t` flags.

*Table 73. TraceType parameter values.*

Value	Description
<b>all</b>	Output data for every trace point in the system (the default). The <code>all</code> parameter activates tracing at default detail level.
<b>api</b>	Output data for trace points associated with the MQI and major queue manager components.
<b>commentary</b>	Output data for trace points associated with comments in the IBM MQ components.

Table 73. *TraceType* parameter values. (continued)

Value	Description
<b>comms</b>	Output data for trace points associated with data flowing over communications networks.
<b>csdata</b>	Output data for trace points associated with internal data buffers in common services.
<b>csflows</b>	Output data for trace points associated with processing flow in common services.
<b>detail</b>	Activate tracing at high-detail level for flow processing trace points.
<b>Explorer</b>	Output data for trace points associated with the IBM MQ Explorer.
<b>java</b>	Output data for trace points associated with applications using the IBM MQ classes for Java API.
<b>lqmdata</b>	Output data for trace points associated with internal data buffers in the local queue manager.
<b>lqmflows</b>	Output data for trace points associated with processing flow in the local queue manager.
<b>otherdata</b>	Output data for trace points associated with internal data buffers in other components.
<b>otherflows</b>	Output data for trace points associated with processing flow in other components.
<b>parms</b>	Activate tracing at default-detail level for flow processing trace points.
<b>remotedata</b>	Output data for trace points associated with internal data buffers in the communications component.
<b>remoteflows</b>	Output data for trace points associated with processing flow in the communications component.
<b>servicedata</b>	Output data for trace points associated with internal data buffers in the service component.
<b>serviceflows</b>	Output data for trace points associated with processing flow in the service component.
<b>spldata</b>	Output data for trace points associated with buffers and control blocks that use a security policy (AMS) operation.
<b>splflows</b>	Output data for trace points associated with entry and exit data for functions that use a security policy (AMS) operation.
<b>soap</b>	Output data for trace points associated with IBM MQ Transport for SOAP.
<b>ssl</b>	Output data associated with using GSKit to enable Secure Sockets Layer (SSL) channel security.
<b>versiondata</b>	Output data for trace points associated with the version of IBM MQ running.

**-x** *TraceType*

The points **not** to trace. By default **all** trace points are enabled and a default-detail trace is generated. The trace points you can specify are those listed for the -t flag.

You can use the -x flag with *tracetype* values to exclude those entry points you do not want to record. This is useful in reducing the amount of trace produced.

If you supply multiple trace types, each must have its own -x flag. You can include any number of -x flags, if each has a valid *tracetype* associated with it.

**-l *MaxSize***

The maximum size of a trace file ( AMQ *ppppp. qq*.TRC) in megabytes (MB). For example, if you specify a *MaxSize* of 1, the size of the trace is limited to 1 MB.

When a trace file reaches the specified maximum, it is renamed to AMQ *ppppp. qq*.TRS and a new AMQ *ppppp. qq*.TRC file is started. If a previous copy of an AMQ *ppppp. qq*.TRS file exists, it is deleted.

The highest value that *MaxSize* can be set to is 2048 MB.

**-d 0**

Trace no user data.

**-d -1 or all**

Trace all user data.

**-d *NumOfBytes***

- For a communication trace; trace the specified number of bytes of data including the transmission segment header (TSH).
- For an MQPUT or MQGET call; trace the specified number of bytes of message data held in the message buffer.
- Values in the range 1 through 15 are not allowed.

**-i *PidTids***

Process identifier (PID) and thread identifier (TID) to which the trace generation is restricted. You cannot use the -i flag with the -e flag. If you try to use the -i flag with the -e flag, then an error message is issued. This parameter must only be used under the guidance of IBM Service personnel.

This parameter is not supported for .NET clients if NMQ\_MQ\_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

**-p *Apps***

The named processes to which the trace generation is restricted. *Apps* is a comma-separated list. You must specify each name in the list exactly as the program name would be displayed in the "Program Name" FDC header. Asterisk (\*) or question mark (?) wildcards are allowed. You cannot use the -p flag with the -e flag. If you try to use the -p flag with the -e flag, then an error message is issued.

This parameter is not supported for .NET clients if NMQ\_MQ\_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

**-s**

Reports the tracing options that are currently in effect. You must use this parameter on its own with no other parameters.

A limited number of slots are available for storing trace commands. When all slots are in use, then no more trace commands can be accepted unless they replace an existing slot. Slot numbers are not fixed, so if the command in slot number 0 is removed, for example by an endmqtrc command, then all the other slots move up, with slot 1 becoming slot 0, for example. An asterisk (\*) in a field means that no value is defined, and is equivalent to the asterisk wildcard.

An example of the output from this command is as follows:

Listing Trace Control Array

Used slots = 2 of 15

```
EarlyTrace    [OFF]
TimedTrace    [OFF]
TraceUserData [0]
MaxSize       [0]
Trace Type    [1]
```

Slot position 1

Untriggered  
Queue Manager [avocet]  
Application [\*]  
PID.TID [\*]  
TraceOptions [1f4ffff]  
TraceInterval [0]  
Trace Start Time [0]  
Trace Stop Time [0]  
Start Trigger [KN346050K]  
Start Trigger [KN346080]

Slot position 2

Untriggered  
Queue Manager [\*]  
Application [\*]  
PID.TID [\*]  
TraceOptions [1fcffff]  
TraceInterval [0]  
Trace Start Time [0]  
Trace Stop Time [0]  
Start Trigger [KN346050K]  
Start Trigger [KN346080]

This parameter is not supported for .NET clients if NMQ\_MQ\_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

**-b Start\_Trigger**

FDC probe IDs for which tracing must be turned on. *Start\_Trigger* is a comma-separated list of FDC probe IDs. You can use asterisk (\*) and question mark (?) wildcards in the specification of probe IDs. You cannot use the -b flag with the -e flag. If you try to use the -b flag with the -e flag, then an error message is issued. This parameter must only be used under the guidance of IBM Service personnel.

Start_Trigger	Effect
FDC=comma-separated list of FDC probe IDs.	Turns on tracing when any FDCs with the specified FDC probe IDs are generated.

This parameter is not supported for .NET clients if NMQ\_MQ\_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

**-c Stop\_Trigger**

FDC probe IDs for which tracing must be turned off, or interval in seconds after which tracing must be turned off. *Stop\_Trigger* is a comma-separated list of FDC probe IDs. You can use asterisk (\*) and question mark (?) wildcards in the specification of probe IDs. This parameter should be used only under the guidance of IBM Service personnel.

Stop_Trigger	Effect
FDC=comma-separated list of FDC probe IDs.	Turns tracing off when any FDCs with the specified FDC probe IDs are generated.
interval=n where n is an unsigned integer between 1 and 32,000,000.	Turns tracing off n seconds after it starts or, if it tracing is already enabled, turns tracing off n seconds after this instance of the command is issued.

This parameter is not supported for .NET clients if NMQ\_MQ\_LIB is set to managed, so that the client uses managed IBM MQ problem diagnostics.

**Return codes**

Return code	Description
AMQ7024	Non-valid arguments supplied to the command.
AMQ7077	You are not authorized to perform the requested operation.
AMQ8304	Nine concurrent traces (the maximum) already running.
58	Inconsistent use of installations detected

## Examples

This command enables tracing of processing flow from common services and the local queue manager for a queue manager called QM1 in IBM MQ for UNIX systems. Trace data is generated at the default level of detail.

```
strmqtrc -m QM1 -t csflows -t lqmflows -t parms
```

This command disables tracing of SSL activity on a queue manager called QM1. Other trace data is generated at the parms level of detail.

```
strmqtrc -m QM1 -x ssl -t parms
```

This command enables high-detail tracing of the processing flow for all components:

```
strmqtrc -t all -t detail
```

This command enables tracing when FDC KN346050 or FDC KN346080 occur on any process that is using queue manager QM1:

```
strmqtrc -m QM1 -b FDC=KN346050,KN346080
```

This command enables tracing when FDC KN346050 occurs, and stops tracing when FDC KN346080 occurs. In both cases the FDC must occur on a process that is using queue manager QM1:

```
strmqtrc -m QM1 -b FDC=KN346050 -c FDC=KN346080
```

The next examples use the `-p` and `-m` flags to show the following:

- How a combination of parameters on an individual invocation of the command are interpreted by IBM MQ as having a logical AND between them.
- How multiple invocations of the command, without an intervening `enmqtrc` command, are interpreted by IBM MQ as having a logical OR between them:
  1. This command enables tracing for all threads that result from any executing process called `amqxxx.exe`:
 

```
strmqtrc -p amqxxx.exe
```
  2.
    - If you start the following command after the command in step 1, without an intervening `endmqtrc` command, then tracing is limited to all threads that result from any executing process called `amqxxx.exe` *and* that are using queue manager QM2:
 

```
strmqtrc -p amqxxx.exe -m QM2
```
    - If you start the following command after the command in step 1, without an intervening `endmqtrc` command, then tracing is limited to all processes and threads that result from executing `amqxxx.exe` *or* that are using queue manager QM2:
 

```
strmqtrc -m QM2
```

## Related commands

Command	Description
dspmqrtrc	Display formatted trace output
endmqtrc	End trace

## Comparing command sets

The tables in this section compare the facilities available from the different administration command sets, and state whether you can perform each function from within the IBM MQ Explorer.

**Note:** The following tables do not apply to IBM MQ for z/OS or IBM MQ for IBM i.  For information on how to use PCF commands on z/OS and on IBM i, see Introduction to Programmable Command Formats.  For information on how to use MQSC commands on z/OS and on IBM i, see Script (MQSC) Commands.

### Queue manager commands:

A table of queue manager commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 74. Queue manager commands

Description	PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Change Queue Manager	Change Queue Manager	ALTER QMGR	No equivalent	Yes
Create Queue Manager	No equivalent	No equivalent	<b>crtmqm</b>	Yes
Delete Queue Manager	No equivalent	No equivalent	<b>dltmqm</b>	Yes
Inquire Queue Manager	Inquire Queue Manager	DISPLAY QMGR	No equivalent	Yes
Inquire Queue Manager Status	Inquire Queue Manager Status	DISPLAY QMSTATUS	<b>dspmqr</b>	Yes
Ping Queue Manager	Ping Queue Manager	PING QMGR	No equivalent	No
Refresh Queue Manager	Refresh Queue Manager	REFRESH QMGR	No equivalent	Yes
Reset Queue Manager	Reset Queue Manager	RESET QMGR	No equivalent	No
Start Queue Manager	No equivalent	No equivalent	<b>strmqm</b>	Yes
Stop Queue Manager	No equivalent	No equivalent	<b>endmqm</b>	Yes

### Command server commands:

A table of command server commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 75. Commands for command server administration

Description	PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Display command server	Inquire Queue Manager Status	DISPLAY QMSTATUS	<b>dspmqcsv</b>	Yes
Start command server	Change Queue Manager	ALTER QMGR	<b>strmqcsv</b>	Yes
Stop command server	No equivalent	No equivalent	<b>endmqcsv</b>	Yes

### Authority commands:

A table of authority commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 76. Commands for authority administration

PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Delete authority record	DELETE AUTHREC	<b>setmqaut</b>	Yes
Inquire authority records	DISPLAY AUTHREC	<b>dmpmqaut</b>	Yes
Inquire entity authority	DISPLAY ENTAUTH	<b>dspmqaut</b>	Yes
Refresh Security	REFRESH SECURITY	No equivalent	Yes
Set authority record	SET AUTHREC	<b>setmqaut</b>	Yes

### Cluster commands:

Resolve Channel	RESOLVE CHANNEL	No equivalent	Yes
Start Channel	START CHANNEL	<b>runmqchl</b>	Yes
Start Channel Initiator	START CHINIT	<b>runmqchi</b>	No
Stop Channel	STOP CHANNEL	No equivalent	Yes

## Listener commands:

A table of listener commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 80. Listener commands

PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Change Listener	ALTER LISTENER	No equivalent	Yes
Copy Listener	DEFINE LISTENER(x) LIKE(y)	No equivalent	Yes
Create Listener	DEFINE LISTENER	No equivalent	Yes
Delete Listener	DELETE LISTENER	No equivalent	Yes
Inquire Listener	DISPLAY LISTENER	No equivalent	Yes
Inquire Listener Status	DISPLAY LSSTATUS	No equivalent	Yes
Start Channel Listener	START LISTENER <sup>1</sup>	<b>runmqlsr</b>	Yes
Stop Listener	STOP LISTENER	<b>endmqlsr</b> <sup>2</sup>	Yes
<b>Notes:</b>			
1. Used with listener objects only			
2. Stops all active listeners			

## Namelist commands:

A table of namelist commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 81. Namelist commands

PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Change Namelist	ALTER NAMELIST	No equivalent	Yes
Copy Namelist	DEFINE NAMELIST(x) LIKE(y)	No equivalent	Yes
Create Namelist	DEFINE NAMELIST	No equivalent	Yes
Delete Namelist	DELETE NAMELIST	No equivalent	Yes
Inquire Namelist	DISPLAY NAMELIST	No equivalent	Yes
Inquire Namelist Names	DISPLAY NAMELIST	No equivalent	Yes

### Process commands:

A table of process commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 82. Process commands

PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Change Process	ALTER PROCESS	No equivalent	Yes
Copy Process	DEFINE PROCESS(x) LIKE(y)	No equivalent	Yes
Create Process	DEFINE PROCESS	No equivalent	Yes
Delete Process	DELETE PROCESS	No equivalent	Yes
Inquire Process	DISPLAY PROCESS	No equivalent	Yes
Inquire Process Names	DISPLAY PROCESS	No equivalent	Yes

### Queue commands:

A table of queue commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 83. Queue commands

PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Change Queue	ALTER QLOCAL ALTER QALIAS ALTER QMODEL ALTER QREMOTE	No equivalent	Yes
Clear Queue	CLEAR QLOCAL	No equivalent	Yes
Copy Queue	DEFINE QLOCAL(x) LIKE(y) DEFINE QALIAS(x) LIKE(y) DEFINE QMODEL(x) LIKE(y) DEFINE QREMOTE(x) LIKE(y)	No equivalent	Yes
Create Queue	DEFINE QLOCAL DEFINE QALIAS DEFINE QMODEL DEFINE QREMOTE	No equivalent	Yes
Delete Queue	DELETE QLOCAL DELETE QALIAS DELETE QMODEL DELETE QREMOTE	No equivalent	Yes
Inquire Queue	DISPLAY QUEUE	No equivalent	Yes
Inquire Queue Names	DISPLAY QUEUE	No equivalent	Yes
Inquire Queue Status	DISPLAY QSTATUS	No equivalent	Yes
Reset Queue Statistics	No equivalent	No equivalent	No

## Service commands:

A table of service commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 84. Service commands

PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Change Service	ALTER SERVICE	No equivalent	Yes
Copy Service	DEFINE SERVICE(x) LIKE(y)	No equivalent	Yes
Create Service	DEFINE SERVICE	No equivalent	Yes
Delete Service	DELETE SERVICE	No equivalent	Yes
Inquire Service	DISPLAY SERVICE	No equivalent	Yes
Inquire Service Status	DISPLAY SVSTATUS	No equivalent	Yes
Start Service	START SERVICE	No equivalent	Yes
Stop Service	STOP SERVICE	No equivalent	Yes

## Other commands:

A table of other commands, showing the command description, and its PCF command, MQSC command, control command equivalents, and IBM MQ Explorer equivalents, if available.

Table 85. Other commands

Description	PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Create conversion exit	No equivalent	No equivalent	<b>crtmqcvx</b>	No
Display files used by objects	No equivalent	No equivalent	<b>dspmqfls</b>	No
Display formatted trace	No equivalent	No equivalent	<b>dspmqtrc</b> <sup>1</sup>	No
Display version information	No equivalent	No equivalent	<b>dspmqver</b>	No
Display transactions	No equivalent	No equivalent	<b>dspmqtrn</b>	No
Dump log	No equivalent	No equivalent	<b>dmpmqlog</b>	No
Dump MQ Configuration	No equivalent	No equivalent	<b>dmpmqcfg</b>	No
End trace	No equivalent	No equivalent	<b>endmqtrc</b>	Yes
Escape	Escape	No equivalent	No equivalent	No
Record media image	No equivalent	No equivalent	<b>rcdmqimg</b>	No
Re-create media object	No equivalent	No equivalent	<b>rcrmqobj</b>	No
Resolve transactions	No equivalent	No equivalent	<b>rsvmqtrn</b>	No
Run client trigger monitor	No equivalent	No equivalent	<b>runmqtrmc</b>	No
Run dead-letter queue handler	No equivalent	No equivalent	<b>runmqdlq</b>	No

Table 85. Other commands (continued)

Description	PCF command	MQSC command	Control command	IBM MQ Explorer equivalent?
Run MQSC commands	No equivalent	No equivalent	<b>runmqsc</b>	No
Run trigger monitor	No equivalent	No equivalent	<b>runmqtrm</b>	No
Set service connection points	No equivalent	No equivalent	<b>setmqscp</b> <sup>2</sup>	No
Start IBM MQ trace	No equivalent	No equivalent	<b>strmqtrc</b>	Yes
IBM MQ Services control	No equivalent	No equivalent	<b>amqmdain</b> <sup>2</sup>	No
<b>Notes:</b>				
1. Not supported on IBM MQ for Windows.				
2. Supported by IBM MQ for Windows only.				

## Managing keys and certificates

Use the **runmqckm** command (Windows and UNIX systems) to manage keys, certificates, and certificate requests.

### The **runmqckm** command

The **runmqckm** command is available on Windows and UNIX systems.

The **runmqckm** command provides functions that are similar to those of iKeyman, described in Security.

Use the **runmqckm** command to do the following:

- Create the type of CMS key database files that IBM MQ requires
- Create certificate requests
- Import personal certificates
- Import CA certificates
- Manage self-signed certificates

### Preparing to use the **runmqckm** and **runmqakm** commands:

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

To run the **runmqckm** command line interfaces, ensure that the systems environment variables are correctly configured. For primary installations of IBM MQ v7.1, you can run the **setmqinst** command. For further information on this command please see “setmqinst” on page 292

## runmqckm, and runmqakm commands:

This section describes the runmqckm, and runmqakm commands according to the object of the command.

An overview of the main differences between the two commands:

- **runmqakm**
  - Supports the creation of certificates and certificate requests with Elliptic Curve public keys whereas the **runmqckm** command does not.
  - Supports stronger encryption of the key repository file than the **runmqckm** command through the **-strong** parameter.
  - Has been certified as FIPS 140-2 compliant, and can be configured to operate in a FIPS compliant manner, using the **-fips** parameter, unlike the **runmqckm** command.
- **runmqckm** supports the JKS and JCEKS key repository file formats whereas the **runmqakm** command does not.

Each command specifies at least one *object*. Commands for PKCS #11 device operations might specify additional objects. Commands for key database, certificate, and certificate request objects also specify an *action*. The object can be one of the following:

- keydb** Actions apply to a key database
- cert** Actions apply to a certificate
- certreq** Actions apply to a certificate request
- help** Displays help
- version** Displays version information

The following subtopics describe the actions that you can take on key database, certificate, and certificate request objects; See “runmqckm and runmqakm options” on page 328 for a description of the options on these commands.

*Commands for a CMS key database only:*

You can use the **runmqckm**, and **runmqakm** commands to manage keys and certificates for a CMS key database.

- keydb -changepw**  
Change the password for a CMS key database:  
`-keydb -changepw -db filename -pw password -new_pw new_password`  
`-stash`
- keydb -create**  
Create a CMS key database:  
`-keydb -create -db filename -pw password`  
`-type cms -expire days -stash`
- keydb -stashpw**  
Stash the password of a CMS key database into a file:  
`-keydb -stashpw -db filename -pw password`
- cert -getdefault**

**Note:** The default certificate is not supported by IBM MQ Version 8.0. You should use certificate label configuration as described in Digital certificate labels, understanding the requirements. Get the default personal certificate:

```
-cert -getdefault -db filename -pw password
```

#### **-cert -modify**

Modify a certificate.

**Note:** Currently, the only field that can be modified is the Certificate Trust field.

```
-cert -modify -db filename -pw password -label label  
-trust enable | disable
```

#### **-cert -setdefault**

**Note:** The default certificate is not supported by IBM MQ Version 8.0. You should use certificate label configuration as described in Digital certificate labels, understanding the requirements. Set the default personal certificate:

```
-cert -setdefault -db filename  
-pw password -label label
```

Command for CMS or PKCS #12 key databases:

You can use the `runmqckm`, and `runmqakm` commands to manage keys and certificates for a CMS key database or PKCS #12 key database.

**Note:** IBM MQ does not support SHA-3 or SHA-5 algorithms. You can use the digital signature algorithm names `SHA384WithRSA` and `SHA512WithRSA` because both algorithms are members of the SHA-2 family.

The digital signature algorithm names `SHA3WithRSA` and `SHA5WithRSA` are deprecated because they are an abbreviated form of `SHA384WithRSA` and `SHA512WithRSA` respectively.

#### **-keydb -changepw**

Change the password for a key database:

```
-keydb -changepw -db filename -pw password  
-new_pw new_password -expire days
```

#### **-keydb -convert**

convert the key database from one format to another:

```
-keydb -convert -db filename -pw password  
-old_format cms | pkcs12 -new_format cms
```

#### **-keydb -create**

Create a key database:

```
-keydb -create -db filename -pw password  
-type cms | pkcs12
```

#### **-keydb -delete**

Delete a key database:

```
-keydb -delete -db filename -pw password
```

#### **-keydb -list**

List currently-supported types of key database:

```
-keydb -list
```

#### **-cert -add**

Add a certificate from a file into a key database:

```
-cert -add -db filename -pw password -label label  
-file filename -format ascii | binary
```

### **-cert -create**

Create a self-signed certificate:

```
-cert -create -db filename -pw password -label label  
-dn distinguished_name  
-size 1024 | 512 -x509version 3 | 1 | 2  
-expire days  
-sig_alg MD2_WITH_RSA | MD2WithRSA |  
          MD5_WITH_RSA | MD5WithRSA |  
          SHA1WithDSA | SHA1WithRSA |  
          SHA256_WITH_RSA | SHA256WithRSA |  
          SHA2WithRSA | SHA384_WITH_RSA |  
          SHA384WithRSA | SHA512_WITH_RSA |  
          SHA512WithRSA | SHA_WITH_DSA |  
          SHA_WITH_RSA | SHAWithDSA | SHAWithRSA
```

### **-cert -delete**

Delete a certificate:

```
-cert -delete -db filename -pw password -label label
```

### **-cert -details**

List the detailed information for a specific certificate:

```
-cert -details -db filename -pw password -label label
```

### **-cert -export**

Export a personal certificate and its associated private key from a key database into a PKCS #12 file, or to another key database:

```
-cert -export -db filename -pw password -label label  
-type cms | pkcs12  
-target filename -target_pw password -target_type cms | pkcs12
```

### **-cert -extract**

Extract a certificate from a key database:

```
-cert -extract -db filename -pw password -label label  
-target filename  
-format ascii | binary
```

### **-cert -import**

Import a personal certificate from a key database:

```
-cert -import -file filename -pw password -type pkcs12 -target filename  
-target_pw password -target_type cms -label label
```

The `-label` option is required and specifies the label of the certificate that is to be imported from the source key database.

The `-new_label` option is optional and allows the imported certificate to be given a different label in the target key database from the label in the source database.

### **-cert -list**

List all certificates in a key database:

```
-cert -list all | personal | CA  
-db filename -pw password
```

### **-cert -receive**

Receive a certificate from a file:

```
-cert -receive -file filename -db filename -pw password  
-format ascii | binary -default_cert yes | no
```

### **-cert -sign**

Sign a certificate:

```

-cert -sign -db filename -file filename -pw password
-label label -target filename
-format ascii | binary -expire days
-sig_alg MD2_WITH_RSA | MD2WithRSA | MD5_WITH_RSA |
          MD5WithRSA | SHA1WithDSA | SHA1WithRSA |
          SHA256_WITH_RSA | SHA256WithRSA |
          SHA2WithRSA | SHA384_WITH_RSA |
          SHA384WithRSA | SHA512_WITH_RSA |
          SHA512WithRSA | SHA_WITH_DSA |
          SHA_WITH_RSA | SHAWithDSA |
          SHAWithRSA

```

### **-certreq -create**

Create a certificate request:

```

-certreq -create -db filename -pw password
-label label -dn distinguished_name
-size 1024 | 512 -file filename
-sig_alg MD2_WITH_RSA | MD2WithRSA |
          MD5_WITH_RSA | MD5WithRSA |
          SHA1WithDSA | SHA1WithRSA |
          SHA256_WITH_RSA | SHA256WithRSA |
          SHA2WithRSA | SHA384_WITH_RSA |
          SHA384WithRSA | SHA512_WITH_RSA |
          SHA512WithRSA | SHA_WITH_DSA |
          SHA_WITH_RSA | SHAWithDSA |
          SHAWithRSA

```

### **-certreq -delete**

Delete a certificate request:

```

-certreq -delete -db filename -pw password -label label

```

### **-certreq -details**

List the detailed information of a specific certificate request:

```

-certreq -details -db filename -pw password -label label

```

List the detailed information about a certificate request and show the full certificate request:

```

-certreq -details -showOID -db filename
-pw password -label label

```

### **-certreq -extract**

Extract a certificate request from a certificate request database into a file:

```

-certreq -extract -db filename -pw password
-label label -target filename

```

### **-certreq -list**

List all certificate requests in the certificate request database:

```

-certreq -list -db filename -pw password

```

### **-certreq -recreate**

Re-create a certificate request:

```

-certreq -recreate -db filename -pw password
-label label -target filename

```

Commands for cryptographic device operations:

You can use the `runmqckm`, and `runmqakm` commands to manage keys and certificates for cryptographic device operations.

**Note:** IBM MQ does not support SHA-3 or SHA-5 algorithms. You can use the digital signature algorithm names `SHA384WithRSA` and `SHA512WithRSA` because both algorithms are members of the SHA-2 family.

The digital signature algorithm names `SHA3WithRSA` and `SHA5WithRSA` are deprecated because they are an abbreviated form of `SHA384WithRSA` and `SHA512WithRSA` respectively.

#### **-keydb -changepw**

Change the password for a cryptographic device:

```
-keydb -changepw -crypto module_name -tokenlabel token_label  
-pw password -new_pw new_password
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that `iKeycmd` and `iKeyman` are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the `iKeyman` and `iKeycmd` programs are 32-bit on those platforms.

#### **-keydb -list**

List currently-supported types of key database:

```
-keydb -list
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that `iKeycmd` and `iKeyman` are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the `iKeyman` and `iKeycmd` programs are 32-bit on those platforms.

#### **-cert -add**

Add a certificate from a file to a cryptographic device:

```
-cert -add -crypto module_name -tokenlabel token_label  
-pw password -label label -file filename -format ascii | binary
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that `iKeycmd` and `iKeyman` are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the `iKeyman` and `iKeycmd` programs are 32-bit on those platforms.

#### **-cert -create**

Create a self-signed certificate on a cryptographic device:

```
-cert -create -crypto module_name -tokenlabel token_label  
  
-pw password -label label -dn distinguished_name  
-size 1024 | 512  
-x509version 3 | 1 | 2  
-default_cert no | yes -expire days  
-sig_alg MD2_WITH_RSA | MD2WithRSA |  
MD5_WITH_RSA | MD5WithRSA |  
SHA1WithDSA | SHA1WithRSA |  
SHA256_WITH_RSA | SHA256WithRSA |  
SHA2WithRSA | SHA384_WITH_RSA |
```

```

SHA384WithRSA | SHA512_WITH_RSA |
SHA512WithRSA | SHA_WITH_DSA |
SHA_WITH_RSA | SHAWithDSA |
SHAWithRSA

```

**Note:** You cannot import a certificate containing multiple OU (organizational unit) attributes in the distinguished

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

#### **-cert -delete**

Delete a certificate on a cryptographic device:

```

-cert -delete -crypto module_name -tokenlabel token_label
      -pw password -label label

```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

#### **-cert -details**

List the detailed information for a specific certificate on a cryptographic device:

```

-cert -details -crypto module_name -tokenlabel token_label
      -pw password -label label

```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

List the detailed information and show the full certificate for a specific certificate on a cryptographic device:

```

-cert -details -showOID -crypto module_name -tokenlabel token_label
      -pw password -label label

```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

#### **-cert -extract**

Extract a certificate from a key database:

```

-cert -extract -crypto module_name -tokenlabel token_label
      -pw password -label label -target filename
      -format ascii | binary

```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

### **-cert -import**

Import a certificate to a cryptographic device with secondary key database support:

```
-cert -import -db filename -pw password -label label  
-type cms  
-crypto module_name -tokenlabel token_label -pw password  
-secondaryDB filename -secondaryDBpw password
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

```
-cert -import -db filename -pw password -label label  
-type cms  
-crypto module_name -tokenlabel token_label -pw password  
-secondaryDB filename -secondaryDBpw password -fips
```

Import a PKCS #12 certificate to a cryptographic device with secondary key database support:

```
-cert -import -file filename -pw password -type pkcs12  
-crypto module_name -tokenlabel token_label -pw password  
-secondaryDB filename -secondaryDBpw password
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

```
-cert -import -file filename -pw password -type pkcs12  
-crypto module_name -tokenlabel token_label -pw password  
-secondaryDB filename -secondaryDBpw password -fips
```

**Note:** You cannot import a certificate containing multiple OU (organizational unit) attributes in the distinguished name.

### **-cert -list**

List all certificates on a cryptographic device:

```
-cert -list all | personal | CA  
-crypto module_name -tokenlabel token_label -pw password
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

### **-cert -receive**

Receive a certificate from a file to a cryptographic device with secondary key database support:

```
-cert -receive -file filename -crypto module_name  
-tokenlabel token_label  
-pw password -default_cert yes | no  
-secondaryDB filename -secondaryDBpw password  
-format ascii | binary
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

Using the **runmqkm** command:

#### **-certreq -create**

Create a certificate request on a cryptographic device:

```
-certreq -create -crypto module_name -tokenlabel token_label
```

```
-pw password -label label -dn distinguished_name  
-size 1024 | 512 -file filename  
-sig_alg MD2_WITH_RSA | MD2WithRSA | MD5_WITH_RSA |  
          MD5WithRSA | SHA1WithDSA | SHA1WithRSA |  
          SHA256_WITH_RSA | SHA256WithRSA  
          SHA2WithRSA | SHA384_WITH_RSA |  
          SHA384WithRSA | SHA512_WITH_RSA |  
          SHA512WithRSA | SHA_WITH_DSA |  
          SHA_WITH_RSA | SHAWithDSA |  
          SHAWithRSA
```

**Note:** You cannot import a certificate containing multiple OU (organizational unit) attributes in the distinguished name.

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

#### **-certreq -delete**

Delete a certificate request from a cryptographic device:

```
-certreq -delete -crypto module_name -tokenlabel token_label
```

```
-pw password -label label
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

#### **-certreq -details**

List the detailed information of a specific certificate request on a cryptographic device:

```
-certreq -details -crypto module_name -tokenlabel token_label
```

```
-pw password -label label
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

List the detailed information about a certificate request and show the full certificate request on a cryptographic device:

```
-certreq -details -showOID -crypto module_name -tokenlabel token_label
```

```
-pw password -label label
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

### **-certreq -extract**

Extract a certificate request from a certificate request database on a cryptographic device into a file:

```
-certreq -extract -crypto module_name -tokenlabel token_label
```

```
-pw password -label label -target filename
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

### **-certreq -list**

List all certificate requests in the certificate request database on a cryptographic device:

```
-certreq -list -crypto module_name -tokenlabel token_label
```

```
-pw password
```

If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 64-bit programs. External modules required for PKCS #11 support will be loaded into a 64-bit process, therefore you must have a 64-bit PKCS #11 library installed for the administration of cryptographic hardware. The Windows and Linux x86 32-bit platforms are the only exceptions, as the iKeyman and iKeycmd programs are 32-bit on those platforms.

### **runmqckm and runmqakm options:**

A table of the **runmqckm** and **runmqakm** options that can be present on the command line.

**Note:** IBM MQ does not support SHA-3 or SHA-5 algorithms. You can use the digital signature algorithm names SHA384WithRSA and SHA512WithRSA because both algorithms are members of the SHA-2 family.

The digital signature algorithm names SHA3WithRSA and SHA5WithRSA are deprecated because they are an abbreviated form of SHA384WithRSA and SHA512WithRSA respectively.

The meaning of an option can depend on the object and action specified in the command.

*Table 86. Options that can be used with runmqckm and runmqakm*

Option	Description
-create	Option to create a key database.
-crypto	Name of the module to manage a PKCS #11 cryptographic device.  The value after -crypto is optional if you specify the module name in the properties file. If you are using certificates or keys stored on PKCS #11 cryptographic hardware, note that iKeycmd and iKeyman are 32-bit programs. External modules required for PKCS #11 support will be loaded into a 32-bit process, therefore you must have a 32-bit PKCS #11 library installed for the administration of cryptographic hardware, and must specify this library to iKeycmd or iKeyman. The HP Itanium platform is the only exception, as the iKeyman program is 64-bit on the HP Itanium platform.
-db	Fully qualified path name of a key database.
-default_cert	Sets a certificate as the default certificate. The value can be yes or no. The default is no.
-dn	X.500 distinguished name. The value is a string enclosed in double quotation marks, for example "CN=John Smith,O=IBM,OU=Test,C=GB". Note that the CN, O, and C attributes are required.

Table 86. Options that can be used with `runmqckm` and `runmqakm` (continued)

Option	Description
-encryption	Strength of encryption used in certificate export command. The value can be <code>strong</code> or <code>weak</code> . The default is <code>strong</code> .
-expire	Expiration time in days of either a certificate or a database password. The default is 365 days for a certificate password.  There is no default time for a database password: use the <code>-expire</code> option to set a database password expiration time explicitly.
-file	File name of a certificate or certificate request.
-fips	specifies that the command is run in FIPS mode. When in FIPS mode, the ICC component uses algorithms that have been FIPS 140-2 validated. If the ICC component does not initialize in FIPS mode, the <code>runmqakm</code> command fails.
-format	Format of a certificate. The value can be <code>ascii</code> for Base64_encoded ASCII or <code>binary</code> for Binary DER data. The default is <code>ascii</code> .
-label	Label attached to a certificate or certificate request. If the certificate is a personal certificate used to identify an IBM MQ client application or queue manager, the label must correspond to the IBM MQ certificate label (CERTLABL) setting, for more information, see Digital certificate labels, understanding the requirements.
-new_format	New format of key database.
-new_label	Used on a certificate import command, this option allows a certificate to be imported with a different label from the label it had in the source key database. If the certificate is a personal certificate used to identify an IBM MQ client application or queue manager, the label must correspond to the IBM MQ certificate label (CERTLABL) setting, for more information, see Digital certificate labels, understanding the requirements.
-new_pw	New database password.
-old_format	Old format of key database.
-pw	Password for the key database or PKCS #12 file.
-secondaryDB	Name of a secondary key database for PKCS #11 device operations.
-secondaryDBpw	Password for the secondary key database for PKCS #11 device operations.
-showOID	Displays the full certificate or certificate request.
-sig_alg	The hashing algorithm used during the creation of a certificate request, a self-signed certificate, or the signing of a certificate. This hashing algorithm is used to create the signature associated with the newly-created certificate or certificate request.  For <code>runmqckm</code> , the value can be <code>MD2_WITH_RSA</code> , <code>MD2WithRSA</code> , <code>MD5_WITH_RSA</code> , <code>MD5WithRSA</code> , <code>SHA1WithDSA</code> , <code>SHA1WithRSA</code> , <code>SHA256_WITH_RSA</code> , <code>SHA256WithRSA</code> , <code>SHA2WithRSA</code> , <code>SHA384_WITH_RSA</code> , <code>SHA384WithRSA</code> , <code>SHA512_WITH_RSA</code> , <code>SHA512WithRSA</code> , <code>SHA_WITH_DSA</code> , <code>SHA_WITH_RSA</code> , <code>SHAWithDSA</code> , or <code>SHAWithRSA</code> . The default value is <code>SHA1WithRSA</code> .  For <code>runmqakm</code> , the value can be <code>md5</code> , <code>MD5_WITH_RSA</code> , <code>MD5WithRSA</code> , <code>SHA_WITH_DSA</code> , <code>SHA_WITH_RSA</code> , <code>sha1</code> , <code>SHA1WithDSA</code> , <code>SHA1WithECDSA</code> , <code>SHA1WithRSA</code> , <code>sha224</code> , <code>SHA224_WITH_RSA</code> , <code>SHA224WithDSA</code> , <code>SHA224WithECDSA</code> , <code>SHA224WithRSA</code> , <code>sha256</code> , <code>SHA256_WITH_RSA</code> , <code>SHA256WithDSA</code> , <code>SHA256WithECDSA</code> , <code>SHA256WithRSA</code> , <code>SHA2WithRSA</code> , <code>sha384</code> , <code>SHA384_WITH_RSA</code> , <code>SHA384WithECDSA</code> , <code>SHA384WithRSA</code> , <code>sha512</code> , <code>SHA512_WITH_RSA</code> , <code>SHA512WithECDSA</code> , <code>SHA512WithRSA</code> , <code>SHAWithDSA</code> , <code>SHAWithRSA</code> , <code>EC_ecdsa_with_SHA1</code> , <code>EC_ecdsa_with_SHA224</code> , <code>EC_ecdsa_with_SHA256</code> , <code>EC_ecdsa_with_SHA384</code> , or <code>EC_ecdsa_with_SHA512</code> . The default value is <code>SHA1WithRSA</code> .

Table 86. Options that can be used with `runmqckm` and `runmqakm` (continued)

Option	Description
<code>-size</code>	<p>Key size.</p> <p>For <code>runmqckm</code>, the value can be 512, 1024, or 2048. The default value is 1024 bits.</p> <p>For <code>runmqakm</code>, the value depends upon the signature algorithm:</p> <ul style="list-style-type: none"> <li>• For RSA signature algorithms (the default algorithm used if no <code>-sig_alg</code> is specified), the value can be 512, 1024, 2048, or 4096. An RSA key size of 512 bits is not permitted if the <code>-fips</code> parameter is enabled. The default RSA key size is 1024 bits.</li> <li>• For Elliptic Curve algorithms, the value can be 256, 384, or 512. The default Elliptic Curve key size depends upon the signature algorithm. For SHA256, it is 256; for SHA384, it is 384; and for SHA512, it is 512.</li> </ul>
<code>-stash</code>	Stash the key database password to a file.
<code>-target</code>	Destination file or database.
<code>-target_pw</code>	Password for the key database if <code>-target</code> specifies a key database.
<code>-target_type</code>	Type of database specified by <code>-target</code> operand. See <code>-type</code> option for permitted values.
<code>-tokenLabel</code>	Label of a PKCS #11 cryptographic device.
<code>-trust</code>	Trust status of a CA certificate. The value can be <code>enable</code> or <code>disable</code> . The default is <code>enable</code> .
<code>-type</code>	<p>Type of database. The value can be any of the following values:</p> <ul style="list-style-type: none"> <li>• <code>cms</code> for a CMS key database</li> <li>• <code>pkcs12</code> for a PKCS #12 file.</li> </ul>
<code>-x509version</code>	Version of X.509 certificate to create. The value can be 1, 2, or 3. The default is 3.
<code>V8.0.0.4 -rfc3339</code>	<p>Use this parameter to output the date in the RFC 3339 format for the <code>runmqakm -cert -details</code> command, which is of the following format:</p> <pre>Not Before : 2015-08-26T08:53:37Z Not After  : 2016-08-26T08:53:37Z</pre> <p>Note that the <code>-rfc3339</code> parameter has to appear in the command after the additional parameters:</p> <pre>runmqakm -cert -details -db exampleDB -stashed -label           certificateLabel -rfc3339</pre>

**Note:** Properties provided with IBM Global Secure Toolkit (GSKit) relating to symmetric-key encryption `-seckey` option in the 'runmqckm' utility are ignored and not supported by IBM MQ.

## runmqakm error codes:

A table of the numeric error codes issued by runmqakm, and what they mean.

Error code	Error Message
0	Success
1	Unknown error occurred
2	An ASN.1 encoding/decoding error occurred.
3	An error occurred while initializing ASN.1 encoder/decoder.
4	An ASN.1 encoding/decoding error occurred because of an out-of-range index or non-existent optional field.
5	A database error occurred.
6	An error occurred while opening the database file, check for file existence and permission.
7	An error occurred while re-opening the database file.
8	Database creation failed.
9	The database already exists.
10	An error occurred while deleting the database file.
11	The database could not be opened.
12	An error occurred while reading the database file.
13	An error occurred while writing data to the database file.
14	A database validation error occurred.
15	An invalid database version was encountered.
16	An invalid database password was encountered.
17	An invalid database file type was encountered.
18	The specified database has been corrupted.
19	An invalid password was provided or the key database has been tampered with or corrupted.
20	A database key entry integrity error occurred.
21	A duplicate certificate already exists in the database.
22	A duplicate key already exists in the database (Record ID).
23	A certificate with the same label already existed in the key database.
24	A duplicate key already exists in the database (Signature).
25	A duplicate key already exists in the database (Unsigned Certificate).
26	A duplicate key already exists in the database (Issuer and Serial Number).
27	A duplicate key already exists in the database (Subject Public Key Info).
28	A duplicate key already exists in the database (Unsigned CRL).
29	The label has been used in the database.

<b>Error code</b>	<b>Error Message</b>
30	A password encryption error occurred.
31	An LDAP related error occurred. (LDAP is not supported by this program)
32	A cryptographic error occurred.
33	An encryption/decryption error occurred.
34	An invalid cryptographic algorithm was found.
35	An error occurred while signing data.
36	An error occurred while verifying data.
37	An error occurred while computing digest of data.
38	An invalid cryptographic parameter was found.
39	An unsupported cryptographic algorithm was encountered.
40	The specified input size is greater than the supported modulus size.
41	An unsupported modulus size was found.
42	A database validation error occurred.
43	Key entry validation failed.
44	A duplicate extension field exists.
45	The version of the key is wrong.
46	A required extension field does not exist.
47	The validity period does not include today or does not fall within its issuer's validity period
48	The validity period does not include today or does not fall within its issuer's validity period.
49	An error occurred while validating private key usage extension.
50	The issuer of the key was not found.
51	A required certificate extension is missing.
52	An invalid basic constraint extension was found.
53	The key signature validation failed.
54	The root key of the key is not trusted.
55	The key has been revoked.
56	An error occurred while validating authority key identifier extension.
57	An error occurred while validating private key usage extension.
58	An error occurred while validating subject alternative name extension.
59	An error occurred while validating issuer alternative name extension.
60	An error occurred while validating key usage extension.
61	An unknown critical extension was found.
62	An error occurred while validating key pair entries.
63	An error occurred while validating CRL.

<b>Error code</b>	<b>Error Message</b>
64	A mutex error occurred.
65	An invalid parameter was found.
66	A null parameter or memory allocation error was encountered.
67	Number or size is too large or too small.
68	The old password is invalid.
69	The new password is invalid.
70	The password has expired.
71	A thread related error occurred.
72	An error occurred while creating threads.
73	An error occurred while a thread was waiting to exit.
74	An I/O error occurred.
75	An error occurred while loading CMS.
76	A cryptography hardware related error occurred.
77	The library initialization routine was not successfully called.
78	The internal database handle table is corrupted.
79	A memory allocation error occurred.
80	An unrecognized option was found.
81	An error occurred while getting time information.
82	Mutex creation error occurred.
83	An error occurred while opening message catalog.
84	An error occurred while opening error message catalog
85	A null file name was found.
86	An error occurred while opening files, check for file existence and permissions.
87	An error occurred while opening files to read.
88	An error occurred while opening files to write.
89	There is no such file.
90	The file cannot be opened because of its permission setting.
91	An error occurred while writing data to files.
92	An error occurred while deleting files.
93	Invalid Base64-encoded data was found.
94	An invalid Base64 message type was found.
95	An error occurred while encoding data with Base64 encoding rule.
96	An error occurred while decoding Base64-encoded data.
97	An error occurred while getting a distinguished name tag.
98	The required common name field is empty.
99	The required country or region name field is empty.

Error code	Error Message
100	An invalid database handle was found.
101	The key database does not exist.
102	The request key pair database does not exist.
103	The password file does not exist.
104	The new password is identical to the old one.
105	No key was found in the key database.
106	No request key was found.
107	No trusted CA was found.
108	No request key was found for the certificate.
109	There is no private key in the key database.
110	There is no default key in the key database.
111	There is no private key in the key record.
112	There is no certificate in the key record.
113	There is no CRL entry.
114	An invalid key database file name was found.
115	An unrecognized private key type was found.
116	An invalid distinguished name input was found.
117	No key entry was found that has the specified key label.
118	The key label list has been corrupted.
119	The input data is not valid PKCS12 data.
120	The password is invalid or the PKCS12 data has been corrupted or been created with later version of PKCS12
121	An unrecognized key export type was found.
122	An unsupported password-based encryption algorithm was found.
123	An error occurred while converting the key ring file to a CMS key database.
124	An error occurred while converting the CMS key database to a key ring file.
125	An error occurred while creating a certificate for the certificate request.
126	A complete issuer chain cannot be built.
127	Invalid WEBDB data was found.
128	There is no data to be written to the key ring file.
129	The number of days that you entered extends beyond the permitted validity period.
130	The password is too short; it must consist of at least {0} characters.
131	A password must contain at least one numeric digit.
132	All characters in the password are either alphabetic or numeric characters.
133	An unrecognized or unsupported signature algorithm was specified.

<b>Error code</b>	<b>Error Message</b>
134	An invalid database type was encountered.
135	The specified secondary key database is in use by another PKCS#11 device.
136	No secondary key database was specified.
137	The label does not exist on the PKCS#11 device.
138	Password required to access the PKCS#11 device.
139	Password not required to access the PKCS#11 device.
140	Unable to load the cryptographic library.
141	PKCS#11 is not supported for this operation.
142	An operation on a PKCS#11 device has failed.
143	The LDAP user is not a valid user. (LDAP is not supported by this program)
144	The LDAP user is not a valid user. (LDAP is not supported by this program)
145	The LDAP query failed. (LDAP is not supported by this program)
146	An invalid certificate chain was found.
147	The root certificate is not trusted.
148	A revoked certificate was encountered.
149	A cryptographic object function failed.
150	There is no certificate revocation list data source available.
151	There is no cryptographic token available.
152	FIPS mode is not available.
153	There is a conflict with the FIPS mode settings.
154	The password entered does not meet the minimum required strength.
200	There was a failure during initialization of the program.
201	Tokenization of the arguments passed to the runmqkm Program failed.
202	The object identified in the command is not a recognized object.
203	The action passed is not a known -keydb action.
204	The action passed is not a known -cert action.
205	The action passed is not a known -certreq action.
206	There is a tag missing for the requested command.
207	The value passed with the -version tag is not a recognized value.
208	The value passed with the -size tag is not a recognized value.
209	The value passed in with the -dn tag is not in the correct format.
210	The value passed in with the -format tag is not a recognized value.

Error code	Error Message
211	There was an error associated with opening the file.
212	PKCS12 is not supported at this stage.
213	The cryptographic token you are trying to change the password for is not password protected.
214	PKCS12 is not supported at this stage.
215	The password entered does not meet the minimum required strength.
216	FIPS mode is not available.
217	The number of days you have entered as the expiry date is out of the allowed range.
218	Password strength failed the minimum requirements.
219	No Default certificate was found in the requested key database.
220	An invalid trust status was encountered.
221	An unsupported signature algorithm was encountered. At this stage only MD5 and SHA1 are supported.
222	PCKS11 not supported for that particular operation.
223	The action passed is not a known -random action.
224	A length than less than zero is not allowed.
225	When using the -strong tag the minimum length password is 14 characters.
226	When using the -strong tag the maximum length password is 300 characters.
227	The MD5 algorithm is not supported when in FIPS mode.
228	The site tag is not supported for the -cert -list command. This attribute is added for backward compatibility and potential future enhancement.
229	The value associated with the -ca tag is not recognized. The value must be either 'true' or 'false'.
230	The value passed in with the -type tag is not valid.
231	The value passed in with the -expire tag is below the allowed range.
232	The encryption algorithm used or requested is not supported.
233	The target already exists.

## IBM MQ for IBM i CL commands

A list of IBM MQ for IBM i CL commands grouped according to command type:

- Authentication Information Commands
  - CHGMQMAUTI, Change IBM MQ Authentication Information
  - CPYMQMAUTI, Copy IBM MQ Authentication Information
  - CRTMQMAUTI, Create IBM MQ Authentication Information
  - DLTMQMAUTI, Delete IBM MQ Authentication Information
  - DSPMQMAUTI, Display IBM MQ Authentication Information
  - WRKMQMAUTI, Work with IBM MQ Authentication Information
- Authority Commands
  - DSPMQMAUT, Display IBM MQ Object Authority
  - GRMQMAUT, Grant IBM MQ Object Authority
  - RFRMQMAUT, Refresh IBM MQ Object Authority
  - RVKMQMAUT, Revoke IBM MQ Object Authority
  - WRKMQMAUT, Work with IBM MQ Authority
  - WRKMQMAUTD, Work with IBM MQ Authority Data
- Broker Commands

The following commands do not perform any function and are only provided for compatibility with previous releases of IBM MQ.

  - CLRMQMBRK, Clear IBM MQ Broker
  - DLTMQMBRK, Delete IBM MQ Broker
  - DSPMQMBRK, Display IBM MQ Pub/Sub Broker
  - DSPMQMBRK, Display IBM MQ Broker
  - ENDMQMBRK, End IBM MQ Broker
  - STRMQMBRK, Start IBM MQ Broker
- Channel Commands
  - CHGMQMCHL, Change IBM MQ Channel
  - CPYMQMCHL, Copy IBM MQ Channel
  - CRTMQMCHL, Create IBM MQ Channel
  - DLTMQMCHL, Delete IBM MQ Channel
  - DSPMQMCHL, Display IBM MQ Channel
  - ENDMQMCHL, End IBM MQ Channel
  - PNGMQMCHL, Ping IBM MQ Channel
  - RSTMQMCHL, Reset IBM MQ Channel
  - RSVMQMCHL, Resolve IBM MQ Channel
  - STRMQMCHL, Start IBM MQ Channel
  - STRMQMCHLI, Start IBM MQ Channel Initiator
  - WRKMQMCHL, Work with IBM MQ Channels
  - WRKMQMCHST, Work with IBM MQ Channel Status
- Cluster Commands
  - RFRMQMCL, Refresh IBM MQ Cluster
  - RSMMQMCLQM, Resume IBM MQ Cluster Queue Manager
  - RSTMQMCL, Reset IBM MQ Cluster
  - SPDMQMCLQM, Suspend IBM MQ Cluster Queue Manager
  - WRKMQMCL, Work with IBM MQ Clusters

- WRKMQMCLQ, Work with IBM MQ Cluster Queues
- Command Server Commands
  - DSPMQMCSVR, Display IBM MQ Command Server
  - ENDMQMCSVR, End IBM MQ Command Server
  - STRMQMCSVR, Start IBM MQ Command Server
- Connection Commands
  - ENDMQMCONN, End IBM MQ Connection
  - WRKMQMCONN, Work with IBM MQ Connections
- Data Conversion Exit Command
  - CVTMQMMDTA, Convert IBM MQ Data Type
- Listener Commands
  - CHGMQMLSR, Change IBM MQ Listener Object
  - CPYMQMLSR, Copy IBM MQ Listener Object
  - CRTMQMLSR, Create IBM MQ Listener Object
  - DLTMQMLSR, Delete IBM MQ Listener Object
  - DSPMQMLSR, Display IBM MQ Listener Object
  - ENDMQMLSR, End IBM MQ Listener
  - STRMQMLSR, Start IBM MQ Listener
  - WRKMQMLSR, Work with IBM MQ Listeners
- Media Recovery Commands
  - RCDMQMIMG, Record IBM MQ Object Image
  - RCRMQMOBJ, Re-create IBM MQ Object
  - WRKMQMTRN, Work with IBM MQ Transactions
- Name Command
  - DSPMQMOBJN, Display IBM MQ Object Names
- Namelist Commands
  - CHGMQMNL, Change IBM MQ Namelist
  - CPYMQMNL, Copy IBM MQ Namelist
  - CRTMQMNL, Create IBM MQ Namelist
  - DLTMQMNL, Delete IBM MQ Namelist
  - DSPMQMNL, Display IBM MQ Namelist
  - WRKMQMNL, Work with IBM MQ Namelists
- Process Commands
  - CHGMQMPRC, Change IBM MQ Process
  - CPYMQMPRC, Copy IBM MQ Process
  - CRTMQMPRC, Create IBM MQ Process
  - DLTMQMPRC, Delete IBM MQ Process
  - DSPMQMPRC, Display IBM MQ Process
  - WRKMQMPRC, Work with IBM MQ Processes
- Queue Commands
  - CHGMQMQ, Change IBM MQ Queue
  - CLRMQMQ, Clear IBM MQ Queue
  - CPYMQMQ, Copy IBM MQ Queue
  - CRTMQMQ, Create IBM MQ Queue
  - DLTMQMQ, Delete IBM MQ Queue

- DSPMQMQ, Display IBM MQ Queue
- WRKMQMMSG, Work with IBM MQ Messages
- WRKMQMQ, Work with IBM MQ Queues
- WRKMQMQSTS, Work with IBM MQ Queue Status
- Queue Manager Commands
  - CCTMQM, Connect to Message Queue Manager
  - CHGMQM, Change Message Queue Manager
  - CRTMQM, Create Message Queue Manager
  - DLTMQM, Delete Message Queue Manager
  - DSCMQM, Disconnect from Message Queue Manager
  - DSPMQM, Display Message Queue Manager
  - DSPMQMSTS, Display Message Queue Manager Status
  - ENDMQM, End Message Queue Manager
  - **V8.0.0.4** RFRMQM, Refresh Message Queue Manager
  - STRMQM, Start Message Queue Manager
  - STRMQMTRM, Start IBM MQ Trigger Monitor
  - WRKMQM, Work with Message Queue Manager
- Service Commands
  - CHGMQMSVC, Change IBM MQ Service
  - CPYMQMSVC, Copy IBM MQ Service
  - CRTMQMSVC, Create IBM MQ Service
  - DLTMQMSVC, Delete IBM MQ Service
  - DSPMQMSVC, Display IBM MQ Service
  - ENDMQMSVC, End IBM MQ Service
  - STRMQMSVC, Start IBM MQ Service
  - WRKMQMSVC, Work with IBM MQ Services
- Subscription Commands
  - CHGMQMSUB, Change IBM MQ Subscription
  - CPYMQMSUB, Copy IBM MQ Subscription
  - CRTMQMSUB, Create IBM MQ Subscription
  - DLTMQMSUB, Delete IBM MQ Subscription
  - DSPMQMSUB, Display IBM MQ Subscription
  - WRKMQMSUB, Work with IBM MQ Subscription
- Topic Commands
  - CHGMQMTOP, Change IBM MQ Topic
  - CLRMQMTOP, Clear IBM MQ Topic
  - CPYMQMTOP, Copy IBM MQ Topic
  - CRTMQMTOP, Create IBM MQ Topic
  - DLTMQMTOP, Delete IBM MQ Topic
  - DSPMQMTOP, Display IBM MQ Topic
  - WRKMQMTOP, Work with IBM MQ Topics
- Trace Command
  - TRCMQM, Trace IBM MQ Job
- IBM MQSC Commands
  - RUNMQSC, Run IBM MQSC Commands

- STRMQMMQSC, Start IBM MQSC Commands
- IBM MQ Dead-Letter Queue Handler Command
  - STRMQMDLQ, Start IBM MQ Dead-Letter Queue Handler
- IBM MQ Route Information
  - DSPMQMRTE, Display IBM MQ Route Information
- IBM MQ Configuration Dump
  - Dump MQ Configuration (DMPMQMCFG)
- IBM MQ Version Details
  - DSPMQMVER, Display IBM MQ Version

## MQSC reference

Use MQSC commands to manage queue manager objects, including the queue manager itself, queues, process definitions, channels, client connection channels, listeners, services, namelists, clusters, and authentication information objects.

For an overview of using MQSC commands for administering IBM MQ, see *Performing local administration tasks using MQSC commands*.

MQSC commands use certain special characters to have certain meanings. For more information about these special characters and how to use them, see *“Generic values and characters with special meanings.”*

To find out how you can build scripts using MQSC commands, see *“Building command scripts”* on page 341.

 For an explanation of the symbols in the z/OS column, see *Using commands on z/OS*.

For the full list of MQSC commands, see *“The MQSC commands”* on page 343.

### Related concepts:

*“IBM MQ Control commands”* on page 178

Find out how to use the IBM MQ control commands.

*“Programmable command formats reference”* on page 1044

Programmable Command Formats (PCFs) define command and reply messages that can be exchanged between a program and any queue manager (that supports PCFs) in a network. PCFs simplify queue manager administration and other network administration.

 *“IBM MQ for IBM i CL commands”* on page 337

A list of IBM MQ for IBM i CL commands grouped according to command type:

## Generic values and characters with special meanings

The following information describes generic values, and characters that have special meaning when you build MQSC commands.

Wherever a parameter can have a generic value, it is entered ending with an asterisk (\*), for example ABC\*. A generic value means 'all values beginning with'; so ABC\* means 'all values beginning with ABC'.

If characters that require quotation marks are used in the value, the asterisk must be placed inside the quotation marks, thus 'abc\*'. The asterisk must be the last or only character in the value.

The question mark (?) and colon (:) are not allowed in generic values.

Character	Description
	Blanks are used as separators. Multiple blanks are equivalent to a single blank, except in strings that have apostrophes (') round them. Any trailing blanks in those string attributes which are based on MQCHARV types are treated as significant.
,	Commas are used as separators. Multiple commas are equivalent to a single comma, except in strings that have apostrophes (') round them.
'	An apostrophe indicates the beginning or end of a string. IBM MQ leaves all characters that have quotation marks round them exactly as they are entered. The containing apostrophes are not included when calculating the length of the string.
"	Single quotation marks inside a string are treated by IBM MQ as one character when calculating the length of the string and the string is not terminated.
=	On z/OS, an equals sign indicates the start of a parameter value which is ended by a comma or blank.
(	An open parenthesis indicates the beginning of a parameter value or list of values.
)	A close parenthesis indicates the end of a parameter value or list of values.
:	A colon indicates an inclusive range. For example (1:5) means (1,2,3,4,5). This notation can be used only in TRACE commands.
*	An asterisk means "all". For example, DISPLAY TRACE (*) means display all traces, and DISPLAY QUEUE (PAY*) means display all queues with names that begin with PAY.

When you need to use any of these special characters in a field (for example as part of a description), you must enclose the whole string in single quotation marks.

## Building command scripts

Use this information to learn how to build command scripts.

You might want to build the MQSC commands into a script when you use:

- The CSQINP1, CSQINP2, and CSQINPX initialization data sets or the CSQUTIL batch utility on z/OS.
- The STRMQM command on IBM i.
- The **runmqsc** command on UNIX, Linux, and Windows systems.

When you do this, follow these rules:

- Each command must start on a new line.
- On each platform, there might be platform-specific rules about the line length and record format. If scripts are to be readily portable to different platforms, the significant length of each line should be restricted to 72 characters.
  - On z/OS, scripts are held in a fixed-format data set, with a record length of 80. Only columns 1 through 72 can contain meaningful information; columns 73 through 80 are ignored.
  - On AIX, HP-UX, Linux, IBM i, Solaris, and Windows, each line can be of any length up to a maximum of 2048 characters.
  - On other UNIX systems, each line can be of any length up to and including 80 characters.
- A line must not end in a keyboard control character (for example, a tab).
- If the last nonblank character on a line is:
  - A minus sign (-), this indicates that the command is to be continued from the start of the next line.
  - A plus sign (+), this indicates that the command is to be continued from the first nonblank character in the next line. If you use + to continue a command remember to leave at least one blank before the next parameter (except on z/OS where this is not necessary).

Either of these can occur within a parameter, data value, or a string enclosed in quotation marks. For example,

```
'Fr+  
ed'
```

and

```
'Fr-  
ed'
```

(where the 'e' of the second line of the second example is in the first position of the line) are both equivalent to

```
'Fred'
```

MQSC commands that are contained within an Escape PCF (Programmable Command Format) command cannot be continued in this way. The entire command must be contained within a single Escape command. (For information about the PCF commands, see Introduction to Programmable Command Formats ).

- + and - values used at the ends of lines are discarded when the command is reassembled into a single string.
- On AIX, HP-UX, Linux, IBM i, Solaris Solaris, and Windows you can use a semicolon character (;) to terminate a command, even if you have entered a plus sign (+) at the end of the previous line. You can also use the semicolon in the same way on z/OS for commands issued from the CSQUTIL batch utility program.
- A line starting with an asterisk (\*) in the first position is ignored. This can be used to insert comments into the file.

A blank line is also ignored.

If a line ends with a continuation character (- or +), the command continues with the next line that is not a comment line or a blank line.

- When running MQSC commands interactively, you end the interactive session by typing the END command. This applies to:
  - UNIX, Linux, and Windows systems, where you start the interactive session by entering **runmqsc**
  - IBM i systems, where you start the interactive session from the WRKMQM panel
- On Windows, if certain special characters such as the pound sign (£) and the logical NOT (!) are used in a command script (for example, as part of an object description), they are displayed differently in the output from a command such as DISPLAY QLOCAL.

## Using commands on z/OS

z/OS

MQSC commands can be issued from various sources, depending on the command.

Commands can be issued from the following sources:

- The z/OS console or equivalent
- The initialization input data sets CSQINP1, CSQINP2, CSQINPT and CSQINPX
- The CSQUTIL batch utility
- Suitably authorized applications, sending commands as messages to the SYSTEM.COMMAND.INPUT queue

z/OS

For further details, see Issuing commands,

However, not all commands can be issued from all these sources. Commands can be classified according to whether they can be issued from:

- 1 CSQINP1
- 2 CSQINP2
- C The z/OS console

R The command server and command queue, by means of CSQUTIL, CSQINPT, CSQINPX, or applications

Within the command descriptions that follow, these sources are identified by the use of the characters 1, 2, C, and R in the z/OS column of the tables for each command description.

## The MQSC commands

Use this topic as a reference to the MQSC commands.

This section describes, in alphabetical order, all the MQSC commands that can be issued by operators and administrators.

Clustering: Using REFRESH CLUSTER best practices

**ALTER AUTHINFO:**

Use the MQSC command ALTER AUTHINFO to alter an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

Parameters not specified in the ALTER AUTHINFO command result in the existing values for those parameters being left unchanged.

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram for TYPE(CRLLDAP)
- Syntax diagram for TYPE(OCSP)

- Syntax diagram for TYPE(IDPWLDAP)
- "Parameter descriptions for ALTER AUTHINFO" on page 349

**Synonym:** ALT AUTHINFO

**Syntax diagram for TYPE(CRLLDAP)**

## ALTER AUTHINFO

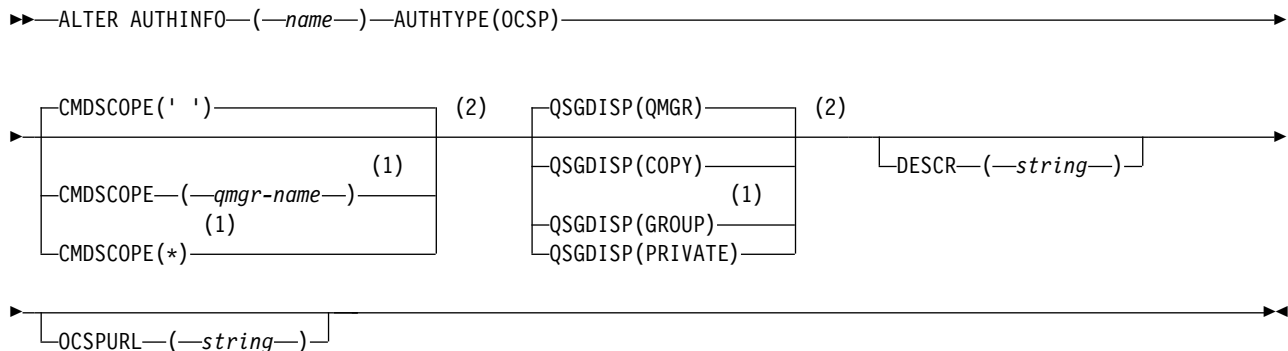

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 2 Valid only on z/OS.

### Syntax diagram for TYPE(OCSP)

## ALTER AUTHINFO

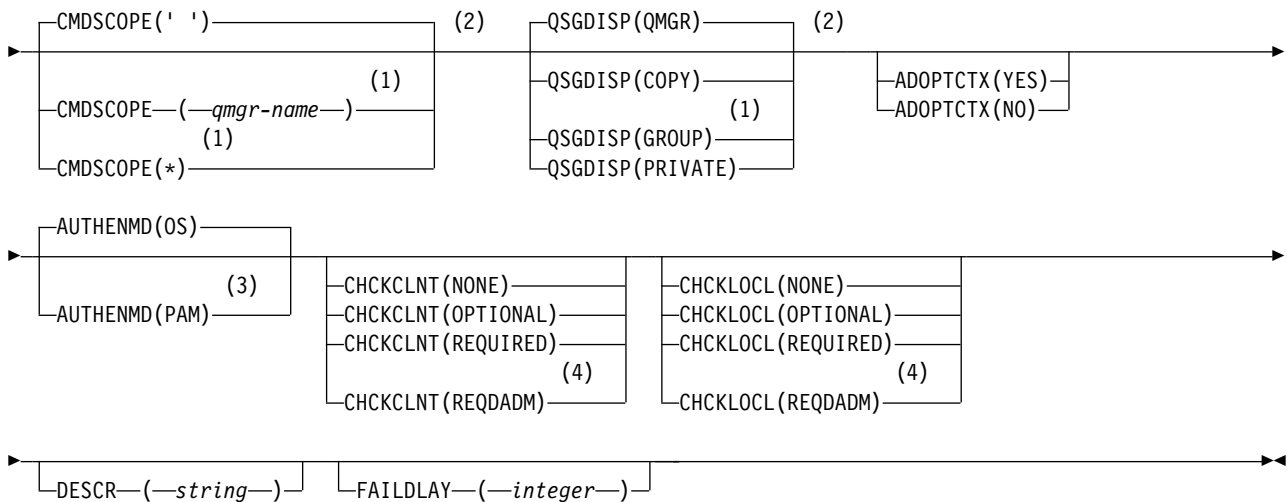

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 2 Valid only on z/OS.

### Syntax diagram for TYPE(IDPWOS)

## ALTER AUTHINFO

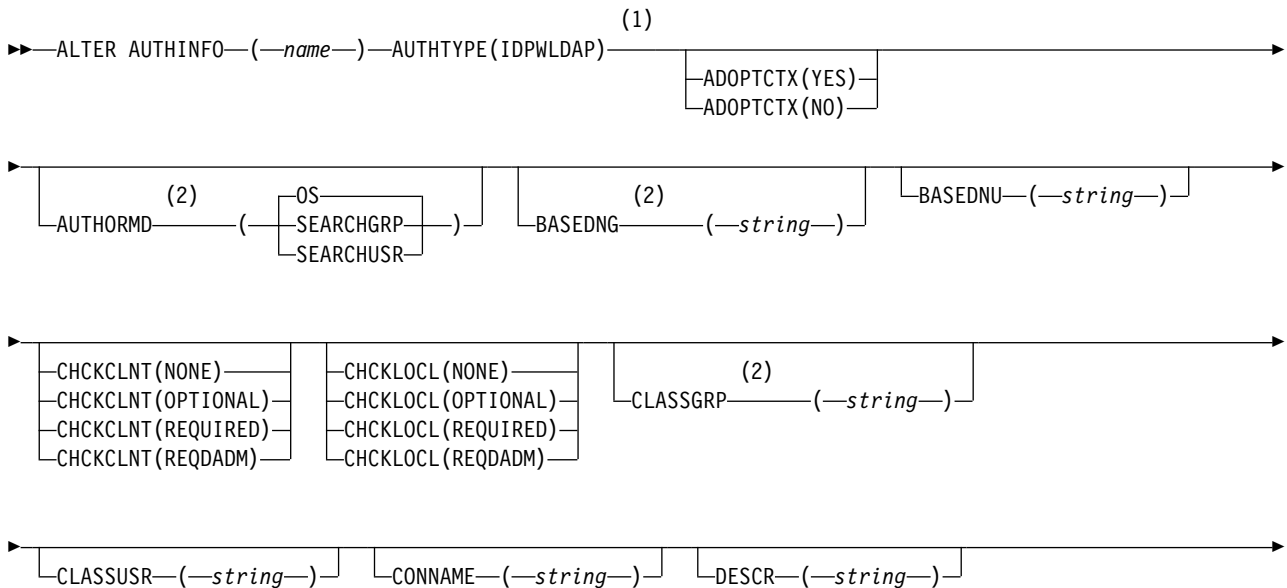

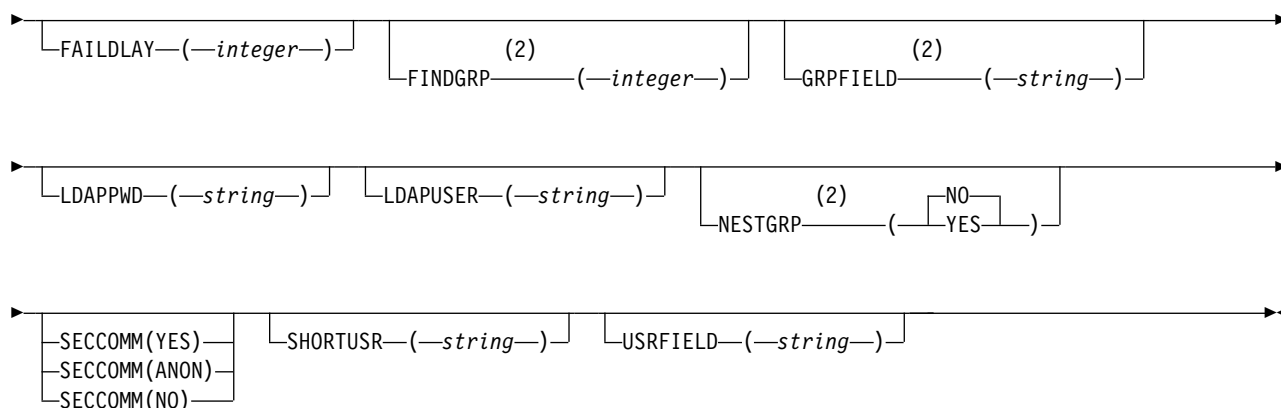

**Notes:**

- 1 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS and PAM value can be set only on UNIX platforms.
- 4 Not valid on z/OS.

**Syntax diagram for TYPE(IDPWLDAP)**

**ALTER AUTHINFO**

**Notes:**

- 1 Not valid on z/OS.
- 2 Not valid on Windows.

**Parameter descriptions for ALTER AUTHINFO**

*name* Name of the authentication information object. This parameter is required.

The name must not be the same as any other authentication information object name currently defined on this queue manager (unless REPLACE or ALTER is specified). See Rules for naming IBM MQ objects.

**ADOPTCTX**

Whether to use the presented credentials as the context for this application. This means that they are used for authorization checks, shown on administrative displays, and appear in messages.

**YES** The user ID presented in the MQCSP structure, which has been successfully validated by password, is adopted as the context to use for this application. Therefore, this user ID will be the credentials checked for authorization to use IBM MQ resources.

If the user ID presented is an LDAP user ID, and authorization checks are done using operating system user IDs, the SHORTUSR associated with the user entry in LDAP will be adopted as the credentials for authorization checks to be done against.

**NO** Authentication will be performed on the user ID and password presented in the MQCSP structure, but then the credentials will not be adopted for further use. Authorization will be performed using the user ID the application is running under.

This attribute is only valid for an AUTHTYPE of IDPWOS and IDPWLDAP.

**V8.0.0.3 AUTHENMD**

Authentication method. Whether to use the operating system or Pluggable Authentication Method (PAM) to authenticate user passwords.

**OS** Use the traditional UNIX platforms password verification method.

**PAM**

Use the PAM to authenticate the user password.

You can set the PAM value only on UNIX and Linux platforms.

Changes to this attribute are effective only after you run the REFRESH SECURITY TYPE(CONNAUTH) command.

This attribute is valid only for an AUTHTYPE of IDPWOS.

## **V 8.0.0.2** AUTHORMD

Authorization method.

**OS** Use operating system groups to determine permissions associated with a user.

This is how IBM MQ has previously worked, and is the default value.

### **SEARCHGRP**

A group entry in the LDAP repository contains an attribute listing all the users belonging to that group. Membership is indicated by the attribute defined in FINDGRP. This value is typically *member* or *uniqueMember*.

### **SEARCHUSR**

A user entry in the LDAP repository contains an attribute listing all the groups to which the specified user belongs. The attribute to query is defined by the FINDGRP value, typically *memberOf*.

Many LDAP servers use an attribute of the group object to determine group membership and you should, therefore, set this value to *SEARCHGRP*.

Microsoft Active Directory typically stores group memberships as a user attribute. The IBM Tivoli Directory Server supports both methods.

In general, retrieving memberships through a user attribute will be faster than searching for groups that list the user as a member.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2**, and is not applicable to Windows platforms.

## **AUTHTYPE**

The type of authentication information.

### **CRLLDAP**

Certificate Revocation List checking is done using LDAP servers.

### **IDPWLDAP**

Connection authentication user ID and password checking is done using an LDAP server.

### **IDPWOS**

Connection authentication user ID and password checking is done using the operating system.

### **OCSP**

Certificate revocation checking is done using OCSP.

An authentication information object with **AUTHTYPE(OCSP)** does not apply for use on IBM i or z/OS queue managers. However, it can be specified on those platforms to be copied to the client channel definition table (CCDT) for client use.

This parameter is required.

You cannot define an authentication information object as **LIKE** one with a different **AUTHTYPE**. You cannot alter the **AUTHTYPE** of an authentication information object after you have created it.

## **V 8.0.0.2** BASEDNG

Base DN for groups

In order to be able to find group names, this parameter must be set with the base DN to search for groups in the LDAP server.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2**, and is not applicable to Windows platforms.

## BASEDNU( *base DN* )

In order to be able to find the short user name attribute (see SHORTUSR ) this parameter must be set with the base DN to search for users within the LDAP server.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

## CHCKCLNT

This attribute determines the authentication requirements for client applications, and is valid only for an **AUTHTYPE** of *IDPWOS* or *IDPWLDAP* . The possible values are:

**NONE** No user ID and password checks are made. If any user ID or password is supplied by a client application, the credentials are ignored.

### OPTIONAL

Client applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

### REQUIRED

All client applications must provide a user ID and password in the MQCSP structure. This user ID and password is authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

### REQDADM

All client applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the *OPTIONAL* setting.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

**Note:** The *REQDADM* value for the *CHCKCLNT* attribute is irrelevant if the authentication type is *LDAP*. This is because there is no concept of privileged user id when using *LDAP* user accounts. *LDAP* user accounts and groups must be assigned permission explicitly.

 (This setting is not allowed on z/OS systems.)

### Important:

1. This attribute can be overridden by the **CHCKCLNT** attribute of the *CHLAUTH* rule that matches the client connection. The *CONNAUTH AUTHINFO CHCKCLNT* attribute on the queue manager therefore determines the default client checking behavior for client connections that do not match a *CHLAUTH* rule, or where the *CHLAUTH* rule matched has **CHCKCLNT ASQMGR**.
2. If you select *NONE* and the client connection matches a *CHLAUTH* record with **CHCKCLNT REQUIRED** (or *REQDADM* on platforms other than z/OS), the connection fails. You receive message *AMQ9793* on platforms other than z/OS, and message *CSQX793E* on z/OS.
3. This parameter is valid only with *TYPE (USERMAP)*, *TYPE (ADDRESSMAP)* and *TYPE (SSLPEERMAP)*, and only when **USERSRC** is not set to *NOACCESS*.
4. This parameter applies only to inbound connections that are server-connection channels.

## CHCKLOCL

This attribute determines the authentication requirements for locally bound applications, and is valid only for an **AUTHTYPE** of *IDPWOS* or *IDPWLDAP*. The possible values are:

**NONE** No user ID and password checks are made. If any user ID or password is supplied by a locally bound application, the credentials are ignored.

### OPTIONAL

Locally bound applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

### REQUIRED

All locally bound applications must provide a user ID and password in the MQCSP structure. This user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

▶ **z/OS** If your user ID has UPDATE access to the BATCH profile in the MQCONN class, you can treat **CHCKLOCL(REQUIRED)** as if it is **CHCKLOCL(OPTIONAL)**. That is, you do not have to supply a password, but if you do, the password must be the correct one. See Using **CHCKLOCL** on locally bound applications.

### REQDADM

All locally bound applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the OPTIONAL setting.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

▶ **z/OS** (This setting is not allowed on z/OS systems.)

## ▶ V 8.0.0.2 CLASSGRP

The LDAP object class used for group records in the LDAP repository.

If the value is blank, *groupOfNames* is used.

Other commonly used values include *groupOfUniqueNames* or *group*.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* ▶ **V 8.0.0.2**, and is not applicable to Windows platforms.

## CLASSUSR( LDAP class user )

The LDAP object class used for user records in the LDAP repository.

If blank, the value defaults to *inetOrgPerson*, which is generally the value needed.

For Microsoft Active Directory, the value you require is often *user*.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

## ▶ z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

### CONNNAME( *connection name* )

The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running, with an optional port number.

If you specify the connection name as an IPv6 address, only systems with an IPv6 stack are able to resolve this address. If the AUTHINFO object is part of the CRL namelist of the queue manager, ensure that any clients using the client channel table generated by the queue manager can resolve the connection name.

On z/OS, if a CONNNAME is to resolve to an IPv6 network address, a level of z/OS that supports IPv6 for connection to an LDAP server is required.

The syntax for CONNNAME is the same as for channels. For example,

```
connname(' hostname ( nnn )')
```

where *nnn* is the port number.

The maximum length for the field is 264 characters on IBM i, UNIX systems, and Windows, and 48 characters on z/OS.

This attribute is valid only for an **AUTHTYPE** of *CRLLDAP* and *IDPWLDAP*, when the attribute is mandatory.

When used with an **AUTHTYPE** of *IDPWLDAP*, this can be a comma separated list of connection names.

### DESCR( *string* )

Plain-text comment. It provides descriptive information about the authentication information object when an operator issues the DISPLAY AUTHINFO command (see "DISPLAY AUTHINFO" on page 715 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

### FAILDLAY( *delay time* )

When a user ID and password are provided for connection authentication, and the authentication fails due to the user ID or password being incorrect, this is the delay, in seconds, before the failure is returned to the application.

This can aid in avoiding busy loops from an application that simply retries, continuously, after receiving a failure.

The value must be in the range 0 - 60 seconds. The default value is 1.

This attribute is valid only for an **AUTHTYPE** of *IDPWOS* and *IDPWLDAP* .

#### **V 8.0.0.2 FINDGRP**

Name of the attribute used within an LDAP entry to determine group membership.

When **AUTHORMD** = *SEARCHGRP*, the **FINDGRP** attribute is typically set to *member* or *uniqueMember*.

When **AUTHORMD** = *SEARCHUSR*, the **FINDGRP** attribute is typically set to *memberOf*.

When left blank, if:

- **AUTHORMD** = *SEARCHGRP*, the **FINDGRP** attribute defaults to *memberOf*
- **AUTHORMD** = *SEARCHUSR*, the **FINDGRP** attribute defaults to *member*

#### **V 8.0.0.2 GRPFIELD**

LDAP attribute that represents a simple name for the group.

If the value is blank, commands like *setmqaut* must use a qualified name for the group. The value can either be a full DN, or a single attribute.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2** , and is not applicable to Windows platforms.

#### **LDAPPWD( LDAP password )**

The password associated with the Distinguished Name of the user who is accessing the LDAP server. Its maximum size is 32 characters.

On z/OS, the LDAPPWD used for accessing the LDAP server might not be the one defined in the **AUTHINFO** object. If more than one **AUTHINFO** object is placed in the namelist referred to by the **QMGR** parameter **SSLCRLNL**, the LDAPPWD in the first **AUTHINFO** object is used for accessing all LDAP Servers.

This attribute is valid only for an **AUTHTYPE** of *CRLLDAP* and *IDPWLDAP*.

#### **LDAPUSER( LDAP user )**

The Distinguished Name of the user who is accessing the LDAP server. (See the **SSLPEER** parameter for more information about distinguished names.)

The maximum size for the user name is 1024 characters on IBM i, UNIX systems, and Windows, and 256 characters on z/OS.

On z/OS, the LDAPUSER used for accessing the LDAP Server might not be the one defined in the **AUTHINFO** object. If more than one **AUTHINFO** object is placed in the namelist referred to by the **QMGR** parameter **SSLCRLNL**, the LDAPUSER in the first **AUTHINFO** object is used for accessing all LDAP Servers.

On IBM i, UNIX systems, and Windows, the maximum accepted line length is defined to be **BUFSIZ**, which can be found in *stdio.h*.

This attribute is valid only for an **AUTHTYPE** of *CRLLDAP* and *IDPWLDAP*.

#### **V 8.0.0.2 NESTGRP**

Group nesting.

**NO** Only the initially discovered groups are considered for authorization.

**YES**

The group list is searched recursively to enumerate all the groups to which a user belongs.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2** , and is not applicable to Windows platforms.

### OCSPURL( Responder URL )

The URL of the OCSP responder used to check for certificate revocation. This value must be an HTTP URL containing the host name and port number of the OCSP responder. If the OCSP responder is using port 80, which is the default for HTTP, then the port number can be omitted. HTTP URLs are defined in RFC 1738.

This field is case sensitive. It must start with the string `http://` in lowercase. The rest of the URL might be case sensitive, depending on the OCSP server implementation. To preserve case, use single quotation marks to specify the OCSPURL parameter value, for example:

```
OCSPURL ('http://ocsp.example.ibm.com')
```

This parameter is applicable only for AUTHTYPE(OCSP), when it is mandatory.

### ▶ z/OS QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	ALTER
<b>COPY</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.
<b>GROUP</b>	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to refresh local copies on page set zero:  DEFINE AUTHINFO(name) REPLACE QSGDISP(COPY)  The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
<b>PRIVATE</b>	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY). Any object residing in the shared repository is unaffected.
<b>QMGR</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

### SECCOMM

Whether connectivity to the LDAP server should be done securely using SSL/TLS

**YES** Connectivity to the LDAP server is made securely using SSL/TLS.

The certificate used is the default certificate for the queue manager, named in CERTLABL on the queue manager object, or if that is blank, the one described in Digital certificate labels, understanding the requirements.

The certificate is located in the key repository specified in SSLKEYR on the queue manager object. A cipherspec will be negotiated that is supported by both IBM MQ and the LDAP server.

If the queue manager is configured to use SSLFIPS(YES) or SUITEB cipher specs, then this is taken account of in the connection to the LDAP server as well.

**ANON**

Connectivity to the LDAP server is made securely using SSL/TLS just as for SECCOMM(YES) with one difference.

No certificate is sent to the LDAP server; the connection will be made anonymously. To use this setting, ensure that the key repository specified in SSLKEYR, on the queue manager object, does not contain a certificate marked as the default.

**NO** Connectivity to the LDAP server does not use SSL/TLS.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

**SHORTUSR( user name )**

A field in the user record to be used as a short user name in IBM MQ.

This field must contain values of 12 characters or less. This short user name is used for the following purposes:

- If LDAP authentication is enabled, but LDAP authorization is not enabled, this is used as an operating system user ID for authorization checks. In this case, the attribute must represent an operating system user ID.
- If LDAP authentication and authorization are both enabled, this is used as the user ID carried with the message in order for the LDAP user name to be rediscovered when the user ID inside the message needs to be used.

For example, on another queue manager, or when writing report messages. In this case, the attribute does not need to represent an operating system user ID, but must be a unique string. An employee serial number is an example of a good attribute for this purpose.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* and is mandatory.

**USRFIELD( user field )**

If the user ID provided by an application for authentication does not contain a qualifier for the field in the LDAP user record, that is, it does not contain an ' = ' sign, this attribute identifies the field in the LDAP user record that is used to interpret the provided user ID.

This field can be blank. If this is the case, any unqualified user IDs use the SHORTUSR parameter to interpret the provided user ID.

The contents of this field will be concatenated with an ' = ' sign, together with the value provided by the application, to form the full user ID to be located in an LDAP user record. For example, the application provides a user of fred and this field has the value cn, then the LDAP repository will be searched for cn=fred.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

## ALTER BUFFPOOL: z/OS

Use the MQSC command ALTER BUFFPOOL to dynamically change the settings of a predefined buffer pool.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

Parameters not specified in the ALTER BUFFPOOL command result in the existing values for those parameters being left unchanged.

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for ALTER BUFFPOOL”
- “Parameter descriptions for ALTER BUFFPOOL”

**Synonym:** ALT BP

### ALTER BUFFPOOL

### Usage notes for ALTER BUFFPOOL

1. Buffers are added or removed according to whether the value is more than or less than the current allocation (which can be shown by the DISPLAY USAGE command).
2. If there is insufficient storage, of the type specified by the PAGECLAS attribute to add the requested number, as many as possible are added.
3. The command is processed asynchronously. Message CSQP023I is sent to the console when the command is complete.
4. ALTER BUFFPOOL cannot be issued from CSQINPT.

### Parameter descriptions for ALTER BUFFPOOL

(*buf-pool-id*)

Buffer pool identifier.

This parameter is an integer in the range zero through 15. If OPMODE is set to OPMODE=(NEWFUNC, 800), this parameter is an integer in the range zero through 99.

**BUFFERS**( *integer* )

This parameter is optional and is the number of 4096 byte buffers to be used in this buffer pool.

If the value of the LOCATION parameter is BELOW, the minimum value of buffers is 100 and the maximum value is 500,000. If the value of the LOCATION parameter is ABOVE then valid values are in the range of 100 to 999999999 (nine nines). The storage used for buffers in a buffer pool with LOCATION ABOVE is obtained in multiples of 4MB. Therefore specifying a BUFFERS value which is a multiple of 1024 will make the most efficient use of storage.

See Buffers and buffer pools for guidance on the number of buffers you can define in each buffer pool.

When defining a buffer pool care should be taken to ensure that there is sufficient storage available for it either above or below the bar. For more information, see Address space storage.

**Note:** Creating a large buffer pool can take several minutes depending on size of the buffer pool and machine configuration. In some cases message CSQP061I might be output.

#### LOCATION(LOC)( *BELOW* or *ABOVE* )

The LOCATION or LOC parameter specifies where the memory used by the specified buffer pool is located.

LOCATION and LOC are synonyms and either, but not both, can be used.

This memory location can be either ABOVE (64 bit) or BELOW (31 bit) the bar. Valid values for this parameter are BELOW or ABOVE, with BELOW being the default.

ABOVE can only be specified if OPMODE(NEWFUNC, 800) is in effect. BELOW can be specified regardless of OPMODE(NEWFUNC, 800) being used and has the same effect as not specifying the LOCATION parameter.

When altering a buffer pool, you should take care to make sure that there is sufficient storage available if increasing the number of buffers, or changing the LOCATION value. Switching the location of the buffer pool can be a CPU and I/O intensive task. You should perform this task when the queue manager is not being heavily utilized.

For more information, see Address space storage.

#### PAGECLAS( *4KB* or *FIXED4KB* )

Optional parameter that describes the type of virtual storage pages used for backing the buffers in the buffer pool.

This attribute applies to all buffers in the buffer pool, including any that are added later as a result of using the ALTER BUFFPOOL command. The default value is 4KB, which means that pageable 4KB pages are used to back the buffers in the pool.

4KB is the only valid value if the buffer pool has its location attribute set to BELOW. If the buffer pool has its LOCATION attribute set to ABOVE, it is also possible to specify FIXED4KB. This means that fixed 4KB pages, which are permanently in real storage and will never be paged out to auxiliary storage, are used to back the buffers in the buffer pool.

FIXED4KB can only be specified if OPMODE(NEWFUNC, 800) is in effect whereas 4KB can be specified regardless of the setting of OPMODE(NEWFUNC, 800).

The PAGECLAS attribute of a buffer pool can be altered at any time. However, the alteration only takes place when the buffer pool switches location from above the bar, to below the bar, or the other way round. Otherwise, the value is stored in the log of the queue manager and is applied when the queue manager next restarts.

The current value of PAGECLAS can be checked by issuing the DISPLAY USAGE PSID(\*) command. Doing this also results in a CSQP062I message being output, if the current value of PAGECLAS is different from the value in the log of the queue manager.

For example:

- Buffer pool 7 currently has LOCATION(ABOVE) and PAGECLAS(4KB) specified. If ALTER BUFFPOOL(7) PAGECLAS(FIXED4KB) is specified, the buffer pool continues to be backed by pageable 4KB pages as the LOCATION has not been changed.

- Buffer pool 8 currently has LOCATION(BELOW) and PAGECLAS(4KB) specified. If ALTER BUFFPOOL(8) LOCATION(ABOVE) PAGECLAS(FIXED4KB) is specified, the buffer pool is moved above the bar and has its buffers backed by fixed 4KB pages, if any are available.

When you specify PAGECLAS(FIXED4KB) the whole buffer pool is backed by page-fixed 4KB pages, so ensure that there is sufficient real storage available on the LPAR. Otherwise, the queue manager might not start up, or other address spaces might be impacted; for more information, see Address space storage.

See IBM MQ Support Pac MP16: IBM MQ for z/OS - Capacity planning & tuning for advice on when to use the FIXED4KB value of the PAGECLAS attribute.

**Attention:** The queue manager records the current buffer pool settings in checkpoint log records. These buffer pool settings are automatically restored when a queue manager is later restarted. This restoration occurs after processing of the CSQINP1 data set. Therefore, if you have used ALTER BUFFPOOL since the buffer pool was last defined, any DEFINE BUFFPOOL command in CSQINP1 has been ignored at restart, unless the REPLACE attribute has been specified.

**ALTER CFSTRUCT:** z/OS

Use the MQSC command ALTER CFSTRUCT to alter the CF application structure backup and recovery parameters, and offload environment parameters for any specified application structure.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

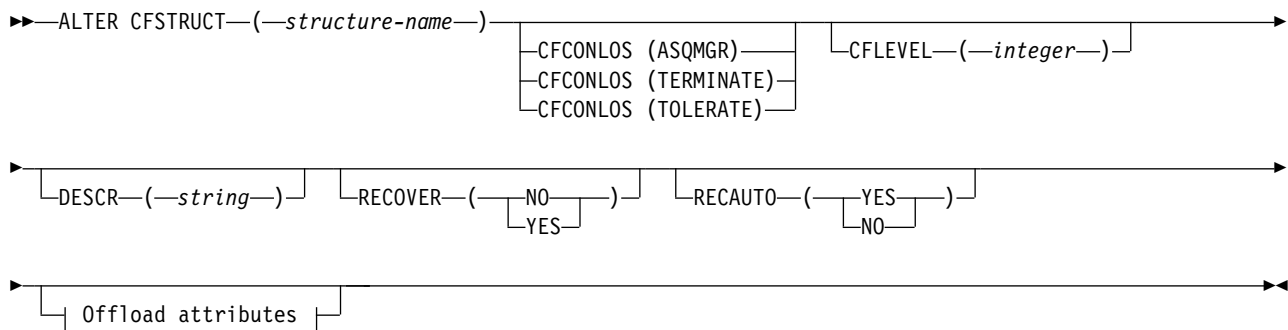

Parameters not specified in the ALTER CFSTRUCT command result in the existing values for those parameters being left unchanged.

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

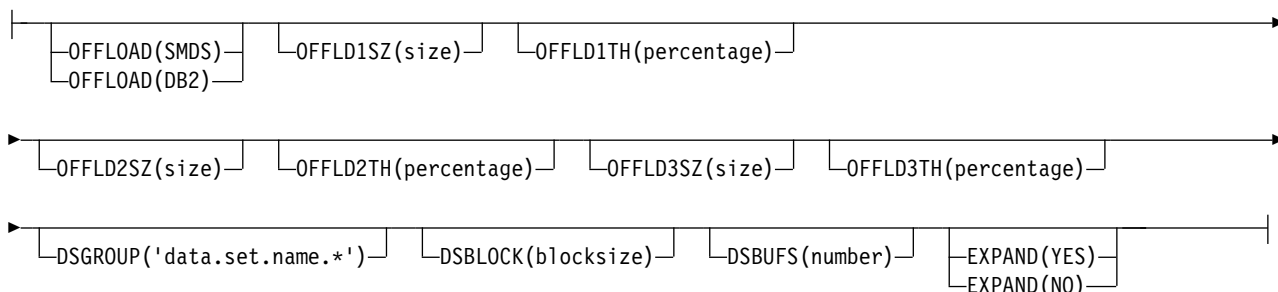

- Syntax diagram
- “Usage notes” on page 360
- “Parameter descriptions for ALTER CFSTRUCT” on page 360

**Synonym:** ALT CFSTRUCT

**ALTER CFSTRUCT**

## Offload attributes:

## Usage notes

- This command cannot specify the CF administration structure (CSQ\_ADMIN).
- This command is valid only when the queue manager is a member of a queue-sharing group.

## Parameter descriptions for ALTER CFSTRUCT

*(structure-name)*

Name of the coupling facility application structure with queue manager CF level capability and backup and recovery parameters you want to define. This parameter is required.

The name:

- Cannot have more than 12 characters.
- Must start with an uppercase letter (A through Z).
- Can include only the characters A through Z and 0 through 9.

The name of the queue-sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue-sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue-sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue-sharing group (in this case NY03CSQ\_ADMIN) cannot be used for storing messages.

## CFCONLOS

This parameter specifies the action to be taken when a queue manager loses connectivity to the CF structure. The value can be:

### ASQMGR

The action taken is based on the setting of the CFCONLOS queue manager attribute.

### TERMINATE

The queue manager terminates when connectivity to the structure is lost. This is the default value when CFLEVEL is increased to 5.

### TOLERATE

The queue manager tolerates loss of connectivity to the structure without terminating.

This parameter is only valid from CFLEVEL(5).

## CFLEVEL( *integer* )

Specifies the functional capability level for this CF application structure. Value can be one of the following:

- 1 A CF structure that can be "auto-created" by a queue manager at command level 520.

2 A CF structure at command level 520 that can only be created or deleted by a queue manager at command level 530 or greater.

3

A CF structure at command level 530. This CFLEVEL is required if you want to use persistent messages on shared queues (if RECOVER(YES) is set), or for message grouping (when a local queue is defined with INDXTYPE(GROUPID)), or both.

You can only increase the value of CFLEVEL to 3 if all the queue managers in the queue-sharing group are at command level 530 or greater - this is to ensure that there are no latent command level 520 connections to queues referencing the structure.

You can only decrease the value of CFLEVEL from 3 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

4

This CFLEVEL supports all the CFLEVEL(3) functions. CFLEVEL(4) allows queues defined with CF structures at this level to have messages with a length greater than 63 KB.

Only a queue manager with a command level of 600 or greater can connect to a CF structure at CFLEVEL(4).

You can only increase the value of CFLEVEL to 4 if all the queue managers in the queue-sharing group are at command level 600 or greater.

You can only decrease the value of CFLEVEL from 4 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

5

This CFLEVEL supports all functions for CFLEVEL(4). In addition, CFLEVEL(5) enables the following new functions. If altering an existing CFSTRUCT to CFLEVEL(5), you must review other attributes as indicated:

- queues defined with CF structures at this level can have message data offloaded to either shared message data sets (SMDS), or Db2, under control of the OFFLOAD attribute. The offload threshold and size parameters (such as OFFLD1TH, and OFFLD1SZ) determine whether any particular messages are offloaded given its size and current CF structure utilization. If using SMDS offload, the DSGROUP, DSBUFS, DSEXPAND and DSBLOCK attributes are respected.
- structures at CFLEVEL(5) allow the queue manager to tolerate a loss of connectivity to the CF structure. The CFCONLOS attribute determines queue manager behavior when a loss of connectivity is detected, and the RECAUTO attribute controls subsequent automatic structure recovery behavior.
- messages containing IBM MQ message properties are stored in a different format on shared queues in a CFLEVEL(5) structure. This format leads to internal processing optimizations. Additional application migration capabilities are also available and these are enabled via the queue PROPCTL attribute.

Only a queue manager with a command level of 710 or above can connect to a CF structure at CFLEVEL(5).

**Note:**

You can only increase the value of CFLEVEL to 5 if all the queue managers in the queue-sharing group are at command level 710 or greater and have IBM WebSphere MQ Version 7.1.0 new functions enabled with OPMODE.

You can decrease the value of CFLEVEL from 5 if all the queues that reference the CF structure are both empty, that is the queues, and CF structure have no messages or uncommitted activity, and are closed.

#### **DESCR( *string* )**

Plain-text comment that provides descriptive information about the object when an operator issues the DISPLAY CFSTRUCT command.

The string should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

#### **OFFLOAD**

Specify whether offloaded message data is to be stored in a group of shared message data sets or in Db2.

##### **SMDS**

Offload messages from coupling facility to shared message data set (SMDS).

**Db2** Offload messages from coupling facility to Db2. This value is the default assumption when CFLEVEL is increased to 5.

Offloading messages using Db2 has significant performance impact. If you want to use offload rules as a means of increasing capacity, the SMDS option should be specified.

This parameter is only valid from CFLEVEL(5). At CFLEVEL(4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

##### **Note:**

If you change the offload technique (from Db2 to SMDS or the other way) then all new messages will be written using the new method but any existing large messages stored using the previous technique can still be retrieved. The relevant Db2 message table or shared message data sets will continue to be used until the queue managers have detected that there are no further messages stored in the old format.

If SMDS is specified, then the DSGROUP parameter is also required. It can be specified either on the same command or on a previous DEFINE or ALTER command for the same structure.

#### **OFFLD1TH(percentage) OFFLD1SZ(size)**

#### **OFFLD2TH(percentage) OFFLD2SZ(size)**

#### **OFFLD3TH(percentage) OFFLD3SZ(size)**

Specify rules for when messages smaller than the maximum coupling facility entry size are to be offloaded to external storage (shared message data sets or Db2 tables) instead of being stored in the application structure. These rules can be used to increase the effective capacity of the structure. The offloaded message still requires an entry in the coupling facility containing message control information, and a descriptor referring to the offloaded message data, but the amount of structure space required is less than the amount that would be needed to store the whole message.

If the message data is very small (less than approximately 140 bytes) it may fit into the same coupling facility entry as the message control information, without needing additional data elements. In this case, no space can be saved, so any offload rules are ignored and the message data is not offloaded.

Messages exceeding the maximum coupling facility entry size (63.75 KB including control information) are always offloaded as they cannot be stored in a coupling facility entry. Messages

where the message body exceeds 63 KB are also offloaded to ensure that enough space is available for the control information. Additional rules to request offloading of smaller messages can be specified using these pairs of keywords. Each rule indicates that when the usage of the structure (in either elements or entries) exceeds the specified threshold percentage value, the message data will be offloaded if the total size of the coupling facility entry required to store the whole message (including message data, headers and descriptors) exceeds the specified size value. Headers and descriptors typically require approximately 400 bytes.

**percentage**

The usage threshold percentage value is an integer in the range 0 (meaning this rule always applies) to 100 (meaning this rule only applies when the structure is full).

**size**

The message size value should be specified as an integer followed by K, giving the number of kilobytes in the range **0K** to **64K**. As messages exceeding 63.75 KB are always offloaded, the value **64K** is allowed as a simple way to indicate that the rule is not being used.

In general, the smaller the numbers, the more messages are offloaded.

A message is offloaded if any offload rule matches. The normal convention is that a later rule would be for a higher usage level and a smaller message size than an earlier one, but no check is made for consistency or redundancy between the rules.

When structure ALTER processing is active, the number of used elements or entries can temporarily exceed the reported total number, giving a percentage exceeding 100, because the new elements or entries are made available during ALTER processing but the total is only updated when the ALTER completes. At such times, a rule specifying 100 for the threshold may temporarily take effect. If a rule is not intended to be used at all, it should specify 64K for the size.

The default values assumed for the offload rules when defining a new structure at CFLEVEL(5) or upgrading an existing structure to CFLEVEL(5) depend on the OFFLOAD method option. For OFFLOAD(SMDS), the default rules specify increasing amounts of offloading as the structure becomes full. This increases the effective structure capacity with minimal performance impact. For OFFLOAD( Db2 ), the default rules have the same threshold values as for SMDS but the size values are set to 64K so that the rules never apply and messages are offloaded only if they are too large to be stored in the structure, as for CFLEVEL(4).

For OFFLOAD(SMDS) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(32K)
- OFFLD2TH(80) OFFLD2SZ(4K)
- OFFLD3TH(90) OFFLD3SZ(0K)

For OFFLOAD( Db2 ) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(64K)
- OFFLD2TH(80) OFFLD2SZ(64K)
- OFFLD3TH(90) OFFLD3SZ(64K)

If the OFFLOAD method option is changed from Db2 to SMDS or back when the current offload rules all match the default values for the old method, the offload rules are switched to the default values for the new method. However, if any of the rules have been changed, the current values are kept when switching method.

These parameters are only valid from CFLEVEL(5). At CFLEVEL(4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

## DSGROUP

For OFFLOAD(SMDS), specify the generic data set name to be used for the group of shared message data sets associated with this structure (one for each queue manager), with exactly one asterisk indicating where the queue manager name should be inserted to form the specific data set name.

**'data.set.name.\*'**

The value must be a valid data set name when the asterisk is replaced by a queue manager name of up to four characters. The queue manager name can form all or part of any qualifier in the data set name.

The entire parameter value must be enclosed in quotation marks.

This parameter cannot be changed after any data sets have been activated for the structure.

If SMDS is specified, then the DSGROUP parameter must also be specified.

This parameter is only valid from CFLEVEL(5).

## DSBLOCK

For OFFLOAD(SMDS), specify the logical block size, which is the unit in which shared message data set space is allocated to individual queues.

**8K**

**16K**

**32K**

**64K**

**128K**

**256K**

**512K**

**1M** Each message is written starting at the next page within the current block and is allocated further blocks as needed. A larger size decreases space management requirements and reduces I/O for large messages, but increases buffer space requirements and disk space requirements for small queues.

This parameter cannot be changed after any data sets have been activated for the structure.

This parameter is only valid from CFLEVEL(5).

## DSBUFS

For OFFLOAD(SMDS), specify the number of buffers to be allocated in each queue manager for accessing shared message data sets, as a number in the range 1 - 9999. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

**number**

This parameter can be overridden for individual queue managers using the DSBUFS parameter on ALTER SMDS.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSBUFS override value) dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager adjusts the DSBUFS parameter associated with its own individual SMDS definition (as for the ALTER SMDS command) to match the actual new number of buffers.

This parameter is only valid from CFLEVEL(5).

These buffers use virtual storage. You should work with the z/OS systems programmer to ensure there is sufficient auxiliary storage available before increasing the number of buffers.

## DSEXPAND

For OFFLOAD(SMDS), this parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

**YES** Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used

**NO** No automatic data set expansion is to take place.

This parameter can be overridden for individual queue managers using the DSEXPAND parameter on ALTER SMDS.

If an expansion attempt fails, the DSEXPAND override for the affected queue manager is automatically changed to NO to prevent further expansion attempts, but it can be changed back to YES using the ALTER SMDS command to enable further expansion attempts.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSEXPAND override value) immediately start using the new parameter value.

This parameter is only valid from CFLEVEL(5).

## RECOVER

Specifies whether CF recovery is supported for the application structure. Values are:

**NO** CF application structure recovery is not supported. (The synonym is N.)

**YES** CF application structure recovery is supported. (The synonym is Y.)

You can only set RECOVER(YES) if the structure has a CFLEVEL of 3 or higher. Set RECOVER(YES) if you intend to use persistent messages.

You can only change RECOVER(NO) to RECOVER(YES) if all the queue managers in the queue-sharing group are at command level 530 or greater ; this is to ensure that there are no latent command level 520 connections to queues referencing the CFSTRUCT.

You can only change RECOVER(YES) to RECOVER(NO) if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

## RECAUTO

Specifies the automatic recovery action to be taken when a queue manager detects that the structure is failed or when a queue manager loses connectivity to the structure and no systems in the SysPlex have connectivity to the Coupling Facility that the structure is allocated in. Values can be:

**YES** The structure and associated shared message data sets which also need recovery are automatically recovered. (The synonym is Y ).

**NO** The structure is not automatically recovered. (The synonym is N ). This is the default value when CFLEVEL is increased to 5.

This parameter has no effect for structures defined with RECOVER(NO).

This parameter is only valid from CFLEVEL(5)

## ALTER CHANNEL:

Use the MQSC command ALTER CHANNEL to alter the parameters of a channel.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

Parameters not specified in the ALTER CHANNEL command result in the existing values for those parameters being left unchanged.

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

### Synonym: ALT CHL

- “Usage notes”
- “Parameter descriptions for ALTER CHANNEL”

### Usage notes

- Changes take effect after the channel is next started.
- For cluster channels (the CLUSSDR and CLUSRCVR columns in the table), if an attribute can be set on both channels, set it on both and ensure that the settings are identical. If there is any discrepancy between the settings, those that you specify on the CLUSRCVR channel are likely to be used. This is explained in Cluster channels.
- If you change the XMITQ name or the CONNAME, you must reset the sequence number at both ends of the channel. (See “RESET CHANNEL” on page 961 for information about the SEQNUM parameter.)
- Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER CHANNEL step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for ALTER CHANNEL

The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

## AFFINITY

The channel affinity attribute is used so client applications that connect multiple times using the same queue manager name can choose whether to use the same client channel definition for each connection. This attribute is intended to be used when multiple applicable channel definitions are available.

## PREFERRED

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions based on the weighting with any applicable CLNTWGHT(0) definitions first and in alphabetical order. Each connection in the process attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful non-CLNTWGHT(0) definitions are moved to the end of the list. CLNTWGHT(0) definitions remain at the start of the list and are selected first for each connection. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT has been modified since the list was created. Each client process with the same host name creates the same list.

## NONE

The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any applicable CLNTWGHT(0) definitions selected first in alphabetical order. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT has been modified since the list was created.

For example, suppose we had the following definitions in the CCDT:

```
CHLNAME(A) QMNAME(QM1) CLNTWGHT(3)
CHLNAME(B) QMNAME(QM1) CLNTWGHT(4)
CHLNAME(C) QMNAME(QM1) CLNTWGHT(4)
```

The first connection in a process creates its own ordered list based on the weightings. So it might, for example, create the ordered list CHLNAME(B), CHLNAME(A), CHLNAME(C).

For AFFINITY(PREFERRED), each connection in the process attempts to connect using CHLNAME(B). If a connection is unsuccessful the definition is moved to the end of the list which now becomes CHLNAME(A), CHLNAME(C), CHLNAME(B). Each connection in the process then attempts to connect using CHLNAME(A).

For AFFINITY(NONE), each connection in the process attempts to connect using one of the three definitions selected at random based on the weightings.

When sharing conversations is enabled with a non-zero channel weighting and AFFINITY(NONE), multiple connections in a process using the same queue manager name can connect using different applicable definitions rather than sharing an existing channel instance.

### **distributed** V 8.0.0.4 **AMQPKA( integer )**

The keep alive time for an AMQP channel in seconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a `amqp:resource-limit-exceeded` AMQP error condition.

This parameter is valid only for channels with a channel type ( `CHLTYPE` ) of AMQP

### **BATCHHB( integer )**

Specifies whether batch heartbeats are to be used. The value is the length of the heartbeat in milliseconds.

Batch heartbeats allow a sending channel to verify that the receiving channel is still active just before committing a batch of messages, so that if the receiving channel is not active, the batch can be backed out rather than becoming in-doubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they could, for example, be redirected to another channel.

If the sending channel has had a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active. If not, a 'heartbeat' is sent to the receiving channel to check.

The value must be in the range zero through 999999. A value of zero indicates that batch heartbeating is not used.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, CLUSSDR, and CLUSRCVR.

#### **BATCHINT( *integer* )**

The minimum amount of time, in milliseconds, that a channel keeps a batch open.

The batch is terminated when one of the following conditions is met:

- BATCHSZ messages have been sent.
- BATCHLIM bytes have been sent.
- The transmission queue is empty and BATCHINT is exceeded.

The value must be in the range 0 - 999999999. Zero means that the batch is terminated as soon as the transmission queue becomes empty (or the BATCHSZ limit is reached).

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, CLUSSDR, or CLUSRCVR.

#### **BATCHLIM( *integer* )**

The limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point. A sync point is taken after the message that caused the limit to be reached has flowed across the channel. A value of zero in this attribute means that no data limit is applied to batches over this channel.

The batch is terminated when one of the following conditions is met:

- BATCHSZ messages have been sent.
- BATCHLIM bytes have been sent.
- The transmission queue is empty and BATCHINT is exceeded.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, CLUSSDR, or CLUSRCVR.

The value must be in the range 0 - 999999. The default value is 5000.

This parameter is supported on all platforms.

#### **BATCHSZ( *integer* )**

The maximum number of messages that can be sent through a channel before taking a sync point.

The maximum batch size used is the lowest of the following values:

- The BATCHSZ of the sending channel.
- The BATCHSZ of the receiving channel.
-  On z/OS, three less than the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
- On distributed platforms, the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
-  On z/OS, three less than the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).
- On distributed platforms, the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).

The maximum number of uncommitted messages is specified by the MAXUMSGS parameter of the ALTER QMGR command.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

The value must be in the range 1 through 9999.

## CERTLABL

Certificate label for this channel to use.

The label identifies which personal certificate in the key repository is sent to the remote peer. If this attribute is blank, the certificate is determined by the queue manager **CERTLABL** parameter.

Note that inbound channels (including receiver, cluster-receiver, unqualified server, and server-connection channels) only send the configured certificate if the IBM MQ version of the remote peer fully supports certificate label configuration, and the channel is using a TLS CipherSpec.

See Interoperability of Elliptic Curve and RSA CipherSpecs for further information.

In all other cases, the queue manager **CERTLABL** parameter determines the certificate sent. In particular, the following only ever receive the certificate configured by the **CERTLABL** parameter of the queue manager, regardless of the channel-specific label setting:

- All current Java and JMS clients.
- Versions of IBM MQ prior to Version 8.0.

You do not need to run the REFRESH SECURITY TYPE(SSL) command if you make any changes to CERTLABL on a channel. However, you must run a REFRESH SECURITY TYPE(SSL) command if you make any changes to CERTLABL on the queue manager.

**Note:** It is an error to inquire, or set, this attribute for cluster-sender channels. If you attempt to do so, you receive the error MQRCCF\_WRONG\_CHANNEL\_TYPE. However, the attribute is present in cluster-sender channel objects (including MQCD structures) and a channel auto-definition (CHAD) exit might set it programmatically if required.

*(channel-name)*

The name of the new channel definition.

This parameter is required on all types of channel. On CLUSSDR channels, it can take a different form from the other channel types. If your convention for naming cluster-sender channels includes the name of the queue manager, you can define a cluster-sender channel using the +QMNAME+ construction. After connection to the matching cluster-receiver channel, IBM MQ substitutes the correct repository queue manager name in place of +QMNAME+ in the cluster-sender channel definition. This facility applies to AIX, HP-UX, Linux, IBM i, Solaris, and Windows only; for further information see Components of a cluster.

The name must not be the same as any existing channel defined on this queue manager (unless REPLACE or ALTER is specified).

▶ **z/OS** On z/OS, client-connection channel names can duplicate others.

The maximum length of the string is 20 characters, and the string must contain only valid characters; see Rules for naming IBM MQ objects.

## CHLTYPE

Channel type. This parameter is required. It must follow immediately after the *(channel-name)* parameter ▶ **z/OS** on all platforms except z/OS.

**SDR** Sender channel

**SVR** Server channel

**RCVR** Receiver channel

**RQSTR** Requester channel

**CLNTCONN**

Client-connection channel

**SVRCONN**

Server-connection channel

**CLUSSDR**

Cluster-sender channel

**CLUSRCVR**

Cluster-receiver channel

**Note:** If you are using the REPLACE option, you cannot change the channel type.

**CLNTWGHT**

The client channel weighting attribute is used so client channel definitions can be selected at random based on their weighting when more than one suitable definition is available. Specify a value in the range 0 - 99.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetical order. To enable random load balancing the value can be in the range 1 through 99 where 1 is the lowest weighting and 99 is the highest.

When a client issues an MQCONN with queue manager name "*\*<name>*" and more than one suitable definition is available in the CCDT the choice of definition to use is randomly selected based on the weighting with any applicable CLNTWGHT(0) definitions selected first in alphabetical order. The distribution is not guaranteed.

For example, suppose we had the following two definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(2)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(4)
```

A client MQCONN with queue manager name "*\*GRP1*" would choose one of the two definitions based on the weighting of the channel definition. (A random integer 1 - 6 would be generated. If the integer was in the range 1 through 2 address1 would be used otherwise address2 would be used). If this connection was unsuccessful the client would then use the other definition.

The CCDT might contain applicable definitions with both zero and non-zero weighting. In this situation, the definitions with zero weightings are chosen first and in alphabetical order. If these connections are unsuccessful the definitions with non-zero weighting are chosen based on their weighting.

For example, suppose we had the following four definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(1)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(2)
CHLNAME(TO.QM3) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address3) CLNTWGHT(0)
CHLNAME(TO.QM4) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address4) CLNTWGHT(0)
```

A client MQCONN with queue manager name "*\*GRP1*" would first choose definition "TO.QM3". If this connection was unsuccessful the client would then choose definition "TO.QM4". If this connection was also unsuccessful the client would then randomly choose one of the remaining two definitions based on their weighting.

CLNTWGHT support is added for all supported transport protocols.

**CLUSNL( *nlname* )**

The name of the namelist that specifies a list of clusters to which the channel belongs.

This parameter is valid only for channels with a channel type (CHLTYPE) of CLUSSDR and CLUSRCVR channels. Only one of the resultant values of CLUSTER or CLUSNL can be nonblank, the other must be blank.

**CLUSTER( *clustname* )**

The name of the cluster to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type (CHLTYPE) of CLUSSDR or CLUSRCVR. Only one of the resultant values of CLUSTER or CLUSNL can be nonblank, the other must be blank.

#### **CLWLPRTY( *integer* )**

Specifies the priority of the channel for the purposes of cluster workload distribution. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest.

This parameter is valid only for channels with a channel type (CHLTYPE) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see CLWLPRTY queue attribute.

#### **CLWLRANK( *integer* )**

Specifies the rank of the channel for the purposes of cluster workload distribution. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest.

This parameter is valid only for channels with a channel type (CHLTYPE) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see CLWLRANK channel attribute.

#### **CLWLWGHT( *integer* )**

Specifies the weighting to be applied to the channel for the purposes of cluster workload distribution so that the proportion of messages sent down the channel can be controlled. The value must be in the range 1 through 99 where 1 is the lowest rank and 99 is the highest.

This parameter is valid only for channels with a channel type (CHLTYPE) of CLUSSDR or CLUSRCVR.

For more information about this attribute, see CLWLWGHT channel attribute.

z/OS

#### **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

#### ***qmgr-name***

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

#### **COMPHDR**

The list of header data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference with the first compression technique supported by the remote end of the channel being used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits.

**NONE** No header data compression is performed.

**SYSTEM** Header data compression is performed.

## COMPMSG

The list of message data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference with the first compression technique supported by the remote end of the channel being used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel where the compression technique used can be altered on a per message basis. Compression alters the data passed to send and receive exits.

**NONE** No message data compression is performed.

**RLE** Message data compression is performed using run-length encoding.

### ZLIBFAST

Message data compression is performed using ZLIB encoding with speed prioritized.

### ZLIBHIGH

Message data compression is performed using ZLIB encoding with compression prioritized.

**ANY** Any compression technique supported by the queue manager can be used. This value is only valid for receiver, requester, and server-connection channels.

## CONNNAME( *string* )

Connection name.

For cluster-receiver channels (when specified) CONNNAME relates to the local queue manager, and for other channels it relates to the target queue manager.

 On z/OS, the maximum length of the string is 48 characters.

On distributed platforms, the maximum length of the string is 264 characters

A workaround to the 48 character limit might be one of the following suggestions:

- Set up your DNS servers so that you use, for example, host name of "myserver" instead of "myserver.location.company.com", ensuring you can use the short host name.
- Use IP addresses.

Specify CONNNAME as a comma-separated list of names of machines for the stated TRPTYPE. Typically only one machine name is required. You can provide multiple machine names to configure multiple connections with the same properties. The connections are usually tried in the order they are specified in the connection list until a connection is successfully established. The order is modified for clients if the CLNTWGHT attribute is provided. If no connection is successful, the channel attempts the connection again, as determined by the attributes of the channel. With client channels, a connection-list provides an alternative to using queue manager groups to configure multiple connections. With message channels, a connection list is used to configure connections to the alternative addresses of a multi-instance queue manager.

This parameter is required for channels with a channel type (CHLTYPE) of SDR, RQSTR, CLNTCONN, and CLUSSDR. It is optional for SVR channels, and for CLUSRCVR channels of TRPTYPE(TCP), and is not valid for RCVR or SVRCONN channels.

Providing multiple connection names in a list was first supported in IBM WebSphere MQ Version 7.0.1. It changes the syntax of the CONNNAME parameter. Earlier clients and queue managers connect using the first connection name in the list, and do not read the rest of the connection names in the list. In order for the earlier clients and queue managers to parse the new syntax, you must specify a port number on the first connection name in the list. Specifying a port number avoids problems when connecting to the channel from a client or queue manager that is running at a level earlier than IBM WebSphere MQ Version 7.0.1.

On AIX, HP-UX, IBM i, Linux, Solaris, and Windows platforms, the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM

MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example:

(1415)

The generated CONNAME is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

**Note:** If you are using any of the special characters in your connection name (for example, parentheses) you must enclose the string in single quotation marks.

The value you specify depends on the transport type (TRPTYPE) to be used:

## LU 6.2

- ▶ **z/OS** On z/OS, there are two forms in which to specify the value:

### Logical unit name

The logical unit information for the queue manager, comprising the logical unit name, TP name, and optional mode name. Logical unit name can be specified in one of three forms:

Form	Example
luname	IGY12355
luname/TPname	IGY12345/APING
luname/TPname/modename	IGY12345/APINGD/#INTER

For the first form, the TP name and mode name must be specified for the TPNAME and MODENAME parameters; otherwise these parameters must be blank.

**Note:** For client-connection channels, only the first form is allowed.

### Symbolic name

The symbolic destination name for the logical unit information for the queue manager, as defined in the side information data set. The TPNAME and MODENAME parameters must be blank.

**Note:** For cluster-receiver channels, the side information is on the other queue managers in the cluster. Alternatively, in this case it can be a name that a channel auto-definition exit can resolve into the appropriate logical unit information for the local queue manager.

The specified or implied LU name can be that of a VTAM generic resources group.

- On IBM i, Windows, UNIX and Linux systems, CONNAME is the name of the CPI-C communications side object or, if the TPNAME is not blank, CONNAME is the fully qualified name of the partner logical unit.

▶ **z/OS** See Configuration parameters for an LU 6.2 connection for more information about configuration parameters for an LU 6.2 connection for your platform.

## NetBIOS

A unique NetBIOS name (limited to 16 characters).

**SPX** The 4 byte network address, the 6 byte node address, and the 2 byte socket number. These values must be entered in hexadecimal, with a period separating the network and node addresses. The socket number must be enclosed in brackets, for example:

CONNNAME('0a0b0c0d.804abcde23a1(5e86)')

**TCP** Either the host name, or the network address of the remote machine (or the local machine for cluster-receiver channels). This address can be followed by an optional port number, enclosed in parentheses.

If the CONNNAME is a host name, the host name is resolved to an IP address.

The IP stack used for communication depends on the value specified for CONNNAME **and** the value specified for LOCLADDR. See LOCLADDR for information about how this value is resolved.

**z/OS** On z/OS, the connection name can include the IP\_name of an z/OS dynamic DNS group or a Network Dispatcher input port. Do **not** include the IP\_name or input port for channels with a channel type (CHLTYPE) of CLUSSDR.

On all platforms, when you define a channel with a channel type (CHLTYPE) of CLUSRCVR that is using TCP/IP, you do not need to specify the network address of your queue manager. IBM MQ generates a CONNNAME for you, assuming the default port and using the current IPv4 address of the system. If the system does not have an IPv4 address, the current IPv6 address of the system is used.

**Note:** If you are using clustering between IPv6-only and IPv4-only queue managers, do not specify an IPv6 network address as the CONNNAME for CLUSRCVR channels. A queue manager that is capable only of IPv4 communication is unable to start a cluster sender channel definition that specifies the CONNNAME in IPv6 hexadecimal form. Consider, instead, using host names in a heterogeneous IP environment.

## CONVERT

Specifies whether the sending message channel agent attempts conversion of the application message data, if the receiving message channel agent cannot perform this conversion.

**NO** No conversion by sender

**YES** Conversion by sender

**z/OS** On z/OS, N and Y are accepted as synonyms of NO and YES.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, CLUSSDR, or CLUSRCVR.

## DEFCDISP

Specifies the default channel disposition of the channel.

### PRIVATE

The intended disposition of the channel is as a PRIVATE channel.

### FIXSHARED

The intended disposition of the channel is as a FIXSHARED channel.

### SHARED

The intended disposition of the channel is as a SHARED channel.

This parameter does not apply to channels with a channel type (CHLTYPE) of CLNTCONN, CLUSSDR, or CLUSRCVR.

## DEFRECON

Specifies whether a client connection automatically reconnects a client application if its connection breaks.

**NO** Unless overridden by MQCONNX, the client is not reconnected automatically.

**YES** Unless overridden by MQCONNX, the client reconnects automatically.

**QMGR** Unless overridden by MQCONNX, the client reconnects automatically, but only to the same queue manager. The QMGR option has the same effect as MQCNO\_RECONNECT\_Q\_MGR.

**DISABLED**

Reconnection is disabled, even if requested by the client program using the MQCONNX MQI call.

Table 88. Automatic reconnection depends on the values set in the application and in the channel definition

DEFRECON	Reconnection options set in the application			
	MQCNO_RECONNECT	MQCNO_RECONNECT_Q_MGR	MQCNO_RECONNECT_AS_DEF	MQCNO_RECONNECT_DISABLED
NO	YES	QMGR	NO	NO
YES	YES	QMGR	YES	NO
QMGR	YES	QMGR	QMGR	NO
DISABLED	NO	NO	NO	NO

**DESCR( string )**

Plain-text comment. It provides descriptive information about the channel when an operator issues the DISPLAY CHANNEL command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**DISCINT( integer )**

The minimum time in seconds for which the channel waits for a message to arrive on the transmission queue, after a batch ends, before terminating the channel. A value of zero causes the message channel agent to wait indefinitely.

The value must be in the range zero through 999 999.

This parameter is valid only for channels with a channel type (CHLTYPE) of SVRCONN , SDR, SVR, CLUSSDR, CLUSRCVR.

For SVRCONN channels using the TCP protocol, this parameter is the minimum time in seconds for which the SVRCONN instance remains active without any communication from its partner client. A value of zero disables this disconnect processing. The SVRCONN inactivity interval only applies between IBM MQ API calls from a client, so no client is disconnected during an extended MQGET with wait call. This attribute is ignored for SVRCONN channels using protocols other than TCP.

**HBINT( integer )**

This attribute specifies the approximate time between heartbeat flows that are to be passed from a sending MCA when there are no messages on the transmission queue.

Heartbeat flows unblock the receiving MCA, which is waiting for messages to arrive or for the disconnect interval to expire. When the receiving MCA is unblocked it can disconnect the channel without waiting for the disconnect interval to expire. Heartbeat flows also free any storage buffers that have been allocated for large messages and close any queues that have been left open at the receiving end of the channel.

The value is in seconds and must be in the range 0 through 999999. A value of zero means that no heartbeat flows are to be sent. The default value is 300. To be most useful, the value needs to be less than the disconnect interval value.

For server-connection and client-connection channels, heartbeats can flow from both the server side as well as the client side independently. If no data has been transferred across the channel for the heartbeat interval, the client-connection MQI agent sends a heartbeat flow and the server-connection MQI agent responds to it with another heartbeat flow. This happens irrespective of the state of the channel, for example, irrespective of whether it is inactive while making an API call, or is inactive waiting for client user input. The server-connection MQI agent is also capable of initiating a heartbeat to the client, again irrespective of the state of the channel. To prevent both server-connection and client-connection MQI agents heart beating to each other at the same time, the server heartbeat is flowed after no data has been transferred across the channel for the heartbeat interval plus 5 seconds.

For server-connection and client-connection channels working in the channel mode before IBM WebSphere MQ Version 7.0, heartbeats flow only when a server MCA is waiting for an MQGET command with the WAIT option specified, which it has issued on behalf of a client application.

For more information, see Heartbeat interval (HBINT).

### **KAIN**( *integer* )

The value passed to the communications stack for KeepAlive timing for this channel.

For this attribute to be effective, TCP/IP keepalive must be enabled both in the queue manager and in TCP/IP.

▶ **z/OS** On z/OS, you enable TCP/IP keepalive in the queue manager by issuing the ALTER QMGR TCPKEEP(YES) command; if the TCPKEEP queue manager parameter is NO, the value is ignored, and the KeepAlive facility is not used.

On distributed platforms, TCP/IP keepalive is enabled when the KEEPALIVE=YES parameter is specified in the TCP stanza in the distributed queuing configuration file, `qm.ini`, or through the MQ Explorer.

Keepalive must also be switched on within TCP/IP itself. Refer to your TCP/IP documentation for information about configuring keepalive. On AIX, use the **no** command. On HP-UX, use the **ndd** command. On Windows, edit the registry.

▶ **z/OS** On z/OS, update your TCP/IP PROFILE data set and add or change the INTERVAL parameter in the TCPCONFIG section.

▶ **z/OS** Although this parameter is available on all platforms, its setting is implemented only on z/OS.

On distributed platforms, you can access and modify the parameter, but it is only stored and forwarded; there is no functional implementation of the parameter. This functionality is useful in a clustered environment where a value set in a cluster-receiver channel definition on Solaris, for example, flows to (and is implemented by) z/OS queue managers that are in, or join, the cluster.

On distributed platforms, if you need the functionality provided by the KAIN parameter, use the Heartbeat Interval (HBINT) parameter, as described in HBINT.

( *integer* )

The KeepAlive interval to be used, in seconds, in the range 1 through 99 999.

**0** The value used is that specified by the INTERVAL statement in the TCP profile configuration data set.

### **AUTO**

The KeepAlive interval is calculated based upon the negotiated heartbeat value as follows:

- If the negotiated HBINT is greater than zero, KeepAlive interval is set to that value plus 60 seconds.
- If the negotiated HBINT is zero, the value used is that specified by the INTERVAL statement in the TCP profile configuration data set.

This parameter is valid for all channel types. It is ignored for channels with a TRPTYPE other than TCP or SPX.

**LIKE( *channel-name* )**

The name of a channel. The parameters of this channel are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from one of the following default channels, depending upon the channel type:

**SYSTEM.DEF.SENDER**

Sender channel

**SYSTEM.DEF.SERVER**

Server channel

**SYSTEM.DEF.RECEIVER**

Receiver channel

**SYSTEM.DEF.REQUESTER**

Requester channel

**SYSTEM.DEF.SVRCONN**

Server-connection channel

**SYSTEM.DEF.CLNTCONN**

Client-connection channel

**SYSTEM.DEF.CLUSSDR**

Cluster-sender channel

**SYSTEM.DEF.CLUSRCVR**

Cluster-receiver channel

This parameter is equivalent to defining the following object for a sender channel, and similarly for other channel types:

LIKE(SYSTEM.DEF.SENDER)

These default channel definitions can be altered by the installation to the default values required.

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object and channel type you are defining.

**Note:**

1. QSGDISP (GROUP) objects are not searched.
2. # LIKE is ignored if QSGDISP(COPY) is specified. However, the group object defined is used as a LIKE object.

**LOCLADDR ( *string* )**

LOCLADDR is the local communications address for the channel. For channels other than AMQP channels, use this parameter if you want a channel to use a particular IP address, port, or port range for outbound communications. LOCLADDR might be useful in recovery scenarios where a channel is restarted on a different TCP/IP stack. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 stack on a dual-stack system. You can also use LOCLADDR to force a channel to use a dual-mode stack on a single-stack system.

**Note:** AMQP channels do not support the same format of LOCLADDR as other IBM MQ channels. For the format supported by AMQ, see the next parameter AMQP: LOCLADDR.

For channels other than AMQP channels, the LOCLADDR parameter is valid only for channels with a transport type ( TRPTYPE ) of TCP. If TRPTYPE is not TCP, the data is ignored and no error message is issued.

The value is the optional IP address, and optional port or port range used for outbound TCP/IP communications. The format for this information is as follows:

```
LOCLADDR([ip-addr][(low-port[,high-port])][, [ip-addr][(low-port[,high-port])]])
```

The maximum length of LOCLADDR, including multiple addresses, is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

Note, that you can set LOCLADDR for a C client using the Client Channel Definition Table (CCDT).

All the parameters are optional. Omitting the ip-addr part of the address is useful to enable the configuration of a fixed port number for an IP firewall. Omitting the port number is useful to select a particular network adapter without having to identify a unique local port number. The TCP/IP stack generates a unique port number.

Specify [, [ip-addr][(low-port[,high-port])]] multiple times for each additional local address. Use multiple local addresses if you want to specify a specific subset of local network adapters. You can also use [, [ip-addr][(low-port[,high-port])]] to represent a particular local network address on different servers that are part of a multi-instance queue manager configuration.

**ip-addr**

ip-addr is specified in one of three forms:

**IPv4 dotted decimal**

For example 192.0.2.1

**IPv6 hexadecimal notation**

For example 2001:DB8:0:0:0:0:0:0

**Alphanumeric host name form**

For example WWW.EXAMPLE.COM

**low-port and high-port**

low-port and high-port are port numbers enclosed in parentheses.

The following table shows how the LOCLADDR parameter can be used:

*Table 89. Examples of how the LOCLADDR parameter can be used*

LOCLADDR	Meaning
9.20.4.98	Channel binds to this address locally
9.20.4.98, 9.20.4.99	Channel binds to either IP address. The address might be two network adapters on one server, or a different network adapter on two different servers in a multi-instance configuration.
9.20.4.98(1000)	Channel binds to this address and port 1000 locally
9.20.4.98(1000,2000)	Channel binds to this address and uses a port in the range 1000 - 2000 locally
(1000)	Channel binds to port 1000 locally
(1000,2000)	Channel binds to port in range 1000 - 2000 locally

This parameter is valid only for channels with a channel type ( CHLTYPE ) of SDR, SVR, RQSTR, CLNTCONN, CLUSSDR, OR CLUSRCVR.

On CLUSSDR channels, the IP address and port to which the outbound channel binds, is a combination of fields. It is a concatenation of the IP address, as defined in the LOCLADDR parameter, and the port range from the cluster cache. If there is no port range in the cache, the port range defined in the LOCLADDR parameter is used.

► **z/OS** This port range does not apply to z/OS systems.

Even though this parameter is similar in form to CONNAME, it must not be confused with it. The LOCLADDR parameter specifies the characteristics of the local communications, whereas the CONNAME parameter specifies how to reach a remote queue manager.

When a channel is started, the values specified for CONNAME and LOCLADDR determine the IP stack to be used for communication; see Table 3 and Local Address ( LOCLADDR ).

If the TCP/IP stack for the local address is not installed or configured, the channel does not start and an exception message is generated.

► **z/OS** For example, on z/OS systems, the message is "CSQO015E: Command issued but no reply received." The message indicates that the connect() request specifies an interface address that is not known on the default IP stack. To direct the connect() request to the alternative stack, specify the **LOCLADDR** parameter in the channel definition as either an interface on the alternative stack, or a DNS host name. The same specification also works for listeners that might not use the default stack. To find the value to code for **LOCLADDR**, run the **NETSTAT HOME** command on the IP stacks that you want to use as alternatives.

Table 90. How the IP stack to be used for communication is determined

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 only	IPv4 address <sup>1</sup>		Channel binds to IPv4 stack
	IPv6 address <sup>2</sup>		Channel fails to resolve CONNAME
	IPv4 and 6 host name <sup>3</sup>		Channel binds to IPv4 stack
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	Any address <sup>4</sup>	IPv6 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv4 stack
IPv4 and IPv6	IPv4 address		Channel binds to IPv4 stack
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to stack determined by IPADDRV
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	IPv4 address	IPv6 address	Channel maps CONNAME to IPv6 <sup>5</sup>
	IPv6 address	IPv6 address	Channel binds IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to stack determined by IPADDRV

Table 90. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv6 only	IPv4 address		Channel maps CONNAME to IPv6 <sup>5</sup>
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to IPv6 stack
	Any address	IPv4 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv6 address	Channel maps CONNAME to IPv6 <sup>5</sup>
	IPv6 address	IPv6 address	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds to IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel maps CONNAME to IPv6 <sup>5</sup>
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv6 stack

**Notes:**

1. IPv4 address. An IPv4 host name that resolves only to an IPv4 network address or a specific dotted notation IPv4 address, for example 1.2.3.4. This note applies to all occurrences of 'IPv4 address' in this table.
2. IPv6 address. An IPv6 host name that resolves only to an IPv6 network address or a specific hexadecimal notation IPv6 address, for example 4321:54bc. This note applies to all occurrences of 'IPv6 address' in this table.
3. IPv4 and 6 host name. A host name that resolves to both IPv4 and IPv6 network addresses. This note applies to all occurrences of 'IPv4 and 6 host name' in this table.
4. Any address. IPv4 address, IPv6 address, or IPv4 and 6 host name. This note applies to all occurrences of 'Any address' in this table.
5. Maps IPv4 CONNAME to IPv4 mapped IPv6 address. IPv6 stack implementations that do not support IPv4 mapped IPv6 addressing fail to resolve the CONNAME. Mapped addresses might require protocol translators in order to be used. The use of mapped addresses is not recommended.

### AMQP: LOCLADDR ( *ip-addr* )

**Note:** For the format of LOCLADDR that other IBM MQ channels use, see the previous parameter LOCLADDR.

For AMQP channels, LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of LOCLADDR is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

#### **ip-addr**

ip-addr is a single network address, specified in one of three forms:

##### **IPv4 dotted decimal**

For example 192.0.2.1

##### **IPv6 hexadecimal notation**

For example 2001:DB8:0:0:0:0:0

##### **Alphanumeric host name form**

For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

### LONGRTY( *integer* )

When a sender, server, or cluster-sender channel is attempting to connect to the remote queue

manager, and the count specified by `SHORTRTY` has been exhausted, this parameter specifies the maximum number of further attempts that are made to connect to the remote queue manager, at intervals specified by `LONGTMR`.

If this count is also exhausted without success, an error is logged to the operator, and the channel is stopped. The channel must then be restarted with a command (it is not started automatically by the channel initiator).

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (`CHLTYPE`) of `SDR`, `SVR`, `CLUSSDR`, or `CLUSRCVR`.

#### `LONGTMR`( *integer* )

For long retry attempts, this parameter is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between retries might be extended if the channel has to wait to become active.

The value must be in the range zero through 999999999.

**Note:** For implementation reasons, the maximum retry interval that can be used is 999,999; values exceeding this maximum are treated as 999,999. Similarly, the minimum retry interval that can be used is 2; values less than this minimum are treated as 2.

This parameter is valid only for channels with a channel type (`CHLTYPE`) of `SDR`, `SVR`, `CLUSSDR`, or `CLUSRCVR`.

#### `MAXINST`( *integer* )

**V 8.0.0.4** The maximum number of simultaneous instances of an individual server-connection channel or AMQP channel that can be started.

The value must be in the range zero through 999999999.

A value of zero prevents all client access on this channel.

If the value of this parameter is reduced to a number that is less than the number of instances of the server-connection channel that are currently running, then those running instances are not affected. However, new instances cannot start until sufficient existing instances have ceased to run so that the number of currently running instances is less than the value of this parameter.

**V 8.0.0.4** If an AMQP client attempts to connect to an AMQP channel, and the number of connected clients has reached `MAXINST`, the channel closes the connection with a close frame. The close frame contains the following message: `amqp:resource-limit-exceeded`. If a client connects with an ID that is already connected (that is, it performs a client-takeover), and the client is permitted to take over the connection, the takeover will succeed regardless of whether the number of connected clients has reached `MAXINST`.

This parameter is valid only for channels with a channel type ( `CHLTYPE` ) of `SVRCONN` or of `AMQP`.

#### `MAXINSTC`( *integer* )

The maximum number of simultaneous individual server-connection channels that can be started from a single client. In this context, connections that originate from the same remote network address are regarded as coming from the same client.

The value must be in the range zero through 999999999.

A value of zero prevents all client access on this channel.

If the value of this parameter is reduced to a number that is less than the number of instances of the server-connection channel that is currently running from individual clients, then those

running instances are not affected. However, new instances from those clients cannot start until sufficient instances have ceased to run that the number of running instances is less than the value of this parameter.

This parameter is valid only for channels with a channel type (CHLTYPE) of SVRCONN.

#### **MAXMSGL( *integer* )**

Specifies the maximum message length that can be transmitted on the channel. This parameter is compared with the value for the partner and the actual maximum used is the lower of the two values. The value is ineffective if the MQCB function is being executed and the channel type (CHLTYPE) is SVRCONN.

The value zero means the maximum message length for the queue manager.

On distributed platforms, specify a value in the range zero through to the maximum message length for the queue manager.

▶ **z/OS** On z/OS, specify a value in the range zero through 104857600 bytes (100 MB).

See the MAXMSGL parameter of the ALTER QMGR command for more information.

#### **MCANAME( *string* )**

Message channel agent name.

This parameter is reserved, and if specified must only be set to blanks (maximum length 20 characters).

#### **MCTYPE**

Specifies whether the message-channel-agent program on an outbound message channel runs as a thread or a process.

##### **PROCESS**

The message channel agent runs as a separate process.

**THREAD** The message channel agent runs as a separate thread

In situations where a threaded listener is required to service many incoming requests, resources can become strained. In this case, use multiple listener processes and target incoming requests at specific listeners though the port number specified on the listener.

On distributed platforms, this parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, RQSTR, CLUSSDR, or CLUSRCVR.

▶ **z/OS** On z/OS, this parameter is supported only for channels with a channel type of CLUSRCVR. When specified in a CLUSRCVR definition, MCTYPE is used by a remote machine to determine the corresponding CLUSSDR definition.

#### **MCAUSER( *string* )**

Message channel agent user identifier.

**Note:** An alternative way of providing a user ID for a channel to run under is to use channel authentication records. With channel authentication records, different connections can use the same channel while using different credentials. If both MCAUSER on the channel is set and channel authentication records are used to apply to the same channel, the channel authentication records take precedence. The MCAUSER on the channel definition is only used if the channel authentication record uses USERSRC(CHANNEL). For more details, see Channel authentication records.

This parameter interacts with PUTAUT, see the definition of that parameter for more information.

If it is nonblank, it is the user identifier that is to be used by the message channel agent for authorization to access IBM MQ resources, including (if PUTAUT is DEF) authorization to put the message to the destination queue for receiver or requester channels.

If it is blank, the message channel agent uses its default user identifier.

The default user identifier is derived from the user ID that started the receiving channel. The possible values are:

- **z/OS** On z/OS, the user ID assigned to the channel-initiator started task by the z/OS started-procedures table.
- For TCP/IP **z/OS**, other than z/OS, the user ID from the `inetd.conf` entry, or the user that started the listener.
- For SNA **z/OS**, other than z/OS, the user ID from the SNA server entry or, in the absence of this user ID the incoming attach request, or the user that started the listener.
- For NetBIOS or SPX, the user ID that started the listener.

The maximum length of the string is 64 characters on Windows and 12 characters on other platforms. On Windows, you can optionally qualify a user identifier with the domain name in the format `user@domain`.

This parameter is not valid for channels with a channel type (CHLTYPE) of SDR, SVR, CLNTCONN, CLUSSDR.

### MODENAME( *string* )

LU 6.2 mode name (maximum length 8 characters).

This parameter is valid only for channels with a transport type (TRPTYPE) of LU 6.2. If TRPTYPE is not LU 6.2, the data is ignored and no error message is issued.

If specified, this parameter must be set to the SNA mode name unless the CONNAME contains a side-object name, in which case it must be set to blanks. The actual name is then taken from the CPI-C Communications Side Object, or APPC side information data set.

**z/OS** See Configuration parameters for an LU 6.2 connection for more information about configuration parameters for an LU 6.2 connection for your platform.

This parameter is not valid for channels with a channel type (CHLTYPE) of RCVR or SVRCONN.

### MONCHL

Controls the collection of online monitoring data for channels:

**QMGR** Collect monitoring data according to the setting of the queue manager parameter MONCHL.

**OFF** Monitoring data collection is turned off for this channel.

**LOW** If the value of the queue manager MONCHL parameter is not NONE, online monitoring data collection is turned on, with a low rate of data collection, for this channel.

**MEDIUM** If the value of the queue manager MONCHL parameter is not NONE, online monitoring data collection is turned on, with a moderate rate of data collection, for this channel.

**HIGH** If the value of the queue manager MONCHL parameter is not NONE, online monitoring data collection is turned on, with a high rate of data collection, for this channel.

For cluster channels, the value of this parameter is not replicated in the repository and, therefore, not used in the auto-definition of cluster-sender channels.

For auto-defined cluster-sender channels, the value of this parameter is taken from the queue manager attribute MONACLS. If you want to modify the value, use the command `ALTER QMGR MONACLS(HIGH)`, then restart the auto-defined sender channel.

Changes to this parameter take effect only on channels started after the change occurs.

### MRDATA( *string* )

Channel message-retry exit user data. The maximum length is 32 characters.

This parameter is passed to the channel message-retry exit when it is called.

This parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, or CLUSRCVR.

**MREXIT**( *string* )

Channel message-retry exit name.

The format and maximum length of the name is the same as for MSGEXIT, however you can only specify one message-retry exit.

This parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, or CLUSRCVR.

**MRRTY**( *integer* )

The number of times the channel tries again before it decides it cannot deliver the message.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of MRRTY is passed to the exit to use, but the number of retries performed (if any) is controlled by the exit, and not by this parameter.

The value must be in the range zero through 999999999. A value of zero means that no retries are performed.

This parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, or CLUSRCVR.

**MRTMR**( *integer* )

The minimum interval of time that must pass before the channel can try the MQPUT operation again. This time interval is in milliseconds.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of MRTMR is passed to the exit to use, but the retry interval is controlled by the exit, and not by this parameter.

The value must be in the range zero through 999 999 999. A value of zero means that the retry is performed as soon as possible (if the value of MRRTY is greater than zero).

This parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, or CLUSRCVR.

**MSGDATA**( *string* )

User data for the channel message exit. The maximum length is 32 characters.

This data is passed to the channel message exit when it is called.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

 On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of message exit data for each channel.

**Note:** This parameter is accepted but ignored for server-connection and client-connection channels.

**MSGEXIT**( *string* )

Channel message exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after a message has been retrieved from the transmission queue (sender or server), or immediately before a message is put to a destination queue (receiver or requester).  
The exit is given the entire application message and transmission queue header for modification.
- At initialization and termination of the channel.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

**z/OS** On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one message exit name for each channel.

For channels with a channel type (CHLTYPE) of CLNTCONN or SVRCONN, this parameter is accepted but ignored, because message exits are not invoked for such channels.

The format and maximum length of the name depends on the environment:

- On UNIX and Linux systems, it is of the form:

`libraryname(functionname)`

The maximum length of the string is 128 characters.

- On Windows, it is of the form:

`dllname(functionname)`

where *dllname* is specified without the suffix (".DLL"). The maximum length of the string is 128 characters.

- On IBM i, it is of the form:

`progrname libname`

where *program name* occupies the first 10 characters and *libname* the second 10 characters (both padded to the right with blanks if necessary). The maximum length of the string is 20 characters.

- **z/OS** On z/OS, it is a load module name, maximum length 8 characters (128 characters are allowed for exit names for client-connection channels, subject to a maximum total length including commas of 999).

### NETPRTY( *integer* )

The priority for the network connection. Distributed queuing chooses the path with the highest priority if there are multiple paths available. The value must be in the range zero through 9; zero is the lowest priority.

This parameter is valid only for CLUSRCVR channels.

### NPMSPEED

The class of service for nonpersistent messages on this channel:

**FAST** Fast delivery for nonpersistent messages; messages might be lost if the channel is lost. Messages are retrieved using MQGMO\_SYNCPOINT\_IF\_PERSISTENT and so are not included in the batch unit of work.

**NORMAL** Normal delivery for nonpersistent messages.

If the sending side and the receiving side do not agree about this parameter, or one does not support it, NORMAL is used.

This parameter is valid only for channels with a CHLTYPE of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

**PASSWORD**( *string* )

Password used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent. The maximum length is 12 characters.

On distributed platforms, this parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

**z/OS** On z/OS, it is supported only for channels with a channel type (CHLTYPE) of CLNTCONN.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

**V8.0.0.4** **PORT** ( *integer* )

The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672. If you are already using port 5672, you can specify a different port.

**PROPCTL**

Property control attribute.

Specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

This parameter is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

This parameter is optional.

Permitted values are:

**COMPAT**

COMPAT allows applications which expect JMS-related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

Message properties	Result
The message contains a property with a prefix of <b>mcd.</b> , <b>jms.</b> , <b>usr.</b> or <b>mqext.</b>	All optional message properties (where the <b>Support</b> value is MQPD_SUPPORT_OPTIONAL), except properties in the message descriptor or extension, are placed in one or more MQRFH2 headers in the message data before the message is sent to the remote queue manager.
The message does not contain a property with a prefix of <b>mcd.</b> , <b>jms.</b> , <b>usr.</b> or <b>mqext.</b>	All message properties, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the <b>Support</b> field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.
The message contains one or more properties where the <b>Support</b> field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL but other fields of the property descriptor are set to non-default values.	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the <i>content='properties'</i> attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to a V6 or prior queue manager.

**NONE**

All properties of the message, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD\_SUPPORT\_OPTIONAL then the message is rejected with reason MQRC\_UNSUPPORTED\_PROPERTY and treated in accordance with its report options.

**ALL** All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

## PUTAUT

Specifies which user identifiers are used to establish authority to put messages to the destination queue (for messages channels) or to execute an MQI call (for MQI channels).

**DEF** The default user ID is used.

▶ **z/OS** On z/OS, DEF might involve using both the user ID received from the network and that derived from MCAUSER.

**CTX** The user ID from the *UserIdentifier* field of the message descriptor is used.

▶ **z/OS** On z/OS, CTX might involve also using the user ID received from the network or that derived from MCAUSER, or both.

▶ **z/OS** **ONLYMCA**

The user ID derived from MCAUSER is used. Any user ID received from the network is not used. This value is supported only on z/OS.

▶ **z/OS** **ALTMCA**

The user ID from the *UserIdentifier* field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

▶ **z/OS** On z/OS, the user IDs that are checked, and how many user IDs are checked, depends on the setting of the MQADMIN RACF class hlq.RESLEVEL profile. Depending on the level of access the user ID of the channel initiator has to hlq.RESLEVEL, zero, one or two user IDs are checked. To see how many user IDs are checked, see RESLEVEL and channel initiator connections. For more information about which user IDs are checked, see User IDs used by the channel initiator.

On distributed platforms, this parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, or CLUSRCVR.

▶ **z/OS** On z/OS, this parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, CLUSRCVR, or SVRCONN. CTX and ALTMCA are not valid for SVRCONN channels.

## QMNAME( *string* )

Queue manager name.

For channels with a channel type (CHLTYPE) of CLNTCONN, this parameter is the name of a queue manager to which an application that is running in a client environment and using the client channel definition table can request connection. This parameter need not be the name of the queue manager on which the channel is defined, to allow a client to connect to different queue managers.

For channels of other types, this parameter is not valid.

▶ **z/OS** **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	ALTER
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.
GROUP	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE CHANNEL(channel-name) CHLTYPE(type) REPLACE QSGDISP(COPY)</pre> <p>The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
PRIVATE	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY). Any object residing in the shared repository is unaffected.
QMGR	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

### RCVDATA( *string* )

Channel receive exit user data (maximum length 32 characters).

This parameter is passed to the channel receive exit when it is called.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

 On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of receive exit data for each channel.

### RCVEXIT( *string* )

Channel receive exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before the received network data is processed.  
The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.
- At initialization and termination of the channel.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

▶ **z/OS** On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one receive exit name for each channel.

The format and maximum length of the name is the same as for MSGEXIT.

## **REPLACE and NOREPLACE**

Whether the existing definition ▶ **z/OS** (and on z/OS, with the same disposition) is to be replaced with this one. This parameter is optional. Any object with a different disposition is not changed.

### **REPLACE**

The definition replaces any existing definition of the same name. If a definition does not exist, one is created. REPLACE does not alter the channel status.

### **NOREPLACE**

The definition does not replace any existing definition of the same name.

## **SCYDATA( *string* )**

Channel security exit user data (maximum length 32 characters).

This parameter is passed to the channel security exit when it is called.

## **SCYEXIT( *string* )**

Channel security exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after establishing a channel.  
Before any messages are transferred, the exit is able to instigate security flows to validate connection authorization.
- Upon receipt of a response to a security message flow.  
Any security message flows received from the remote processor on the remote queue manager are given to the exit.
- At initialization and termination of the channel.

The format and maximum length of the name is the same as for MSGEXIT but only one name is allowed.

## **SENDDATA( *string* )**

Channel send exit user data. The maximum length is 32 characters.

This parameter is passed to the channel send exit when it is called.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

▶ **z/OS** On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of send exit data for each channel.

## **SENDEXIT( *string* )**

Channel send exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before data is sent out on the network.

The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.

- At initialization and termination of the channel.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

 On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one send exit name for each channel.

The format and maximum length of the name is the same as for MSGEXIT.

### **SEQWRAP**( *integer* )

When this value is reached, sequence numbers wrap to start again at 1.

This value is nonnegotiable and must match in both the local and remote channel definitions.

The value must be in the range 100 through 999999999.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

### **SHARECNV**( *integer* )

Specifies the maximum number of conversations that can be sharing each TCP/IP channel instance. A SHARECNV value of:

- 1** Specifies no sharing of conversations over a TCP/IP channel instance. Client heartbeating is available whether in an MQGET call or not. Read ahead and client asynchronous consumption are also available, and channel quiescing is more controllable.
- 0** Specifies no sharing of conversations over a TCP/IP channel instance.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (CHLTYPE) of CLNTCONN or SVRCONN. If the client-connection SHARECNV value does not match the server-connection SHARECNV value, the lower of the two values is used. This parameter is ignored for channels with a transport type (TRPTYPE) other than TCP.

All the conversations on a socket are received by the same thread.

High SHARECNV limits have the advantage of reducing queue manager thread usage. However, if many conversations sharing a socket are all busy, there is a possibility of delays as the conversations contend with one another to use the receiving thread. In this situation, a lower SHARECNV value is better.

The number of shared conversations does not contribute to the MAXINST or MAXINSTC totals.

**Note:** You should restart the client for this change to take effect.

### **SHORTRTY**( *integer* )

The maximum number of attempts that are made by a sender, server, or cluster-sender channel to connect to the remote queue manager, at intervals specified by SHORTTMR, before the (normally longer) LONGRTY and LONGTMR are used.

Retry attempts are made if the channel fails to connect initially (whether it is started automatically by the channel initiator or by an explicit command), and also if the connection fails after the channel has successfully connected. However, if the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, CLUSSDR, or CLUSRCVR.

### SHORTTMR( *integer* )

For short retry attempts, this parameter is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between retries might be extended if the channel has to wait to become active.

The value must be in the range zero through 999999999.

**Note:** For implementation reasons, the maximum retry interval that can be used is 999999; values exceeding this maximum are treated as 999999. Similarly, the minimum retry interval that can be used is 2; values less than this minimum are treated as 2.

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, CLUSSDR, or CLUSRCVR.

### SSLCAUTH

Defines whether IBM MQ requires a certificate from the SSL client. The initiating end of the channel acts as the SSL client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the SSL server.

This parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, SVRCONN, CLUSRCVR, SVR, or RQSTR.

The parameter is used only for channels with SSLCIPH specified. If SSLCIPH is blank, the data is ignored and no error message is issued.

#### REQUIRED

IBM MQ requires and validates a certificate from the SSL client.

#### OPTIONAL

The peer SSL client system might still send a certificate. If it does, the contents of this certificate are validated as normal.

### SSLCIPH (*string*)

SSLCIPH specifies the CipherSpec that is used on the channel. The maximum length is 32 characters. This parameter is valid on all channel types which use transport type TRPTYPE(TCP). If the SSLCIPH parameter is blank, no attempt is made to use SSL on the channel.

**Note:** When SSLCIPH is used with a telemetry channel, it means "SSL Cipher Suite". See the SSLCIPH description in "ALTER CHANNEL (MQTT)".

Specify the name of the CipherSpec you are using. The CipherSpecs that can be used with IBM MQ SSL support are shown in the following table. The SSLCIPH values must specify the same CipherSpec on both ends of the channel.

**Note:**   On  IBM MQ for z/OS;  IBM i; you can also specify the two digit hexadecimal code of a CipherSpec, whether or not it appears in the table. On IBM i, installation of AC3 is a prerequisite for the use of SSL.

Platform support <sup>1</sup>	CipherSpec name	Protocol used	Data integrity	Encryption algorithm	Encryption bits	FIPS <sup>2</sup>	Suite B
> Linux > Windows > UNIX > z/OS	TLS_RSA_WITH_AES_128_CBC_SHA	TLS 1.0	SHA-1	AES	128	Yes	No

**Notes:**

1. If no specific platform is noted, the CipherSpec is available on all platforms.
2. Specifies whether the CipherSpec is FIPS-certified on a FIPS-certified platform. See Federal Information Processing Standards (FIPS) for an explanation of FIPS.
3. This CipherSpec cannot be used to secure a connection from the MQ Explorer to a queue manager unless the appropriate unrestricted policy files are applied to the JRE used by the Explorer.
4. Following a recommendation by NIST, GCM CipherSpecs now have a restriction which means that after 2022 TLS records are sent, using the same session key, the connection will be terminated with message AMQ9288. To prevent this error from happening: avoid using GCM Ciphers, enable secret key reset, or start your IBM MQ queue manager with the environment variable GSK\_ENFORCE\_GCM\_RESTRICTION=GSK\_FALSE set. **Important:** The GCM restriction is active, regardless of the FIPS mode being used.
5. The CipherSpecs listed as supported on IBM i apply to Versions 7.2 and 7.3 of IBM i.

When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake can depend on the size stored in the certificate and on the CipherSpec:

- On  z/OS, Windows, UNIX and Linux systems, when a CipherSpec name includes \_EXPORT, the maximum handshake key size is 512 bits. If either of the certificates exchanged during the SSL handshake has a key size greater than 512 bits, a temporary 512-bit key is generated for use during the handshake.
- On Windows, UNIX and Linux systems, when a CipherSpec name includes \_EXPORT1024, the handshake key size is 1024 bits.
- Otherwise the handshake key size is the size stored in the certificate.

**SSLPEER( *string* )**

Specifies the filter to use to compare with the Distinguished Name of the certificate from the peer queue manager or client at the other end of the channel. (A Distinguished Name is the identifier of the SSL certificate.) If the Distinguished Name in the certificate received from the peer does not match the SSLPEER filter, the channel does not start.

**Note:** An alternative way of restricting connections into channels by matching against the SSL or TLS Subject Distinguished Name, is to use channel authentication records. With channel authentication records, different SSL or TLS Subject Distinguished Name patterns can be applied to the same channel. If both SSLPEER on the channel and a channel authentication record are

used to apply to the same channel, the inbound certificate must match both patterns in order to connect. For more information, see Channel authentication records.

This parameter is optional; if it is not specified, the Distinguished Name of the peer is not checked at channel start up. (The Distinguished Name from the certificate is still written into the SSLPEER definition held in memory, and passed to the security exit). If SSLCIPH is blank, the data is ignored and no error message is issued.

This parameter is valid for all channel types.

The SSLPEER value is specified in the standard form used to specify a Distinguished Name. For example:

```
SSLPEER('SERIALNUMBER=4C:D0:49:D5:02:5F:38,CN="H1_C_FR1",O=IBM,C=GB')
```

You can use a semi-colon as a separator instead of a comma.

The possible attribute types supported are:

*Table 91. Attribute types supported by SSLPEER.*

A two column table describing the attributes supported by the SSLPEER attribute

Summary attribute	Description
SERIALNUMBER	Certificate serial number
MAIL	Email address
E	Email address (Deprecated in preference to MAIL)
UID or USERID	User identifier
CN	Common Name
T	Title
OU	Organizational Unit name
DC	Domain component
O	Organization name
STREET	Street / First line of address
L	Locality name
ST (or SP or S)	State or Province name
PC	Postal code / zip code
C	Country
UNSTRUCTUREDNAME	Host name
UNSTRUCTUREDADDRESS	IP address
DNQ	Distinguished name qualifier

IBM MQ accepts only uppercase letters for the attribute types.

If any of the unsupported attribute types are specified in the SSLPEER string, an error is output either when the attribute is defined or at run time (depending on which platform you are running on), and the string is deemed not to have matched the Distinguished Name of the flowed certificate.

If the Distinguished Name of the flowed certificate contains multiple OU (organizational unit) attributes, and SSLPEER specifies these attributes to be compared, they must be defined in

descending hierarchical order. For example, if the Distinguished Name of the flowed certificate contains the OUs OU=Large Unit, OU=Medium Unit, OU=Small Unit, specifying the following SSLPEER values works:

```
('OU=Large Unit,OU=Medium Unit')
('OU=*,OU=Medium Unit,OU=Small Unit')
('OU=*,OU=Medium Unit')
```

but specifying the following SSLPEER values fails:

```
('OU=Medium Unit,OU=Small Unit')
('OU=Large Unit,OU=Small Unit')
('OU=Medium Unit')
('OU=Small Unit, Medium Unit, Large Unit')
```

As indicated in these examples, attributes at the low end of the hierarchy can be omitted. For example, ('OU=Large Unit,OU=Medium Unit') is equivalent to ('OU=Large Unit,OU=Medium Unit,OU=\*')

If two DNs are equal in all respects except for their DC values, the same matching rules apply as for OUs except that in DC values the left-most DC is the lowest-level (most specific) and the comparison ordering differs accordingly.

Any or all the attribute values can be generic, either an asterisk (\*) on its own, or a stem with initiating or trailing asterisks. Asterisks allow the SSLPEER to match any Distinguished Name value, or any value starting with the stem for that attribute.

If an asterisk is specified at the beginning or end of any attribute value in the Distinguished Name on the certificate, you can specify '\\*' to check for an exact match in SSLPEER. For example, if you have an attribute of CN='Test\*' in the Distinguished Name of the certificate, you can use the following command:

```
SSLPEER('CN=Test\*')
```

The maximum length of the parameter is 1024 bytes on Windows, IBM i, UNIX and Linux platforms

► **z/OS** The maximum length of the parameter is 256 bytes on z/OS.

Channel authentication records provide greater flexibility when using SSLPEER and support 1024 bytes on all platforms.

## STATCHL

It controls the collection of statistics data for channels:

**QMGR** The value of the STATCHL parameter of the queue manager is inherited by the channel.

**OFF** Statistics data collection is turned off for this channel.

**LOW** If the value of the STATCHL parameter of the queue manager is not NONE, statistics data collection is turned on, with a low rate of data collection, for this channel.

**MEDIUM** If the value of the STATCHL parameter of the queue manager is not NONE, statistics data collection is turned on, with a moderate rate of data collection, for this channel.

**HIGH** If the value of the STATCHL parameter of the queue manager is not NONE, statistics data collection is turned on, with a high rate of data collection, for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

► **z/OS** On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

For cluster channels, the value of this parameter is not replicated in the repository and used in the auto-definition of cluster-sender channels. For auto-defined cluster-sender channels, the value

of this parameter is taken from the attribute STATACLS of the queue manager. This value might then be overridden in the channel auto-definition exit.

### TPNAME( *string* )

LU 6.2 transaction program name (maximum length 64 characters).

This parameter is valid only for channels with a transport type (TRPTYPE) of LU 6.2.

Set this parameter to the SNA transaction program name, unless the CONNAME contains a side-object name in which case set it to blanks. The actual name is taken instead from the CPI-C Communications Side Object, or the APPC side information data set.

▶ **z/OS** See Configuration parameters for an LU 6.2 connection for more information about configuration parameters for an LU 6.2 connection for your platform.

On Windows SNA Server, ▶ **z/OS** and in the side object on z/OS, the TPNAME is wrapped to uppercase.

This parameter is not valid for channels with a channel type (CHLTYPE) of RCVR.

### ▶ **V 8.0.0.4** TPROOT

The topic root for an AMQP channel. The default value for TPROOT is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other MQ pub/sub applications. To have AMQP clients publish and subscribe under a topic prefix, first create an MQ topic object with a topic string set to the prefix you want, then set TPROOT to the name of the MQ topic object you created.

This parameter is valid only for channels with a channel type ( CHLTYPE ) of AMQP

### TRPTYPE

Transport type to be used.

On AIX, IBM i, HP-UX, Linux, Solaris, and Windows ▶ **z/OS** , and z/OS, this parameter is optional because, if you do not enter a value, the value specified in the SYSTEM.DEF. *channel-type* definition is used. However, no check is made that the correct transport type has been specified if the channel is initiated from the other end.

▶ **z/OS** On z/OS, if the SYSTEM.DEF. *channel-type* definition does not exist, the default is LU62.

This parameter is required on all other platforms.

**LU62** SNA LU 6.2

### NETBIOS

NetBIOS (supported only on Windows, and DOS).

▶ **z/OS** This attribute also applies to z/OS for defining client-connection channels that connect to servers on the platforms supporting NetBIOS.

**SPX** Sequenced packet exchange (supported only on Windows, and DOS).

▶ **z/OS** This attribute also applies to z/OS for defining client-connection channels that connect to servers on the platforms supporting SPX.

**TCP** Transmission Control Protocol - part of the TCP/IP protocol suite

### ▶ **V 8.0.0.4** USECLTID

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

### USEDLQ

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

**NO** Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the NPMSPEED setting.

**YES** When the DEADQ queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

**USERID( string )**

Task user identifier. The maximum length is 12 characters.

This parameter is used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent.

On distributed platforms this parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

**z/OS** On z/OS, it is supported only for CLNTCONN channels.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

On the receiving end, if passwords are kept in encrypted format and the LU 6.2 software is using a different encryption method, an attempt to start the channel fails with invalid security details. You can avoid invalid security details by modifying the receiving SNA configuration to either:

- Turn off password substitution, or
- Define a security user ID and password.

**XMITQ( string )**

Transmission queue name.

The name of the queue from which messages are retrieved. See Rules for naming IBM MQ objects.

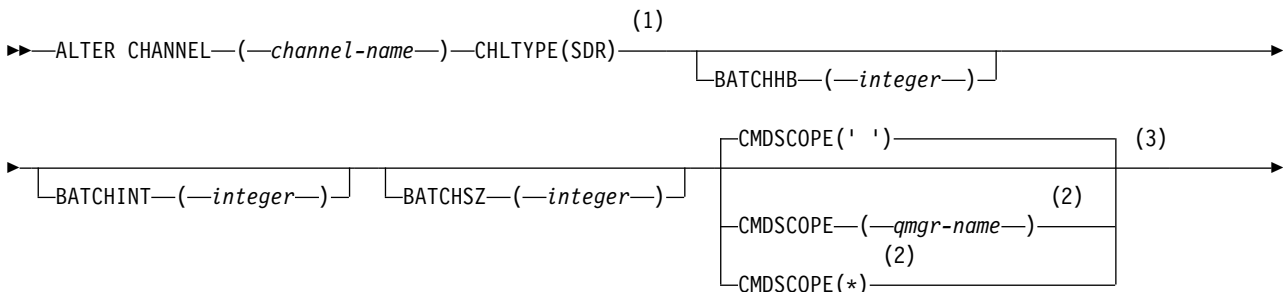

This parameter is valid only for channels with a channel type (CHLTYPE) of SDR or SVR. For these channel types, this parameter is required.

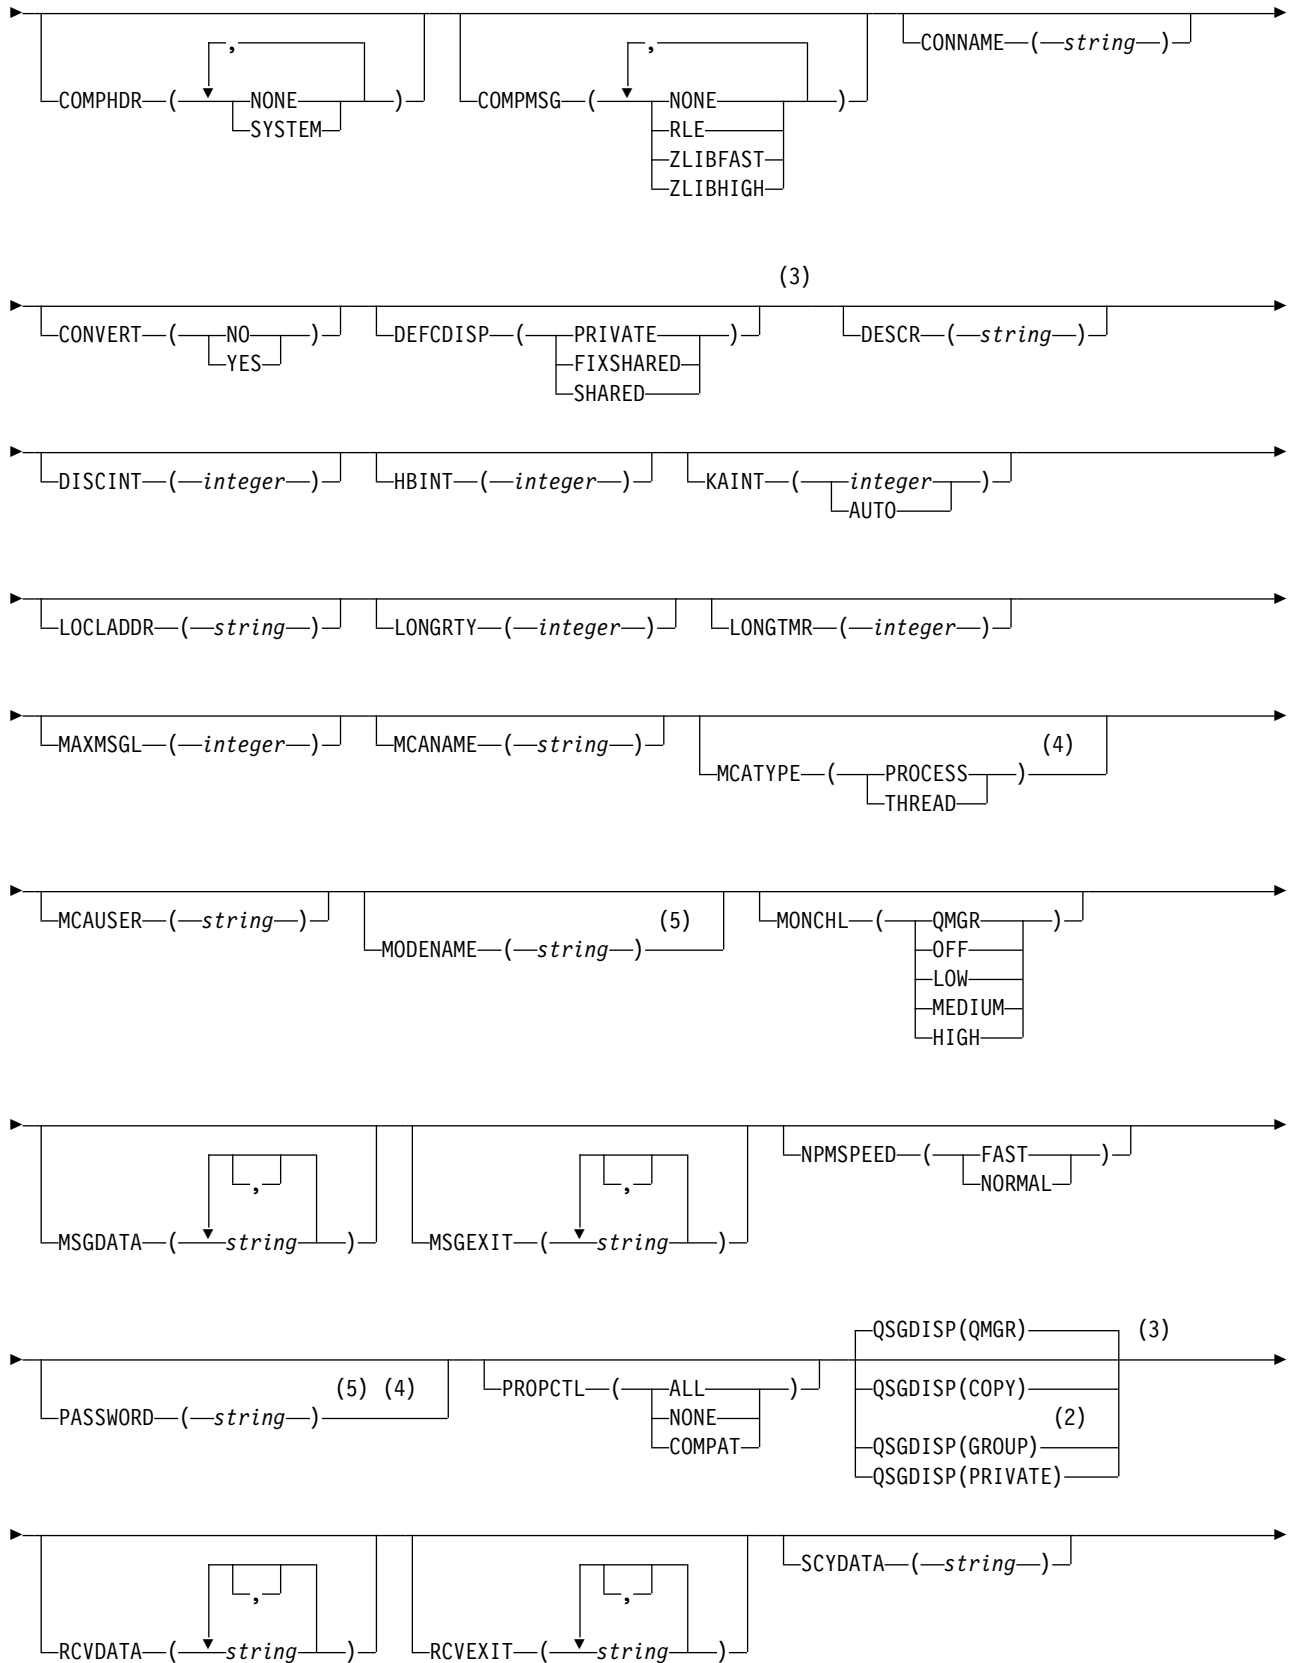

There is a separate syntax diagram for each type of channel:

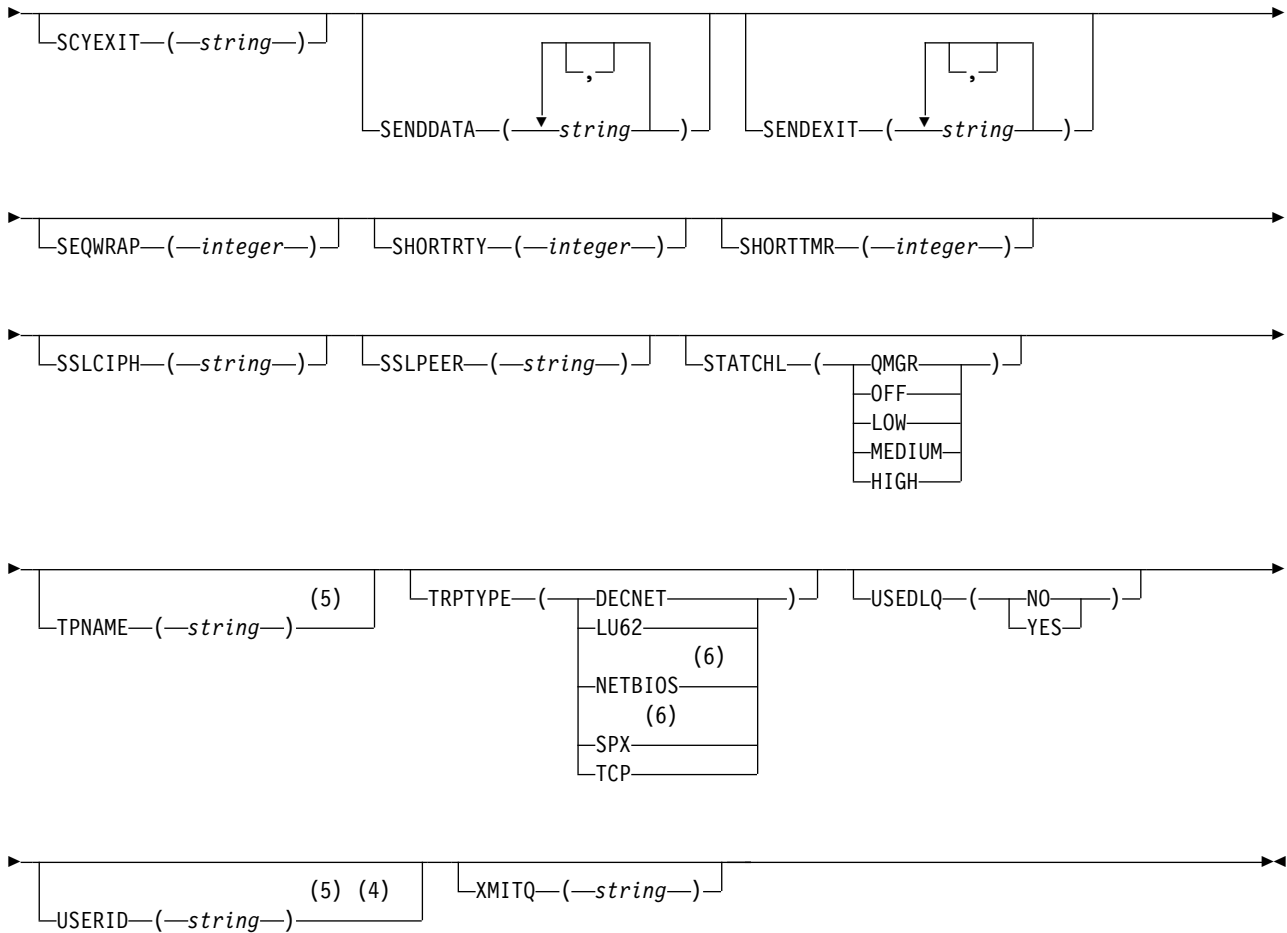

*Sender channel:*

Syntax diagram for a sender channel when using the ALTER CHANNEL command.

**ALTER CHANNEL**

**Notes:**

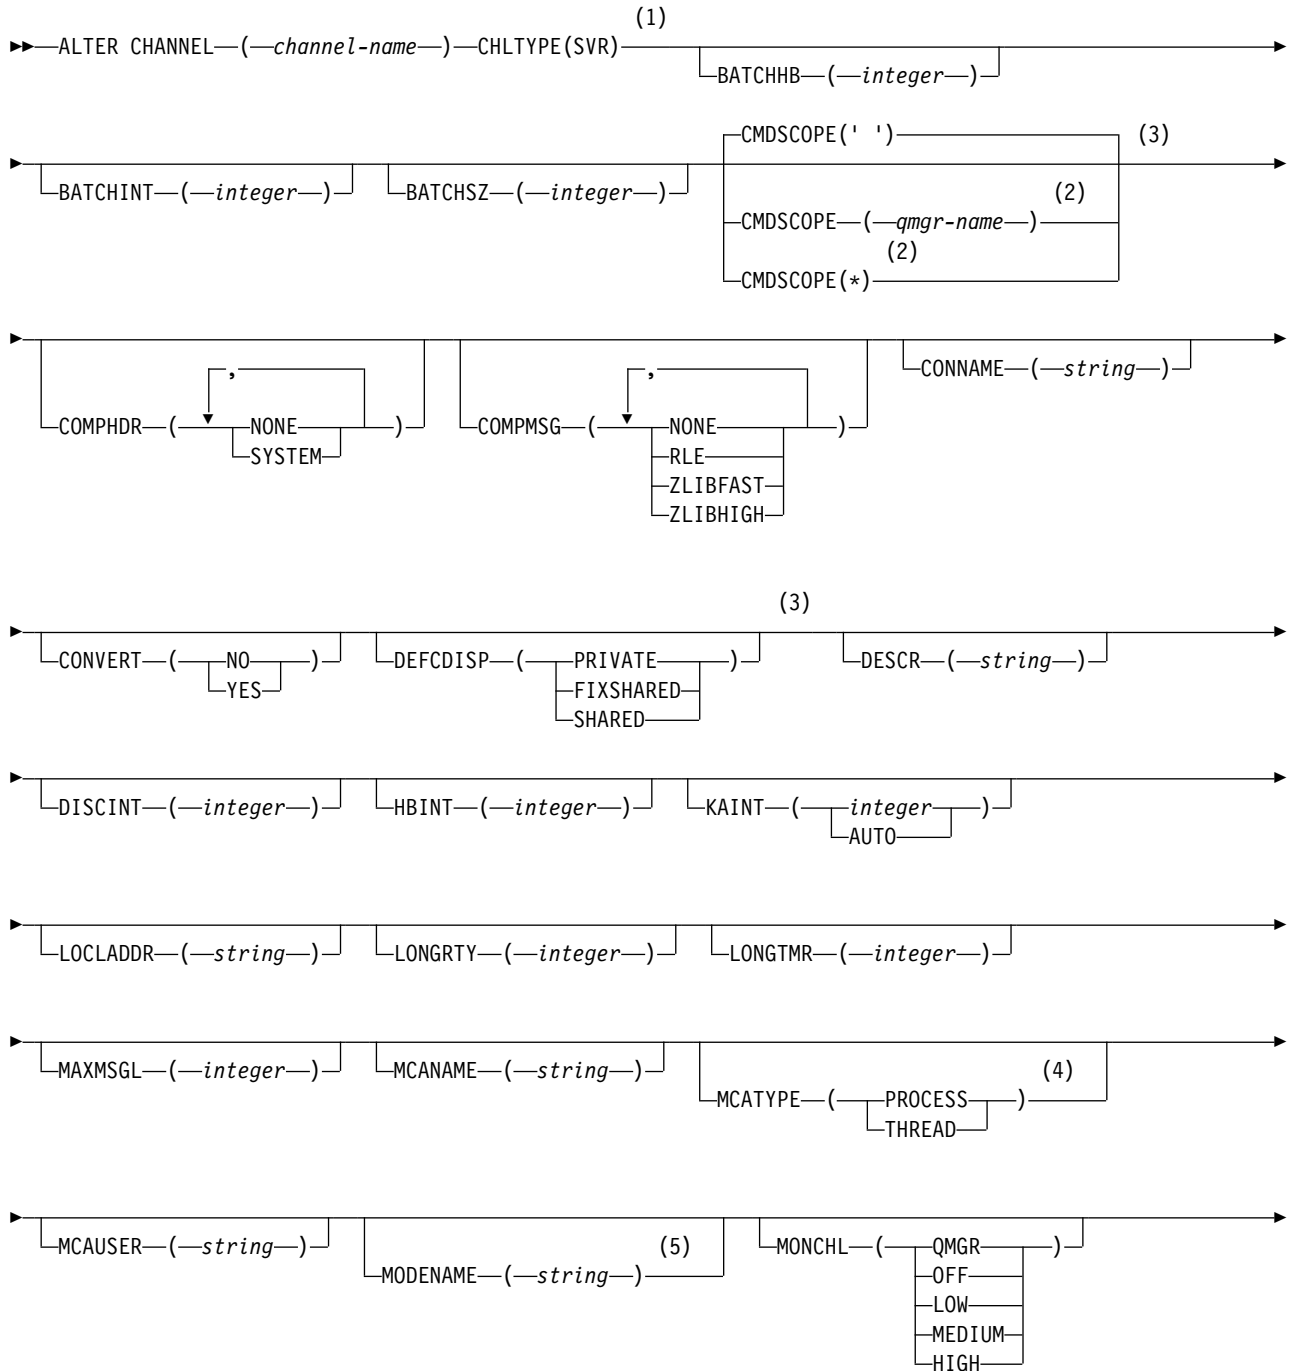

- 1 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Valid only Windows.

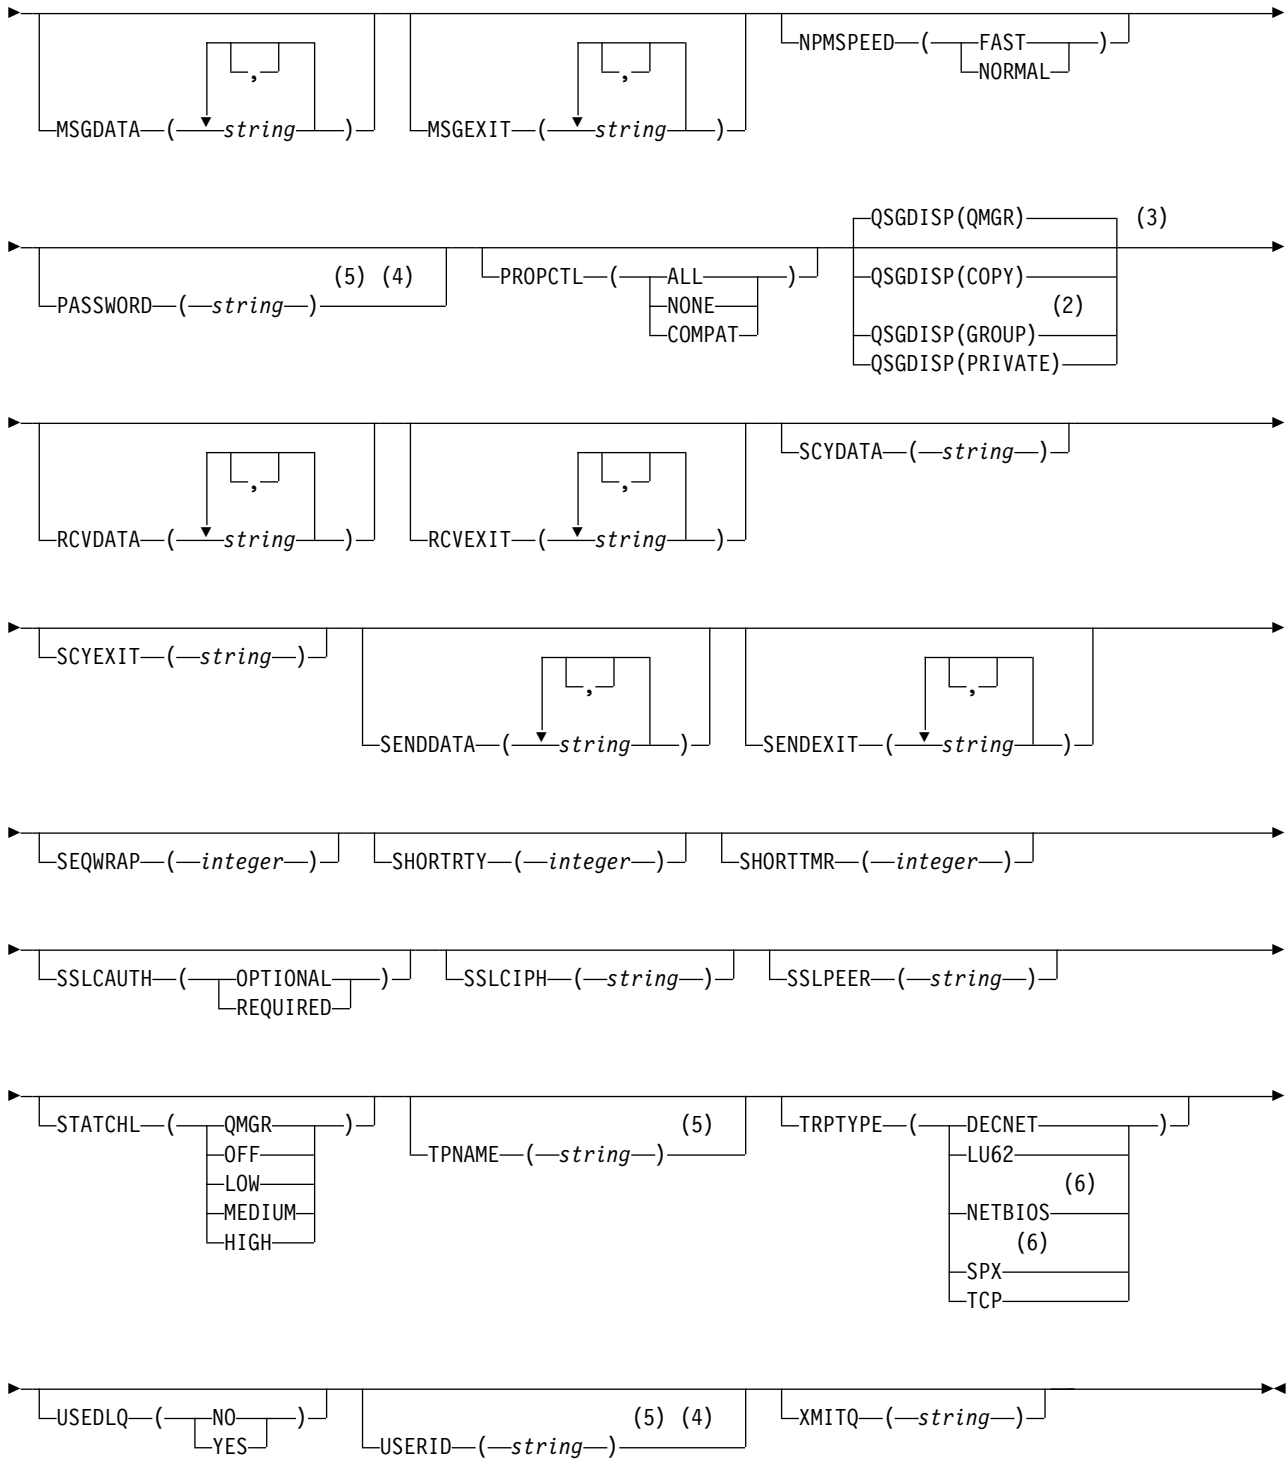

The parameters are described in “ALTER CHANNEL” on page 366.

Server channel:

Syntax diagram for a server channel when using the ALTER CHANNEL command.

### ALTER CHANNEL

**Notes:**

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS.

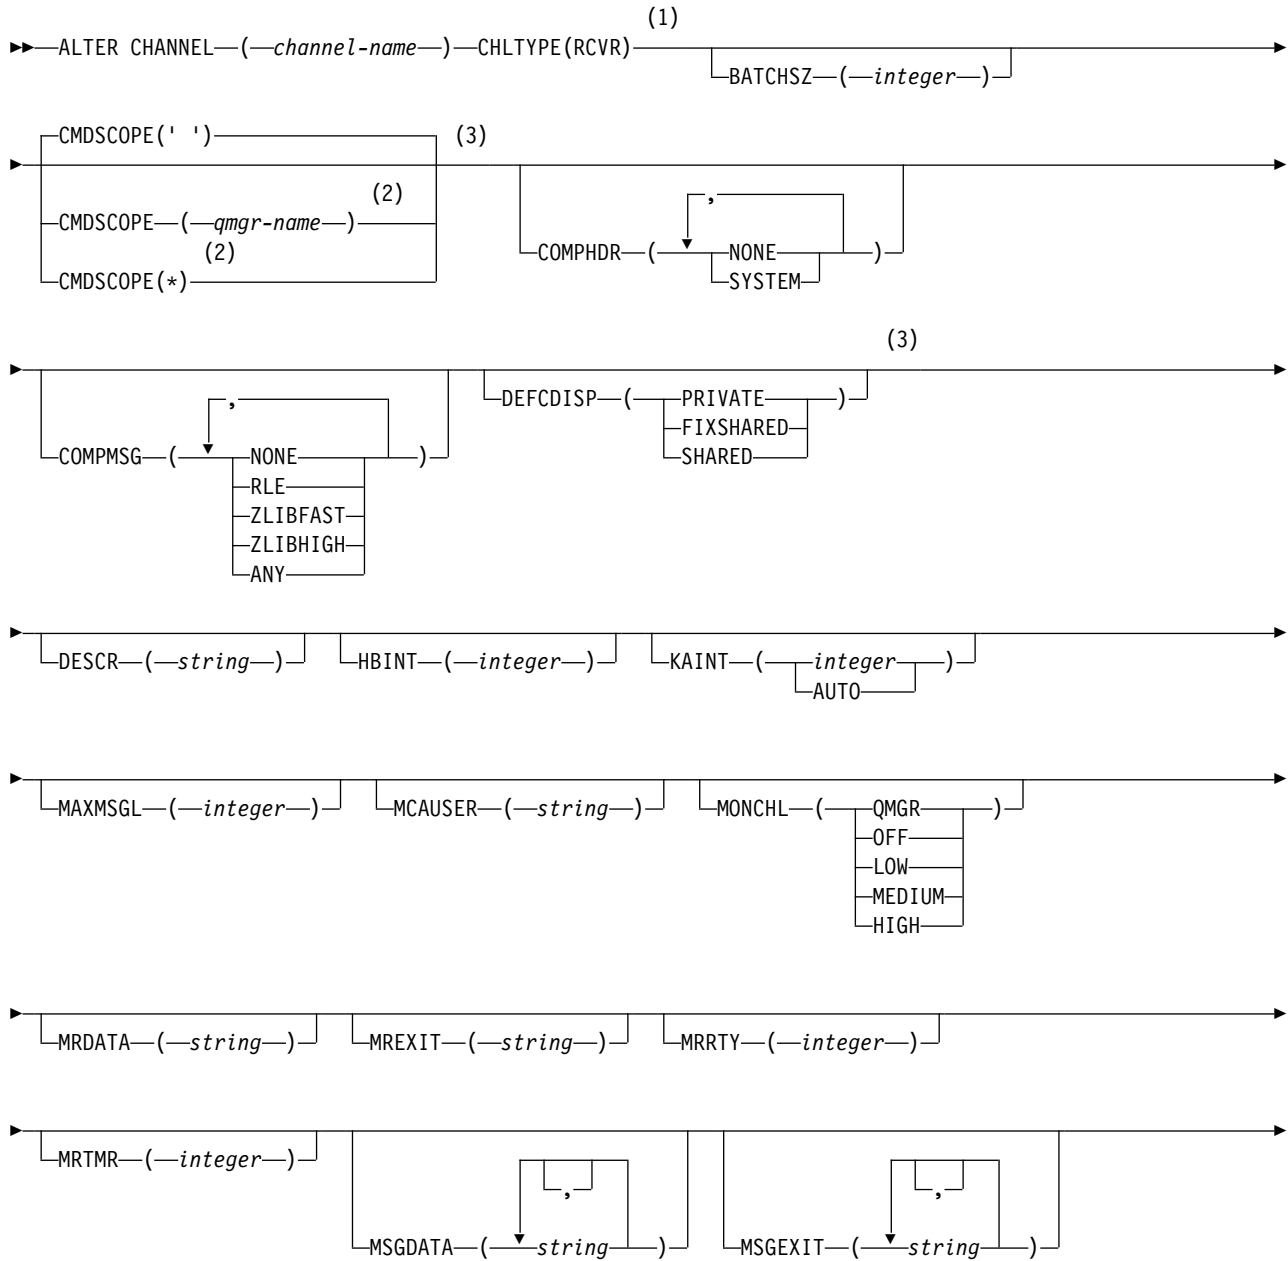

- 5 Valid only if TRPTYPE is LU62.
- 6 Valid only on Windows.

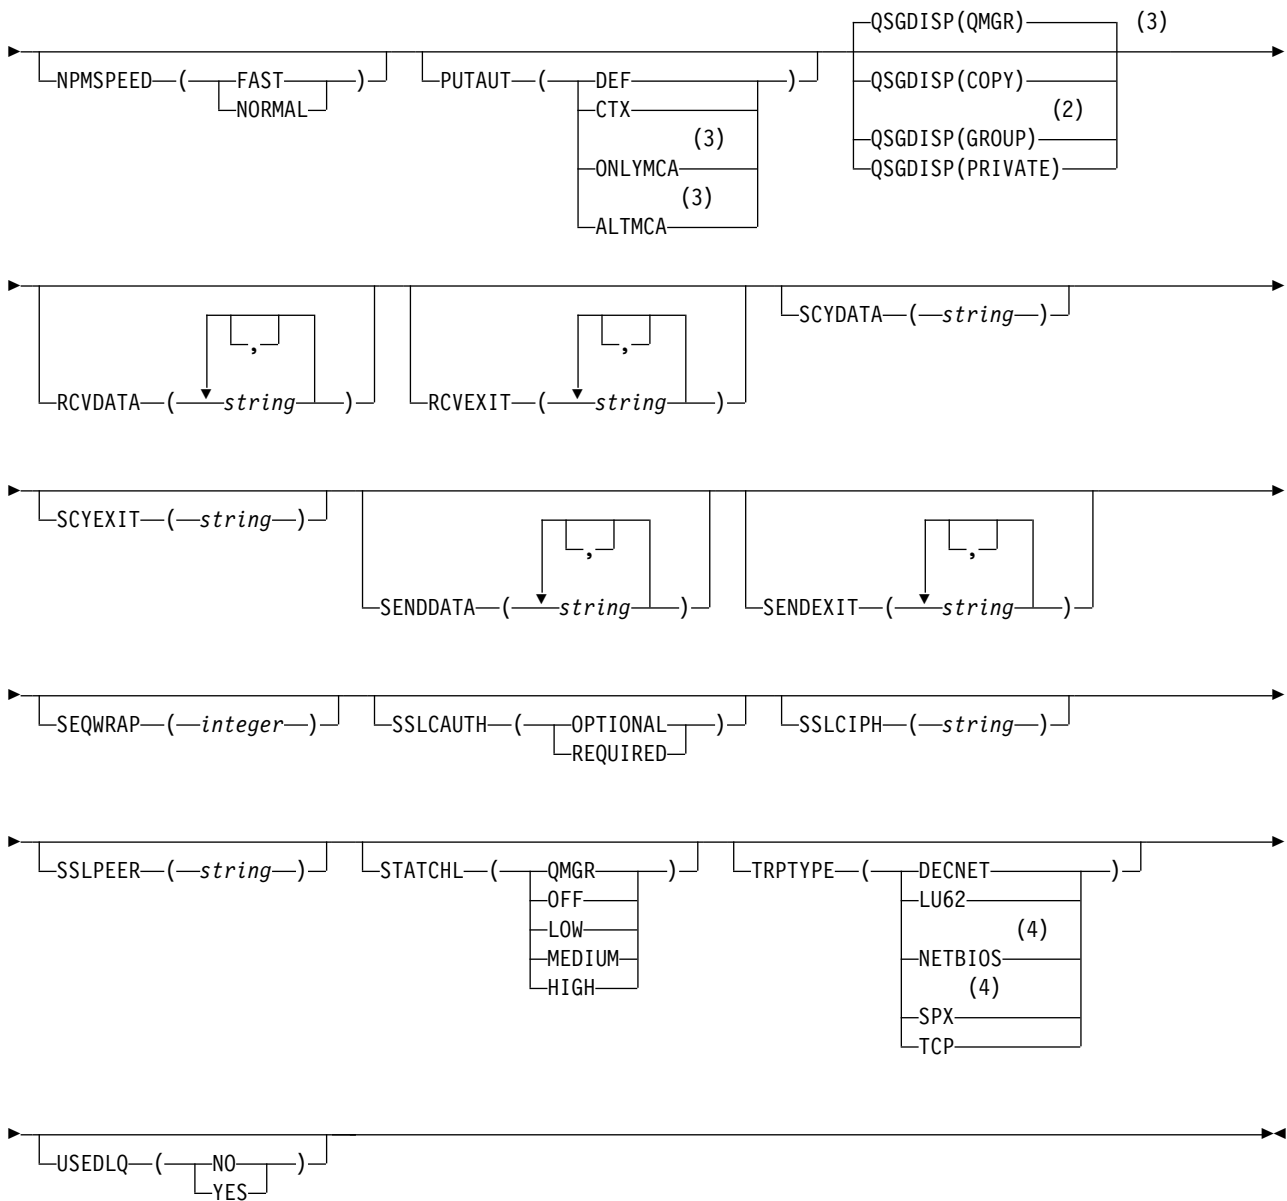

The parameters are described in "ALTER CHANNEL" on page 366.

Receiver channel:

Syntax diagram for a receiver channel when using the ALTER CHANNEL command.

**ALTER CHANNEL**

**Notes:**

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Valid only on Windows.

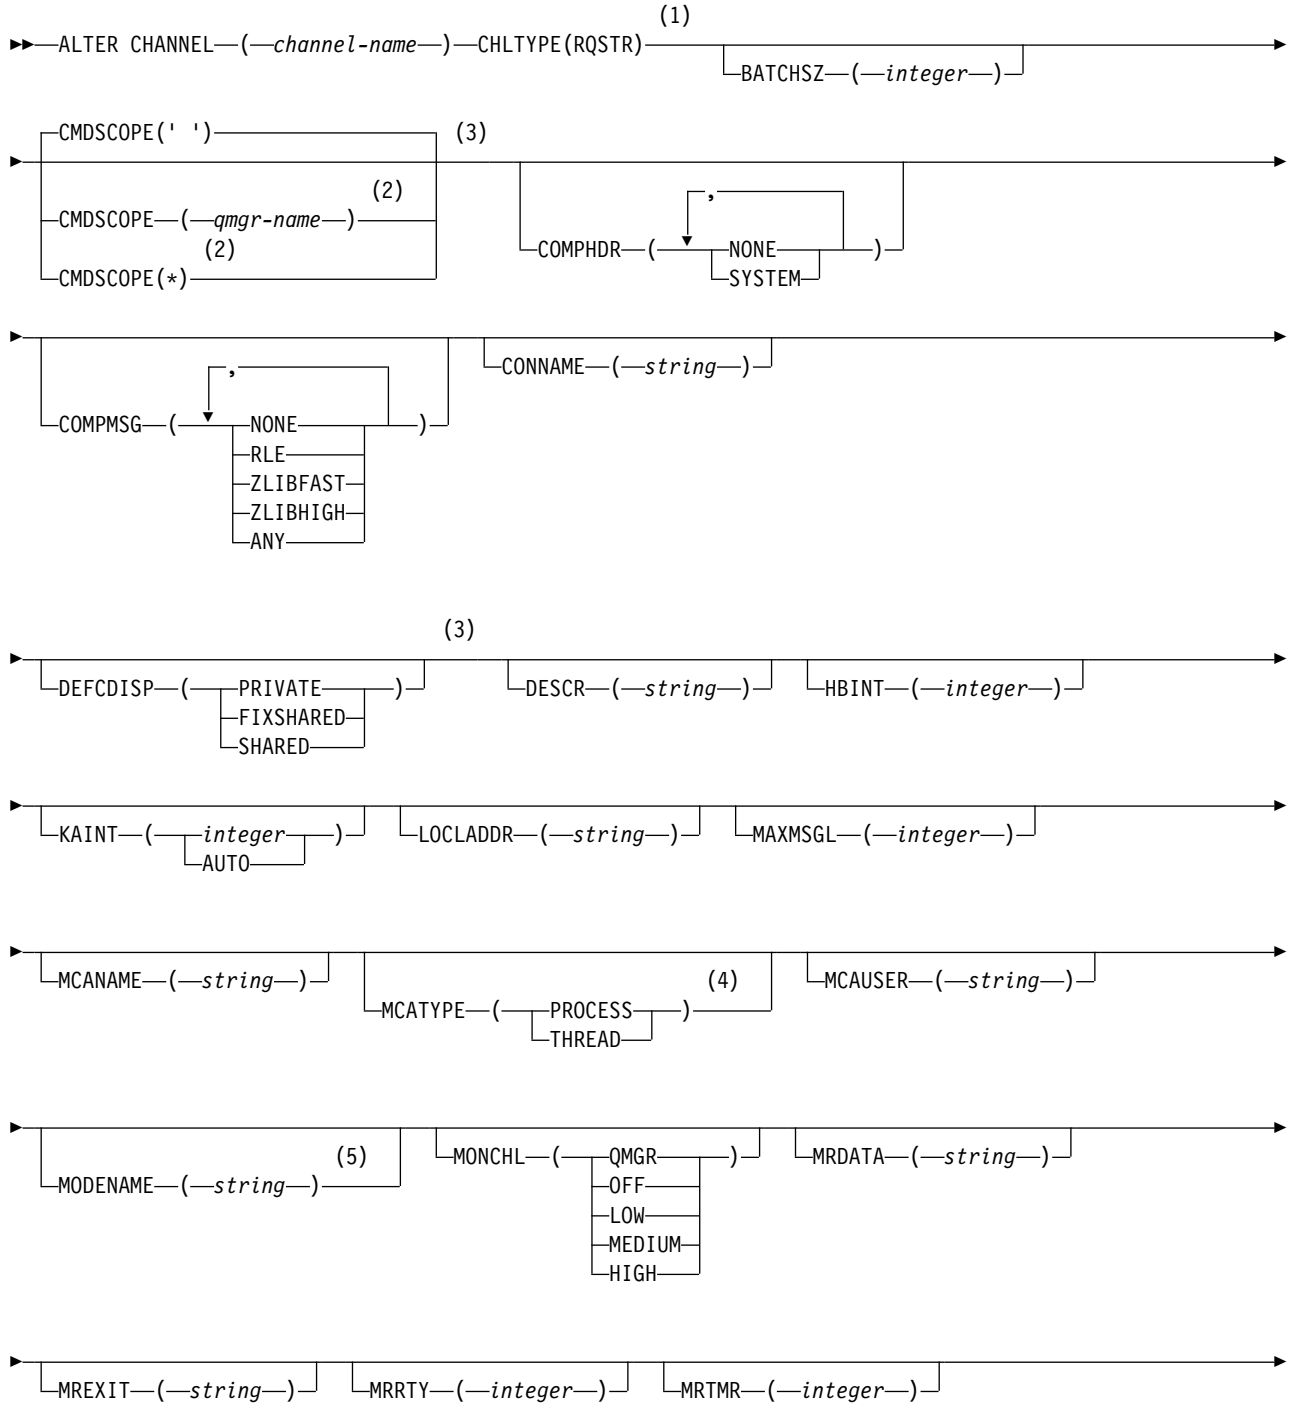

The parameters are described in "ALTER CHANNEL" on page 366.

Requester channel:

Syntax diagram for a requester channel when using the ALTER CHANNEL command.

**ALTER CHANNEL**

**Notes:**

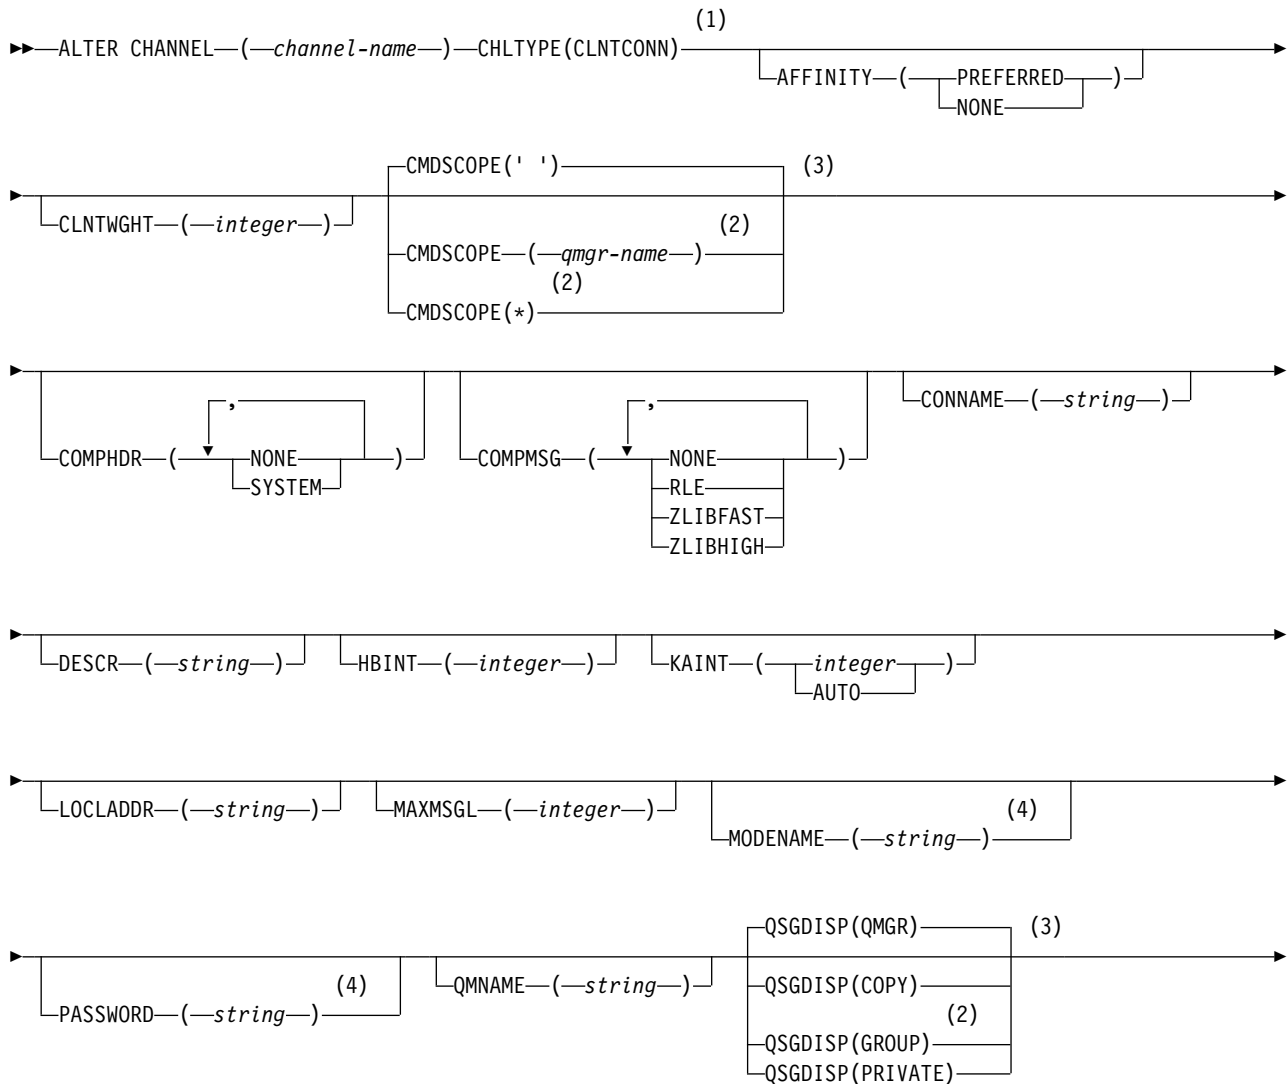

- 1 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Valid only on Windows.

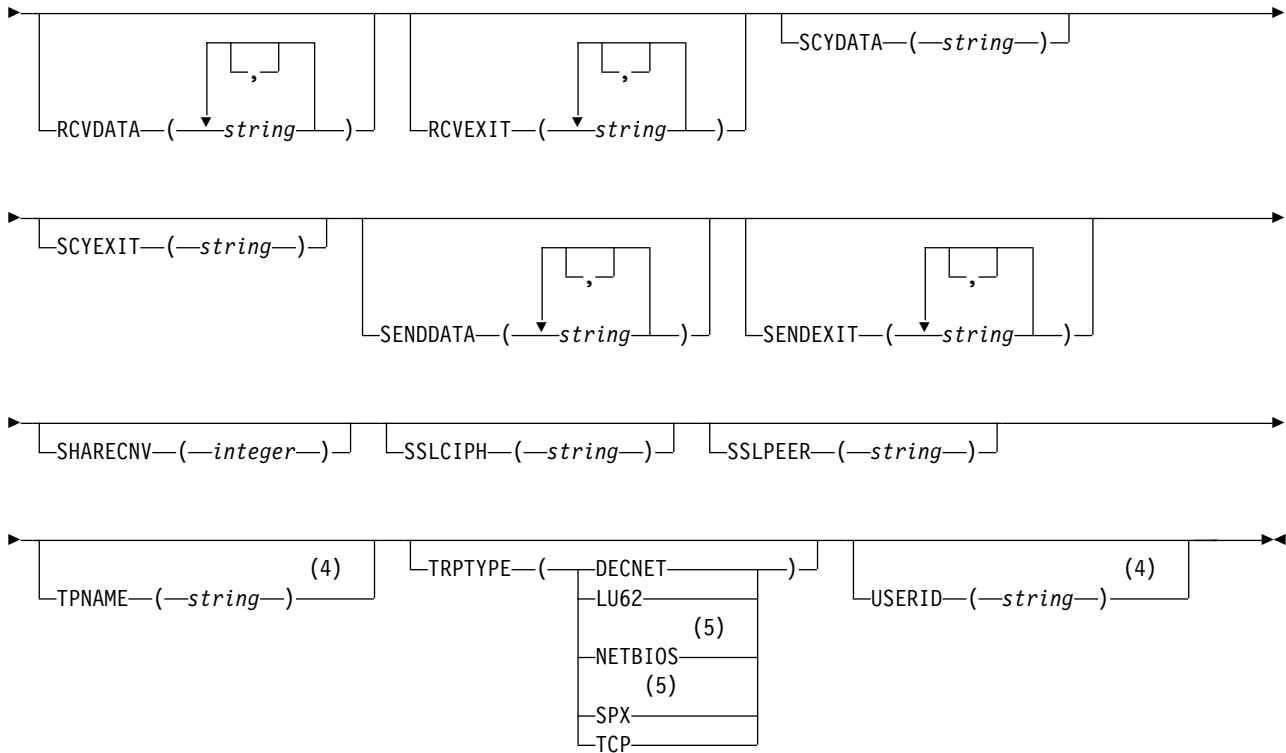

The parameters are described in “ALTER CHANNEL” on page 366.

*Client-connection channel:*

Syntax diagram for a client-connection channel when using the ALTER CHANNEL command.

**ALTER CHANNEL**

**Notes:**

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Valid only if TRPTYPE is LU62.
- 5 Valid only for clients to be run on DOS and Windows.

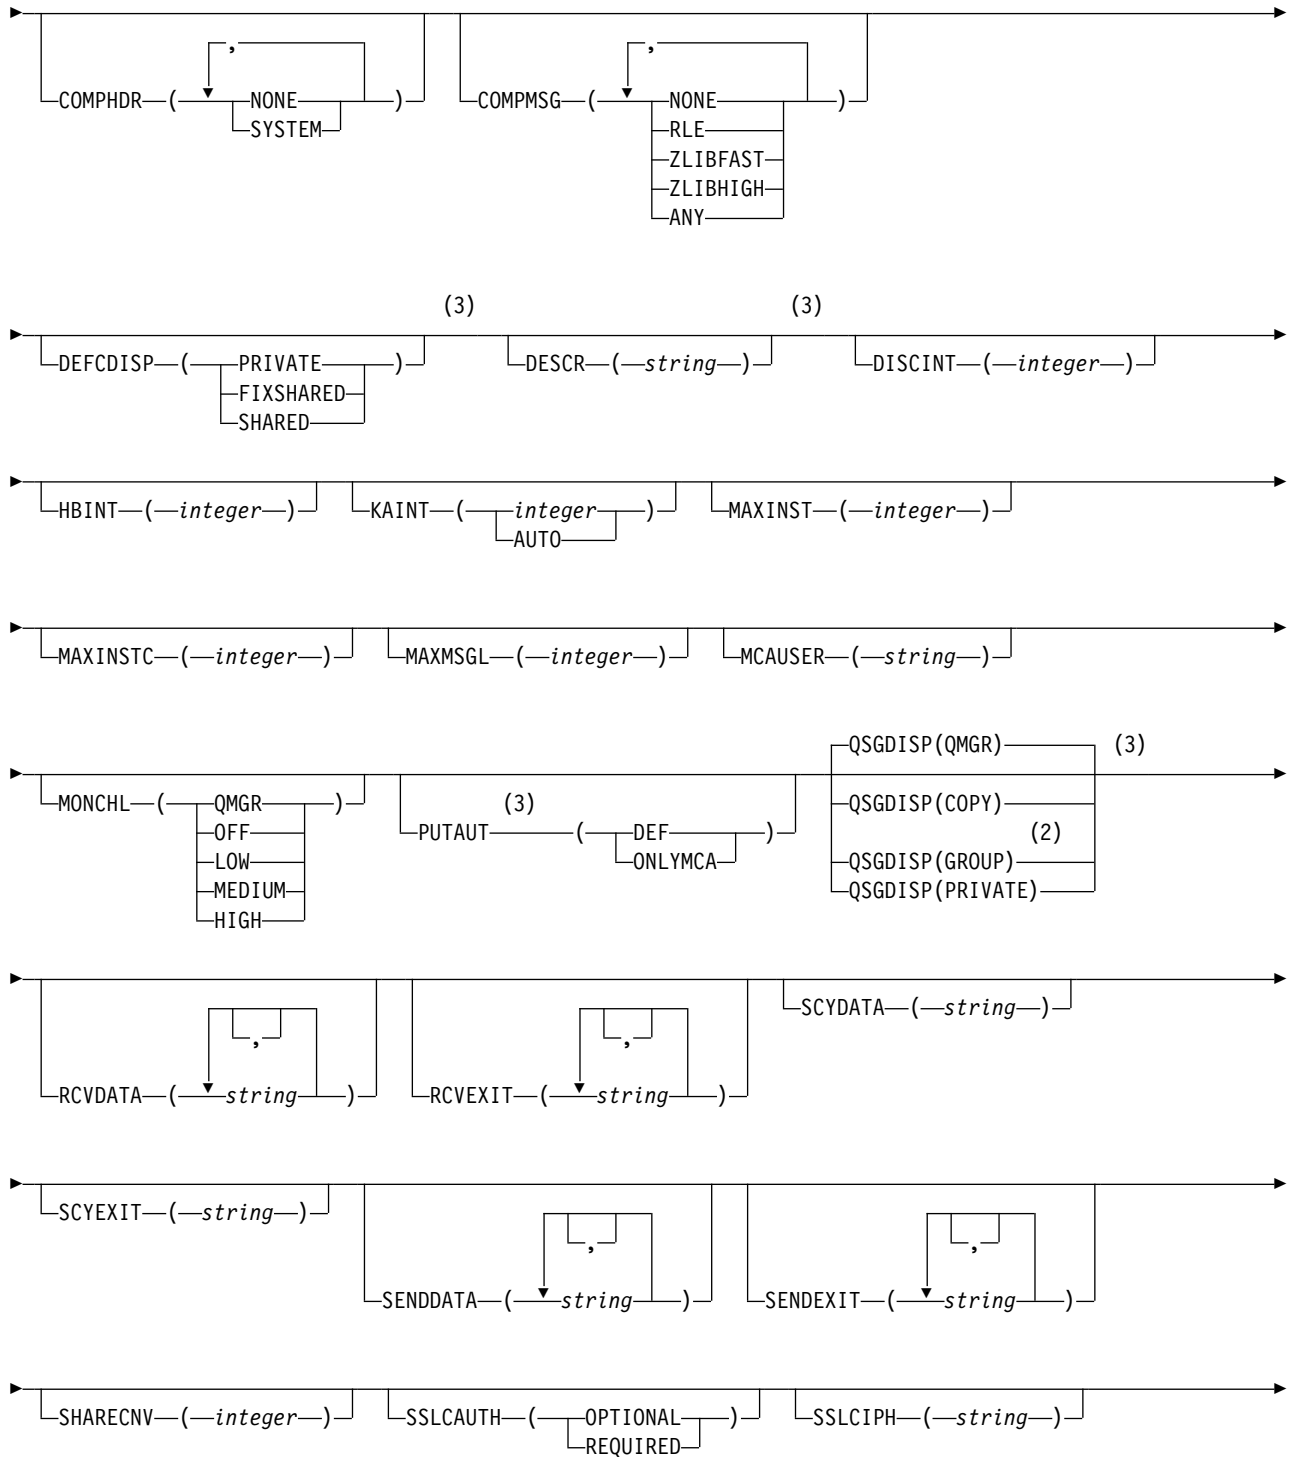

The parameters are described in "ALTER CHANNEL" on page 366.

*Server-connection channel:*

Syntax diagram for a server-connection channel when using the ALTER CHANNEL command.

**ALTER CHANNEL**

**Notes:**

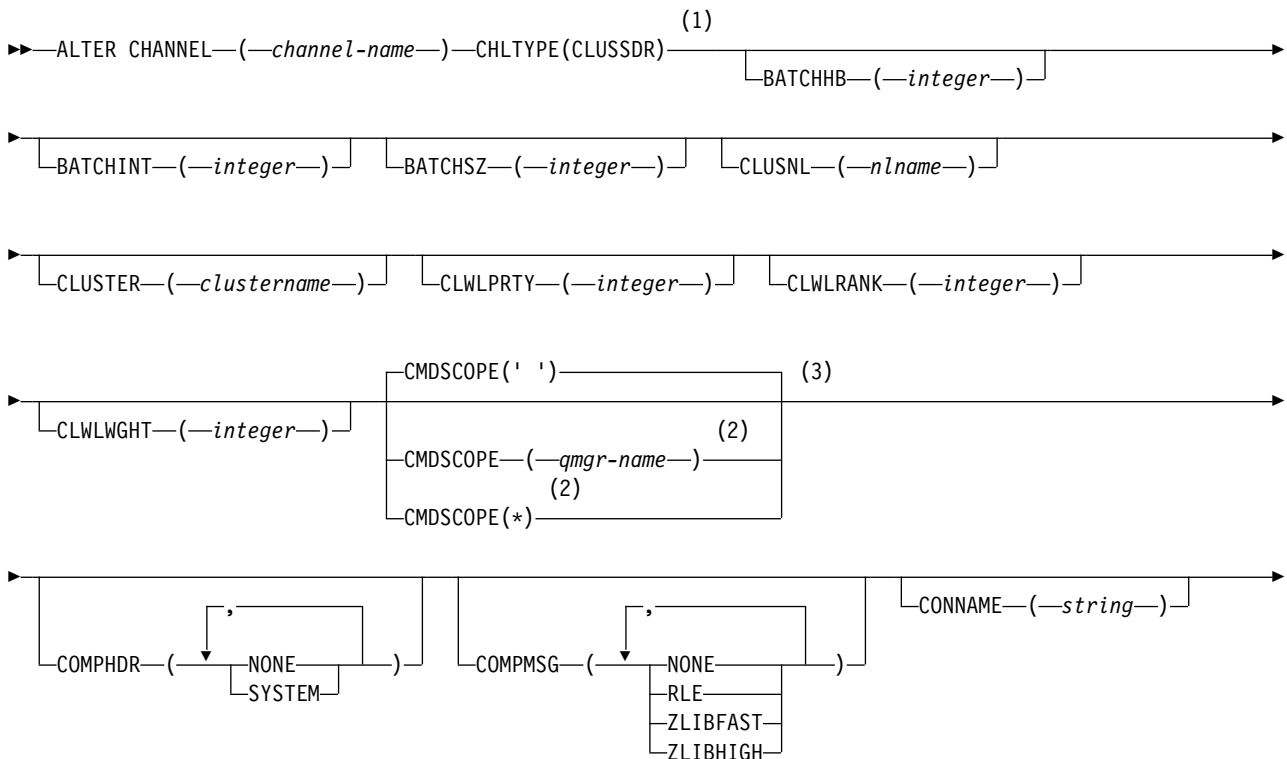

- 1 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Valid only for clients to be run on Windows.

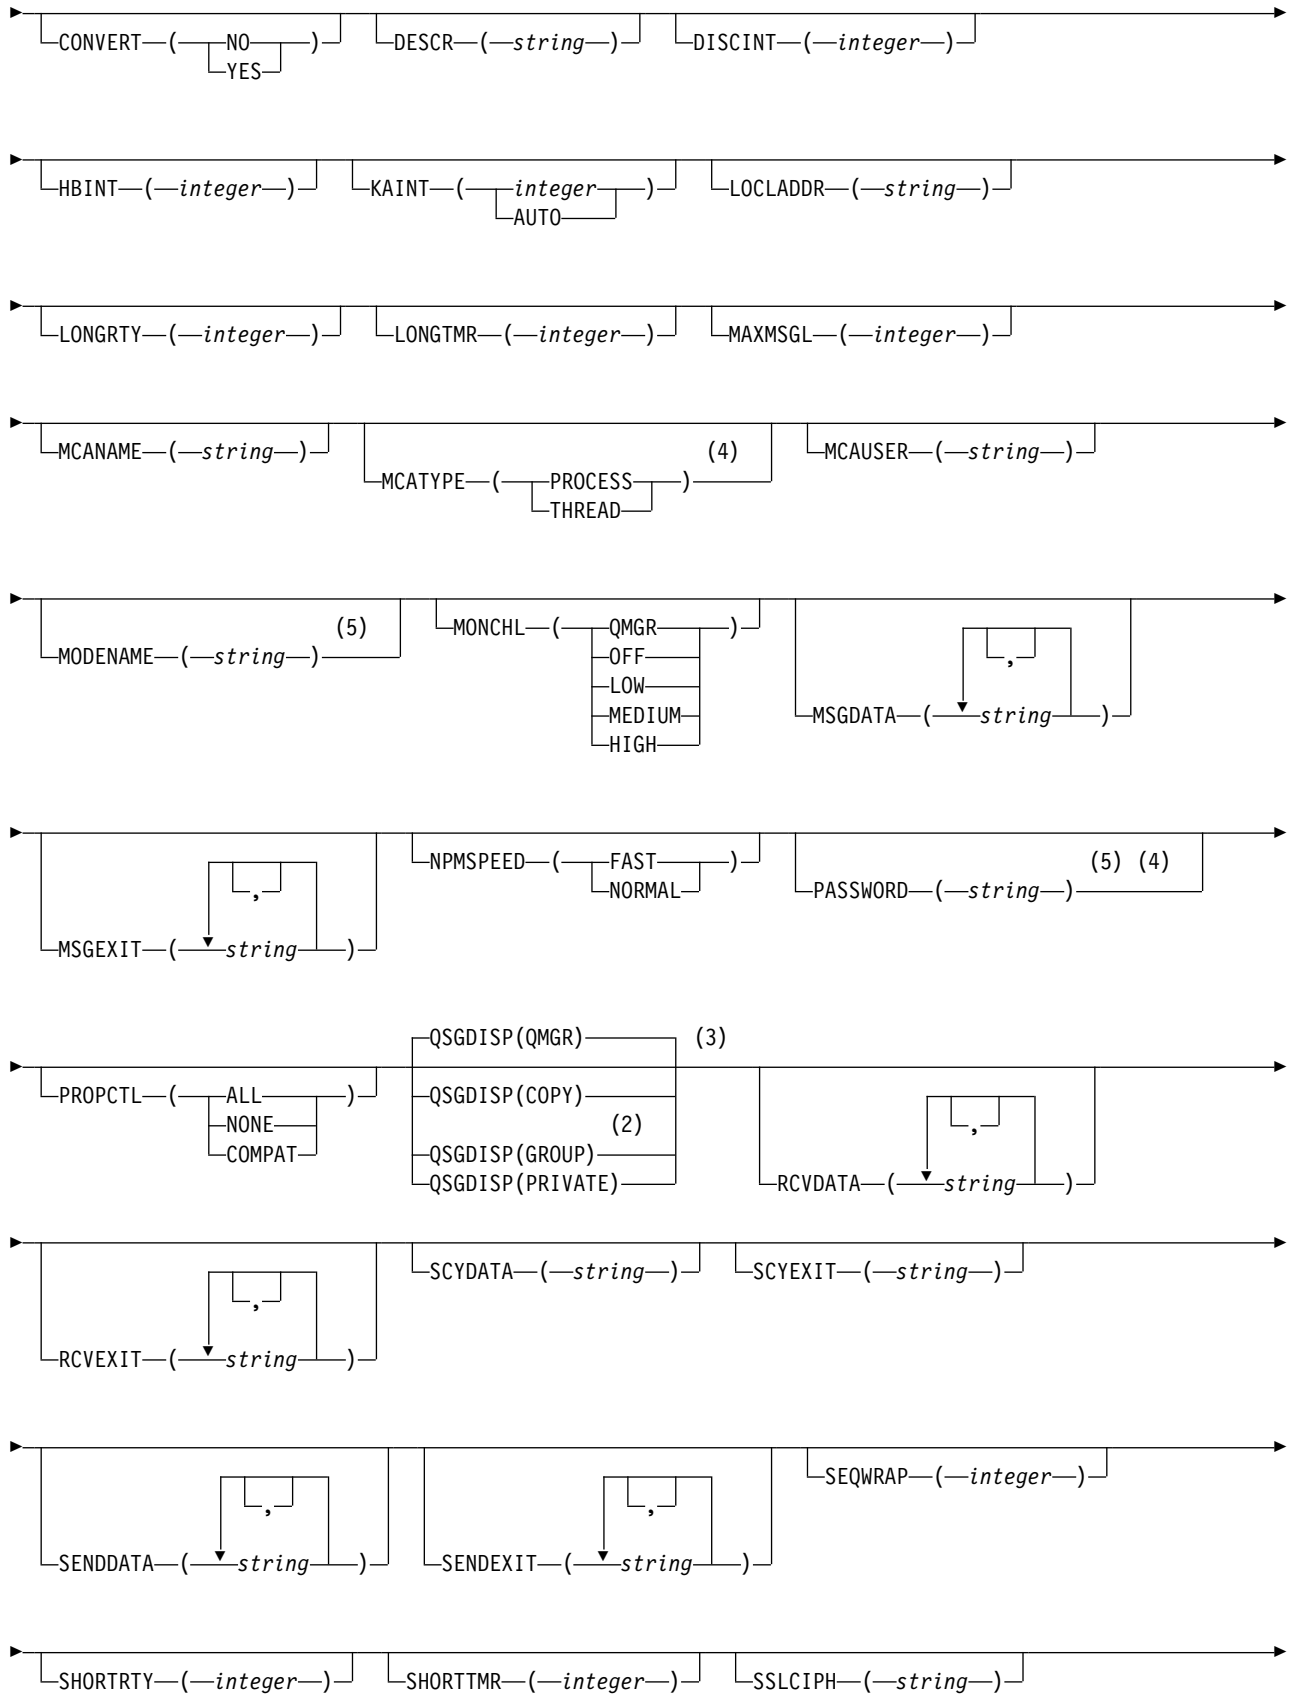

The parameters are described in “ALTER CHANNEL” on page 366.

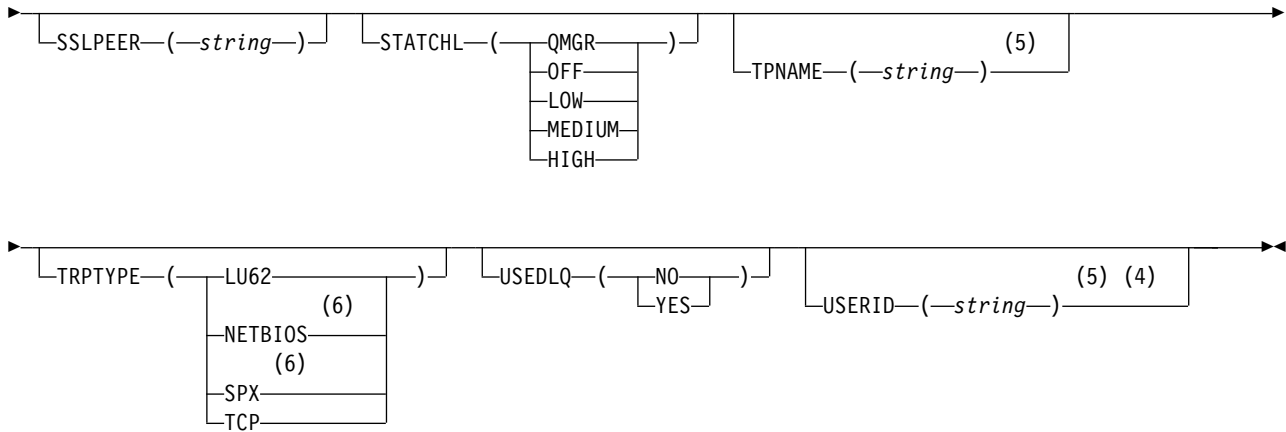

*Cluster-sender channel:*

Syntax diagram for a cluster-sender channel when using the ALTER CHANNEL command.

**ALTER CHANNEL**

**Notes:**

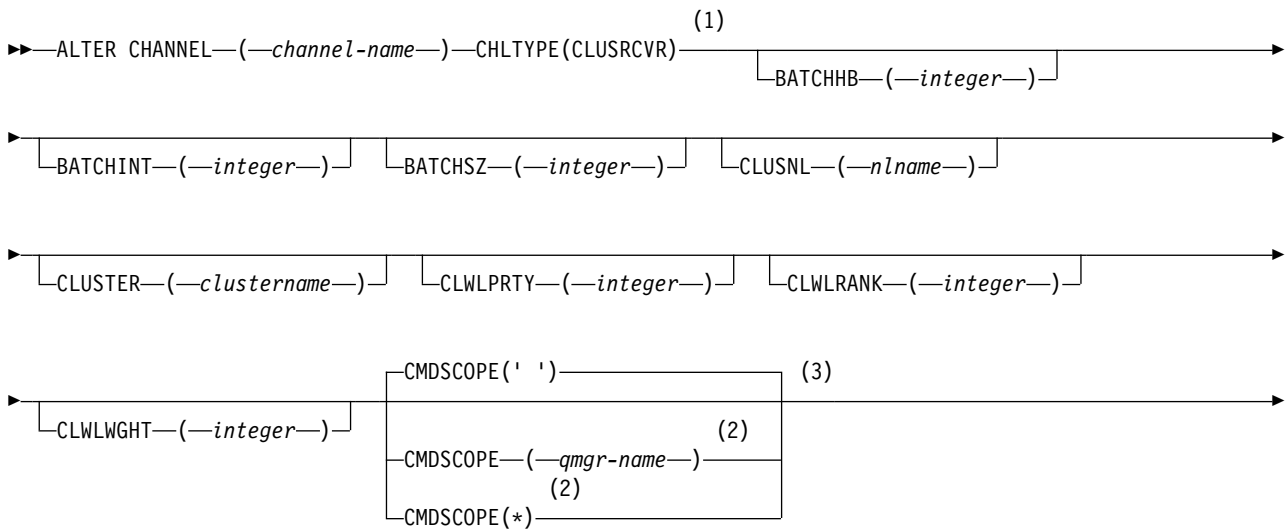

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Valid only Windows.

The parameters are described in "ALTER CHANNEL" on page 366.

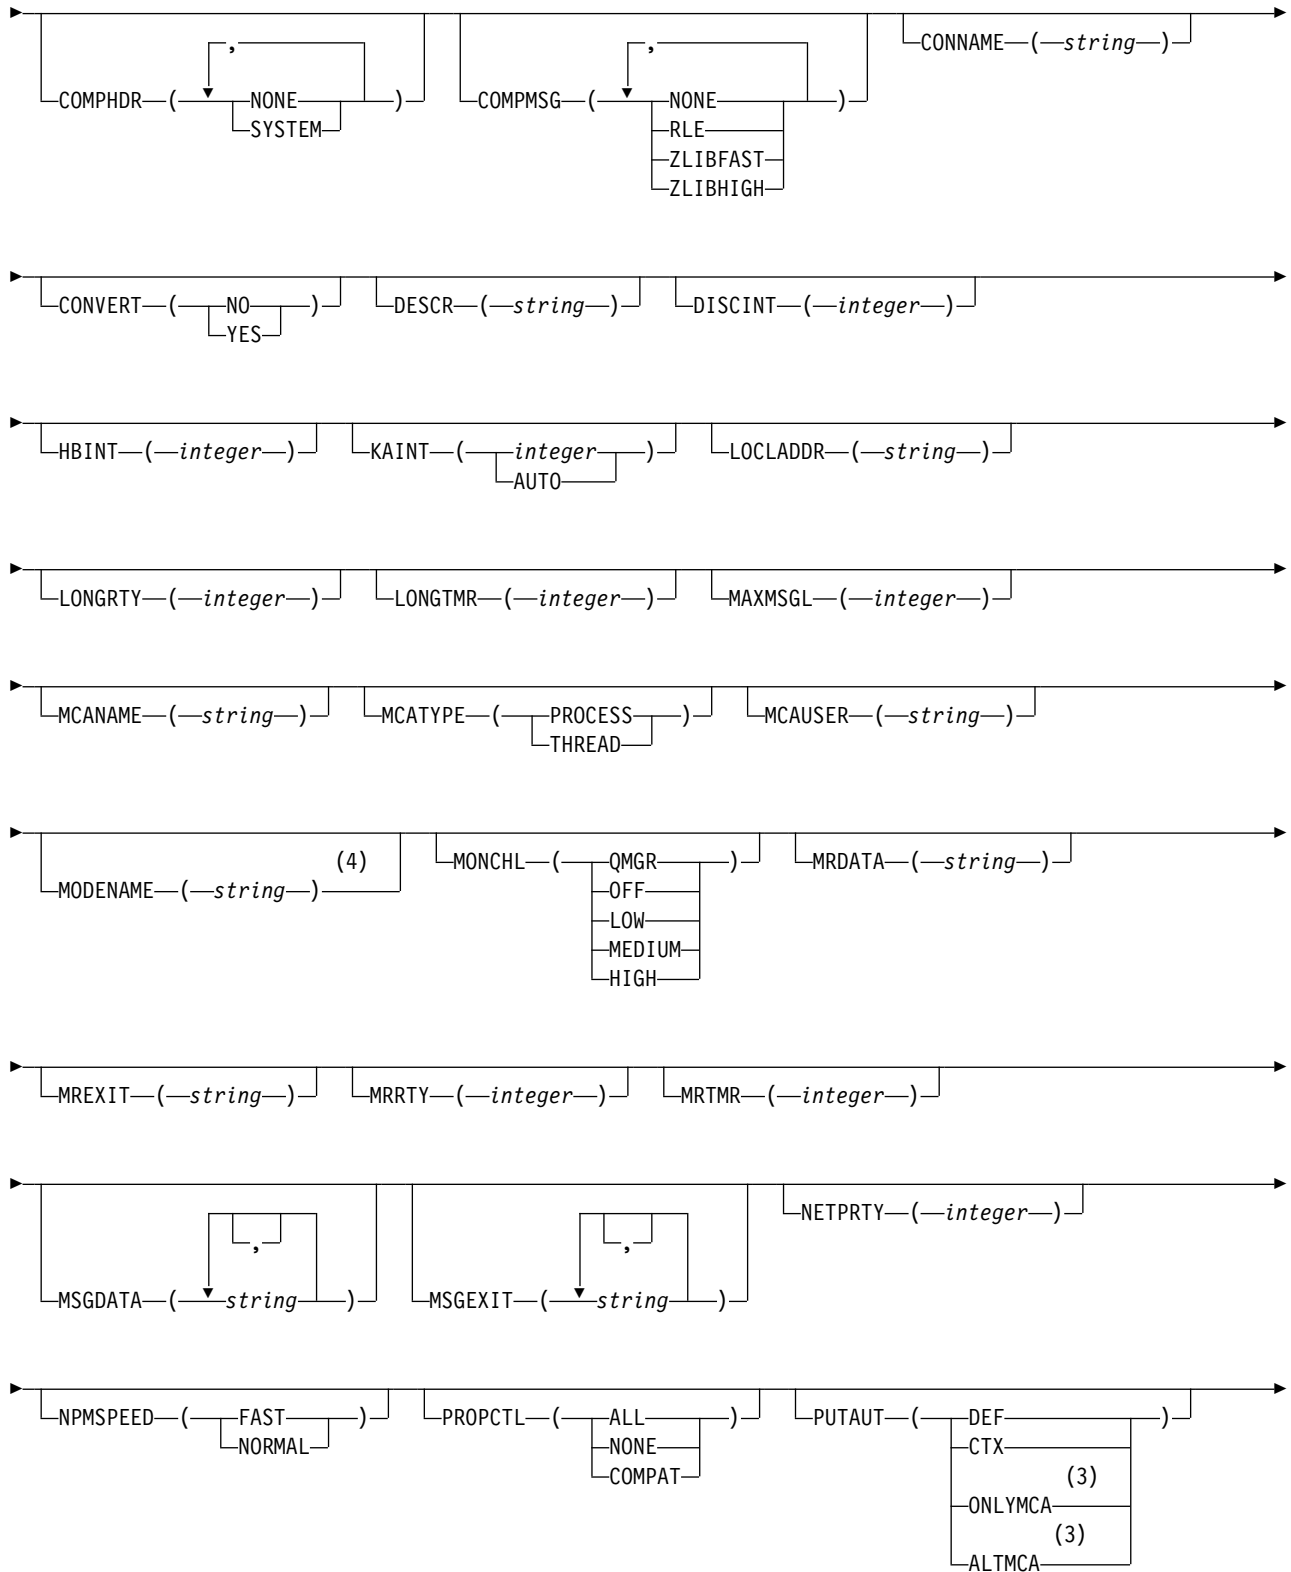

*Cluster-receiver channel:*

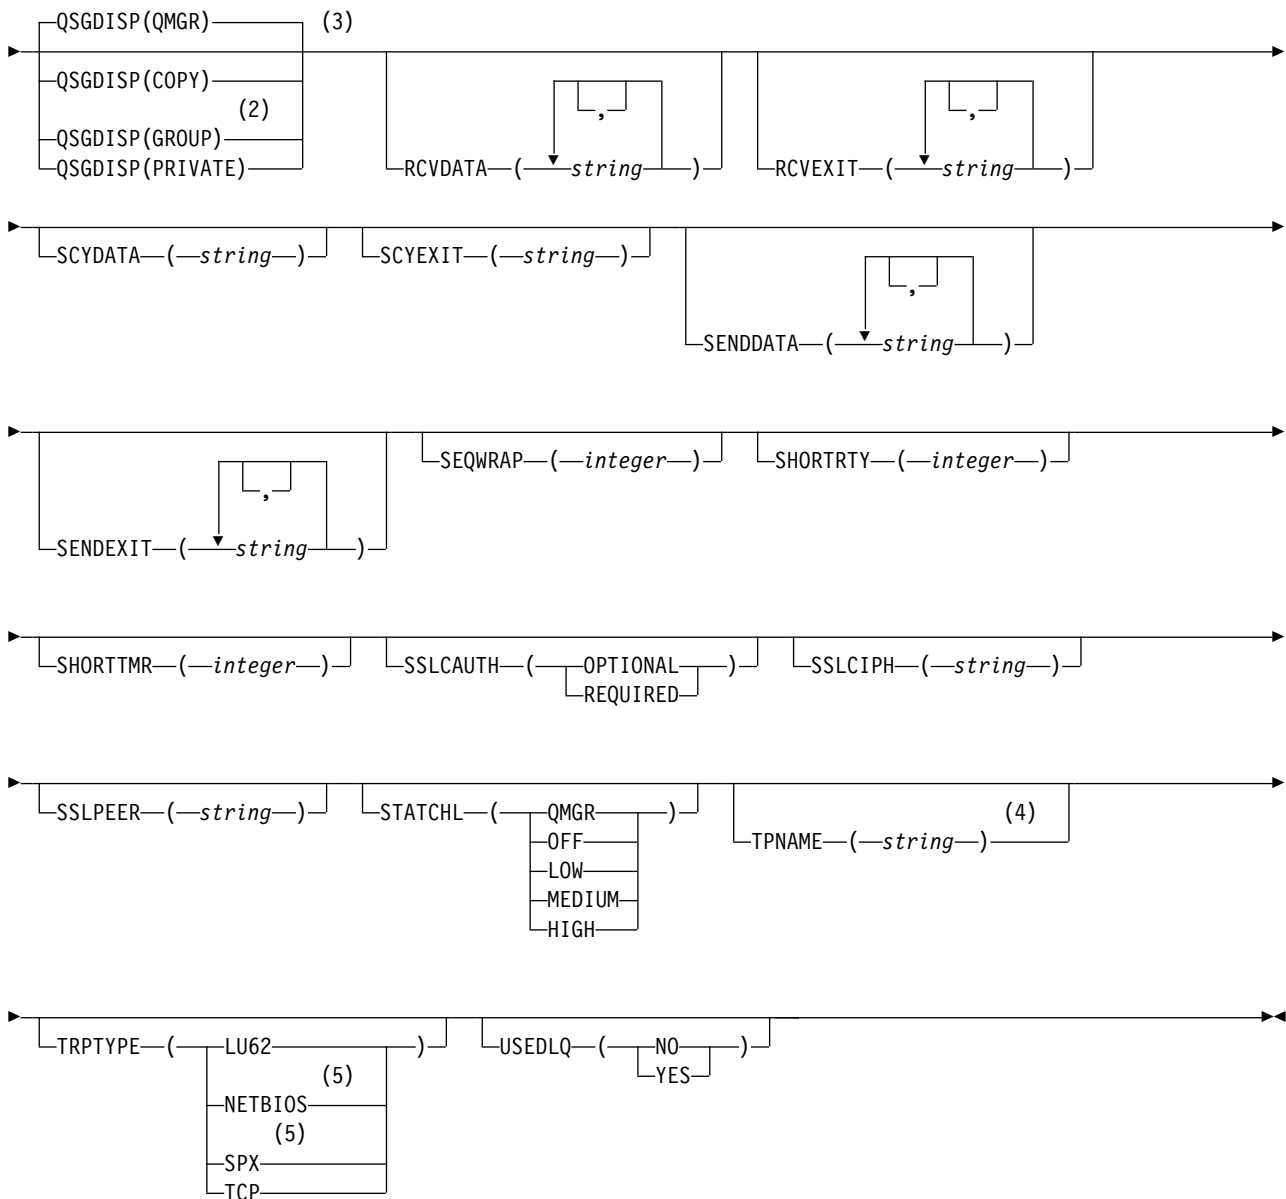

Syntax diagram for a cluster-receiver channel when using the ALTER CHANNEL command.

**ALTER CHANNEL**

**Notes:**

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Valid only if TRPTYPE is LU62.
- 5 Valid only on Windows.

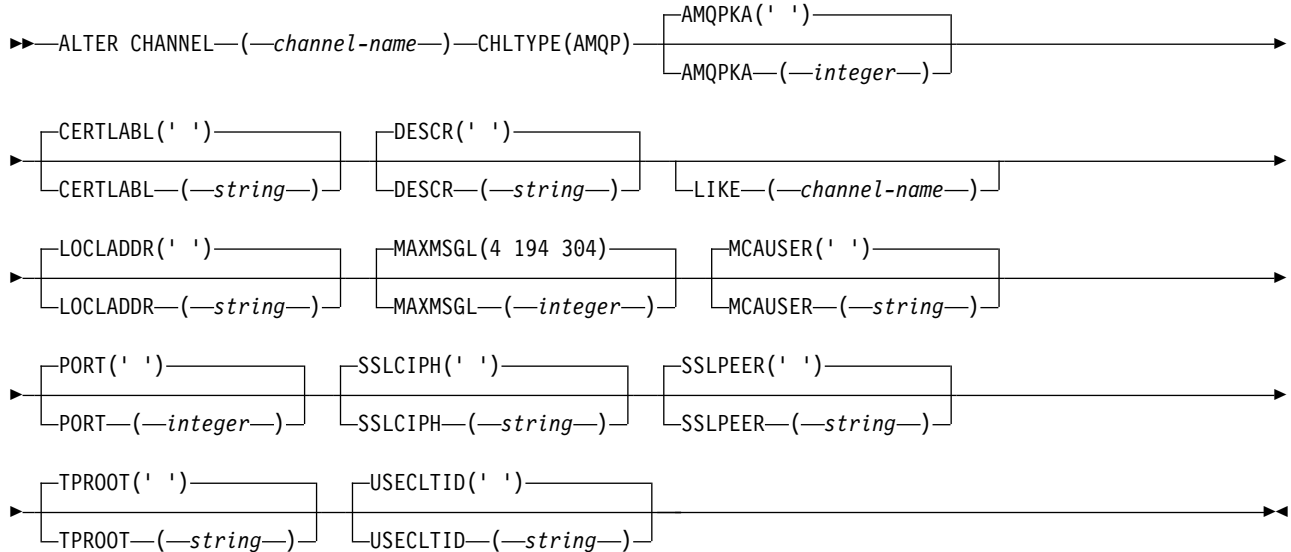

The parameters are described in "ALTER CHANNEL" on page 366.

AMQP channel: **distributed** **V8.0.0.4**

Syntax diagram for an AMQP channel when using the ALTER CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

### DEFINE CHANNEL

The parameters are described in “ALTER CHANNEL” on page 366.

### ALTER CHANNEL (MQTT):

Syntax diagram for a telemetry channel when using the ALTER CHANNEL command.

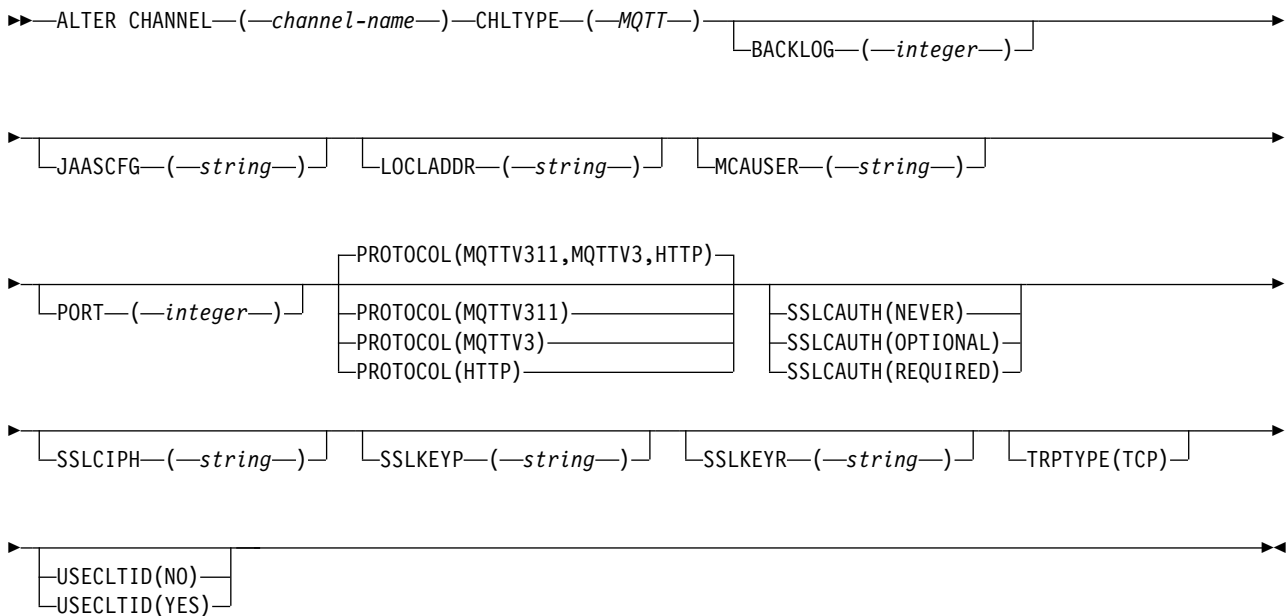

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	AIX and Linux	Windows	z/OS
	✓	✓	

**Note:** For the telemetry server, AIX is the only supported UNIX platform.

## ALTER CHANNEL ( MQTT )

### Usage notes

The telemetry (MQXR) service must be running when you issue this command. For instructions on how to start the telemetry (MQXR) service, see [Configuring a queue manager for telemetry on Linux](#) or [Configuring a queue manager for telemetry on Windows](#).

### Parameter descriptions for ALTER CHANNEL (MQTT)

*(channel-name)*

The name of the channel definition.

### BACKLOG ( integer )

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed.

The value is in the range 0 - 999999999.

The default value is 4096.

### CHLTYPE

Channel type. MQTT (telemetry) channel.

### JAASCFG ( string )

The name of a stanza in the JAAS configuration file.

See [Authenticating an MQTT client Java app with JAAS](#)

### LOCLADDR ( ip-addr )

LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of LOCLADDR is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

#### **ip-addr**

ip-addr is a single network address, specified in one of three forms:

##### **IPv4 dotted decimal**

For example 192.0.2.1

##### **IPv6 hexadecimal notation**

For example 2001:DB8:0:0:0:0:0:0

##### **Alphanumeric host name form**

For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

#### **MCAUSER ( *string* )**

Message channel agent user identifier.

The maximum length of the string is 64 characters on Windows and 12 characters on other platforms. On Windows, you can optionally qualify a user identifier with the domain name in the format user@domain.

If this parameter is nonblank, and **USECLNTID** is set to NO, then this user identifier is used by the telemetry service for authorization to access IBM MQ resources.

If this parameter is blank, and **USECLNTID** is set to NO, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

#### **PORT ( *integer* )**

The port number on which the telemetry (MQXR) service accepts client connections. The default port number for a telemetry channel is 1883; and the default port number for a telemetry channel secured using SSL is 8883. Specifying a port value of 0 causes MQTT to dynamically allocate an available port number.

#### **PROTOCOL**

The following communication protocols are supported by the channel:

##### **▶ V8.0.0.3 MQTTV311**

The channel accepts connections from clients using the protocol defined by the MQTT Version 3.1.1 Oasis standard. The functionality provided by this protocol is almost identical to that provided by the pre-existing MQTTV3 protocol.

**MQTTV3** The channel accepts connections from clients using the MQTT V3.1 Protocol Specification from mqtt.org.

**HTTP** The channel accepts HTTP requests for pages, or WebSockets connections to IBM MQ Telemetry.

To accept connections from clients using different protocols, specify the acceptable values as a comma-delimited list. For example if you specify MQTTV3,HTTP the channel accepts connections from clients using either MQTTV3 or HTTP. If you specify no client protocols, the channel accepts connections from clients using any of the supported protocols.

**▶ V8.0.0.3** If you are using IBM MQ Version 8.0.0, Fix Pack 3 or later, and your configuration includes an MQTT channel that was last modified in an earlier version of IBM MQ, you must explicitly change the protocol setting to prompt the channel to use the MQTTV311 option. This is so even if the channel does not specify any client protocols, because the specific protocols to use with the channel are stored at the time the channel is configured, and previous versions of the

product have no awareness of the MQTTV311 option. To prompt a channel in this state to use the MQTTV311 option, explicitly add the option then save your changes. The channel definition is now aware of the option. If you subsequently change the settings again, and specify no client protocols, the MQTTV311 option is still included in the stored list of supported protocols.

## SSLCAUTH

Defines whether IBM MQ requires a certificate from the SSL client. The initiating end of the channel acts as the SSL client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the SSL server.

**NEVER** IBM MQ never requests a certificate from the SSL client.

### REQUIRED

IBM MQ requires and validates a certificate from the SSL client.

### OPTIONAL

IBM MQ lets the SSL client decide whether to provide a certificate. If the client sends a certificate, the contents of this certificate are validated as normal.

## SSLCIPH (*string*)

When SSLCIPH is used with a telemetry channel, it means "SSL Cipher Suite". The SSL cipher suite is the one supported by the JVM that is running the telemetry (MQXR) service. If the SSLCIPH parameter is blank, no attempt is made to use SSL on the channel.

If you plan to use SHA-2 cipher suites, see System requirements for using SHA-2 cipher suites with MQTT channels.

## SSLKEYP (*string*)

The passphrase for the Secure Sockets Layer (SSL) key repository.

## SSLKEYR (*string*)

The full path name of the Secure Sockets Layer (SSL) key repository file, the store for digital certificates and their associated private keys. If you do not specify a key file, SSL is not used.

The maximum length of the string is 256 characters. On UNIX and Linux, the name is of the form *pathname/keyfile* and on Windows *pathname\keyfile*, where *keyfile* is specified without the suffix *.kdb*, and identifies a Java keystore file.

## TRPTYPE (*string*)

The transmission protocol to be used:

### TCP

TCP/IP.

## USECLTID

Decide whether you want to use the MQTT client ID for the new connection as the IBM MQ user ID for that connection. If this property is specified, the user name supplied by the client is ignored.

If you set this parameter to YES, then **MCAUSER** must be blank.

If **USECLTID** is set to NO, and **MCAUSER** is blank, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

**Related reference:**

“DEFINE CHANNEL (MQTT)” on page 610

Syntax diagram for a telemetry channel when using the **DEFINE CHANNEL** command.

**ALTER COMMINFO:**

Use the MQSC command ALTER COMMINFO to alter the parameters of a communication information object.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	✓

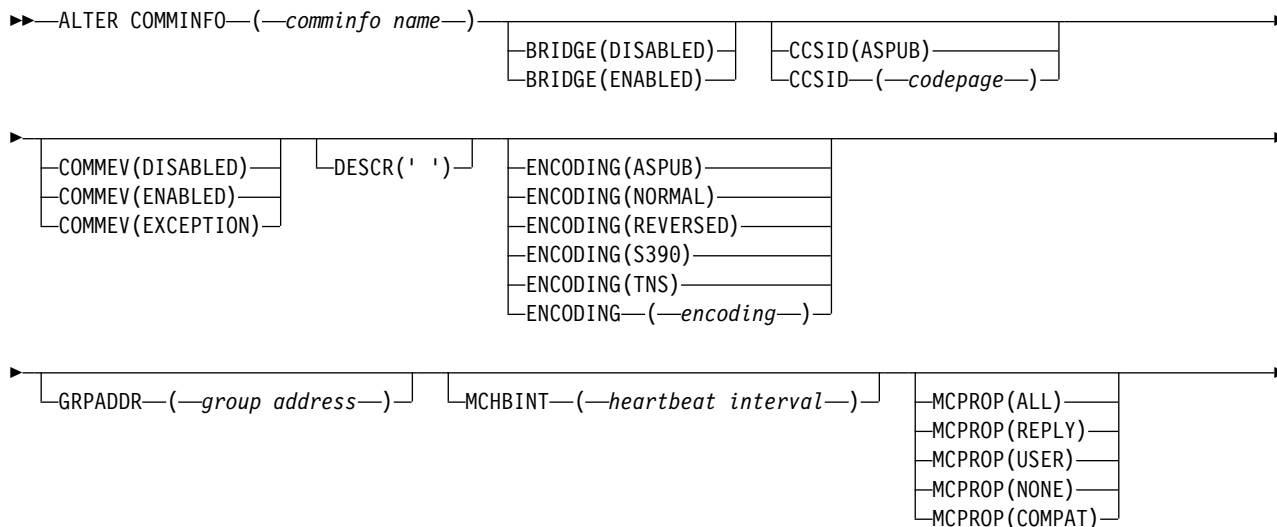

Parameters not specified in the ALTER COMMINFO command result in the existing values for those parameters being left unchanged.

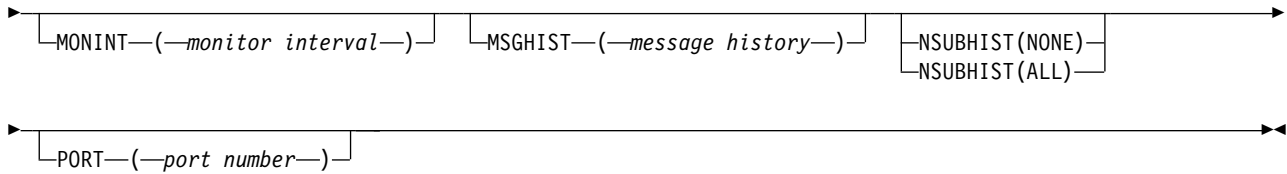

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for ALTER COMMINFO” on page 422

**Synonym:** ALT COMMINFO

**ALTER COMMINFO**

## Parameter descriptions for ALTER COMMINFO

(*comminfo name*)

Name of the communications information object. This parameter is required.

The name must not be the same as any other communications information object name currently defined on this queue manager. See Rules for naming IBM MQ objects.

### BRIDGE

Controls whether publications from applications not using Multicast are bridged to applications using Multicast. Bridging does not apply to topics that are marked as **MCAST(ONLY)**. As these topics can only be Multicast traffic, it is not applicable to bridge to the queue's publish/subscribe domain.

#### DISABLED

Publications from applications not using Multicast are not bridged to applications that do use Multicast.

#### ENABLED

Publications from applications not using Multicast are bridged to applications that do use Multicast.

### CCSID( *integer* )

The coded character set identifier that messages are transmitted on. Specify a value in the range 1 through 65535.

The CCSID must specify a value that is defined for use on your platform, and use a character set that is appropriate to the queue manager's platform. If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original CCSID therefore you must stop and restart all running applications before you continue. Running applications include the command server and channel programs. Stop and restart all running applications, stop and restart the queue manager after changing this parameter.

The CCSID can also be set to ASPUB which means that the coded character set is taken from that supplied in the published message.

### COMMEV

Controls whether event messages are generated for Multicast handles that are created using this COMMINFO object. Events will only be generated if they are enabled using the **MONINT** parameter.

#### DISABLED

Publications from applications not using Multicast are not bridged to applications that do use Multicast.

#### ENABLED

Publications from applications not using Multicast are bridged to applications that do use Multicast.

#### EXCEPTION

Event messages are written if the message reliability is below the reliability threshold. The reliability threshold is set to 90 by default.

**DESCR**( *string* )

Plain-text comment. It provides descriptive information about the communication information object when an operator issues the DISPLAY COMMINFO command (see “DISPLAY COMMINFO” on page 798 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**ENCODING**

The encoding that the messages are transmitted in.

**AS PUB**

The encoding of the message is taken from that supplied in the published message.

**NORMAL****REVERSED****S390****TNS*****encoding*****GRPADDR**

The group IP address or DNS name.

It is the responsibility of the administrator to manage the group addresses. It is possible for all multicast clients to use the same group address for every topic; only the messages that match outstanding subscriptions on the client are delivered. Using the same group address can be inefficient because every client has to examine and process every multicast packet in the network. It is more efficient to allocate different IP group addresses to different topics or sets of topics, but this allocation requires careful management, especially if other non-MQ multicast applications are in use on the network.

**MCHBINT**

The heartbeat interval is measured in milliseconds, and specifies the frequency at which the transmitter notifies any receivers that there is no further data available.

**MCPROP**

The multicast properties control how many of the MQMD properties and user properties flow with the message.

**A11**

All user properties and all the fields of the MQMD are transported.

**Reply**

Only user properties, and MQMD fields that deal with replying to the messages, are transmitted. These properties are:

- MsgType
- MessageId
- CorrelId
- ReplyToQ
- ReplyToQmgr

**User**

Only the user properties are transmitted.

**NONE**

No user properties or MQMD fields are transmitted.

**COMPAT**

This value causes the transmission of the message to be done in a compatible mode to RMM allowing some inter-operation with the current XMS applications and Broker RMM applications.

**MONINT( *integer* )**

How frequently, in seconds, that monitoring information is updated. If events messages are enabled, this parameter also controls how frequently event messages are generated about the status of the Multicast handles created using this COMMINFO object.

A value of 0 means that there is no monitoring.

**MSGHIST**

The maximum message history is the amount of message history that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

A value of 0 gives the least level of reliability.

**NSUBHIST**

The new subscriber history controls whether a subscriber joining a publication stream receives as much data as is currently available, or receives only publications made from the time of the subscription.

**NONE**

A value of NONE causes the transmitter to transmit only publication made from the time of the subscription.

**ALL**

A value of ALL causes the transmitter to retransmit as much history of the topic as is known. In some circumstances, this retransmission can give a similar behavior to retained publications.

**Note:** Using the value of ALL might have a detrimental effect on performance if there is a large topic history because all the topic history is retransmitted.

**PORT( *integer* )**

The port number to transmit on.

**ALTER LISTENER:**

Use MQSC command ALTER LISTENER to alter the parameters of an existing IBM MQ listener definition. If the listener is already running, any changes you make to its definition are effective only after the next time that the listener is started.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

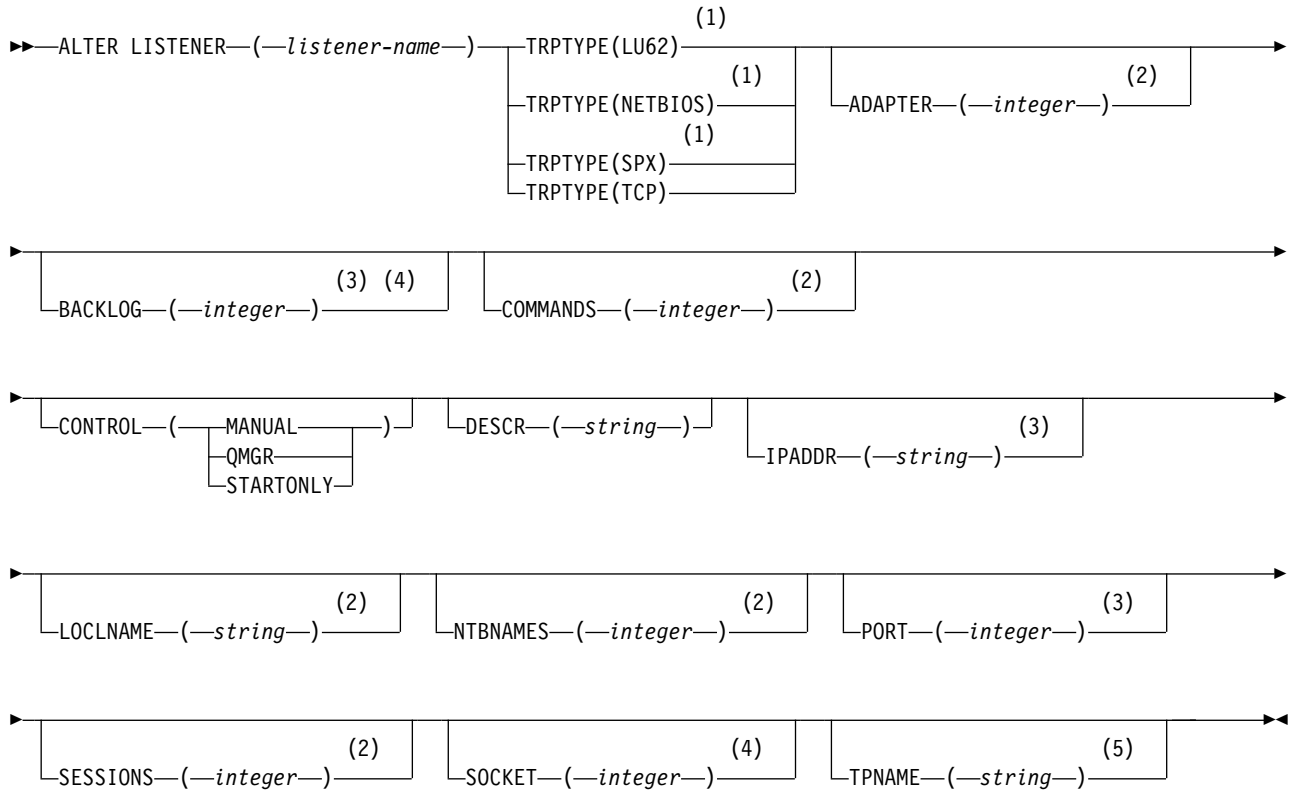

Parameters not specified in the ALTER LISTENER command result in the existing values for those parameters being left unchanged.

- Syntax diagram

- “Parameter descriptions for ALTER LISTENER”

Synonym: ALT LSTR

## ALTER LISTENER

### Notes:

- 1 Valid only on Windows.
- 2 Valid only on Windows when TRPTYPE is NETBIOS.
- 3 Valid when TRPTYPE is TCP.
- 4 Valid on Windows when TRPTYPE is SPX.
- 5 Valid only on Windows when TRPTYPE is LU62.

### Parameter descriptions for ALTER LISTENER

(*listener-name*)

Name of the IBM MQ listener definition (see Rules for naming IBM MQ objects ). This is required.

The name must not be the same as any other listener definition currently defined on this queue manager (unless REPLACE is specified).

**ADAPTER**( *integer* )

The adapter number on which NetBIOS listens. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**BACKLOG**( *integer* )

The number of concurrent connection requests that the listener supports.

**COMMANDS( *integer* )**

The number of commands that the listener can use. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**CONTROL( *string* )**

Specifies how the listener is to be started and stopped.:

**MANUAL**

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the START LISTENER and STOP LISTENER commands.

**QMGR**

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

**STARTONLY**

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

**DESCR( *string* )**

Plain-text comment. It provides descriptive information about the listener when an operator issues the DISPLAY LISTENER command (see "DISPLAY LISTENER" on page 816 ).

It should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**IPADDR( *string* )**

IP address for the listener specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric host name form. If you do not specify a value for this parameter, the listener listens on all configured IPv4 and IPv6 stacks.

**LIKE( *listener-name* )**

The name of a listener, with parameters that are used to model this definition.

This parameter applies only to the DEFINE LISTENER command.

If this field is not filled in, and you do not complete the parameter fields related to the command, the values are taken from the default definition for listeners on this queue manager. This is equivalent to specifying:

```
LIKE(SYSTEM.DEFAULT.LISTENER)
```

A default listener is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

**LOCLNAME( *string* )**

The NetBIOS local name that the listener uses. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**NTBNAMES( *integer* )**

The number of names that the listener can use. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**PORT( *integer* )**

The port number for TCP/IP. This is valid only when TRPTYPE is TCP. It must not exceed 65535.

**SESSIONS( *integer* )**

The number of sessions that the listener can use. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**SOCKET( integer )**

The SPX socket on which to listen. This is valid only if TRPTYPE is SPX.

**TPNAME( string )**

The LU 6.2 transaction program name (maximum length 64 characters). This parameter is valid only on Windows when TRPTYPE is LU62.

**TRPTYPE( string )**

The transmission protocol to be used:

**LU62**

SNA LU 6.2. This is valid only on Windows.

**NETBIOS**

NetBIOS. This is valid only on Windows.

**SPX**

Sequenced packet exchange. This is valid only on Windows.

**TCP**

TCP/IP.

**ALTER NAMELIST:**

Use the MQSC command ALTER NAMELIST to alter a list of names. This list is most commonly a list of cluster names or queue names.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

Parameters not specified in the ALTER NAMELIST command result in the existing values for those parameters being left unchanged.

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes” on page 428
- “Parameter descriptions for ALTER NAMELIST” on page 428

**Synonym:** ALT NL

**ALTER NAMELIST**

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Usage notes

- On UNIX systems, the command is valid only on AIX, HP-UX, Linux and Solaris.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER NAMESPACE step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for ALTER NAMESPACE

*(name)*

Name of the list.

The name must not be the same as any other namespace name currently defined on this queue manager (unless REPLACE or ALTER is specified). See Rules for naming IBM MQ objects.

#### z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of specifying \* is the same as entering the command on every queue manager in the queue-sharing group.

**DESCR** (*string* )

Plain-text comment. It provides descriptive information about the namespace when an operator issues the DISPLAY NAMESPACE command (see "DISPLAY NAMESPACE" on page 826 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**NAMES**( *name, ...* )

List of names.

The names can be of any type, but must conform to the rules for naming IBM MQ objects, with a maximum length of 48 characters.

An empty list is valid: specify NAMES(). The maximum number of names in the list is 256.

#### NLTYPE

Indicates the type of names in the namelist.

This parameter is valid only on z/OS.

#### NONE

The names are of no particular type.

#### QUEUE or Q

A namelist that holds a list of queue names.

#### CLUSTER

A namelist that is associated with clustering, containing a list of the cluster names.

#### AUTHINFO

This namelist is associated with SSL and contains a list of authentication information object names.

Namelist used for clustering must have NLTYPE(CLUSTER) or NLTYPE(NONE).

Namelist used for SSL must have NLTYPE(AUTHINFO).

#### z/OS QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	ALTER
<b>COPY</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.
<b>GROUP</b>	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE NAMELIST(name) REPLACE QSGDISP(COPY)</pre> <p>The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
<b>PRIVATE</b>	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY). Any object residing in the shared repository is unaffected.
<b>QMGR</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

## ALTER PROCESS:

Use the MQSC command ALTER PROCESS to alter the parameters of an existing IBM MQ process definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

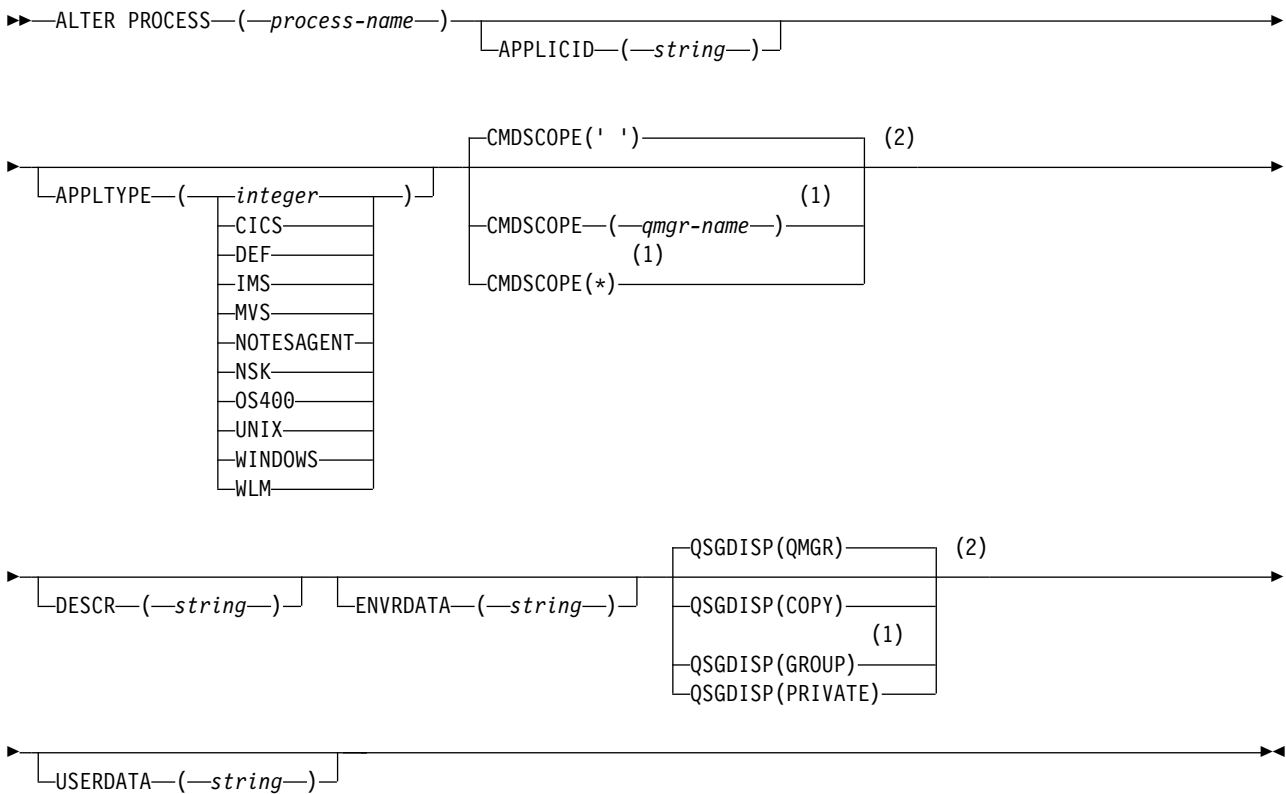

Parameters not specified in the ALTER PROCESS command result in the existing values for those parameters being left unchanged.

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for ALTER PROCESS” on page 431

**Synonym:** ALT PRO

## ALTER PROCESS

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

2 Valid only on z/OS.

### Parameter descriptions for ALTER PROCESS

(*process-name*)

Name of the IBM MQ process definition (see Rules for naming IBM MQ objects ). *process-name* is required.

The name must not be the same as any other process definition currently defined on this queue manager (unless REPLACE is specified).

**APPLICID**( *string* )

The name of the application to be started. The name might typically be a fully qualified file name of an executable object. Qualifying the file name is particularly important if you have multiple IBM MQ installations, to ensure the correct version of the application is run. The maximum length is 256 characters.

For a CICS application the name is a CICS transaction ID, and for an IMS™ application it is an IMS transaction ID.

▶ **z/OS** On z/OS, for distributed queuing, it must be "CSQX start".

**APPLTYPE**( *string* )

The type of application to be started. Valid application types are:

**integer**

A system-defined application type in the range zero through 65 535 or a user-defined application type in the range 65 536 through 999 999 999.

For certain values in the system range, a parameter from the following list can be specified instead of a numeric value:

**CICS** Represents a CICS transaction.

▶ **z/OS** **IMS**  
Represents an IMS transaction.

▶ **z/OS** **MVS**  
Represents a z/OS application (batch or TSO).

**NOTESAGENT**  
Represents a Lotus Notes® agent.

**NSK** Represents an HP Integrity NonStop Server application.

**OS400**  
Represents an IBM i application.

**UNIX** Represents a UNIX application.

**WINDOWS**  
Represents a Windows application.

▶ **z/OS** **WLM**  
Represents a z/OS workload manager application.

**DEF** Specifying DEF causes the default application type for the platform at which the command is interpreted to be stored in the process definition. This default cannot be changed by the installation. If the platform supports clients, the default is interpreted as the default application type of the server.

Only use application types (other than user-defined types) that are supported on the platform at which the command is executed:

- ▶ **z/OS** On z/OS, CICS, IMS, MVS, UNIX, WINDOWS, WLM, and DEF are supported

- On IBM i, OS400, CICS, and DEF are supported
- On UNIX systems, UNIX, WINDOWS, CICS, and DEF are supported
- On Windows, WINDOWS, UNIX, CICS, and DEF are supported

z/OS

## CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

In a shared queue environment, you can provide a different queue manager name from the one you are using to enter the command. The command server must be enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect is the same as entering the command on every queue manager in the queue-sharing group.

## DESCR( *string* )

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY PROCESS command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** Use characters from the coded character set identifier (CCSID) for this queue manager. Other characters might be translated incorrectly if the information is sent to another queue manager.

## ENVRDATA( *string* )

A character string that contains environment information pertaining to the application to be started. The maximum length is 128 characters.

The meaning of ENVRDATA is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends ENVRDATA to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by ENVRDATA with trailing blanks removed.

### **Note:**

1. On z/OS, ENVRDATA is not used by the trigger-monitor applications provided by IBM MQ.
2. On z/OS, if APPLTYPE is WLM, the default values for the ServiceName and ServiceStep fields in the work information header (MQWIH) can be supplied in ENVRDATA. The format must be:

```
SERVICENAME=servname,SERVICESTEP=stepname
```

where:

#### **SERVICENAME=**

is the first 12 characters of ENVRDATA.

#### **servname**

is a 32-character service name. It can contain embedded blanks or any other data, and have trailing blanks. It is copied to the MQWIH as is.

#### **SERVICESTEP=**

is the next 13 characters of ENVRDATA.

**stepname**

is a 1 - 8 character service step name. It is copied as-is to the MQWIH, and padded to eight characters with blanks.

If the format is incorrect, the fields in the MQWIH are set to blanks.

- 3. On UNIX systems, ENVRDATA can be set to the ampersand character to make the started application run in the background.

**z/OS QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	ALTER
<b>COPY</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.
<b>GROUP</b>	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). On the page set of the queue manager that executes the command, only a local copy of the object is altered by this command. If the command is successful, the following command is generated.  <pre>DEFINE PROCESS(process-name) REPLACE QSGDISP(COPY)</pre> <p>The command is sent to all active queue managers in the queue-sharing group to attempt to refresh local copies on page set zero. The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
<b>PRIVATE</b>	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY). Any object residing in the shared repository is unaffected.
<b>QMGR</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

**USERDATA( string )**

A character string that contains user information pertaining to the application defined in the APPLICID that is to be started. The maximum length is 128 characters.

The meaning of USERDATA is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ simply passes USERDATA to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing USERDATA), followed by one blank, followed by ENVRDATA with trailing blanks removed.

For IBM MQ message channel agents, the format of this field is a channel name of up to 20 characters. See Managing objects for triggering for information about what APPLICID to provide to message channel agents.

For Microsoft Windows, the character string must not contain double quotation marks if the process definition is going to be passed to **runmqtrm**.

## ALTER PSID: z/OS

Use the MQSC command ALTER PSID to change the expansion method for a page set.

### Using MQSC commands

For information on how you use MQSC commands, see [Performing local administration tasks using MQSC commands](#).

IBM i	UNIX and Linux	Windows	z/OS
			CR

Parameters not specified in the ALTER PSID command result in the existing values for those parameters being left unchanged.

z/OS For an explanation of the symbols in the z/OS column, see [Using commands on z/OS](#).

- Syntax diagram
- “Parameter descriptions for ALTER PSID”

**Synonym:** ALT PSID

### ALTER PSID

### Parameter descriptions for ALTER PSID

*(psid-number)*

Identifier of the page set. This is required.

#### EXPAND

Controls how the queue manager should expand a page set when it becomes nearly full, and further pages are required in it.

#### USER

The secondary extent size that was specified when the page set was defined is used. If no secondary extent size was specified, or if it was specified as zero, then no dynamic page set expansion can take place.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set. Only one extent is required to reach this size.

#### SYSTEM

A secondary extent size that is approximately 10 per cent of the current size of the page set is used. It might be rounded up depending on the characteristics of the DASD.

The secondary extent size that was specified when the page set was defined is ignored; dynamic expansion can occur if it was zero or not specified.

#### NONE

No further page set expansion is to take place.

## Usage note

You can use ALTER PSID to reset an internal IBM MQ indicator that prevents the pageset from being expanded; for example, once the data set has been ALTERed to ADDVOLUMES.

In this instance, although the EXPAND keyword must be specified with a value, you do not have to change the value from that already configured. For example, if DISPLAY USAGE shows pageset 3 configured with EXPAND(SYSTEM), you issue the command ALTER PSID(3) EXPAND(SYSTEM) to allow IBM MQ to retry pageset expansion.

## ALTER QMGR:

Use the MQSC command **ALTER QMGR** to alter the queue manager parameters for the local queue manager.

## Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

Parameters not specified in the **ALTER QMGR** command result in the existing values for those parameters being left unchanged.

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

This information is divided into three sections:

- “ALTER QMGR”
- “Parameter descriptions for ALTER QMGR” on page 439
- “Queue manager parameters” on page 439

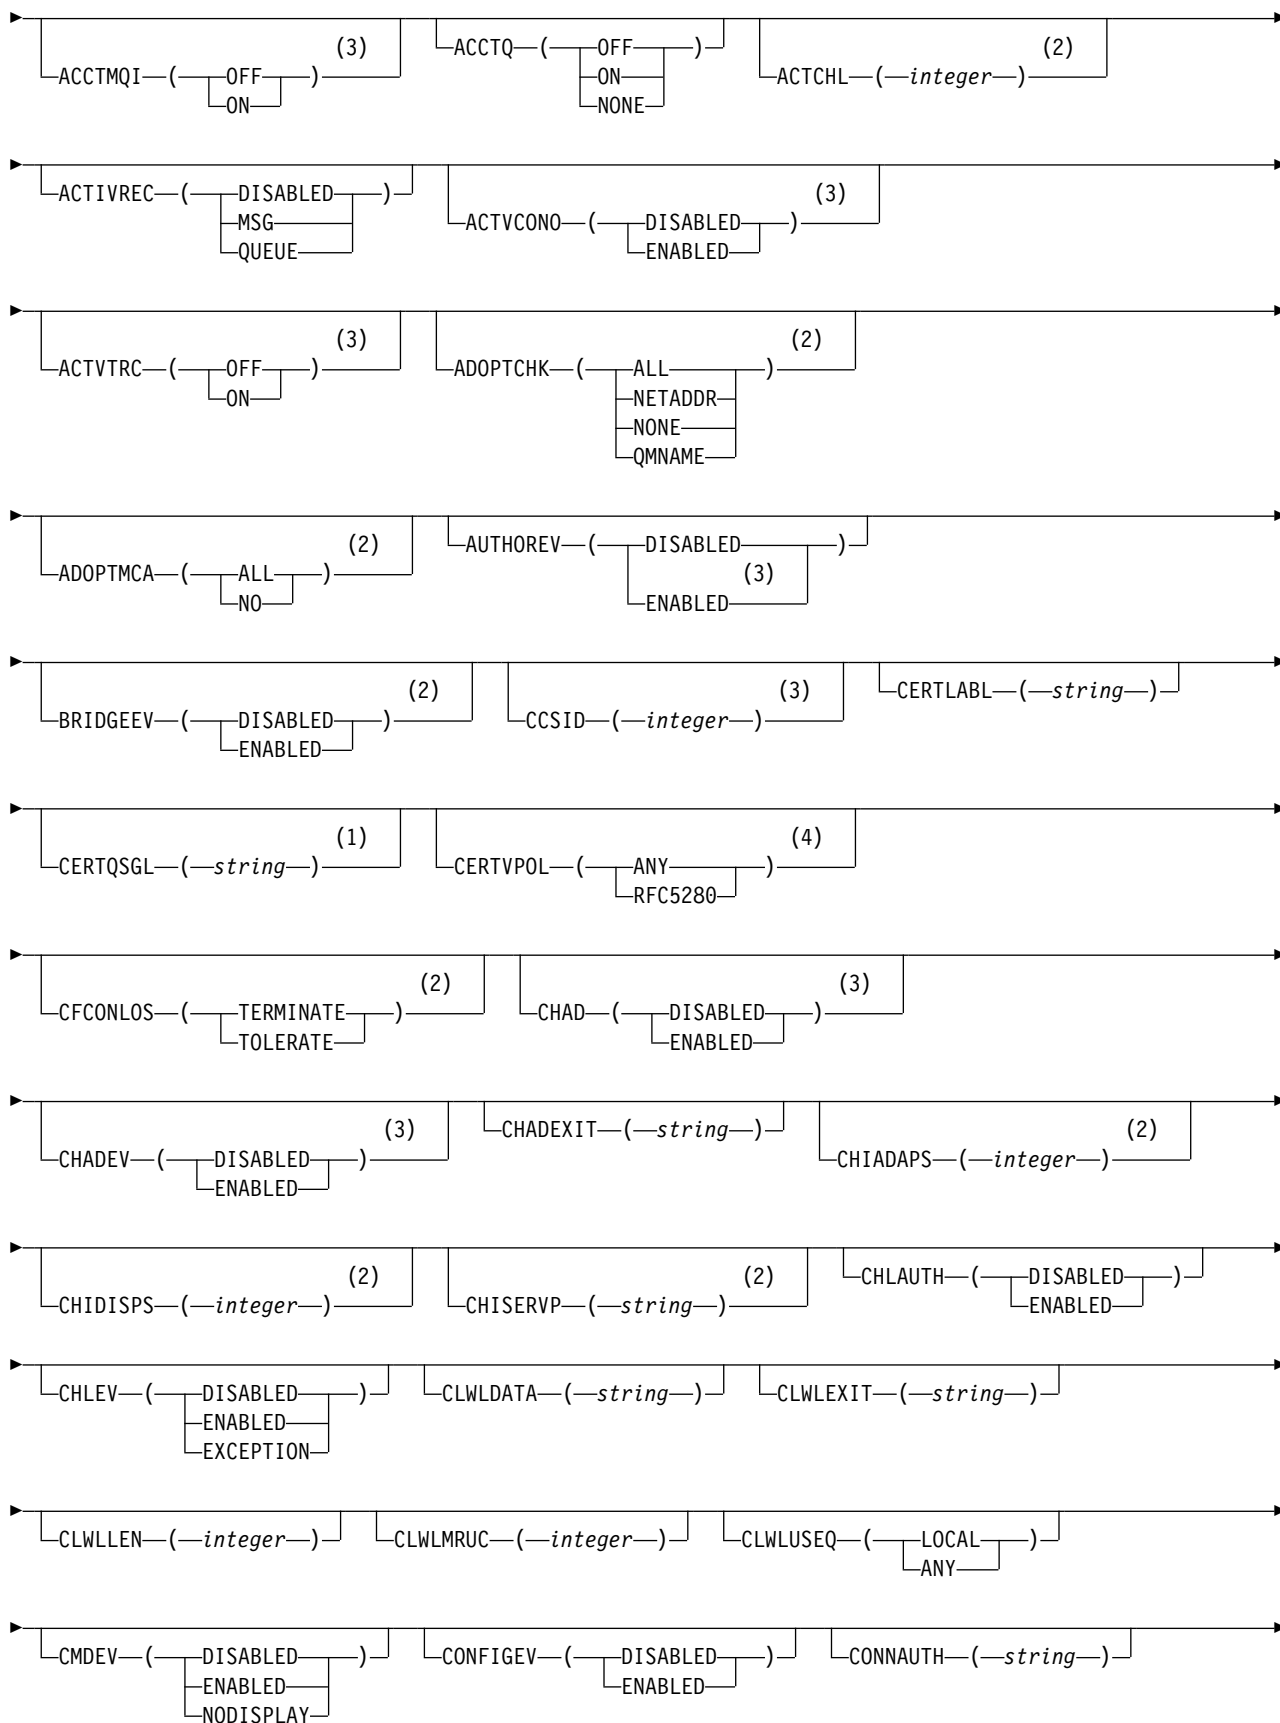

## ALTER QMGR

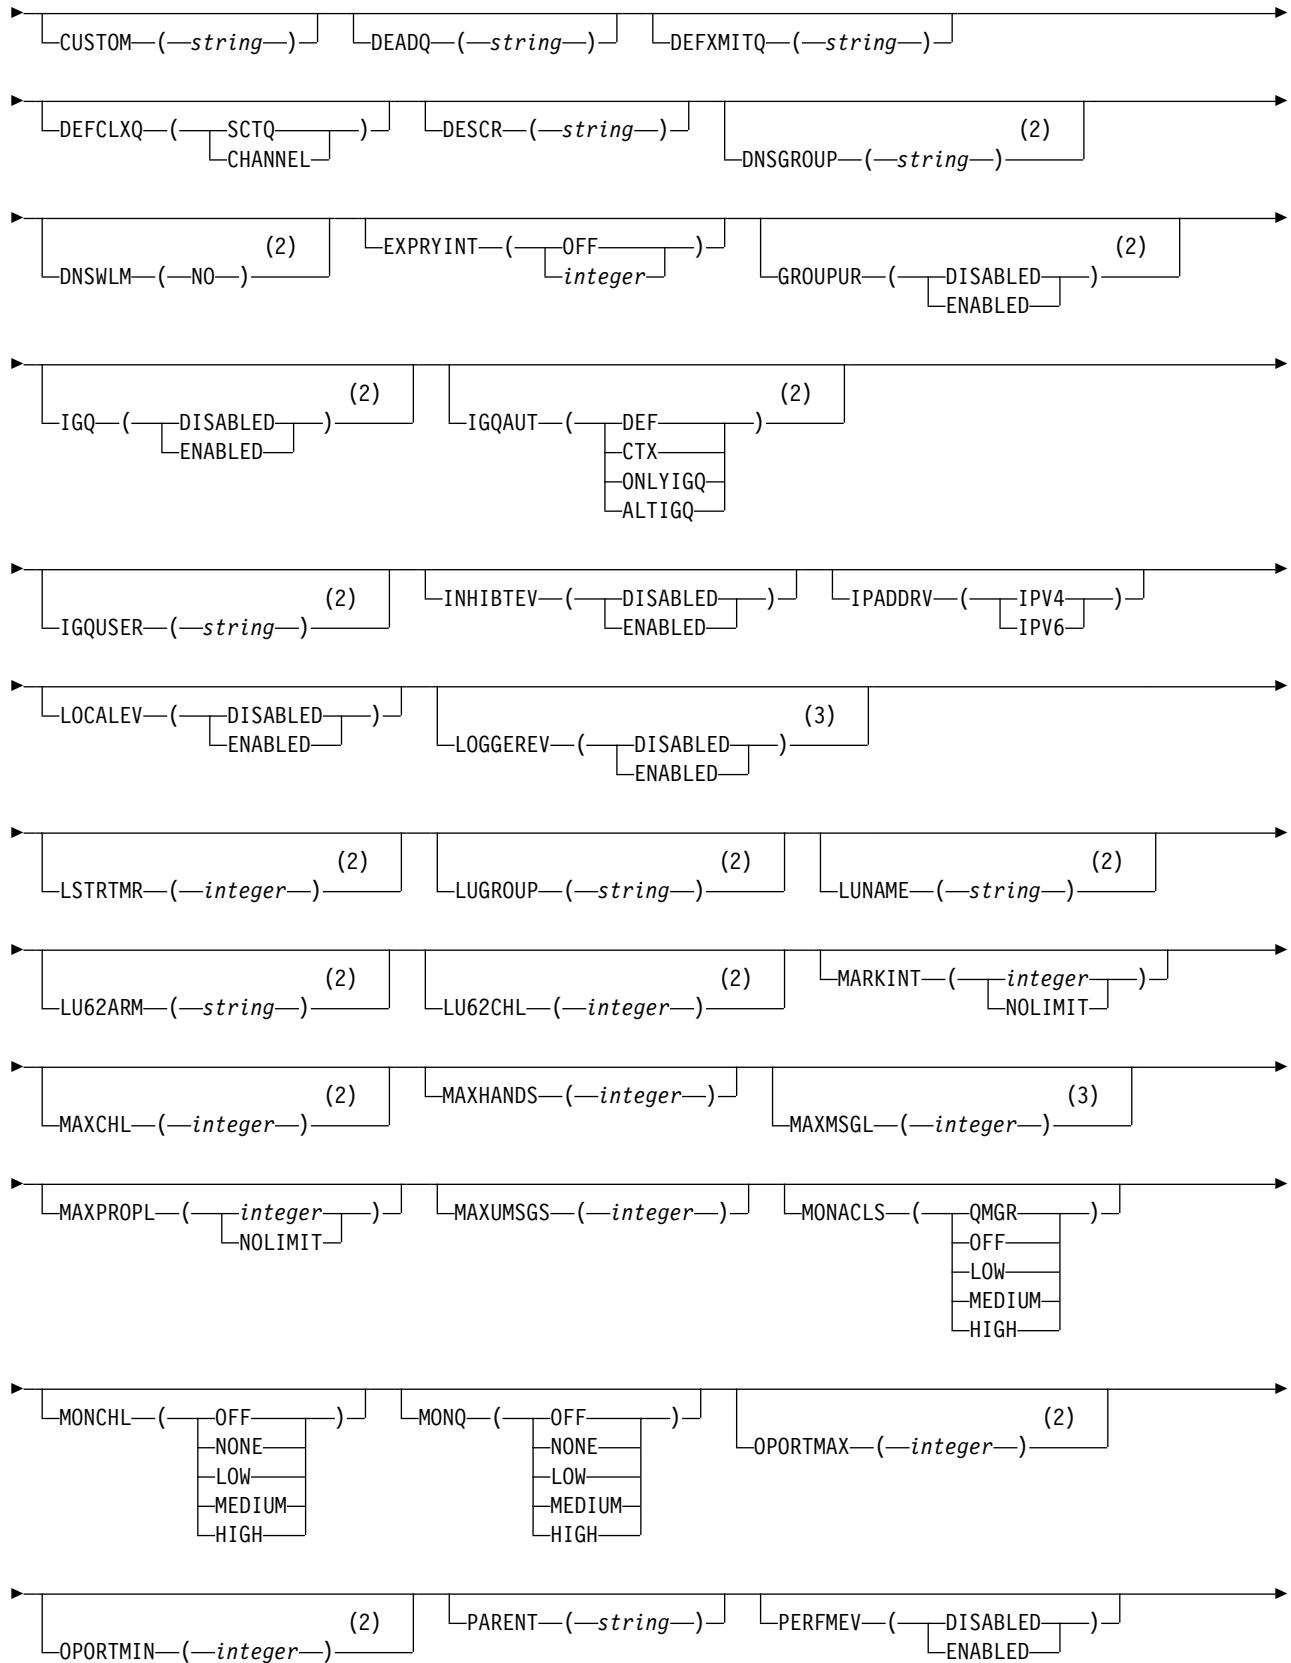

**Synonym:** ALT QMGR

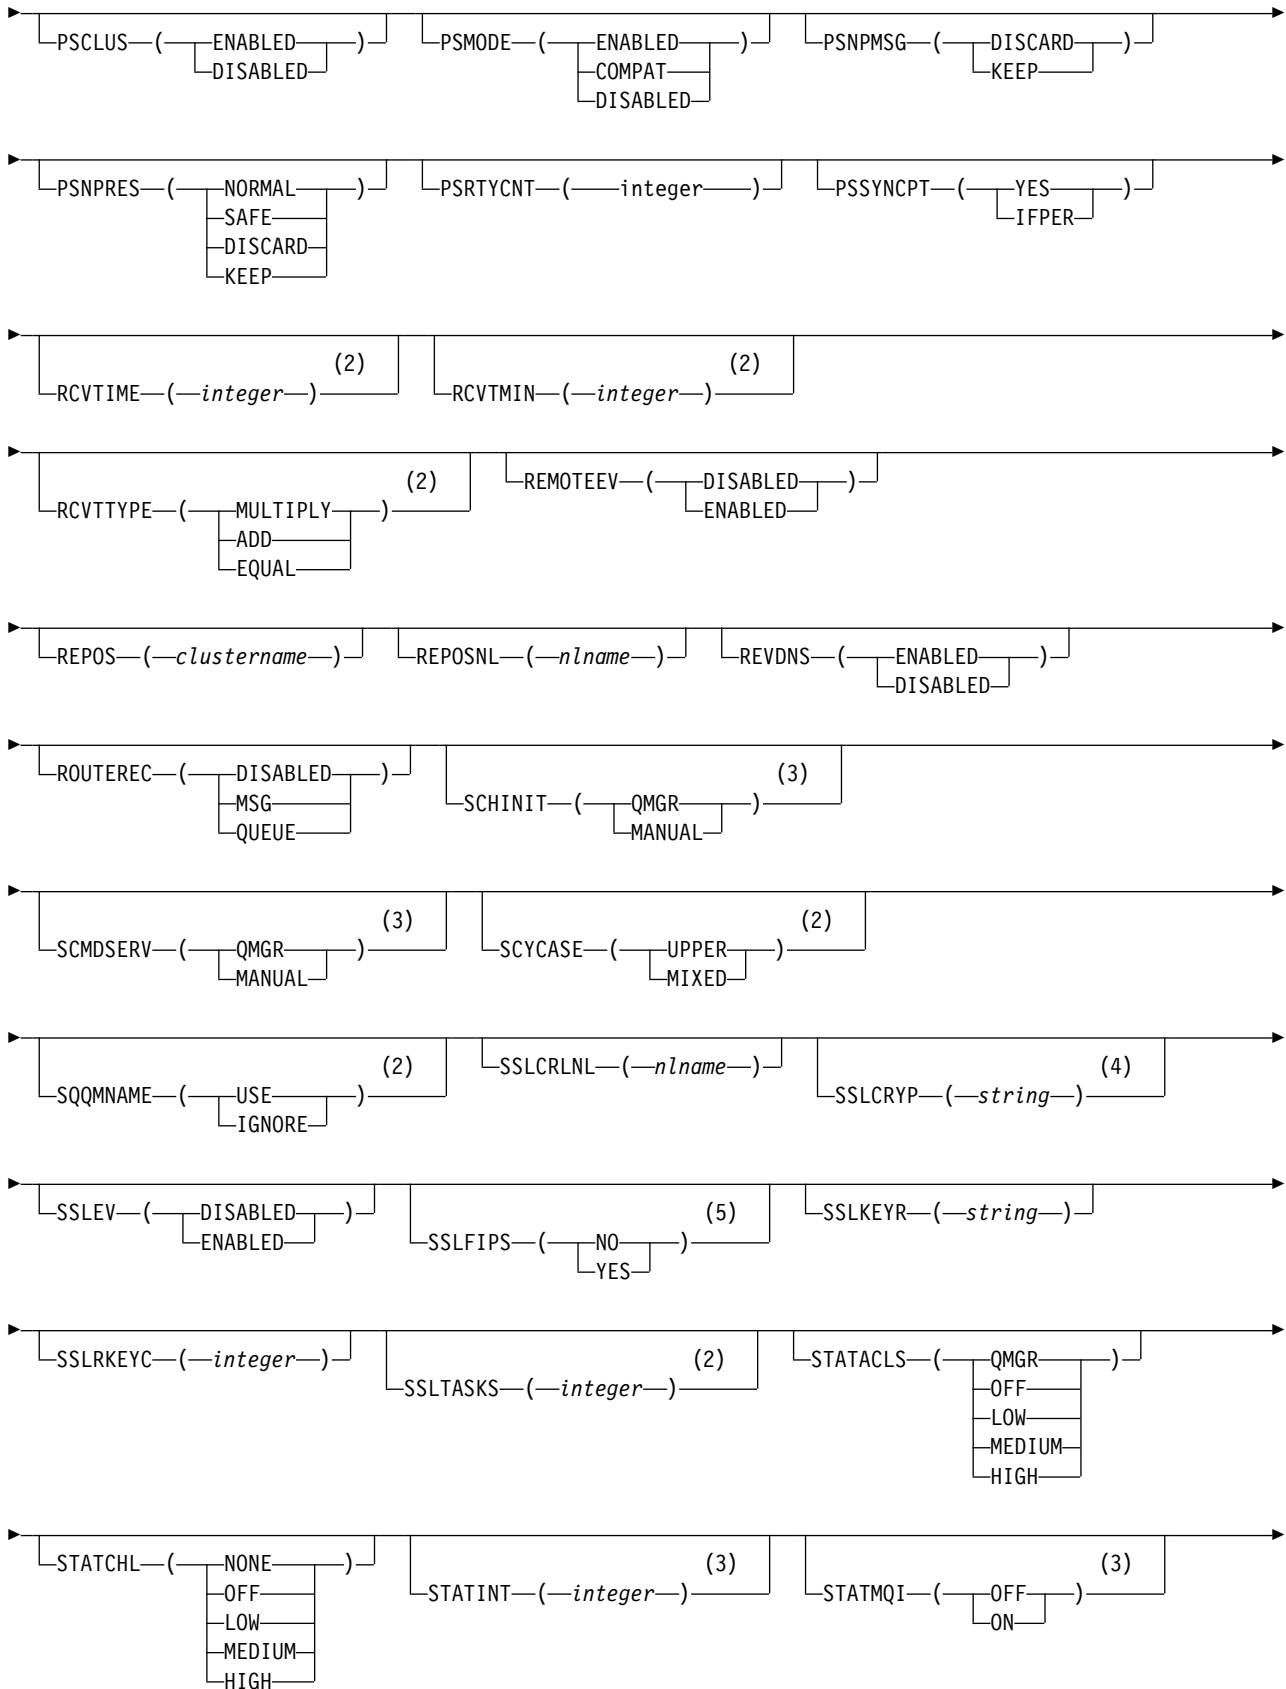

## Queue manager attributes:

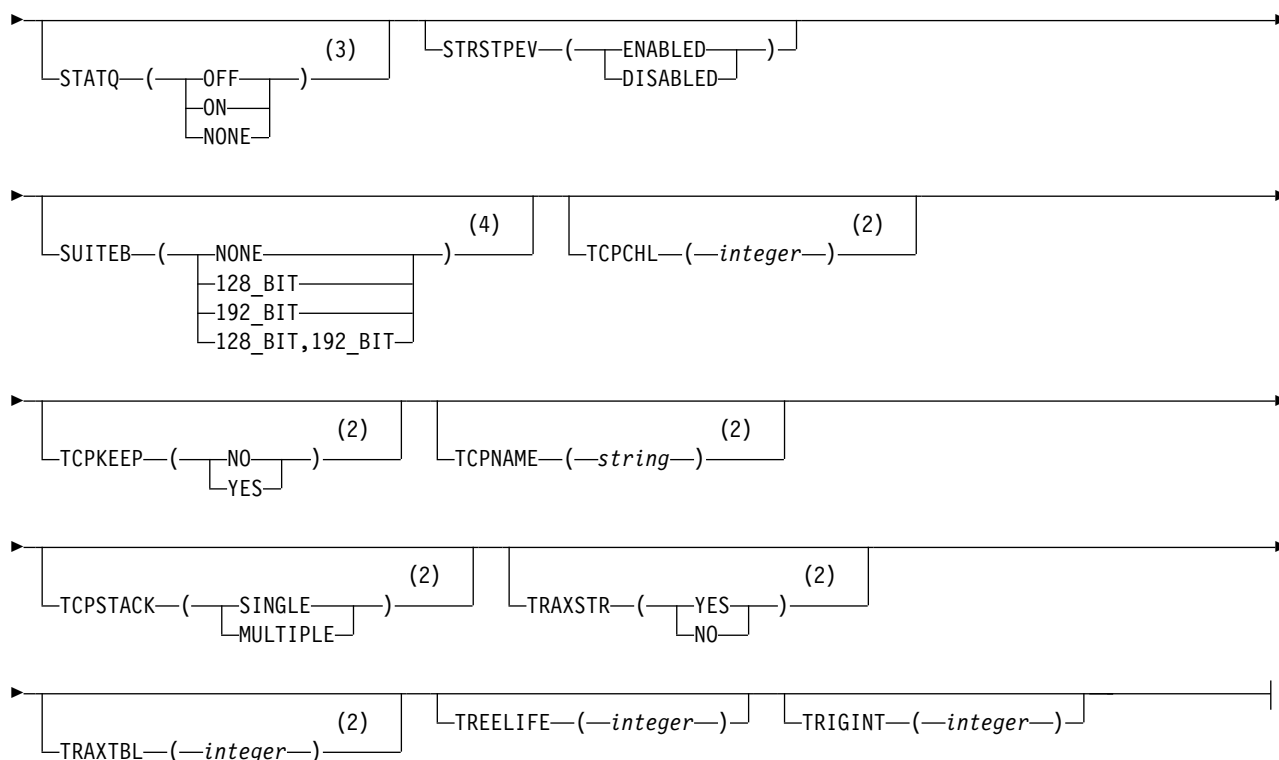

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.
- 4 Valid only on UNIX, Linux, and Windows.
- 5 Not valid on IBM i

**Parameter descriptions for ALTER QMGR**

The parameters you specify override the current values. Attributes that you do not specify are unchanged.

**Note:**

1. If you do not specify any parameters, the command completes successfully, but no queue manager options are changed.
2. Changes made using this command persist when the queue manager is stopped and restarted.

**FORCE**

Specify this parameter to force completion of the command if both of the following are true:

- The DEFXMITQ parameter is specified
- An application has a remote queue open, the resolution for which would be affected by this change

If FORCE is not specified in these circumstances, the command is unsuccessful.

**Queue manager parameters**

These parameters are the queue manager parameters for the **ALTER QMGR** command:

## ACCTCONO

Specifies whether applications can override the settings of the ACCTQ and ACCTMQI queue manager parameters:

### DISABLED

Applications cannot override the settings of the ACCTQ and ACCTMQI parameters.

This is the queue manager's initial default value.

### ENABLED

Applications can override the settings of the ACCTQ and ACCTMQI parameters by using the options field of the MQCNO structure of the MQCONN API call.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

## ACCTINT ( *integer* )

The time interval, in seconds, at which intermediate accounting records are written.

Specify a value in the range 1 through 604800.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

## ACCTMQI

Specifies whether accounting information for MQI data is to be collected:

**OFF** MQI accounting data collection is disabled.

This is the queue manager's initial default value.

**ON** MQI accounting data collection is enabled.

If queue manager attribute ACCTCONO is set to ENABLED, the value of this parameter can be overridden using the options field of the MQCNO structure.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

## ACCTQ

Specifies whether accounting data is to be collected for all queues.

 On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting).

**OFF** Accounting data collection is disabled for all queues which specify QMGR as the value for their ACCTQ parameter.

**ON** Accounting data collection is enabled for all queues which specify QMGR as the value of their ACCTQ parameter.

 On z/OS systems, you must switch on class 3 accounting by the START TRACE command.

### NONE

Accounting data collection for all queues is disabled regardless of the value of the ACCTQ parameter of the queue.

Changes to this parameter are effective only for connections to the queue manager occurring after the change to the parameter.

**ACTCHL ( integer )**

The maximum number of channels that can be *active* at any time, unless the value is reduced below the number of currently active channels.

Specify a value from 1 through 9999 that is not greater than the value of MAXCHL. MAXCHL defines the maximum number of channels available.

If you change this value, you must also review the MAXCHL, LU62CHL, and TCPCHL values to ensure that there is no conflict of values

For an explanation of which channel states are considered active; see Channel states.

If the value of ACTCHL is reduced to less than its value when the channel initiator was initialized, channels continue to run until they stop. When the number of running channels falls below the value of ACTCHL, more channels can be started. Increasing the value of ACTCHL to more than its value when the channel initiator was initialized does not have immediate effect. The higher value of ACTCHL takes effect at the next channel initiator restart.

Sharing conversations do not contribute to the total for this parameter.

This parameter is valid on z/OS only.

**ACTIVREC**

Specifies whether activity reports are generated if requested in the message:

**DISABLED**

Activity reports are not generated.

**MSG** Activity reports are generated and sent to the reply queue specified by the originator in the message causing the report.

This is the queue manager's initial default value.

**QUEUE**

Activity reports are generated and sent to SYSTEM.ADMIN.ACTIVITY.QUEUE

See Activity recording.

**ACTVCONO**

Specifies whether applications can override the settings of the ACTVTRC queue manager parameter:

**DISABLED**

Applications cannot override the settings of the ACTVTRC queue manager parameter.

This is the queue manager's initial default value.

**ENABLED**

Applications can override the settings of the ACTVTRC queue manager parameter by using the options field of the MQCNO structure of the MQCONN API call.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**ACTVTRC**

Specifies whether MQI application activity tracing information is to be collected. See Setting ACTVTRC to control collection of activity trace information.

**OFF** IBM MQ MQI application activity tracing information collection is not enabled.

This is the queue manager's initial default value.

**ON** IBM MQ MQI application activity tracing information collection is enabled.

If the queue manager attribute ACTVCONO is set to ENABLED, the value of this parameter can be overridden using the options field of the MQCNO structure.

Changes to this parameter are effective for connections to the queue manager that occur after the change.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

▶ **z/OS** **ADOPTCHK**

Specifies which elements are checked to determine whether an MCA is adopted. The check is made when a new inbound channel is detected with the same name as an already active MCA.

**ALL** Check the queue manager name and the network address. Perform this check to prevent your channels from being inadvertently or maliciously shut down.

This is the queue manager's initial default value.

**NETADDR**

Check the network address.

**NONE**

Do no checking.

**QMNAME**

Check the queue manager name.

This parameter is valid on z/OS only.

Changes to this parameter take effect the next time that a channel attempts to adopt an MCA.

▶ **z/OS** **ADOPTMCA**

Specifies whether an orphaned instance of an MCA restarts immediately when a new inbound channel request matching the ADOPTCHK parameter is detected:

**ALL** Adopt all channel types.

This is the queue manager's initial default value.

**NO** Adoption of orphaned channels is not required.

This parameter is valid on z/OS only

Changes to this parameter take effect the next time that a channel attempts to adopt an MCA.

**AUTHOREV**

Specifies whether authorization (Not Authorized) events are generated:

**DISABLED**

Authorization events are not generated.

This is the queue manager's initial default value.

**ENABLED**

Authorization events are generated.

▶ **z/OS** This value is not supported on z/OS.

▶ **z/OS** **BRIDGEEV**

Specifies whether IMS bridge events are generated.

**DISABLED**

IMS bridge events are not generated.

This is the queue manager's initial default value.

**ENABLED**

All IMS bridge events are generated.

This parameter is valid on z/OS only.

## CCSID ( integer )

The coded character set identifier for the queue manager. The CCSID is the identifier used with all character string fields defined by the API. If the CCSID in the message descriptor is set to the value MQCCSI\_Q\_MGR, the value applies to application data in the body of a message. The value is set when the message is put to a queue.

Specify a value in the range 1 through 65535. The CCSID specifies a value that is defined for use on your platform, and use a character set that is appropriate to the platform.

If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original CCSID. Therefore, stop and restart all running applications before you continue including the command server and channel programs. To stop and restart all running applications, stop and restart the queue manager after changing the parameter value.

▶ **z/OS** This parameter is not valid on z/OS. To carry out the equivalent tasks on z/OS, use CSQ6SYSP to set your system parameters.

See Code page conversion for details of the supported CCSIDs for each platform.

## CERTLABL

Certificate label for this queue manager to use. The label identifies which personal certificate in the key repository has been selected.

The default and migrated queue manager values are:

- ▶ **z/OS** On z/OS: *ibmWebSphereMQXXXX* where XXXX is the queue manager name.
- On IBM i:
  - If you specified SSLKEYR(\*SYSTEM), the value is blank.  
Note that it is forbidden to use a nonblank queue manager CERTLABL with SSLKEYR(\*SYSTEM). Attempting to do so results in an MQRCCF\_Q\_MGR\_ATTR\_CONFLICT error.
  - Otherwise, *ibmwebspheremqxxxx* where xxxx is the queue manager name folded to lower case.
- On UNIX and Linux and Windows, *ibmwebspheremqxxxx* where xxxx is the queue manager name folded to lower case.

You should specify the preceding values. However, leaving CERTLABL as a blank value on the queue manager is interpreted by the system to mean the default values specified.

**Important:** You must run a REFRESH SECURITY TYPE(SSL) command if you make any changes to CERTLABL on the queue manager. However, you do not need to run the REFRESH SECURITY TYPE(SSL) command if you make any changes to CERTLABL on a channel.

## ▶ **z/OS** CERTQSGL

Queue sharing group (QSG) certificate label.

This parameter takes precedence over CERTLABL in the event that the queue manager is a member of a QSG.

The default value for this parameter is *ibmWebSphereMQXXXX* where XXXX is the QSG name.

This parameter is valid on z/OS only.

## CERTVPOL

Specifies which SSL/TLS certificate validation policy is used to validate digital certificates received from remote partner systems. This attribute can be used to control how strictly the certificate chain validation conforms to industry security standards.

**ANY** Apply each of the certificate validation policies supported by the secure sockets library and accept the certificate chain if any of the policies considers the certificate chain valid. This setting can be used for maximum backwards compatibility with older digital certificates which do not comply with the modern certificate standards.

## RFC5280

Apply only the RFC 5280 compliant certificate validation policy. This setting provides stricter validation than the ANY setting, but rejects some older digital certificates.

For more information about certificate validation policies, see Certificate validation policies in IBM MQ.

This parameter is valid on only UNIX, Linux, and Windows. Changes to the parameter take effect only after a **REFRESH SECURITY TYPE(SSL)** command is issued.

▶ z/OS

## CFCONLOS

Specifies the action to be taken when the queue manager loses connectivity to the administration structure, or any CF structure with CFCONLOS set to ASQMGR

### TERMINATE

The queue manager terminates when connectivity to CF structures is lost.

### TOLERATE

The queue manager tolerates loss of connectivity to CF structures without terminating.

This parameter is valid on z/OS only.

All queue managers in the queue-sharing group must be at command level 710 or greater and OPMODE set to NEWFUNC for **TOLERATE** to be selected.

## CHAD

Specifies whether receiver and server-connection channels can be defined automatically:

### DISABLED

Auto-definition is not used.

This is the queue manager's initial default value.

### ENABLED

Auto-definition is used.

Cluster-sender channels can always be defined automatically, regardless of the setting of this parameter.

▶ z/OS

This parameter is not valid on z/OS.

## CHADEV

Specifies whether channel auto-definition events are generated.

### DISABLED

Auto-definition events are not generated.

This is the queue manager's initial default value.

### ENABLED

Auto-definition events are generated.

▶ z/OS

This parameter is not valid on z/OS.

## CHADEXIT ( *string* )

Auto-definition exit name.

If this name is nonblank, the exit is called when an inbound request for an undefined receiver, server-connection, or cluster-sender channel is received. It is also called when starting a cluster-receiver channel.

The format and maximum length of the name depends on the environment:

- On Windows, it is of the form *dllname(functionname)* where *dllname* is specified without the suffix .DLL. The maximum length is 128 characters.
- On IBM i, it is of the form:

programe libname

where *program name* occupies the first 10 characters and *libname* the second 10 characters (both blank-padded to the right if necessary). The maximum length of the string is 20 characters.

- On UNIX, and Linux, it is of the form *libraryname(functionname)*. The maximum length is 128 characters.

-  On z/OS, it is a load module name, the maximum length is eight characters.

-  On z/OS, this parameter applies only to cluster-sender and cluster-receiver channels.

#### **CHIADAPS ( integer )**

The number of channel initiator adapter subtasks to use for processing IBM MQ calls.

Specify a value in the range 0 - 9999.

Suggested settings:

- Test system: 8
- Production system: 30

This parameter is valid on z/OS only.

Changes to this parameter take effect when the channel initiator is restarted.

For more information about the relationship between CHIADAPS, CHIDISPS and MAXCHL, see Task 18: Tailor the channel initiator parameters.

#### **CHIDISPS ( integer )**

The number of dispatchers to use in the channel initiator.

Specify a value in the range 1 through 9999.

Suggested settings:

- Test system: 5
- Production system: 20

This parameter is valid on z/OS only.

Changes to this parameter take effect when the channel initiator is restarted.

-  For more information about the relationship between CHIADAPS, CHIDISPS and MAXCHL, see Task 18: Tailor the channel initiator parameters.

#### **CHISERV**

This parameter is reserved for IBM use only; it is not for general use.

This parameter is valid on z/OS only.

### **CHLAUTH**

Specifies whether the rules defined by channel authentication records are used. CHLAUTH rules can still be set and displayed regardless of the value of this attribute.

Changes to this parameter take effect the next time that an inbound channel attempts to start.

Channels that are currently started are unaffected by changes to this parameter.

#### **DISABLED**

Channel authentication records are not checked.

#### **ENABLED**

Channel authentication records are checked.

### **CHLEV**

Specifies whether channel events are generated.

**DISABLED**

Channel events are not generated.

This is the queue manager's initial default value.

**ENABLED**

All channel events are generated.

**EXCEPTION**

All exception channel events are generated.

**CLWLDATA ( *string* )**

Cluster workload exit data. The maximum length of the string is 32 characters.

This string is passed to the cluster workload exit when it is called.

**CLWLEXIT ( *string* )**

Cluster workload exit name.

If this name is nonblank, the exit is called when a message is put to a cluster queue. The format and maximum length of the name depends on the environment:

- On UNIX and Linux systems, it is of the form *libraryname(functionname)*. The maximum length is 128 characters.
- On Windows, it is of the form *dllname(functionname)*, where *dllname* is specified without the suffix `.DLL`. The maximum length is 128 characters.
-  On z/OS, it is a load module name. The maximum length is eight characters.
- On IBM i, it is of the form:  

```
progrname libname
```

where *program name* occupies the first 10 characters and *libname* the second 10 characters (both blank-padded to the right if necessary). The maximum length is 20 characters.

This parameter is valid only on IBM i, z/OS, UNIX, Linux, and Windows.

**CLWLLEN ( *integer* )**

The maximum number of bytes of message data that is passed to the cluster workload exit.

Specify a value in the range:

-  0 - 100 MB on IBM MQ for z/OS systems
- 0 - 999,999,999 on distributed platforms

This parameter is valid only on IBM i, z/OS, UNIX, Linux, and Windows.

**CLWLMRUC ( *integer* )**

The maximum number of most recently used outbound cluster channels.

Specify a value in the range 1 through 999,999,999.

See CLWLMRUC queue manager attribute.

**CLWLUSEQ**

The attribute applies to queues with the queue attribute CLWLUSEQ set to QMGR. It specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. It does not apply if the MQPUT originates from a cluster channel.

Specify either:

**LOCAL**

The local queue is the only target for MQPUT operations.

This is the queue manager's initial default value.

**ANY** The queue manager treats the local queue as another instance of the cluster queue for the purposes of workload distribution.

See CLWLUSEQ queue manager attribute.

## CMDEV

Specifies whether command events are generated:

### DISABLED

Command events are not generated.

This is the queue manager's initial default value.

### ENABLED

Command events are generated for all successful commands.

### NODISPLAY

Command events are generated for all successful commands, other than DISPLAY commands.

## CMDSCOPE

This parameter applies to z/OS only and specifies how the command is run when the queue manager is a member of a queue-sharing group.

' The command is run on the queue manager on which it was entered.

*qmgr-name*

The command is run on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a different queue manager. You can do so if you are using a queue-sharing group environment, and if the command server is enabled. You can then specify a different queue manager to the one on which the command is entered.

\*

The command is run on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of entering this value is the same as entering the command on every queue manager in the queue-sharing group.

## CONFIGEV

Specifies whether configuration events are generated:

### ENABLED

Configuration events are generated. After setting this value, issue REFRESH QMGR TYPE(CONFIGEV) commands for all objects to bring the queue manager configuration up to date.

### DISABLED

Configuration events are not generated.

This is the queue manager's initial default value.

## CONNAUTH

The name of an authentication information object that is used to provide the location of user ID and password authentication. If **CONNAUTH** is blank, no user ID and password checking is done by the queue manager. The maximum length of the string is MQ\_AUTH\_INFO\_NAME\_LENGTH.

Only authentication information objects with type IDPWOS or IDPWLDAP can be specified; other types result in an error message when the OAM (on UNIX, Linux, and Windows platforms)

 or the security component (on z/OS platforms) reads the configuration. Changes to this configuration, or the object to which it refers, take effect when a **REFRESH SECURITY TYPE(CONNAUTH)** command is issued.

If you leave **CONNAUTH** blank, and attempt to connect to a channel that has either REQDADM  (on platforms other than z/OS ) or REQUIRED set in the CHCKCLNT field, the connection fails.

#### **CUSTOM** ( *string* )

The custom attribute for new features.

This attribute is reserved for the configuration of new features before named attributes are introduced. It can contain the values of zero or more attributes as pairs of attribute name and value, separated by at least one space. The attribute name and value pairs have the form NAME(VALUE). Escape a single quotation mark with another single quotation mark.

No values are defined for *Custom*.

#### **DEADQ** ( *string* )

The local name of a dead-letter queue (or undelivered-message queue) on which messages that cannot be routed to their correct destination are put.

The queue named must be a local queue; see Rules for naming IBM MQ objects.

#### **DEFCLXQ**

The DFTCLXQ attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

#### **SCTQ**

All cluster-sender channels send messages from SYSTEM.CLUSTER.TRANSMIT.QUEUE. The correlID of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

SCTQ is set when a queue manager is defined. This behavior is implicit in versions of IBM WebSphere MQ, earlier than Version 7.5. In earlier versions, the queue manager attribute DEFCLXQ was not present.

#### **CHANNEL**

Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE.

If the queue manager attribute, DEFCLXQ, is set to CHANNEL, the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

#### **DEFXMITQ** ( *string* )

Local name of the default transmission queue on which messages destined for a remote queue manager are put. The default transmission queue is used if there is no other suitable transmission queue defined.

The cluster transmission queue must not be used as the default transmission queue of the queue manager.

The queue named must be a local transmission queue; see Rules for naming IBM MQ objects.

#### **DESCR** ( *string* )

Plain-text comment. It provides descriptive information about the queue manager.

It contains only displayable characters. The maximum length of the string is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

If the characters in the descriptive information are in the coded character set identifier (CCSID) for this queue manager they are translated correctly. They are translated when the descriptive information is sent to another queue manager. If they are not in the CCSID for this queue manager, they might be translated incorrectly.

▶ **z/OS** **DNSGROUP** ( *string* )

This parameter is no longer used. Refer to WLM/DNS no longer supported. This parameter is valid on z/OS only.

▶ **z/OS** **DNSWLM**

This parameter is no longer used. Refer to WLM/DNS no longer supported.

**NO** This value is the only value accepted.

This parameter is valid on z/OS only.

▶ **z/OS** **EXPRYINT**

Specifies how often queues are scanned to discard expired messages:

**OFF** Queues are not scanned. No internal expiry processing is performed.

*integer* The approximate interval in seconds at which queues are scanned. Each time that the expiry interval is reached, the queue manager looks for candidate queues that are worth scanning to discard expired messages.

The queue manager maintains information about the expired messages on each queue, and therefore whether a scan for expired messages is worthwhile. So, only a selection of queues is scanned at any time.

The value must be in the range 1 through 99999999. The minimum scan interval used is 5 seconds, even if you specify a lower value.

You must set the same EXPRYINT value for all queue managers within a queue-sharing group that support this attribute. Shared queues are scanned by only one queue manager in a queue-sharing group. This queue manager is either the first queue manager to restart, or the first queue manager for which EXPRYINT is set.

Changes to EXPRYINT take effect when the current interval expires. Changes also take effect if the new interval is less than the unexpired portion of the current interval. In this case, a scan is scheduled and the new interval value takes immediate effect.

This parameter is valid only on z/OS.

▶ **z/OS** **GROUPUR**

This parameter controls whether CICS and XA client applications can establish transactions with a GROUP unit of recovery disposition.

This parameter is valid only on z/OS. The property can be enabled only when the queue manager is a member of a queue-sharing group.

**ENABLED**

CICS and XA client applications can establish transactions with a group unit of recovery disposition by specifying a queue-sharing group name when they connect.

**DISABLED**

CICS and XA client applications must connect using a queue manager name.

▶ **z/OS** **IGQ**

Specifies whether intra-group queuing is used.

This parameter is valid only on z/OS when the queue manager is a member of a queue-sharing group.

## ENABLED

Message transfer between queue managers within a queue-sharing group uses the shared transmission queue, `SYSTEM.QSG.TRANSMIT.QUEUE`.

## DISABLED

Message transfer between queue managers within a queue-sharing group uses non-shared transmission queues and channels. Queue managers that are not part of a queue-sharing group also use this mechanism.

If intra-group queuing is enabled, but the intra-group queuing agent is stopped, issue `ALTER QMGR IGQ (ENABLED)` to restart it.

z/OS

## IGQAUT

Specifies the type of authority checking and, therefore, the user IDs, to be used by the IGQ agent (IGQA). This parameter establishes the authority to put messages to a destination queue.

This parameter is valid only on z/OS when the queue manager is a member of a queue-sharing group.

**DEF** Indicates that the default user ID is used to establish authority to put messages to a destination queue.

For a one user ID check, the default user ID is the user ID of a queue manager within the queue-sharing group. The default user ID is the user ID of the queue manager that put the messages to the `SYSTEM.QSG.TRANSMIT.QUEUE`. This user ID is referred to as the `QSGSEND` user ID.

For two user ID checks, the default second user ID is the IGQ user ID.

**CTX** Indicates that the user ID from a *UserIdentifier* field is used to establish authority to put messages to a destination queue. The user ID is the *UserIdentifier* field in the message descriptor of a message on the `SYSTEM.QSG.TRANSMIT.QUEUE`.

For one user ID check, the `QSGSEND` user ID is used.

For two user ID checks, the `QSGSEND` user ID, the IGQ user ID and the alternate user ID are used. The alternate user ID is taken from the *UserIdentifier* field in the message descriptor of a message on the `SYSTEM.QSG.TRANSMIT.QUEUE`. The alternate user ID is referred to as `ALT`.

## ONLYIGQ

Indicates that only the IGQ user ID is used to establish authority to put messages to a destination queue.

For all ID checks, the IGQ user ID is used.

## ALTIGQ

Indicates that the IGQ user ID and the `ALT` user ID are used to establish authority to put messages to a destination queue.

For one user ID check, the IGQ user ID is used.

For two user ID checks, the IGQ user ID and the `ALT` user ID are used.

z/OS

## IGQUSER

Nominates a user ID to be used by the IGQ agent (IGQA) to establish authority to put messages to a destination queue. The user ID is referred to as the IGQ user ID.

This parameter is valid only on z/OS when the queue manager is a member of a queue-sharing group. Possible values are:

### Blanks

Indicates that the user ID of the receiving queue manager within the queue-sharing group is used.

*Specific user ID*

Indicates that the user ID specified in the IGQUSER parameter of the receiving queue manager is used.

**Note:**

1. As the receiving queue manager has authority to all queues it can access, security checking might not be performed for this user ID type.
2. As the value of blanks has a special meaning, you cannot use IGQUSER to specify a real user ID of blanks.

**INHIBTEV**

Specifies whether inhibit events are generated. The events are generated for Inhibit Get and Inhibit Put)

**ENABLED**

Inhibit events are generated.

**DISABLED**

Inhibit events are not generated.

This is the queue manager's initial default value.

**IPADDRV**

Specifies which IP protocol is to be used for channel connections.

**IPV4** The IPv4 IP address is to be used.

This is the queue manager's initial default value.

**IPV6** The IPv6 IP address is to be used.

This parameter is used only in systems running IPv4 and IPv6. It applies to channels defined only with a TRPTYPE of TCP when either of the following two conditions is true:

- The CONNAME parameter of the channel contains a host name that resolves to both an IPv4 and an IPv6 address, and the LOCLADDR parameter is not specified.
- The value of the CONNAME and LOCLADDR parameters of the channel is a host name that resolves to both an IPv4 and IPv6 address.

**LOCALEV**

Specifies whether local error events are generated:

**ENABLED**

Local error events are generated.

**DISABLED**

Local error events are not generated.

This is the queue manager's initial default value.

**LOGGEREV**

Specifies whether recovery log events are generated:

**DISABLED**

Logger events are not generated.

This is the queue manager's initial default value.

**ENABLED**

Logger events are generated.

This parameter is valid only on IBM i, UNIX, Linux, and Windows.

▶ **z/OS** **LSTRTMR** ( *integer* )

The time interval, in seconds, between attempts by IBM MQ to restart a listener after an APPC or TCP/IP failure. When the listener is restarted on TCP/IP, it uses the same port and IP address as it used when it first started.

Specify a value in the range 5 through 9999.

This parameter is valid on z/OS only.

Changes to this parameter take effect for listeners that are later started. Listeners that are currently started are unaffected by changes to this parameter.

▶ **z/OS** **LUGROUP** ( *string* )

The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue-sharing group. The maximum length of this parameter is eight characters.

If this name is blank, the listener cannot be used.

This parameter is valid on z/OS only.

Changes to this parameter take effect for listeners that are later started. Listeners that are currently started are unaffected by changes to this parameter.

▶ **z/OS** **LUNAME** ( *string* )

The name of the LU to use for outbound LU 6.2 transmissions. Set this parameter to be the same as the name of the LU to be used by the listener for inbound transmissions. The maximum length of this parameter is eight characters.

If this name is blank, the APPC/MVS default LU name is used. This name is variable, so LUNAME must always be set if you are using LU 6.2

This parameter is valid on z/OS only.

Changes to this parameter take effect when the channel initiator is restarted.

▶ **z/OS** **LU62ARM** ( *string* )

The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC= *xx* is issued.

If you do not provide a value for this parameter, no SET APPC= *xx* command is issued.

The maximum length of this parameter is two characters.

This parameter is valid on z/OS only.

Changes to this parameter take effect when the channel initiator is restarted.

▶ **z/OS** **LU62CHL** ( *integer* )

The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol.

Specify a value 0- 9999 that is not greater than the value of MAXCHL. MAXCHL defines the maximum number of channels available. If you specify zero, the LU 6.2 transmission protocol is not used.

If you change this value, also review the MAXCHL, LU62CHL, and ACTCHL values. Ensure that there is no conflict of values and if necessary, raise the value of MAXCHL and ACTCHL.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

If the value of **LU62CHL** is non-zero when the channel initiator starts up, the value can be modified dynamically. If the value of **LU62CHL** is zero when the channel initiator starts up, a later ALTER command does not take effect. In this case, you should carry out an ALTER command, either before the channel initiator starts, or in CSQINP2 before you issue the **START CHINIT** command.

This parameter is valid on z/OS only.

### **MARKINT** ( *integer* )

The time interval, expressed in milliseconds, for which messages marked as browsed by a call to MQGET, with the get message option MQGMO\_MARK\_BROWSE\_CO\_OP, are expected to remain mark-browsed.

If messages are marked for more than approximately MARKINT milliseconds, the queue manager might automatically unmark messages. It might unmark messages that are marked as browsed for the cooperating set of handles.

This parameter does not affect the state of any message marked as browse by a call to MQGET with the get message option MQGMO\_MARK\_BROWSE\_HANDLE.

Specify a value in the range 0 - 999,999,999.

The special value NOLIMIT indicates that the queue manager does not automatically unmark messages by this process.

z/OS

### **MAXCHL** ( *integer* )

The maximum number of channels that can be *current* (including server-connection channels with connected clients).

Specify a value in the range 1- 9999. If you change this value, also review the TCPCHL, LU62CHL, and ACTCHL values to ensure that there is no conflict of values. If necessary, increase the number of active channels with the ACTCHL value. The values of ACTCHL, LU62CHL, and TCPCHL must not be greater than the maximum number of channels.

Suggested settings:

- Test system: 200
- Production system: 1000

For an explanation of which channel states are considered current; see Channel states.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

If the value of MAXCHL is reduced to less than its value when the channel initiator was initialized, channels continue to run until they stop. When the number of running channels falls below the value of MAXCHL, more channels can be started. Increasing the value of MAXCHL to more than its value when the channel initiator was initialized does not have immediate effect. The higher value of MAXCHL takes effect at the next channel initiator restart.

Sharing conversations do not contribute to the total for this parameter.

This parameter is valid on z/OS only.

z/OS

For more information about the relationship between CHIADAPS, CHIDISPS, and MAXCHL, see Task 18: Tailor the channel initiator parameters.

### **MAXHANDS** ( *integer* )

The maximum number of open handles that any one connection can have at the same time.

This value is a value in the range 0 - 999,999,999.

### **MAXMSGL** ( *integer* )

The maximum length of messages allowed on queues for this queue manager.

This value is in the range 32 KB through 100 MB.

Ensure that you also consider the length of any message properties when deciding the value for the MAXMSGL parameter of a channel.

If you reduce the maximum message length for the queue manager, you must also reduce the maximum message length of the SYSTEM.DEFAULT.LOCAL.QUEUE definition. You must also reduce

the maximum message length for all other queues defined on the queue manager. This change ensures that the limit of the queue manager is not less than the limit of any of the queues associated with it. If you do not change these lengths, and applications inquire only the MAXMSGL value of the queue, they might not work correctly.

Note that by adding the digital signature and key to the message, IBM MQ Advanced Message Security increases the length of the message.

#### **MAXPROPL** ( *integer* )

The maximum length of property data in bytes that can be associated with a message.

This value is in the range 0 through 100 MB (104 857 600 bytes).

The special value NOLIMIT indicates that the size of the properties is not restricted, except by the upper limit.

#### **MAXUMSGS** ( *integer* )

The maximum number of uncommitted messages within a sync point.

MAXUMSGS is a limit on the number of messages that can be retrieved, plus the number of messages that can be put, within any single sync point. The limit does not apply to messages that are put or retrieved outside sync point.

The number includes any trigger messages and report messages generated within the same unit of recovery.

If existing applications and queue manager processes are putting and getting a larger number of messages in sync point, reducing MAXUMSGS might cause problems.

 An example of queue manager processes that might be affected is clustering on z/OS.

Specify a value in the range 1 through 999,999,999. The default value is 10000.

MAXUMSGS has no effect on IBM MQ Telemetry. IBM MQ Telemetry tries to batch requests to subscribe, unsubscribe, send, and receive messages from multiple clients into batches of work within a transaction.

#### **MONACLS**

Controls the collection of online monitoring data for auto-defined cluster-sender channels:

##### **QMGR**

Collection of online monitoring data is inherited from the setting of the MONCHL parameter of the queue manager.

This is the queue manager's initial default value.

**OFF** Monitoring for the channel is switched off.

**LOW** Unless MONCHL is NONE, monitoring is switched on with a low rate of data collection with a minimal effect on system performance. The data collected is not likely to be the most current.

##### **MEDIUM**

Unless MONCHL is NONE, monitoring is switched on with a moderate rate of data collection with limited effect on system performance.

##### **HIGH**

Unless MONCHL is NONE, monitoring is switched on with a high rate of data collection with a likely effect on system performance. The data collected is the most current available.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

## MONCHL

Controls the collection of online monitoring data for channels. The channels defined with MONCHL(QMGR) are affected by changing the QMGR MONCHL attribute.

**OFF** Online monitoring data collection is turned off for channels specifying a value of QMGR in their MONCHL parameter.

This is the queue manager's initial default value.

### NONE

Online monitoring data collection is turned off for channels regardless of the setting of their MONCHL parameter.

**LOW** Online monitoring data collection is turned on, with a low ratio of data collection, for channels specifying a value of QMGR in their MONCHL parameter.

### MEDIUM

Online monitoring data collection is turned on, with a moderate ratio of data collection, for channels specifying a value of QMGR in their MONCHL parameter.

### HIGH

Online monitoring data collection is turned on, with a high ratio of data collection, for channels specifying a value of QMGR in their MONCHL parameter.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

## MONQ

Controls the collection of online monitoring data for queues.

**OFF** Online monitoring data collection is turned off for queues specifying a value of QMGR in their MONQ parameter.

This is the queue manager's initial default value.

### NONE

Online monitoring data collection is turned off for queues regardless of the setting of their MONQ parameter.

**LOW** Online monitoring data collection is turned on for queues specifying a value of QMGR in their MONQ parameter.

### MEDIUM

Online monitoring data collection is turned on for queues specifying a value of QMGR in their MONQ parameter.

### HIGH

Online monitoring data collection is turned on for queues specifying a value of QMGR in their MONQ parameter.

In contrast to MONCHL, there is no distinction between the values LOW, MEDIUM, and HIGH. These values all turn data collection on, but do not affect the rate of collection.

Changes to this parameter are effective only for queues opened after the parameter is changed.

## z/OS OPORTMAX ( *integer* )

The maximum value in the range of port numbers to be used when binding outgoing channels. When all the port numbers in the specified range are used, outgoing channels bind to any available port number.

Specify a value in the range 0 - 65535. A value of zero means that all outgoing channels bind to any available port number.

Specify a corresponding value for OPORTMIN to define a range of port numbers. Ensure that the value you specify for OPORTMAX is greater than or equal to the value you specify for OPORTMIN.

This parameter is valid on z/OS only.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

**z/OS** **OPORTMIN ( integer )**

The minimum value in the range of port numbers to be used when binding outgoing channels. When all the port numbers in the specified range are used, outgoing channels bind to any available port number.

Specify a value in the range 0 - 65535.

Specify a corresponding value for OPORTMAX to define a range of port numbers. Ensure that the value you specify for OPORTMIN is less than or equal to the value you specify for OPORTMAX.

This parameter is valid on z/OS only.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

**PARENT ( parentname )**

The name of the parent queue manager to which the local queue manager is to connect as its child in a hierarchy.

A blank value indicates that the queue manager has no parent queue manager.

If there is an existing parent queue manager it is disconnected.

IBM MQ hierarchical connections require that the queue manager attribute PSMODE is set to ENABLED.

The value of PARENT can be set to a blank value if PSMODE is set to DISABLED.

Before a queue manager can connect to a queue manager as its child in a hierarchy, channels must exist in both directions. The channels must exist between the parent queue manager and the child queue manager.

If a parent is already defined, the ALTER QMGR PARENT command disconnects from the original parent and sends a connection flow to the new parent queue manager.

Successful completion of the command does not mean that the action completed. To check that this command has completed, see the ALTER QMGR step in Checking that async commands for distributed networks have finished.

**PERFMEV**

Specifies whether performance-related events are generated:

**ENABLED**

Performance-related events are generated.

**DISABLED**

Performance-related events are not generated.

This is the queue manager's initial default value.

**z/OS** On IBM MQ for z/OS, all the queue managers in a queue-sharing group must have the same setting.

**PSCLUS**

Controls whether this queue manager participates in publish subscribe activity across any clusters in which it is a member. No clustered topic objects can exist in any cluster when modifying from ENABLED to DISABLED.

For more information about **PSCLUS**, see Inhibiting clustered publish/subscribe.

**Note:** To change a PSCLUS parameter status, the CHIN address space needs to be running.

#### **ENABLED**

This queue manager can define clustered topic objects, publish to subscribers on other queue managers, and register subscriptions that receive publications from other queue managers. All queue managers in the cluster running a version of IBM MQ that supports this option must specify PSCLUS(ENABLED) for the publish/subscribe activity to function as expected. ENABLED is the default value when a queue manager is created.

#### **DISABLED**

This queue manager cannot define clustered topic objects and ignores their definition on any other queue manager in the cluster.

Publications are not forwarded to subscribers elsewhere in the cluster, and subscriptions are not registered other than on the local queue manager.

To ensure that no publish/subscribe activity occurs in the cluster, all queue managers must specify PSCLUS(DISABLED). As a minimum, full repositories must be consistent in enabling or disabling publish/subscribe participation.

#### **PSMODE**

Controls whether the publish/subscribe engine and the queued publish/subscribe interface are running. It controls whether applications can publish or subscribe by using the application programming interface. It also controls whether the queues that are monitored by the queued publish/subscribe interface, are monitored.

Changing the PSMODE attribute can change the PSMODE status. Use DISPLAY PUBSUB, or on IBM i **DSPMQM**, to determine the current state of the publish/subscribe engine and the queued publish/subscribe interface.

#### **COMPAT**

The publish/subscribe engine is running. It is therefore possible to publish or subscribe by using the application programming interface.

The queued publish/subscribe interface is not running. Any publish/subscribe messages put to the queues that are monitored by the queued publish/subscribe interfaces are not acted upon.

Use this setting for compatibility with WebSphere Message Broker (now known as IBM Integration Bus ) V6 or earlier versions that use this queue manager.

#### **DISABLED**

The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish or subscribe by using the application programming interface. Any publish/subscribe messages put to the queues that are monitored by the queued publish/subscribe interfaces are not acted upon.

If a queue manager is in a publish/subscribe cluster or hierarchy, it might receive publish/subscribe messages from other queue managers in the cluster or hierarchy. Examples of such messages are publication messages or proxy subscriptions. While PSMODE is set to DISABLED those messages are not processed. For this reason, disable any queue manager in a publish/subscribe cluster or hierarchy only for as long as there is little build-up of messages.

#### **ENABLED**

The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish or subscribe by using the application programming interface and the queues that are being monitored by the queued publish/subscribe interface.

This is the queue manager's initial default value.

**Note:** If a queue manager is in a publish/subscribe cluster or hierarchy, and you change PSMODE to ENABLED, you might have to run the command REFRESH QMGR TYPE(PROXY). The command ensures that non-durable subscriptions are known across the cluster or hierarchy when PSMODE is set back to ENABLED. The circumstance in which you must run the command is as follows. If PSMODE is changed from ENABLED to DISABLED and back to ENABLED, and one or more non-durable subscriptions exist across all three stages.

### PSNPMSG

If the queued publish/subscribe interface cannot process a non-persistent input message it might attempt to write the input message to the dead-letter queue. Whether it attempts to do so depends on the report options of the input message. The attempt to write the input message to the dead-letter queue might fail. In this case, the queued publish/subscribe interface might discard the input message. If MQRO\_DISCARD\_MSG is specified on the input message, the input message is discarded. If MQRO\_DISCARD\_MSG is not set, setting PSNPMSG to KEEP prevents the input message from being discarded. The default is to discard the input message.

**Note:** If you specify a value of IFPER for PSSYNCT, you must not specify a value of KEEP for PSNPMSG.

#### DISCARD

Non-persistent input messages might be discarded if they cannot be processed.

**KEEP** Non-persistent input messages are not discarded if they cannot be processed. In this situation, the queued publish/subscribe interface continues to try to process this message again at appropriate intervals and does not continue processing subsequent messages.

### PSNPRES

The PSNPRES attribute controls whether the queued publish/subscribe interface writes an undeliverable reply message to the dead-letter queue, or discards the message. The choice is necessary if the queued publish/subscribe interface cannot deliver a reply message to the reply-to queue.

For new queue managers, the initial value is NORMAL. If you specify a value of IFPER for PSSYNCT, you must not specify a value of KEEP or SAFE for PSNPRES.

For migrated queue managers on IBM i, UNIX, Linux, and Windows systems, the value depends on DLQNonPersistentResponse and DiscardNonPersistentResponse.

#### NORMAL

Non-persistent responses which cannot be placed on the reply queue are put on the dead-letter queue. If they cannot be placed on the dead-letter queue then they are discarded.

**SAFE** Non-persistent responses which cannot be placed on the reply queue are put on the dead-letter queue. If the response cannot be sent and cannot be placed on the dead-letter queue, the queued publish/subscribe interface backs out of the current operation. It tries again at appropriate intervals, and does not continue processing subsequent messages.

#### DISCARD

Non-persistent responses which cannot be placed on the reply queue are discarded

#### KEEP

Non-persistent responses are not placed on the dead-letter queue or discarded. Instead the queued publish/subscribe interface backs out the current operation and then tries it again at appropriate intervals and does not continue processing subsequent messages.

### PSRTYCNT

If the queued publish/subscribe interface fails to process a command message under sync point, the unit of work is backed out. The command tries to process the message a number of times

again, before the publish/subscribe broker processes the command message according to its report options instead. This situation can arise for a number of reasons. For example, if a publish message cannot be delivered to a subscriber, and it is not possible to put the publication on the dead letter queue.

The initial value for this parameter on a new queue manager is 5.

Range is 0 - 999,999,999.

## PSSYNCPT

Controls whether the queued publish/subscribe interface processes command messages (publishes or delete publication messages) under sync point.

**YES** All messages are processed under sync point.

## IFPER

Only persistent messages are part of the sync point

The initial value of the queue manager is IFPER.

## z/OS RCVTIME ( *integer* )

The approximate length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to the inactive state. This parameter applies only to message channels and not to MQI channels.

This number can be qualified as follows:

- To specify that this number is a multiplier to apply to the negotiated HBINT value to determine how long a channel is to wait, set RCVTTYPE to MULTIPLY. Specify an RCVTIME value of zero or in the range 2 through 99. If you specify zero, the channel continues to wait indefinitely to receive data from its partner.
- To specify that RCVTIME is the number of seconds to add to the negotiated HBINT value to determine how long a channel is to wait, set RCVTTYPE to ADD. Specify an RCVTIME value in the range 1 through 999999.
- To specify that RCVTIME is a value, in seconds, that the channel is to wait, set RCVTTYPE to EQUAL. Specify an RCVTIME value in the range 0 - 999,999. If you specify zero, the channel continues to wait indefinitely to receive data from its partner.

This parameter is valid on z/OS only.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see [Checking that the other end of the channel is still available](#).

## z/OS RCVTMIN ( *integer* )

The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state. This parameter applies only to message channels (and not to MQI channels).

The TCP/IP channel wait time can be configured relative to the negotiated value of HBINT. If RCVTTYPE is MULTIPLY or ADD, the resultant value might be less than the value set in RCVTMIN. In this case, the TCP/IP channel wait time is set to RCVTMIN. If RCVTTYPE is EQUAL then RCVTMIN does not apply.

Specify a value, in seconds, between zero and 999999.

This parameter is valid on z/OS only.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see [Checking that the other end of the channel is still available](#).

**RCVTTYPE**

The qualifier to apply to the value in RCVTIME.

**MULTIPLY**

Specifies that RCVTIME is a multiplier to be applied to the negotiated HBINT value to determine how long a channel waits.

**ADD** Specifies that RCVTIME is a value, in seconds, to be added to the negotiated HBINT value to determine how long a channel waits.

**EQUAL**

Specifies that RCVTIME is a value, in seconds, representing how long the channel waits.

This parameter is valid on z/OS only.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

For more information, see [Checking that the other end of the channel is still available](#).

**REMOTEEV**

Specifies whether remote error events are generated:

**DISABLED**

Remote error events are not generated.

This is the queue manager's initial default value.

**ENABLED**

Remote error events are generated.

If you are using the reduced function form of IBM MQ for z/OS supplied with WebSphere Application Server, only DISABLED is valid.

**REPOS ( *clustname* )**

The name of a cluster for which this queue manager provides a repository manager service. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

No more than one of the resultant values of REPOS and REPOSNL can be nonblank.

If you use the REPOS parameter to create a full repository queue manager, connect it to at least one other full repository queue manager in the cluster. Connect it using a cluster-sender channel. See the information in [Components of a cluster](#) for details about using cluster-sender channels with full repository queue managers.

This parameter is valid on IBM i, **z/OS**, UNIX, Linux, and Windows.

Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER QMGR step in [Checking that async commands for distributed networks have finished](#).

**REPOSNL ( *nlname* )**

The name of a namelist of clusters for which this queue manager provides a repository manager service.

No more than one of the resultant values of REPOS and REPOSNL can be nonblank.

Both REPOS and REPOSNL might be blank, or REPOS might be blank and the namelist specified by REPOSNL is empty. In these cases, this queue manager does not have a full repository. It might be a client of other repository services that are defined in the cluster.

If you use the REPOSNL parameter to create a full repository queue manager, connect it to other full repository queue managers. Connect it to at least one other full repository queue manager in

each cluster specified in the namelist using cluster-sender channels. See the information in Components of a cluster for details about using cluster-sender channels with full repository queue managers.

This parameter is valid on IBM i,  z/OS, UNIX, Linux, and Windows.

Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER QMGR step in Checking that async commands for distributed networks have finished.

## REVDNS

Controls whether reverse lookup of the hostname from a Domain Name Server (DNS) is done for the IP address from which a channel has connected. This attribute has an effect only on channels using a transport type (TRPTYPE) of TCP:

### ENABLED

DNS host names are reverse looked-up for the IP addresses of inbound channels when this information is required. This setting is required for matching against CHLAUTH rules that contain host names, and to include the host name in error messages. The IP address is still included in messages that provide a connection identifier.

This is the initial default value for the queue manager.

### DISABLED

DNS host names are not reverse looked-up for the IP addresses of inbound channels. With this setting any CHLAUTH rules using host names are not matched.

## ROUTEREC

Specifies whether trace-route information is recorded if requested in the message. If this parameter is not set to DISABLED, it controls whether any reply generated is sent to SYSTEM.ADMIN.TRACE.ROUTE.QUEUE, or to the destination specified by the message itself. If ROUTEREC is not DISABLED, messages not yet at the final destination might have information added to them.

### DISABLED

Trace-route information is not recorded.

**MSG** Trace-route information is recorded and sent to the destination specified by the originator of the message causing the trace route record.

This is the queue manager's initial default value.

### QUEUE

Trace-route information is recorded and sent to SYSTEM.ADMIN.TRACE.ROUTE.QUEUE.

## SCHINIT

Specifies whether the channel initiator starts automatically when the queue manager starts.

### QMGR

The channel initiator starts automatically when the queue manager starts.

### MANUAL

The channel initiator does not start automatically.

This parameter is valid only on IBM i, UNIX, Linux, and Windows.

## SCMDSERV

Specifies whether the command server starts automatically when the queue manager starts.

### QMGR

The command server starts automatically when the queue manager starts.

### MANUAL

The command server does not start automatically.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

z/OS

## SCYCASE

Specifies whether the security profiles are uppercase or mixed case.

### UPPER

The security profiles are uppercase only. However, MXTOPIC and GMXTOPIC are used for topic security, and can contain mixed-case profiles.

### MIXED

The security profiles are mixed case. MQCMD5 and MQCONN are used for command and connection security but they can contain only uppercase profiles.

Changes to SCYCASE become effective after you run the following command:

```
REFRESH SECURITY(*) TYPE(CLASSES)
```

This parameter is valid only on z/OS

z/OS

## SQQMNAME

The SQQMNAME attribute specifies whether a queue manager in a queue-sharing group opens a shared queue in the same group directly. The processing queue manager calls MQOPEN for a shared queue and sets the *ObjectQmgrName* parameter for the queue. If the shared queue is in the same queue-sharing group as the processing queue manager, the queue can be opened directly by the processing queue manager. Set the SQQMNAME attribute to control if the queue is opened directly, or by the *ObjectQmgrName* queue manager. The attribute will also be honored when opening a QALIAS with copy disposition, if the target queue is a shared queue in the same queue-sharing group as the processing queue-manager. In this situation it is important that the QALIAS copy object on each queue-manager in the queue-sharing group has the same target queue.

**USE** The *ObjectQmgrName* is used, and the appropriate transmission queue is opened.

### IGNORE

The processing queue manager opens the shared queue directly. Setting the parameter to this value can reduce the traffic in your queue manager network.

This parameter is valid only on z/OS.

## SSLCRLNL ( *nlname* )

The name of a namelist of authentication information objects which are used to provide certificate revocation locations to allow enhanced TLS/SSL certificate checking.

If SSLCRLNL is blank, certificate revocation checking is not invoked unless one of the SSL certificates used contains an AuthorityInfoAccess or CrIDistributionPoint X.509 certificate extension.

Changes to SSLCRLNL, or to the names in a previously specified namelist, or to previously referenced authentication information objects become effective either:

- On IBM i, UNIX, Linux, and Windows systems when a new channel process is started.
- For channels that run as threads of the channel initiator on IBM i, UNIX, Linux, and Windows systems, when the channel initiator is restarted.
- For channels that run as threads of the listener on IBM i, UNIX, Linux, and Windows systems, when the listener is restarted.
-  On z/OS, when the channel initiator is restarted.
- When a REFRESH SECURITY TYPE(SSL) command is issued.
- On IBM i queue managers, this parameter is ignored. However, it is used to determine which authentication information objects are written to the AMQCLCHL.TAB file.

Only authentication information objects with types of LDAPCRL or OCSP are allowed in the namelist referred to by SSLCRLNL. Any other type results in an error message when the list is processed and is subsequently ignored.

## SSLCRYP ( *string* )

Sets the name of the parameter string required to configure the cryptographic hardware present on the system.

All supported cryptographic hardware supports the PKCS #11 interface. Specify a string of the following format:

```
GSK_PKCS11= <the PKCS #11 driver path and file name>  
; <the PKCS #11 token label> ;  
<the PKCS #11 token password> ; <symmetric cipher setting>  
;
```

The PKCS #11 driver path is an absolute path to the shared library providing support for the PKCS #11 card. The PKCS #11 driver file name is the name of the shared library. An example of the value required for the PKCS #11 driver path and file name is `/usr/lib/pkcs11/PKCS11_API.so`

To access symmetric cipher operations through GSKit, specify the symmetric cipher setting parameter. The value of this parameter is either:

### **SYMMETRIC\_CIPHER\_OFF**

Do not access symmetric cipher operations.

### **SYMMETRIC\_CIPHER\_ON**

Access symmetric cipher operations.

If the symmetric cipher setting parameter is not specified, it has the same effect as specifying `SYMMETRIC_CIPHER_OFF`.

The maximum length of the string is 256 characters.

If you specify a string that is not in the format listed, you get an error.

When the SSLCRYP value is changed, the cryptographic hardware parameters specified become the ones used for new SSL connection environments. The new information becomes effective:

- When a new channel process is started.
- For channels that run as threads of the channel initiator, when the channel initiator is restarted.
- For channels that run as threads of the listener, when the listener is restarted.
- When a `REFRESH SECURITY TYPE(SSL)` command is issued.

## SSLEV

Specifies whether SSL events are generated.

### **DISABLED**

SSL events are not generated.

This is the queue manager's initial default value.

### **ENABLED**

All SSL events are generated.

## SSLFIPS

This parameter is valid only on  z/OS, UNIX, Linux, and Windows systems.

SSLFIPS specifies whether only FIPS-certified algorithms are to be used if cryptography is carried out in IBM MQ, rather than in cryptographic hardware. If cryptographic hardware is configured, the cryptographic modules used are those modules provided by the hardware product. These might, or might not, be FIPS-certified to a particular level. Whether the modules are FIPS-certified depends on the hardware product in use. For more information about FIPS, see the Federal Information Processing Standards (FIPS) manual.

**NO** If you set SSLFIPS to NO, you can use either FIPS certified or non-FIPS certified CipherSpecs.

If the queue manager runs without using cryptographic hardware, refer to the CipherSpecs listed in Specifying CipherSpecs.

This is the queue manager's initial default value.

**YES** Specifies that only FIPS-certified algorithms are to be used in the CipherSpecs allowed on all SSL connections from and to this queue manager.

For a listing of appropriate FIPS 140-2 certified CipherSpecs; see Specifying CipherSpecs.

Changes to SSLFIPS become effective either:

- On UNIX, Linux, and Windows systems, when a new channel process is started.
- For channels that run as threads of the channel initiator on UNIX, Linux, and Windows systems, when the channel initiator is restarted.
- For channels that run as threads of the listener on UNIX, Linux, and Windows systems, when the listener is restarted.
- For channels that run as threads of a process pooling process, when the process pooling process is started or restarted and first runs an SSL channel. If the process pooling process has already run an SSL channel, and you want the change to become effective immediately, run the MQSC command REFRESH SECURITY TYPE(SSL). The process pooling process is **amqrmppa** on UNIX, Linux, and Windows systems.
-  On z/OS, when the channel initiator is restarted.
- When a REFRESH SECURITY TYPE(SSL) command is issued  , except on z/OS.

### SSLKEYR ( *string* )

The name of the Secure Sockets Layer key repository.

The maximum length of the string is 256 characters.

The format of the name depends on the environment:

-  On z/OS, it is the name of a key ring.
- On IBM i, it is of the form *pathname/keyfile*, where *keyfile* is specified without the suffix *.kdb*, and identifies a GSKit key database file.

If you specify *\*SYSTEM*, IBM MQ uses the system certificate store as the key repository for the queue manager. The queue manager is registered as a server application in the Digital Certificate Manager (DCM). You can assign any server/client certificate in the system store to the queue manager, because you registered it as a server application.

If you change the SSLKEYR parameter to a value other than *\*SYSTEM*, IBM MQ unregisters the queue manager as an application with DCM.

- On UNIX and Linux, it is of the form *pathname/keyfile* and on Windows *pathname\keyfile* , where *keyfile* is specified without the suffix *.kdb*, and identifies a Java keystore file.

On IBM i, UNIX, Linux, and Windows systems, the syntax of this parameter is validated to ensure that it contains a valid, absolute, directory path.

If SSLKEYR is blank, channels using SSL fail to start. If SSLKEYR is set to a value that does not correspond to a key ring or key database file, channels using SSL also fail to start.

Changes to SSLKEYR become effective either:

- On IBM i, UNIX, Linux, and Windows systems, when a new channel process is started.
- For channels that run as threads of the channel initiator on IBM i, UNIX, Linux, and Windows systems, when the channel initiator is restarted.
- For channels that run as threads of the listener on IBM i, UNIX, Linux, and Windows systems, when the listener is restarted.
- For channels that run as threads of a process pooling process, **amqrmppa**, when the process pooling process is started or restarted and first runs an SSL channel. If the process pooling

process has already run an SSL channel, and you want the change to become effective immediately, run the MQSC command REFRESH SECURITY TYPE(SSL).

- **z/OS** On z/OS, when the channel initiator is restarted.
- When a REFRESH SECURITY TYPE(SSL) command is issued.

### SSLRKEYC ( *integer* )

The number of bytes to be sent and received within an SSL conversation before the secret key is renegotiated. The number of bytes includes control information.

SSLRKEYC is used only by SSL channels which initiate communication from the queue manager. For example, the sender channel initiates communication in a sender and receiver channel pairing.

If a value greater than zero is specified, the secret key is also renegotiated before message data is sent or received following a channel heartbeat. The count of bytes until the next secret key renegotiation is reset after each successful renegotiation.

Specify a value in the range 0 - 999,999,999. A value of zero means that the secret key is never renegotiated. If you specify an SSL/TLS secret key reset count in the range 1 - 32767 bytes (32 KB), SSL/TLS channels use a secret key reset count of 32 KB. The larger reset count value avoids the cost of excessive key resets which would occur for small SSL/TLS secret key reset values.

**Attention:** Non-zero values less than 4096 (4 KB) might cause channels to fail to start, or might cause inconsistencies in the values of SSLKEYDA, SSLKEYTI, and SSLRKEYS.

### **z/OS** SSLTASKS ( *integer* )

The number of server subtasks to use for processing SSL calls. To use SSL channels, you must have at least two of these tasks running.

This parameter is valid only on z/OS.

This value is in the range 0 - 9999. To avoid problems with storage allocation, do not set the SSLTASKS parameter to a value greater than 50.

Changes to this parameter are effective when the channel initiator is restarted.

### STATACLS

Specifies whether statistics data is to be collected for auto-defined cluster-sender channels:

#### QMGR

Collection of statistics data is inherited from the setting of the STATCHL parameter of the queue manager.

This is the queue manager's initial default value.

**OFF** Statistics data collection for the channel is switched off.

**LOW** Unless STATCHL is NONE, statistics data collection is switched on with a low ratio of data collection with a minimal effect on system performance.

#### MEDIUM

Unless STATCHL is NONE, statistics data collection is switched on with a moderate ratio of data collection.

**HIGH** Unless STATCHL is NONE, statistics data collection is switched on with a high ratio of data collection.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

**z/OS** On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

## STATCHL

Specifies whether statistics data is to be collected for channels:

### NONE

Statistics data collection is turned off for channels regardless of the setting of their STATCHL parameter.

**OFF** Statistics data collection is turned off for channels specifying a value of QMGR in their STATCHL parameter.

This is the queue manager's initial default value.

**LOW** Statistics data collection is turned on, with a low ratio of data collection, for channels specifying a value of QMGR in their STATCHL parameter.

### MEDIUM

Statistics data collection is turned on, with a moderate ratio of data collection, for channels specifying a value of QMGR in their STATCHL parameter.

**HIGH** Statistics data collection is turned on, with a high ratio of data collection, for channels specifying a value of QMGR in their STATCHL parameter.

A change to this parameter takes effect only on channels started after the change occurs. Any channel started before the change to the parameter continues with the value in force at the time that the channel started.

 On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

## STATINT ( *integer* )

The time interval, in seconds, at which statistics monitoring data is written to the monitoring queue.

Specify a value in the range 1 through 604800.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

Changes to this parameter take immediate effect on the collection of monitoring and statistics data.

## STATMQI

Specifies whether statistics monitoring data is to be collected for the queue manager:

**OFF** Data collection for MQI statistics is disabled.

This is the queue manager's initial default value.

**ON** Data collection for MQI statistics is enabled.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

Changes to this parameter take immediate effect on the collection of monitoring and statistics data.

## STATQ

Specifies whether statistics data is to be collected for queues:

### NONE

Statistics data collection is turned off for queues regardless of the setting of their STATQ parameter.

**OFF** Statistics data collection is turned off for queues specifying a value of QMGR or OFF in their STATQ parameter. OFF is the default value.

**ON** Statistics data collection is turned on for queues specifying a value of QMGR or ON in their STATQ parameter.

This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

Statistics messages are generated only for queues which are opened after statistics collection is enabled. You do not need to restart the queue manager for the new value of STATQ to take effect.

#### **STRSTPEV**

Specifies whether start and stop events are generated:

##### **ENABLED**

Start and stop events are generated.

This is the queue manager's initial default value.

##### **DISABLED**

Start and stop events are not generated.

#### **SUITEB**

Specifies whether Suite B-compliant cryptography is used and what strength is required.

##### **NONE**

Suite B is not used. NONE is the default

##### **128\_BIT**

Suite B 128-bit level security is used.

##### **192\_BIT**

Suite B 192-bit level security is used

##### **128\_BIT,192\_BIT**

Both Suite B 128-bit and 192-bit level security is used

#### **z/OS TCPCHL ( integer )**

The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol.

The maximum number of sockets used is the sum of the values in TCPCHL and CHDISPS. The z/OS UNIX System Services MAXFILEPROC parameter (specified in the BPXPRM xx member of SYS1.PARMLIB ) controls how many sockets each task is allowed, and thus how many channels each dispatcher is allowed. In this case, the number of channels using TCP/IP is limited to the value of MAXFILEPROC multiplied by the value of CHDISPS.

Specify a value 0-9999. The value must not be greater than the value of MAXCHL. MAXCHL defines the maximum number of channels available. TCP/IP might not support as many as 9999 channels. If so, the value you can specify is limited by the number of channels TCP/IP can support. If you specify zero, the TCP/IP transmission protocol is not used.

If you change this value, also review the MAXCHL, LU62CHL, and ACTCHL values to ensure that there is no conflict of values. If necessary, raise the value of MAXCHL and ACTCHL.

If the value of this parameter is reduced, any current channels that exceed the new limit continue to run until they stop.

Sharing conversations do not contribute to the total for this parameter.

If the value of **TCPCHL** is non-zero when the channel initiator starts up, the value can be modified dynamically. If the value of **TCPCHL** is zero when the channel initiator starts up, a later ALTER command does not take effect. In this case, you should carry out an ALTER command, either before the channel initiator starts, or in CSQINP2 before you issue the **START CHINIT** command.

This parameter is valid on z/OS only.

#### **z/OS TCPKEEP**

Specifies whether the KEEPALIVE facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

**NO** The TCP KEEPALIVE facility is not to be used.

This is the queue manager's initial default value.

**YES** The TCP KEEPALIVE facility is to be used as specified in the TCP profile configuration data set. The interval is specified in the KAIN channel attribute.

This parameter is valid on z/OS only.

Changes to this parameter take effect for channels that are later started. Channels that are currently started are unaffected by changes to this parameter.

Using the TCPKEEP parameter is no longer required for 'modern' queue managers. The replacement is a combination of:

- using 'modern' client channels (SHARECNV <> 0); and
- using receive timeout for message channels RCVTIME.

For more information, see the technote "Setting the TCP/IP KeepAlive interval to be used by IBM MQ", at the following address: <http://www.ibm.com/support/docview.wss?uid=swg21216834>

▶ **z/OS** **TCPNAME** ( *string* )

The name of either the only, or preferred, TCP/IP stack to be used, depending on the value of TCPSTACK. This name is the name of the z/OS UNIX System Services stack for TCP/IP, as specified in the SUBFILESYSTYPE NAME parameter in the BPXPRM xx member of SYS1.PARMLIB. TCPNAME is only applicable in CINET multiple stack environments. The queue manager's initial default value is TCPIP.

In INET single stack environments the channel initiator uses the only available TCP/IP stack.

The maximum length of this parameter is eight characters.

This parameter is valid on z/OS only.

Changes to this parameter take effect when the channel initiator is restarted.

▶ **z/OS** **TCPSTACK**

Specifies whether the channel initiator can use only the TCP/IP stack specified in TCPNAME, or optionally bind to any selected TCP/IP stack defined. This parameter is only applicable in CINET multiple stack environments.

**SINGLE**

The channel initiator can use only the TCP/IP address space specified in TCPNAME.

**MULTIPLE**

The channel initiator can use any TCP/IP address space available to it.

This parameter is valid on z/OS only.

Changes to this parameter take effect when the channel initiator is restarted.

▶ **z/OS** **TRAXSTR**

Specifies whether the channel initiator trace starts automatically:

**YES** Channel initiator trace is to start automatically.

**NO** Channel initiator trace is not to start automatically.

This parameter is valid on z/OS only.

Changes to this parameter take effect when the channel initiator is restarted. If you want to start or stop channel initiator trace without restarting the channel initiator, use the START TRACE or STOP TRACE commands after starting the channel initiator.

▶ **z/OS** **TRAXTBL** ( *integer* )

The size, in megabytes, of the trace data space of the channel initiator.

Specify a value in the range 2 through 2048.

This parameter is valid on z/OS only.

**Note:**

1. Changes to this parameter take effect immediately; any existing trace table contents are lost.
2. The **CHINIT** trace is stored in a dataspace called qmidCHIN.CSQXTRDS. When you use large z/OS data spaces, ensure that sufficient auxiliary storage is available on your system to support any related z/OS paging activity. You might also need to increase the size of your SYS1.DUMP data sets.

**TREELIFE** ( *integer* )

The lifetime, in seconds of non-administrative topics.

Non-administrative topics are those topics created when an application publishes to, or subscribes on, a topic string that does not exist as an administrative node. When this non-administrative node no longer has any active subscriptions, this parameter determines how long the queue manager waits before removing that node. Only non-administrative topics that are in use by a durable subscription remain after the queue manager is recycled.

Specify a value in the range 0 through 604000. A value of 0 means that non-administrative topics are not removed by the queue manager.

**TRIGINT** ( *integer* )

A time interval expressed in milliseconds.

The TRIGINT parameter is relevant only if the trigger type ( TRIGTYPE ) is set to FIRST (see “DEFINE QLOCAL” on page 659 for details). In this case trigger messages are normally generated only when a suitable message arrives on the queue, and the queue was previously empty. Under certain circumstances, however, an additional trigger message can be generated with FIRST triggering even if the queue was not empty. These additional trigger messages are not generated more often than every TRIGINT milliseconds; see Special case of trigger type FIRST.

Specify a value in the range 0 - 999,999,999.

**Related information:**

▶ **z/OS** Working with SSL or TLS on z/OS

**ALTER queues:**

Use the MQSC **ALTER** command to alter the parameters of a queue. A queue might be a local queue ( ALTER QLOCAL), alias queue ( ALTER QALIAS), model queue ( ALTER QMODEL), a remote queue, a queue-manager alias, or a reply-to queue alias ( ALTER QREMOTE).

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

This section contains the following commands:

- “ALTER QALIAS” on page 492
- “ALTER QLOCAL” on page 493
- “ALTER QMODEL” on page 496
- “ALTER QREMOTE” on page 498

These commands are supported on the following platforms:

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

Parameters not specified in the **ALTER** queue commands result in the existing values for those parameters being left unchanged.

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

### Usage notes for ALTER queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER queues step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for ALTER QUEUE

The parameters that are relevant for each type of queue are tabulated in Table 92. Each parameter is described after the table.

Table 92. DEFINE and ALTER QUEUE parameters.

Cross-tabulation of queue parameters and queue types. If the parameter applies to the queue type, the cell contains a check mark.

Parameter	Local queue	Model queue	Alias queue	Remote queue
ACCTQ	✓	✓

XMITQ				✓

*queue-name*

Local name of the queue, except the remote queue where it is the local definition of the remote queue.

The name must not be the same as any other queue name of any queue type currently defined on this queue manager, unless you specify **REPLACE** or **ALTER**. See Rules for naming IBM MQ objects.

**ACCTQ**

Specifies whether accounting data collection is to be enabled for the queue. On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting). In order for accounting data to be collected for this queue, accounting data for this connection must also be enabled. Turn on accounting data collection by setting either the **ACCTQ** queue manager attribute, or the options field in the MQCNO structure on the MQCONN call.

**QMGR** The collection of accounting data is based on the setting of the **ACCTQ** parameter on the queue manager definition.

**ON** Accounting data collection is enabled for the queue unless the **ACCTQ** queue manager parameter has a value of NONE. On z/OS systems, you must switch on class 3 accounting using the **START TRACE** command.

**OFF** Accounting data collection is disabled for the queue.

**BOQNAME** ( *queue-name* )

The excessive backout requeue name.

This parameter is supported only on local and model queues.

Use this parameter to set or change the back out queue name attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS transfers a message that is backed out the maximum number of times to this queue. The maximum is specified by the **BOTHRESH** attribute.

**BOTHRESH** ( *integer* )

The backout threshold.

This parameter is supported only on local and model queues.

Use this parameter to set or change the value of the back out threshold attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS use the attribute to determine how many times back a message out. When the value is exceeded the message is transferred to the queue named by the **BOQNAME** attribute.

Specify a value in the range 0 - 999,999,999.

**CFSTRUCT** ( *structure-name* )

Specifies the name of the coupling facility structure where you want messages stored when you use shared queues.

This parameter is supported only on z/OS for local and model queues.

The name:

- Cannot have more than 12 characters
- Must start with an uppercase letter (A - Z)
- Can include only the characters A - Z and 0 - 9

The name of the queue-sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue-sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue-sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue-sharing group (in this case NY03CSQ\_ADMIN) cannot be used for storing messages.

For ALTER QLOCAL, ALTER QMODEL, DEFINE QLOCAL with **REPLACE**, and DEFINE QMODEL with **REPLACE** the following rules apply:

- On a local queue with **QSGDISP** ( SHARED ), **CFSTRUCT** cannot change.  
If you change either the **CFSTRUCT** or **QSGDISP** value you must delete and redefine the queue. To preserve any of the messages on the queue you must offload the messages before you delete the queue. Reload the messages after you redefine the queue, or move the messages to another queue.
- On a model queue with **DEFTYPE** ( SHAREDYN ), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

For DEFINE QLOCAL with **NOREPLACE** and DEFINE QMODEL with **NOREPLACE**, the coupling facility structure:

- On a local queue with **QSGDISP** ( SHARED ) or a model queue with a **DEFTYPE** ( SHAREDYN ), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

**Note:** Before you can use the queue, the structure must be defined in the coupling facility Resource Management (CFRM) policy data set.

**CLCHNAME** ( *channel name* )

This parameter is supported only on transmission queues.

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

You can also set the transmission queue attribute CLCHNAME attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the CLCHNAME attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either SYSTEM.CLUSTER.TRANSMIT. *ChannelName* or SYSTEM.CLUSTER.TRANSMIT.QUEUE, depending on the value of the queue manager DEFCLXQ attribute.

By specifying asterisks, "" \* "" , in CLCHNAME, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. CLCHNAME is limited to a length of 48 characters,

MQ\_OBJECT\_NAME\_LENGTH. A channel name is limited to 20 characters: MQ\_CHANNEL\_NAME\_LENGTH. If you specify an asterisk you must also set the SHARE attribute so that multiple channels can concurrently access the transmission queue.

► **z/OS** If you specify a "\*" in CLCHNAME, to obtain a channel profile name, you must specify the channel profile name within quotation marks. If you do not specify the generic channel name within quotation marks you receive message CSQ9030E.

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, SYSTEM.CLUSTER.TRANSMIT.QUEUE. The default configuration can be changed by modified by changing the queue manager attribute, DEFCLXQ. The default value of the attribute is SCTQ. You can change the value to CHANNEL. If you set the DEFCLXQ attribute to CHANNEL, each cluster-sender channel defaults to using a specific cluster transmission queue, SYSTEM.CLUSTER.TRANSMIT. *ChannelName*.

► **z/OS** On z/OS, if this parameter is set, the queue:

- Must be shareable, by specifying the queue attribute SHARE.
- Must be indexed on the correlation ID by specifying INDXTYPE(CORRELID).
- Must not be a dynamic or a shared queue.

#### **CLUSNL** ( *namelist name* )

The name of the namelist that specifies a list of clusters to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be nonblank; you cannot specify a value for both.

On local queues, this parameter cannot be set for transmission, SYSTEM.CHANNEL. *xx*, SYSTEM.CLUSTER. *xx*, or SYSTEM.COMMAND. *xx* queues ► **z/OS** , and on z/OS only, for SYSTEM.QSG. *xx* queues.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS.

#### **CLUSTER** ( *cluster name* )

The name of the cluster to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

The maximum length is 48 characters conforming to the rules for naming IBM MQ objects. Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be nonblank; you cannot specify a value for both.

On local queues, this parameter cannot be set for transmission, SYSTEM.CHANNEL. *xx*, SYSTEM.CLUSTER. *xx*, or SYSTEM.COMMAND. *xx* queues ► **z/OS** , and on z/OS only, for SYSTEM.QSG. *xx* queues.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS.

#### **CLWLPRTY** ( *integer* )

Specifies the priority of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest. For more information about this attribute, see CLWLPRTY queue attribute.

#### **CLWLRANK** ( *integer* )

Specifies the rank of the queue for the purposes of cluster workload distribution. This parameter

is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest. For more information about this attribute, see CLWLRANK queue attribute.

## CLWLUSEQ

Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. The parameter has no effect when the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

**QMGR** The behavior is as specified by the **CLWLUSEQ** parameter of the queue manager definition.

**ANY** The queue manager is to treat the local queue as another instance of the cluster queue for the purposes of workload distribution.

**LOCAL** The local queue is the only target of the MQPUT operation.

## z/OS **CMDSCOPE**

This parameter applies to z/OS only. It specifies where the command is run when the queue manager is a member of a queue-sharing group.

**CMDSCOPE** must be blank, or the local queue manager, if **QSGDISP** is set to GROUP or SHARED.

**''** The command is run on the queue manager on which it was entered.

### *QmgrName*

The command is run on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can specify another name, only if you are using a queue-sharing group environment and if the command server is enabled.

**\*** The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of **\*** is the same as entering the command on every queue manager in the queue-sharing group.

## **CUSTOM** ( *string* )

The custom attribute for new features.

**V8.0.0.4** This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name and value pairs have the form NAME(VALUE). Single quotation marks must be escaped with another single quotation mark.

## **CAPEXPY** ( *integer* )

The maximum time, expressed in tenths of a second, until a message put using an object handle with this object in the resolution path, becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

*integer* The value must be in the range one through to 999 999 999.

## **NOLIMIT**

There is no limit on the expiry time of messages put using this object. This is the default value.

Specifying a value for **CAPEXPY** that is not valid, does not cause the command to fail. Instead the default value is used.

Note that existing messages in the queue, prior to a change in **CAPEXPY**, are not affected by the change (that is, their expiry time remains intact). Only new messages that are put into the queue after the change in **CAPEXPY** have the new expiry time.

## DEFBIND

Specifies the binding to be used when the application specifies MQ00\_BIND\_AS\_Q\_DEF on the MQOPEN call, and the queue is a cluster queue.

**OPEN** The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

### NOTFIXED

The queue handle is not bound to any instance of the cluster queue. The queue manager selects a specific queue instance when the message is put using MQPUT. It changes that selection later, if the need arises.

**GROUP** Allows an application to request that a group of messages is allocated to the same destination instance.

Multiple queues with the same name can be advertised in a queue manager cluster. An application can send all messages to a single instance, MQ00\_BIND\_ON\_OPEN. It can allow a workload management algorithm to select the most suitable destination on a per message basis, MQ00\_BIND\_NOT\_FIXED. It can allow an application to request that a “group” of messages be all allocated to the same destination instance. The workload balancing reselects a destination between groups of messages, without requiring an MQCLOSE and MQOPEN of the queue.

The MQPUT1 call always behaves as if NOTFIXED is specified.

This parameter is valid only on AIX, HP-UX, Linux, IBM i, Solaris, and Windows , and z/OS.

## DEFPRESP

Specifies the behavior to be used by applications when the put response type, within the MQPMO options, is set to MQPMO\_RESPONSE\_AS\_Q\_DEF.

**SYNC** Put operations to the queue specifying MQPMO\_RESPONSE\_AS\_Q\_DEF are issued as if MQPMO\_SYNC\_RESPONSE is specified instead.

**ASYN** Put operations to the queue specifying MQPMO\_RESPONSE\_AS\_Q\_DEF are issued as if MQPMO\_ASYNC\_RESPONSE is specified instead; see MQPMO options (MQLONG).

## DEFPRTY ( *integer* )

The default priority of messages put on the queue. The value must be in the range 0 - 9. Zero is the lowest priority, through to the **MAXPRTY** queue manager parameter. The default value of **MAXPRTY** is 9.

## DEFPSIST

Specifies the message persistence to be used when applications specify the MQPER\_PERSISTENCE\_AS\_Q\_DEF option.

**NO** Messages on this queue are lost across a restart of the queue manager.

**YES** Messages on this queue survive a restart of the queue manager.

 On z/OS, N and Y are accepted as synonyms of NO and YES.

## DEFREADA

Specifies the default read ahead behavior for non-persistent messages delivered to the client. Enabling read ahead can improve the performance of client applications consuming non-persistent messages.

**NO** Non-persistent messages are not read ahead unless the client application is configured to request read ahead.

**YES** Non-persistent messages are sent to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not delete all the messages it is sent.

**DISABLED**

Read ahead of non-persistent messages is not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

**DEFSOPT**

The default share option for applications opening this queue for input:

**EXCL** The open request is for exclusive input from the queue

**SHARED**

The open request is for shared input from the queue

**DEFTYPE**

Queue definition type.

This parameter is supported only on model queues.

**PERMDYN**

A permanent dynamic queue is created when an application issues an MQOPEN MQI call with the name of this model queue specified in the object descriptor ( MQOD).

▶ **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

▶ **z/OS** **SHAREDYN**

This option is available on z/OS only.

A permanent dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor ( MQOD).

The dynamic queue has a disposition of SHARED.

**TEMPDYN**

A temporary dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor ( MQOD).

▶ **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

Do not specify this value for a model queue definition with a **DEFPSIST** parameter of YES.

If you specify this option, do not specify **INDXTYPE** ( MSGTOKEN ).

**DESCR ( string )**

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY QUEUE command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** Use characters that are in the coded character set identifier (CCSID) of this queue manager. If you do not do so and if the information is sent to another queue manager, they might be translated incorrectly.

**DISTL**

**DISTL** sets whether distribution lists are supported by the partner queue manager.

**YES** Distribution lists are supported by the partner queue manager.

**NO** Distribution lists are not supported by the partner queue manager.

**Note:** You do not normally change this parameter, because it is set by the MCA. However you can set this parameter when defining a transmission queue if the distribution list capability of the destination queue manager is known.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows.

## FORCE

This parameter applies only to the ALTER command on alias, local and remote queues.

Specify this parameter to force completion of the command in the following circumstances.

For an alias queue, if both of the following are true:

- The **TARGQ** parameter is specified
- An application has this alias queue open

For a local queue, if both of the following are true:

- The **NOSHARE** parameter is specified
- More than one application has the queue open for input

**FORCE** is also needed if both of the following are true:

- The **USAGE** parameter is changed
- Either one or more messages are on the queue, or one or more applications have the queue open

Do not change the **USAGE** parameter while there are messages on the queue; the format of messages changes when they are put on a transmission queue.

For a remote queue, if both of the following are true:

- The **XMITQ** parameter is changed
- One or more applications has this queue open as a remote queue

**FORCE** is also needed if both of the following are true:

- Any of the **RNAME**, **RQMNAME**, or **XMITQ** parameters are changed
- One or more applications has a queue open that resolved through this definition as a queue manager alias

**Note:** **FORCE** is not required if this definition is in use as a reply-to queue alias only.

If **FORCE** is not specified in the circumstances described, the command is unsuccessful.

**GET** Specifies whether applications are to be permitted to get messages from this queue:

### **ENABLED**

Messages can be retrieved from the queue, by suitably authorized applications.

### **DISABLED**

Applications cannot retrieve messages from the queue.

This parameter can also be changed using the MQSET API call.

## **HARDENBO & NOHARDENBO**

Specifies whether hardening is used to ensure that the count of the number of times that a message is backed out is accurate.

This parameter is supported only on local and model queues and you can set this parameter on distributed platforms, but it is ineffective..

### **HARDENBO**

The count is hardened.

### **NOHARDENBO**

The count is not hardened.

**Note:**  This parameter affects only IBM MQ for z/OS.

**INDXTYPE**

The type of index maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines the type of MQGET operations that can be used.

This parameter is supported only on local and model queues.

Messages can be retrieved using a selection criterion only if an appropriate index type is maintained, as the following table shows:

Retrieval selection criterion	Index type required	
	Shared queue	Other queue
None (sequential retrieval)	Any	Any
Message identifier	MSGID or NONE	Any
Correlation identifier	CORRELID	Any
Message and correlation identifiers	MSGID or CORRELID	Any
Group identifier	GROUPID	Any
Grouping	GROUPID	GROUPID
Message token	Not allowed	MSGTOKEN

where the value of **INDXTYPE** parameter has the following values:

**NONE** No index is maintained. Use NONE when messages are typically retrieved sequentially or use both the message identifier and the correlation identifier as a selection criterion on the MQGET call.

**MSGID** An index of message identifiers is maintained. Use MSGID when messages are typically retrieved using the message identifier as a selection criterion on the MQGET call with the correlation identifier set to NULL.

**CORRELID**

An index of correlation identifiers is maintained. Use CORRELID when messages are typically retrieved using the correlation identifier as a selection criterion on the MQGET call with the message identifier set to NULL.

**GROUPID**

An index of group identifiers is maintained. Use GROUPID when messages are retrieved using message grouping selection criteria.

**Note:**

1. You cannot set **INDXTYPE** to GROUPID if the queue is a transmission queue.
2. The queue must use a CF structure at CFLEVEL(3), to specify a shared queue with **INDXTYPE ( GROUPID )**.

**MSGTOKEN**

An index of message tokens is maintained. Use MSGTOKEN when the queue is a WLM-managed queue that you are using with the Workload Manager functions of z/OS.

**Note:** You cannot set **INDXTYPE** to MSGTOKEN if:

- The queue is a model queue with a definition type of SHAREDYN
- The queue is a temporary dynamic queue
- The queue is a transmission queue
- You specify **QSGDISP ( SHARED )**

For queues that are not shared and do not use grouping or message tokens, the index type does not restrict the type of retrieval selection. However, the index is used to expedite **GET** operations on the queue, so choose the type that corresponds to the most common retrieval selection.

If you are altering or replacing an existing local queue, you can change the **INDXTYPE** parameter only in the cases indicated in the following table:

Queue type		NON-SHARED			SHARED	
Queue state		Uncommitted activity	No uncommitted activity, messages present	No uncommitted activity, and empty	Open or messages present	Not open, and empty
Change INDXTYPE from:	To:	Change allowed?				
NONE	MSGID	No	Yes	Yes	No	Yes
NONE	CORRELID	No	Yes	Yes	No	Yes
NONE	MSGTOKEN	No	No	Yes	-	-
NONE	GROUPID	No	No	Yes	No	Yes
MSGID	NONE	No	Yes	Yes	No	Yes
MSGID	CORRELID	No	Yes	Yes	No	Yes
MSGID	MSGTOKEN	No	No	Yes	-	-
MSGID	GROUPID	No	No	Yes	No	Yes
CORRELID	NONE	No	Yes	Yes	No	Yes
CORRELID	MSGID	No	Yes	Yes	No	Yes
CORRELID	MSGTOKEN	No	No	Yes	-	-
CORRELID	GROUPID	No	No	Yes	No	Yes
MSGTOKEN	NONE	No	Yes	Yes	-	-
MSGTOKEN	MSGID	No	Yes	Yes	-	-
MSGTOKEN	CORRELID	No	Yes	Yes	-	-
MSGTOKEN	GROUPID	No	No	Yes	-	-
GROUPID	NONE	No	No	Yes	No	Yes
GROUPID	MSGID	No	No	Yes	No	Yes
GROUPID	CORRELID	No	No	Yes	No	Yes
GROUPID	MSGTOKEN	No	No	Yes	-	-

This parameter is supported only on z/OS. On other platforms, all queues are automatically indexed.

**INITQ** ( *string* )

The local name of the initiation queue on this queue manager, to which trigger messages relating to this queue are written; see Rules for naming IBM MQ objects.

This parameter is supported only on local and model queues.

**LIKE** ( *qtype-name* )

The name of a queue, with parameters that are used to model this definition.

If this field is not completed, the values of undefined parameter fields are taken from one of the following definitions. The choice depends on the queue type:

Queue type	Definition
Alias queue	SYSTEM.DEFAULT.ALIAS.QUEUE
Local queue	SYSTEM.DEFAULT.LOCAL.QUEUE
Model queue	SYSTEM.DEFAULT.MODEL.QUEUE
Remote queue	SYSTEM.DEFAULT.REMOTE.QUEUE

For example, not completing this parameter is equivalent to defining the following value of **LIKE** for an alias queue:

```
LIKE(SYSTEM.DEFAULT.ALIAS.QUEUE)
```

If you require different default definitions for all queues, alter the default queue definitions instead of using the **LIKE** parameter.

► **z/OS** On z/OS, the queue manager searches for an object with the name and queue type you specify with a disposition of QMGR, COPY, or SHARED. The disposition of the **LIKE** object is not copied to the object you are defining.

**Note:**

1. **QSGDISP** ( GROUP ) objects are not searched.
2. **LIKE** is ignored if **QSGDISP** ( COPY ) is specified.

**MAXDEPTH** ( *integer* )

The maximum number of messages allowed on the queue.

This parameter is supported only on local and model queues.

On AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS, specify a value in the range zero through 999999999.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS.

On any other IBM MQ platform, specify a value in the range zero through 640000.

Other factors can still cause the queue to be treated as full, for example, if there is no further hard disk space available.

If this value is reduced, any messages that are already on the queue that exceed the new maximum remain intact.

**MAXMSGL** ( *integer* )

The maximum length (in bytes) of messages on this queue.

This parameter is supported only on local and model queues.

On AIX, HP-UX, Linux, Solaris, and Windows, specify a value in the range zero to the maximum message length for the queue manager. See the **MAXMSGL** parameter of the ALTER QMGR command, ALTER QMGR MAXMSGL.

► **z/OS** On z/OS, specify a value in the range zero through 100 MB (104 857 600 bytes).

Message length includes the length of user data and the length of headers. For messages put on the transmission queue, there are additional transmission headers. Allow an additional 4000 bytes for all the message headers.

If this value is reduced, any messages that are already on the queue with length that exceeds the new maximum are not affected.

Applications can use this parameter to determine the size of buffer for retrieving messages from the queue. Therefore, the value can be reduced only if it is known that this reduction does not cause an application to operate incorrectly.

Note that by adding the digital signature and key to the message, IBM MQ Advanced Message Security increases the length of the message.

## MONQ

Controls the collection of online monitoring data for queues.

This parameter is supported only on local and model queues.

**QMGR** Collect monitoring data according to the setting of the queue manager parameter **MONQ**.

**OFF** Online monitoring data collection is turned off for this queue.

**LOW** If the value of the **MONQ** parameter of the queue manager is not **NONE**, online monitoring data collection is turned on for this queue.

### MEDIUM

If the value of the **MONQ** parameter of the queue manager is not **NONE**, online monitoring data collection is turned on for this queue.

**HIGH** If the value of the **MONQ** parameter of the queue manager is not **NONE**, online monitoring data collection is turned on for this queue.

There is no distinction between the values **LOW**, **MEDIUM**, and **HIGH**. These values all turn data collection on, but do not affect the rate of collection.

When this parameter is used in an **ALTER** queue command, the change is effective only when the queue is next opened.

## MSGDLVSQ

Message delivery sequence.

This parameter is supported only on local and model queues.

### PRIORITY

Messages are delivered (in response to **MQGET** API calls) in first-in-first-out (**FIFO**) order within priority.

**FIFO** Messages are delivered (in response to **MQGET** API calls) in **FIFO** order. Priority is ignored for messages on this queue.

The message delivery sequence parameter can be changed from **PRIORITY** to **FIFO** while there are messages on the queue. The order of the messages already on the queue is not changed. Messages added to the queue later take the default priority of the queue, and so might be processed before some of the existing messages.

If the message delivery sequence is changed from **FIFO** to **PRIORITY**, the messages put on the queue while the queue was set to **FIFO** take the default priority.

**Note:**  If **INDXTYPE** ( **GROUPID** ) is specified with **MSGDLVSQ** ( **PRIORITY** ), the priority in which groups are retrieved is based on the priority of the first message within each group. The priorities 0 and 1 are used by the queue manager to optimize the retrieval of messages in logical order. The first message in each group must not use these priorities. If it does, the message is stored as if it was priority two.

## NPMCLASS

The level of reliability to be assigned to non-persistent messages that are put to the queue:

**NORMAL** Non-persistent messages are lost after a failure, or queue manager shutdown. These messages are discarded on a queue manager restart.

**HIGH** The queue manager attempts to retain non-persistent messages on this queue over a queue manager restart or switch over.

 You cannot set this parameter on z/OS.

## PROCESS ( *string* )

The local name of the IBM MQ process.

This parameter is supported only on local and model queues.

This parameter is the name of a process instance that identifies the application started by the queue manager when a trigger event occurs; see Rules for naming IBM MQ objects.

The process definition is not checked when the local queue is defined, but it must be available for a trigger event to occur.

If the queue is a transmission queue, the process definition contains the name of the channel to be started. This parameter is optional for transmission queues on AIX, HP-UX, IBM i, Linux, Solaris, and Windows  z/OS, and z/OS. If you do not specify it, the channel name is taken from the value specified for the **TRIGDATA** parameter.

## PROPCTL

Property control attribute. The attribute is optional. It is applicable to local, alias, and model queues.

**PROPCTL** options are as follows. The options do not affect message properties in the MQMD or MQMD extension.

### ALL

Set ALL so that an application can read all the properties of the message either in MQRFH2 headers, or as properties of the message handle.

The ALL option enables applications that cannot be changed to access all the message properties from MQRFH2 headers. Applications that can be changed, can access all the properties of the message as properties of the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

### COMPAT

Set COMPAT so that unmodified applications that expect JMS-related properties to be in an MQRFH2 header in the message data continue to work as before. Applications that can be changed, can access all the properties of the message as properties of the message handle.

If the message contains a property with a prefix of *mcd.*, *jms.*, *usr.*, or *mqext.*, all message properties are delivered to the application. If no message handle is supplied, properties are returned in an MQRFH2 header. If a message handle is supplied, all properties are returned in the message handle.

If the message does not contain a property with one of those prefixes, and the application does not provide a message handle, no message properties are returned to the application. If a message handle is supplied, all properties are returned in the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

### FORCE

Force all applications to read message properties from MQRFH2 headers.

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the `MQGMO` structure on the `MQGET` call is ignored. Properties of the message are not accessible using the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

#### **NONE**

If a message handle is supplied, all the properties are returned in the message handle.

All message properties are removed from the message body before it is delivered to the application.

**PUT** Specifies whether messages can be put on the queue.

#### **ENABLED**

Messages can be added to the queue (by suitably authorized applications).

#### **DISABLED**

Messages cannot be added to the queue.

This parameter can also be changed using the MQSET API call.

#### **QDEPTHHI** ( *integer* )

The threshold against which the queue depth is compared to generate a Queue Depth High event.

This parameter is supported only on local and model queues.  For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events ( IBM MQ for z/OS ).

This event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDPHIEV** parameter.

The value is expressed as a percentage of the maximum queue depth ( **MAXDEPTH** parameter), and must be in the range zero through 100 and no less than **QDEPTHLO**.

#### **QDEPTHLO** ( *integer* )

The threshold against which the queue depth is compared to generate a Queue Depth Low event.

This parameter is supported only on local and model queues.  For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events ( IBM MQ for z/OS ).

This event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDPLOEV** parameter.

The value is expressed as a percentage of the maximum queue depth ( **MAXDEPTH** parameter), and must be in the range zero through 100 and no greater than **QDEPTHHI**.

#### **QDPHIEV**

Controls whether Queue Depth High events are generated.

This parameter is supported only on local and model queues.

A Queue Depth High event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDEPTHHI** parameter.

**Note:** The value of this parameter can change implicitly  , and shared queues on z/OS affect the event. See the description of Queue Depth High.

#### **ENABLED**

Queue Depth High events are generated

**DISABLED**

Queue Depth High events are not generated

**QDPLOEV**

Controls whether Queue Depth Low events are generated.

This parameter is supported only on local and model queues.

A Queue Depth Low event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDEPTHLO** parameter.

**Note:** The value of this parameter can change implicitly , and shared queues on z/OS affect the event. For more information about this event, see Queue Depth Low.

**ENABLED**

Queue Depth Low events are generated

**DISABLED**

Queue Depth Low events are not generated

**QDPMAXEV**

Controls whether Queue Full events are generated.

This parameter is supported only on local and model queues.

A Queue Full event indicates that a put to a queue was rejected because the queue is full. The queue depth reached its maximum value.

**Note:** The value of this parameter can change implicitly , and shared queues on z/OS affect the event. For more information about this event, see Queue Full.

**ENABLED**

Queue Full events are generated

**DISABLED**

Queue Full events are not generated

 **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

Action of ALTER depending on different values of **QSGDISP**.

<b>QSGDISP</b>	<b>ALTER</b>
COPY	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters <b>QSGDISP ( COPY )</b> . Any object residing in the shared repository, or any object defined using a command that had the parameters <b>QSGDISP ( QMGR )</b> , is not affected by this command.

Action of ALTER depending on different values of QSGDISP.

QSGDISP	ALTER
GROUP	<p>The object definition resides in the shared repository. The object was defined using a command that had the parameters <b>QSGDISP ( GROUP )</b>. Any object residing on the page set of the queue manager that executes the command (except a local copy of the object), or any object defined using a command that had the parameters <b>QSGDISP ( SHARED )</b>, is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to refresh local copies on page set zero:</p> <pre>DEFINE QUEUE(QNAME) REPLACE QSGDISP(COPY)</pre> <p>The ALTER for the group object takes effect regardless of whether the generated command with <b>QSGDISP ( COPY )</b> fails.</p>
PRIVATE	<p>The object resides on the page set of the queue manager that executes the command, and was defined with <b>QSGDISP ( QMGR )</b> or <b>QSGDISP ( COPY )</b>. Any object residing in the shared repository is unaffected.</p>
QMGR	<p>The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters <b>QSGDISP ( QMGR )</b>. Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.</p>
SHARED	<p>This value applies only to local queues. The object definition resides in the shared repository. The object was defined using a command that had the parameters <b>QSGDISP ( SHARED )</b>. Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters <b>QSGDISP ( GROUP )</b>, is not affected by this command. If the queue is clustered, a command is generated and sent to all active queue managers in the queue-sharing group to notify them of this clustered, shared queue.</p>

## QSVCI EV

Controls whether Service Interval High or Service Interval OK events are generated.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

A Service Interval High event is generated when a check indicates that no messages were retrieved from the queue for at least the time indicated by the **QSVCI NT** parameter.

A Service Interval OK event is generated when a check indicates that messages were retrieved from the queue within the time indicated by the **QSVCI NT** parameter.

**Note:** The value of this parameter can change implicitly. For more information, see the description of the Service Interval High and Service Interval OK events in Queue Service Interval High and Queue Service Interval OK.

**HIGH** Service Interval High events are generated

**OK** Service Interval OK events are generated

**NONE** No service interval events are generated

## QSVCI NT ( integer )

The service interval used for comparison to generate Service Interval High and Service Interval OK events.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

See the **QSVCI EV** parameter.

The value is in units of milliseconds, and must be in the range zero through 999999999.

## REPLACE & NOREPLACE

This option controls whether any existing definition , and on IBM MQ for z/OS of the same disposition, is to be replaced with this one.

**Note:**  Any object with a different disposition is not changed.

### REPLACE

If the object does exist, the effect is like issuing the **ALTER** command without the **FORCE** parameter and with all the other parameters specified. In particular, note that any messages that are on the existing queue are retained.

There is a difference between the **ALTER** command without the **FORCE** parameter, and the **DEFINE** command with the **REPLACE** parameter. The difference is that **ALTER** does not change unspecified parameters, but **DEFINE** with **REPLACE** sets all the parameters. If you use **REPLACE**, unspecified parameters are taken either from the object named on the **LIKE** parameter, or from the default definition, and the parameters of the object being replaced, if one exists, are ignored.

The command fails if both of the following are true:

- The command sets parameters that would require the use of the **FORCE** parameter if you were using the **ALTER** command
- The object is open

The **ALTER** command with the **FORCE** parameter succeeds in this situation.

If **SCOPE(CELL)** is specified on UNIX and Linux systems, or Windows, and there is already a queue with the same name in the cell directory, the command fails, even if **REPLACE** is specified.

### NOREPLACE

The definition must not replace any existing definition of the object.

## RETINTVL ( *integer* )

The number of hours from when the queue was defined, after which the queue is no longer needed. The value must be in the range 0 - 999,999,999.

This parameter is supported only on local and model queues.

The CRDATE and CRTIME can be displayed using the **DISPLAY QUEUE** command.

This information is available for use by an operator or a housekeeping application to delete queues that are no longer required.

**Note:** The queue manager does not delete queues based on this value, nor does it prevent queues from being deleted if their retention interval is not expired. It is the responsibility of the user to take any required action.

## RNAME ( *string* )

Name of remote queue. This parameter is the local name of the queue as defined on the queue manager specified by **RQMNAME**.

This parameter is supported only on remote queues.

- If this definition is used for a local definition of a remote queue, **RNAME** must not be blank when the open occurs.
- If this definition is used for a queue manager alias definition, **RNAME** must be blank when the open occurs.

In a queue manager cluster, this definition applies only to the queue manager that made it. To advertise the alias to the whole cluster, add the **CLUSTER** attribute to the remote queue definition.

- If this definition is used for a reply-to queue alias, this name is the name of the queue that is to be the reply-to queue.

The name is not checked to ensure that it contains only those characters normally allowed for queue names; see Rules for naming IBM MQ objects.

#### **RQMNAME** ( *string* )

The name of the remote queue manager on which the queue **RNAME** is defined.

This parameter is supported only on remote queues.

- If an application opens the local definition of a remote queue, **RQMNAME** must not be blank or the name of the local queue manager. When the open occurs, if **XMITQ** is blank there must be a local queue of this name, which is to be used as the transmission queue.
- If this definition is used for a queue manager alias, **RQMNAME** is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if **XMITQ** is blank, when the open occurs there must be a local queue of this name, which is to be used as the transmission queue.
- If **RQMNAME** is used for a reply-to queue alias, **RQMNAME** is the name of the queue manager that is to be the reply-to queue manager.

The name is not checked to ensure that it contains only those characters normally allowed for IBM MQ object names; see Rules for naming IBM MQ objects.

#### **SCOPE**

Specifies the scope of the queue definition.

This parameter is supported only on alias, local, and remote queues.

**QMGR** The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager that owns it. You can open a queue for output that is owned by another queue manager in either of two ways:

1. Specify the name of the owning queue manager.
2. Open a local definition of the queue on the other queue manager.

**CELL** The queue definition has cell scope. Cell scope means that the queue is known to all the queue managers in the cell. A queue with cell scope can be opened for output merely by specifying the name of the queue. The name of the queue manager that owns the queue need not be specified.

If there is already a queue with the same name in the cell directory, the command fails. The **REPLACE** option does not affect this situation.

This value is valid only if a name service supporting a cell directory is configured.

**Restriction:** The DCE name service is no longer supported.

This parameter is valid only on UNIX and Linux systems, and Windows.

#### **SHARE** and **NOSHARE**

Specifies whether multiple applications can get messages from this queue.

This parameter is supported only on local and model queues.

**SHARE** More than one application instance can get messages from the queue.

#### **NOSHARE**

Only a single application instance can get messages from the queue.

## STATQ

Specifies whether statistics data collection is enabled:

**QMGR** Statistics data collection is based on the setting of the **STATQ** parameter of the queue manager.

**ON** If the value of the **STATQ** parameter of the queue manager is not **NONE**, statistics data collection for the queue is enabled.

**OFF** Statistics data collection for the queue is disabled.

If this parameter is used in an **ALTER** queue command, the change is effective only for connections to the queue manager made after the change to the parameter.

This parameter is valid only on IBM i, UNIX and Linux systems, and Windows.

### z/OS **STGCLASS** ( *string* )

The name of the storage class.

This parameter is supported only on local and model queues.

This parameter is an installation-defined name.

This parameter is valid on z/OS only ; see Storage classes.

The first character of the name must be uppercase A through Z, and subsequent characters either uppercase A through Z or numeric 0 through 9.

**Note:** You can change this parameter only if the queue is empty and closed.

If you specify **QSGDISP** ( **SHARED** ) or **DEFTYPE** ( **SHAREDYN** ), this parameter is ignored.

## TARGET ( *string* )

The name of the queue or topic object being aliased; See Rules for naming IBM MQ objects. The object can be a queue or a topic as defined by **TARGETYPE**. The maximum length is 48 characters.

This parameter is supported only on alias queues.

This object needs to be defined only when an application process opens the alias queue.

This parameter is a synonym of the parameter **TARGQ**; **TARGQ** is retained for compatibility. If you specify **TARGET**, you cannot also specify **TARGQ**.

## TARGETYPE ( *string* )

The type of object to which the alias resolves.

**QUEUE** The alias resolves to a queue.

**TOPIC** The alias resolves to a topic.

## TRIGDATA ( *string* )

The data that is inserted in the trigger message. The maximum length of the string is 64 bytes.

This parameter is supported only on local and model queues.

For a transmission queue on AIX, HP-UX, IBM i, Linux, Solaris, and Windows , and z/OS, you can use this parameter to specify the name of the channel to be started.

This parameter can also be changed using the MQSET API call.

## TRIGDPTH ( *integer* )

The number of messages that have to be on the queue before a trigger message is written, if **TRIGTYPE** is **DEPTH**. The value must be in the range 1 - 999,999,999.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

## TRIGGER & NOTRIGGER

Specifies whether trigger messages are written to the initiation queue, named by the **INITQ** parameter, to trigger the application, named by the **PROCESS** parameter:

### TRIGGER

Triggering is active, and trigger messages are written to the initiation queue.

### NOTRIGGER

Triggering is not active, and trigger messages are not written to the initiation queue.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

## TRIGMPRI ( *integer* )

The message priority number that triggers this queue. The value must be in the range zero through to the **MAXPRTY** queue manager parameter; see “DISPLAY QMGR” on page 839 for details.

This parameter can also be changed using the MQSET API call.

## TRIGTYPE

Specifies whether and under what conditions a trigger message is written to the initiation queue. The initiation queue is (named by the **INITQ** parameter).

This parameter is supported only on local and model queues.

**FIRST** Whenever the first message of priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue arrives on the queue.

**EVERY** Every time a message arrives on the queue with priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue.

**DEPTH** When the number of messages with priority equal to or greater than the priority specified by **TRIGMPRI** is equal to the number indicated by the **TRIGDPH** parameter.

**NONE** No trigger messages are written.

This parameter can also be changed using the MQSET API call.

## USAGE

Queue usage.

This parameter is supported only on local and model queues.

### NORMAL

The queue is not a transmission queue.

**XMITQ** The queue is a transmission queue, which is used to hold messages that are destined for a remote queue manager. When an application puts a message to a remote queue, the message is stored on the appropriate transmission queue. It stays there, awaiting transmission to the remote queue manager.

If you specify this option, do not specify values for **CLUSTER** and **CLUSNL**.

 Additionally, on z/OS, do not specify **INDXTYPE** (MSGTOKEN) or **INDXTYPE** (GROUPID).

## XMITQ ( *string* )

The name of the transmission queue to be used for forwarding messages to the remote queue. **XMITQ** is used with either remote queue or queue manager alias definitions.

This parameter is supported only on remote queues.

If **XMITQ** is blank, a queue with the same name as **RQMNAME** is used as the transmission queue.

This parameter is ignored if the definition is being used as a queue manager alias and **RQMNAME** is the name of the local queue manager.

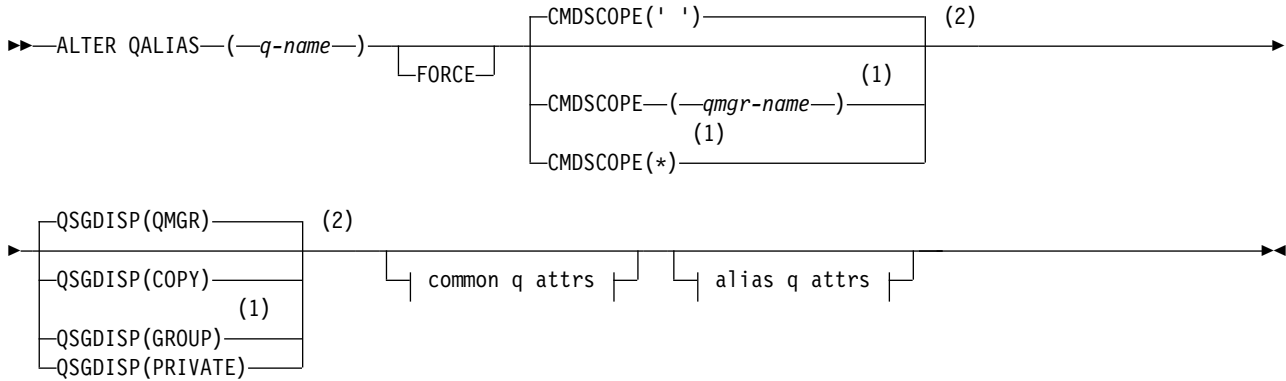

It is also ignored if the definition is used as a reply-to queue alias definition.

**ALTER QALIAS:**

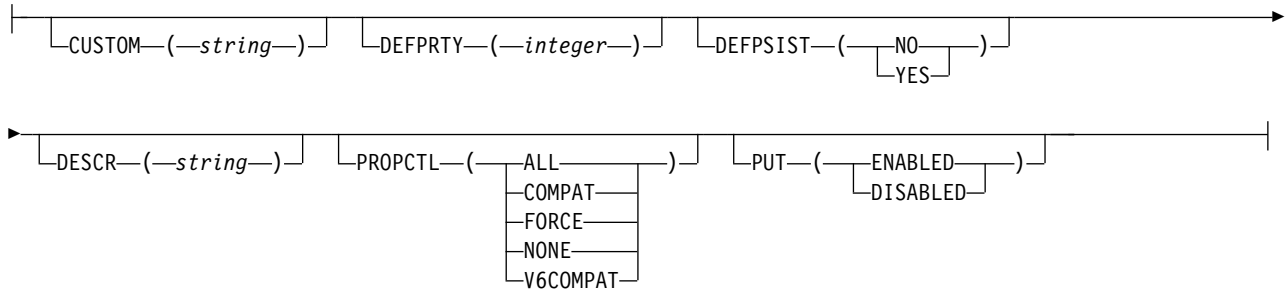

Use the MQSC command ALTER QALIAS to alter the parameters of an alias queue.

**Synonym:** ALT QA

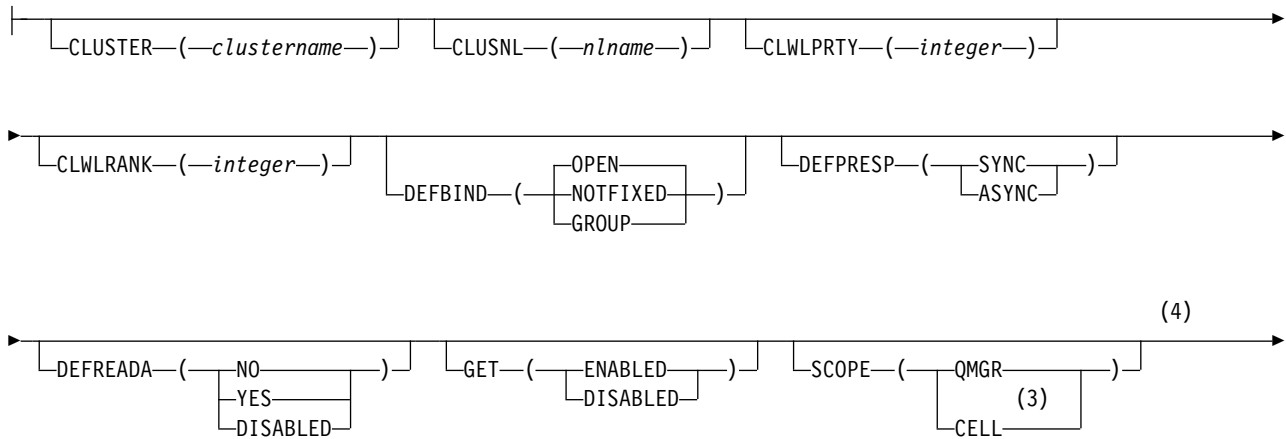

**ALTER QALIAS**

**Common q attrs:**

**Alias q attrs:**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Valid only on Windows, UNIX, and Linux systems.
- 4 Not valid on z/OS.
- 5 The TARGQ parameter is available for compatibility with previous releases. It is a synonym of TARGET; you cannot specify both parameters.

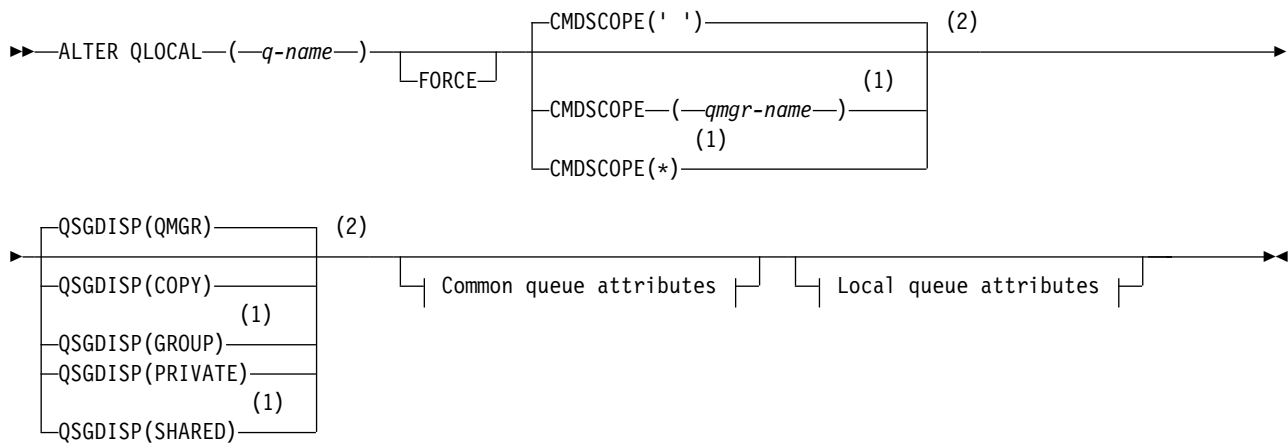

The parameters are described in “ALTER queues” on page 469.

**ALTER QLOCAL:**

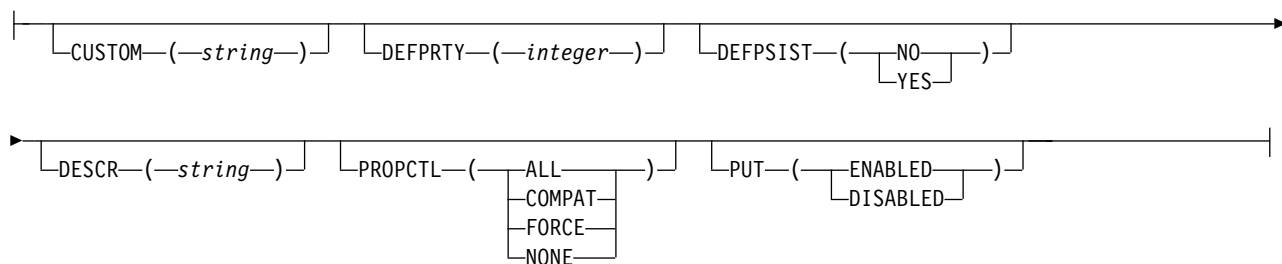

Use the MQSC command **ALTER QLOCAL** to alter the parameters of a local queue.

**Synonym:** ALT QL

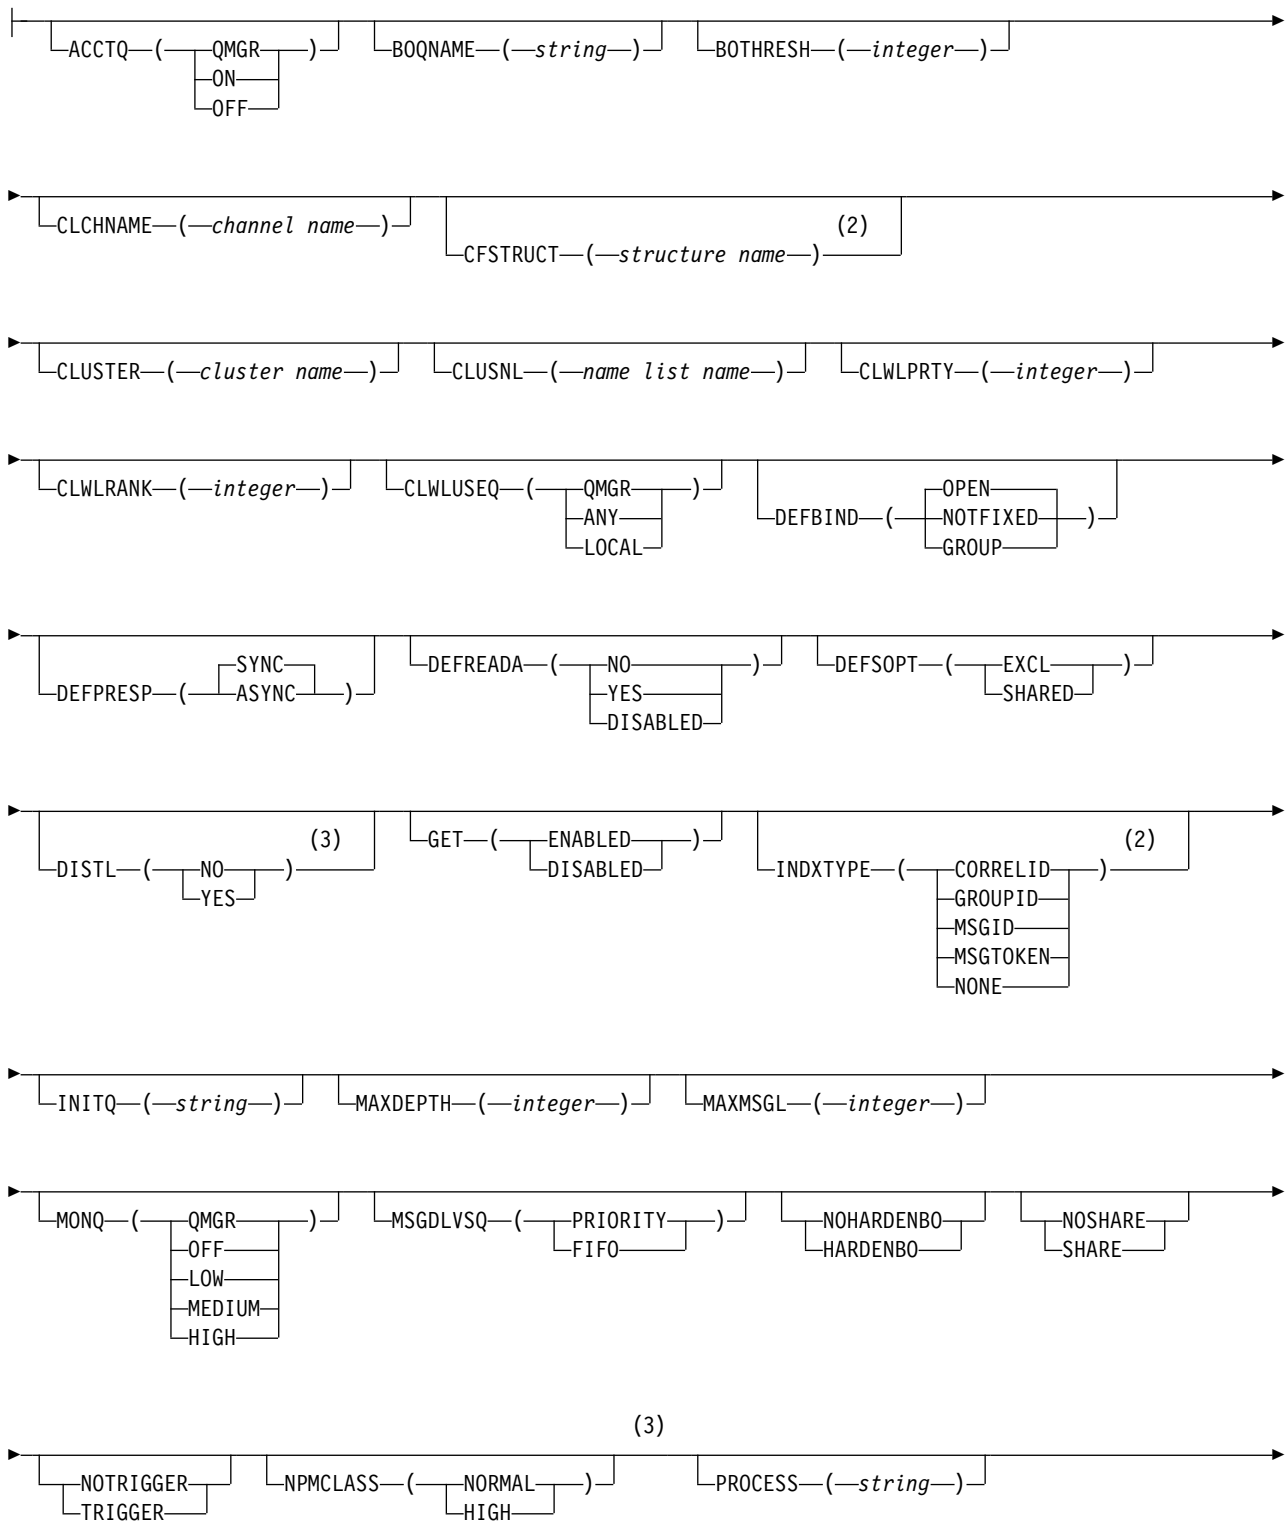

**ALTER QLOCAL**

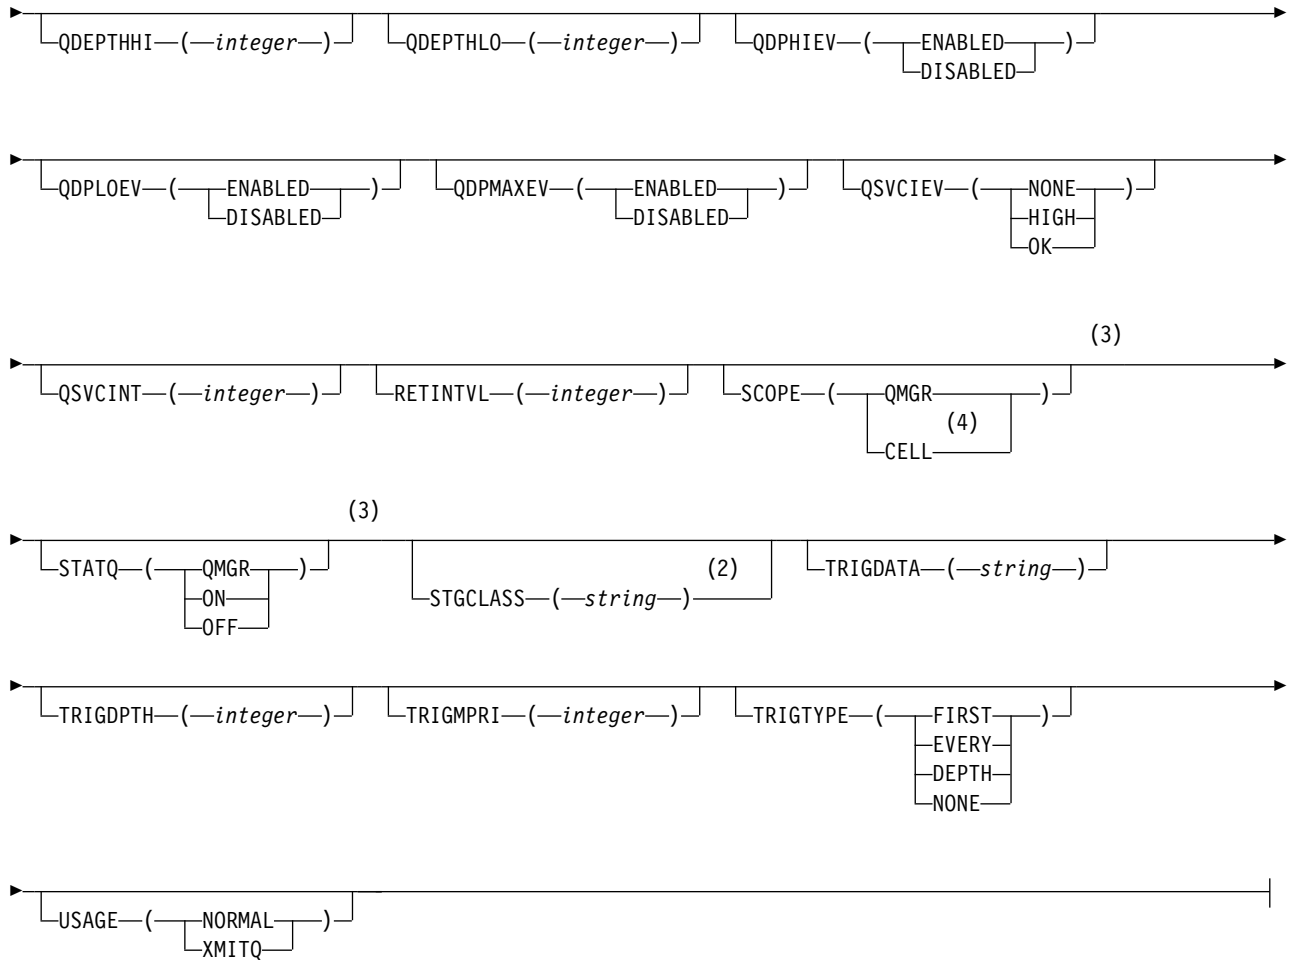

**Common queue attributes:**

**Local queue attributes:**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.
- 4 Valid on UNIX, Linux, and Windows systems.

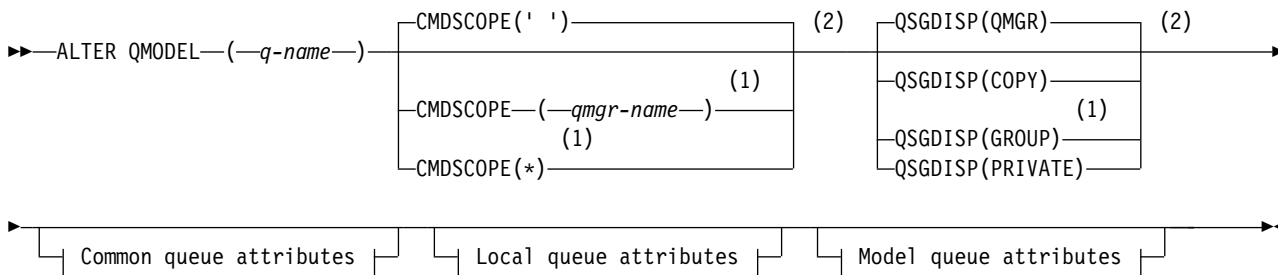

The parameters are described in “ALTER queues” on page 469.

*ALTER QMODEL:*

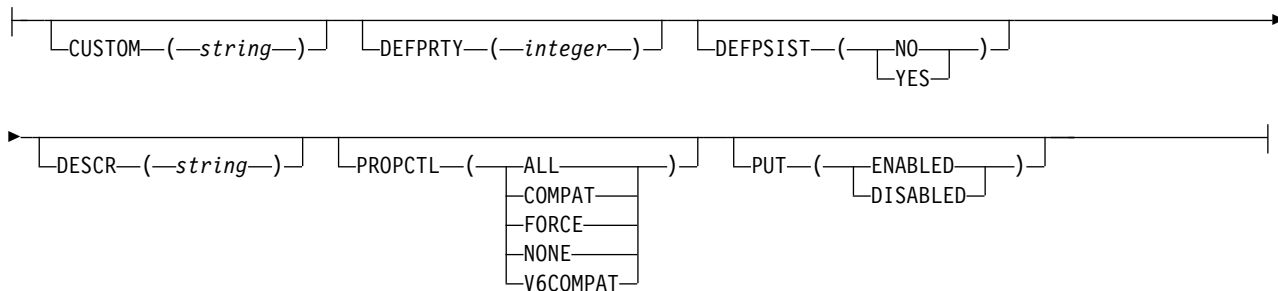

Use the MQSC command ALTER QMODEL to alter the parameters of a model queue.

Synonym: ALT QM

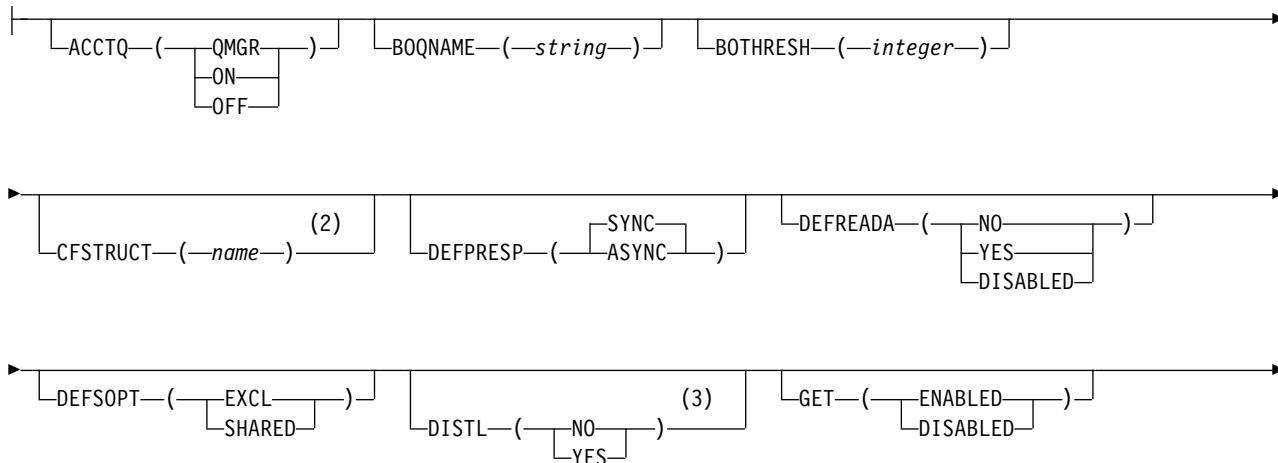

**ALTER QMODEL**

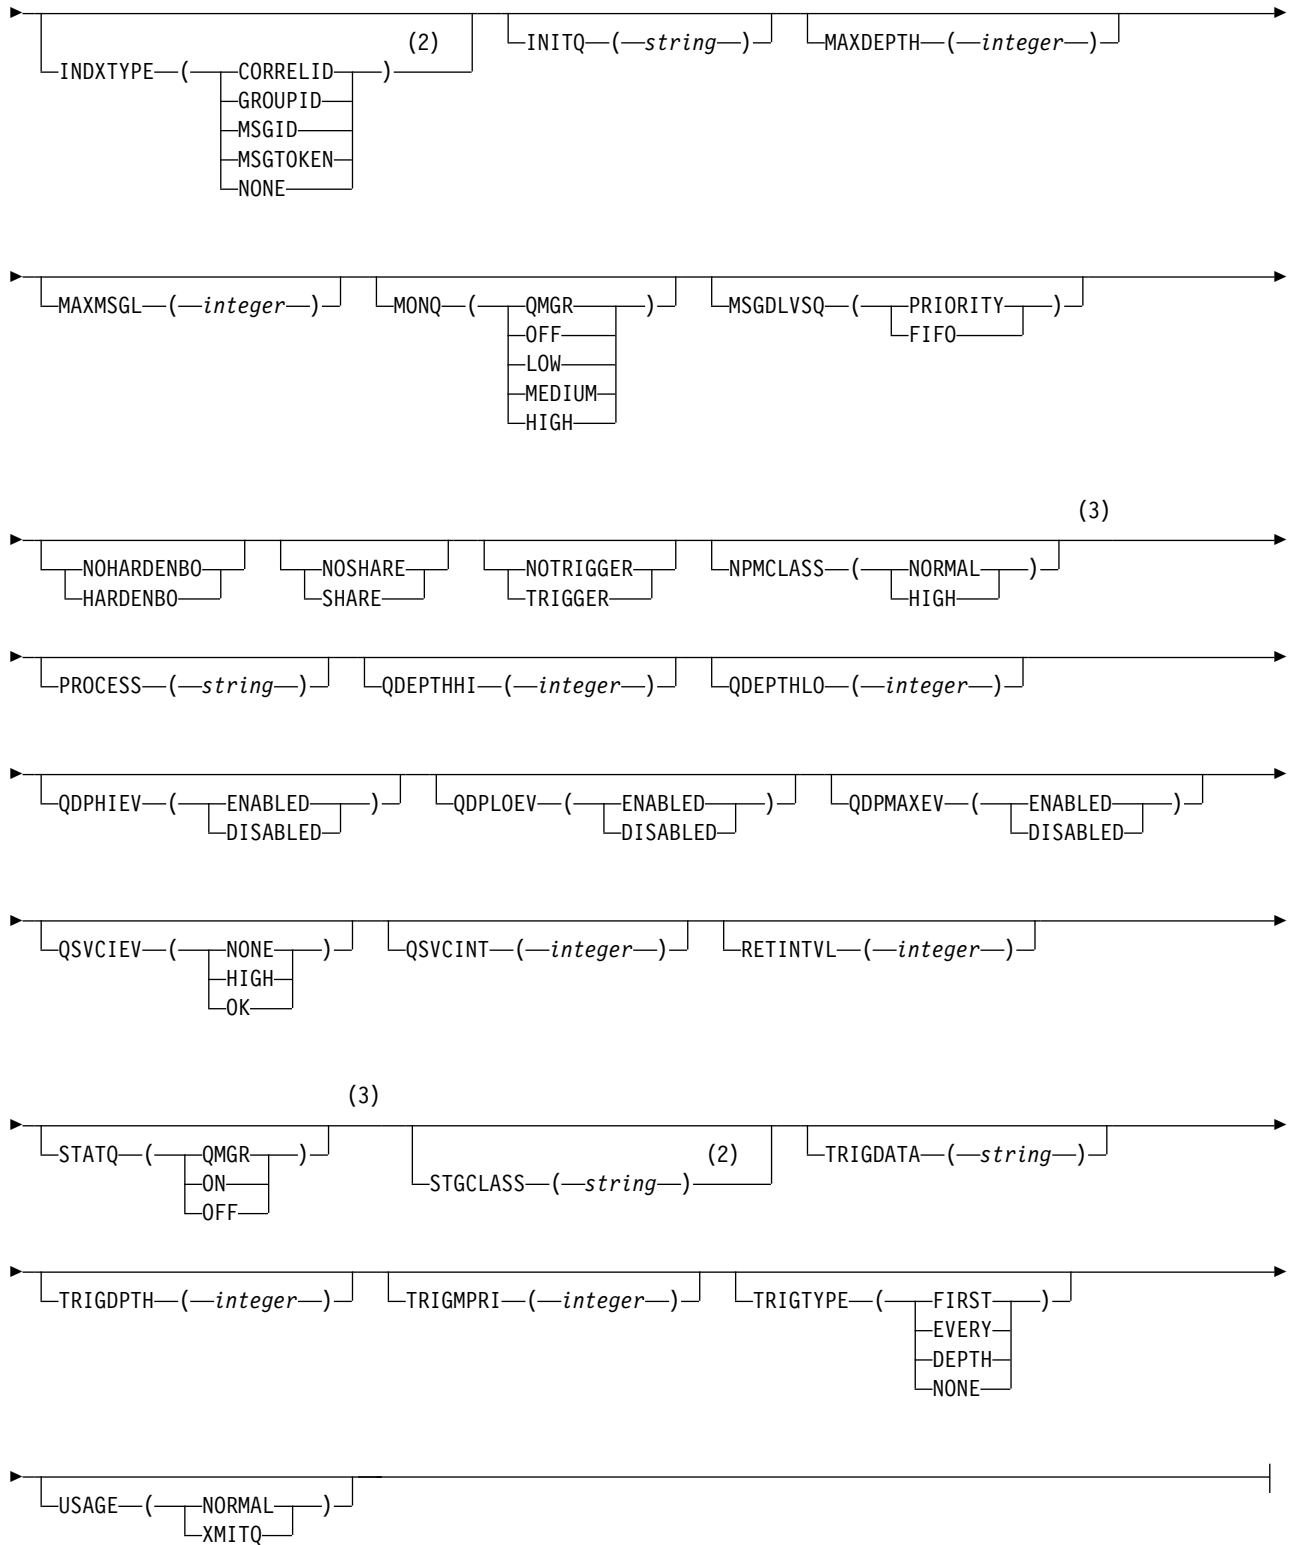

**Common queue attributes:**

**Local queue attributes:**

**Model queue attributes:**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.

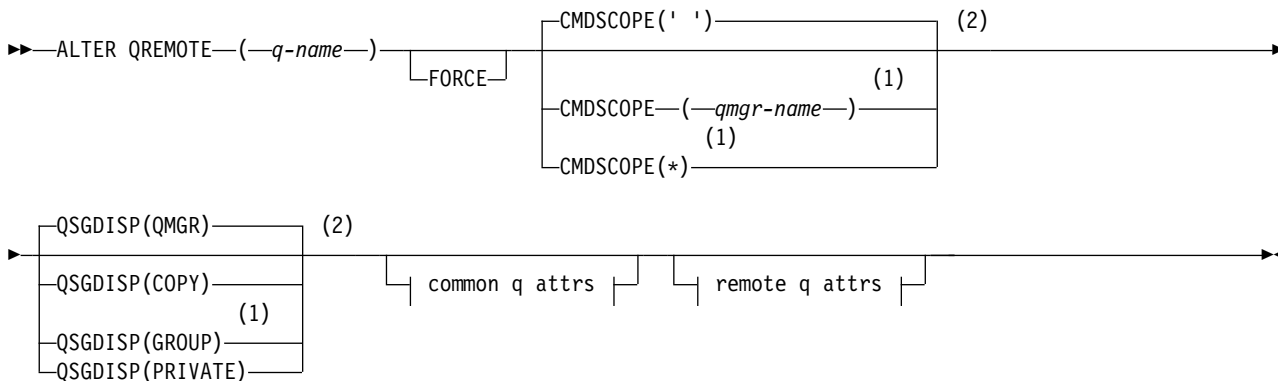

The parameters are described in “ALTER queues” on page 469.

**ALTER QREMOTE:**

Use the MQSC command ALTER QREMOTE to alter the parameters of a local definition of a remote queue, a queue-manager alias, or a reply-to queue alias.

**Synonym:** ALT QR

**ALTER QREMOTE**

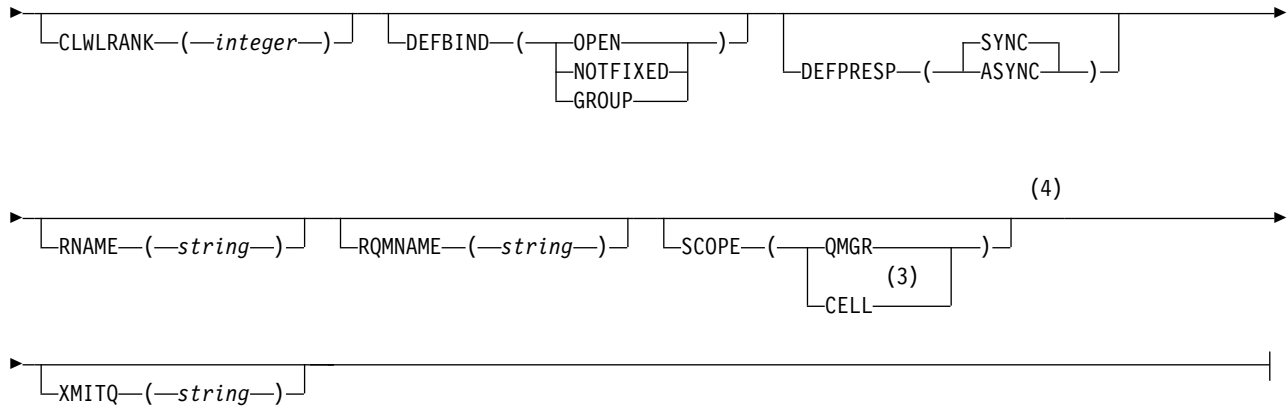

**Common q attrs:**

**Remote q attrs:**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Valid only on Windows, UNIX, and Linux systems.
- 4 Not valid on z/OS.

The parameters are described in “ALTER queues” on page 469.

**ALTER SECURITY:** z/OS

Use the MQSC command ALTER SECURITY to define system-wide security options.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			12CR

Parameters not specified in the ALTER SECURITY command result in the existing values for those parameters being left unchanged.

z/OS For an explanation of the symbols in the z/OS column, see “Using commands on z/OS” on page 342.

- Syntax diagram
- “Parameter descriptions for ALTER SECURITY” on page 500

**Synonym:** ALT SEC

## ALTER SECURITY

### Security attrs:

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

### Parameter descriptions for ALTER SECURITY

The parameters you specify override the current parameter values. Attributes that you do not specify are unchanged.

**Note:** If you do not specify any parameters, the command completes successfully, but no security options are changed.

#### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

#### INTERVAL(*integer*)

The interval between checks for user IDs and their associated resources to determine whether the TIMEOUT has expired. The value is in minutes, in the range zero through 10080 (one week). If INTERVAL is specified as zero, no user timeouts occur.

#### TIMEOUT(*integer*)

How long security information about an unused user ID and associated resources is retained by IBM MQ. The value specifies a number of minutes in the range zero through 10080 (one week). If TIMEOUT is specified as zero, and INTERVAL is nonzero, all such information is discarded by the queue manager every INTERVAL number of minutes.

The length of time that an unused user ID and associated resources are retained by IBM MQ depends on the value of INTERVAL. The user ID times out at a time between TIMEOUT and TIMEOUT plus INTERVAL.

When the TIMEOUT and INTERVAL parameters are changed, the previous timer request is canceled and a new timer request is scheduled immediately, using the new TIMEOUT value. When the timer request is actioned, a new value for INTERVAL is set.

**Related information:**

User ID timeouts

**ALTER SERVICE:**

Use the MQSC command ALTER SERVICE to alter the parameters of an existing IBM MQ service definition.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

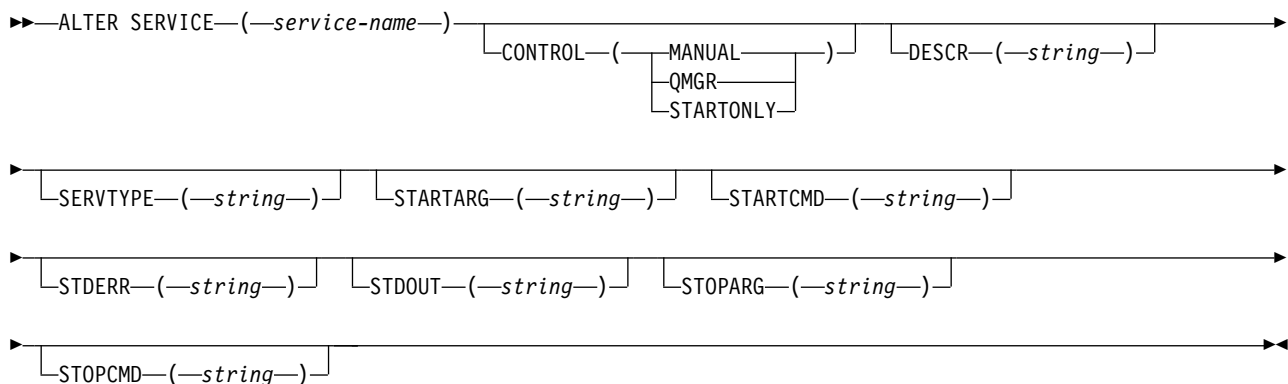

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

Parameters not specified in the ALTER SERVICE command result in the existing values for those parameters being left unchanged.

- Syntax diagram
- "Parameter descriptions for ALTER SERVICE"

**Synonym:**

**ALTER SERVICE**

**Parameter descriptions for ALTER SERVICE**

The parameter descriptions apply to the ALTER SERVICE and DEFINE SERVICE commands, with the following exceptions:

- The **LIKE** parameter applies only to the DEFINE SERVICE command.
- The **NOREPLACE** and **REPLACE** parameter applies only to the DEFINE SERVICE command.

(*service-name*)

Name of the IBM MQ service definition (see Rules for naming IBM MQ objects ).

The name must not be the same as any other service definition currently defined on this queue manager (unless REPLACE is specified).

#### **CONTROL**( *string* )

Specifies how the service is to be started and stopped:

##### **MANUAL**

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the START SERVICE and STOP SERVICE commands.

##### **QMGR**

The service being defined is to be started and stopped at the same time as the queue manager is started and stopped.

##### **STARTONLY**

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

#### **DESCR**( *string* )

Plain-text comment. It provides descriptive information about the service when an operator issues the DISPLAY SERVICE command (see "DISPLAY SERVICE" on page 889 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

#### **LIKE**( *service-name* )

The name of a service the parameters of which are used to model this definition.

This parameter applies only to the DEFINE SERVICE command.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for services on this queue manager. Not completing this parameter is equivalent to specifying:

LIKE(SYSTEM.DEFAULT.SERVICE)

A default service is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

#### **REPLACE and NOREPLACE**

Whether the existing definition is to be replaced with this one.

This parameter applies only to the DEFINE SERVICE command.

##### **REPLACE**

The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

##### **NOREPLACE**

The definition should not replace any existing definition of the same name.

#### **SERVTYPE**

Specifies the mode in which the service is to run:

##### **COMMAND**

A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

**SERVER**

A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the DISPLAY SVSTATUS command.

**STARTARG( *string* )**

Specifies the arguments to be passed to the user program at queue manager startup.

**STARTCMD( *string* )**

Specifies the name of the program which is to run. You must specify a fully qualified path name to the executable program.

**STDERR( *string* )**

Specifies the path to a file to which the standard error (stderr) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stderr by the service program is discarded.

**STDOUT( *string* )**

Specifies the path to a file to which the standard output (stdout) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stdout by the service program is discarded.

**STOPARG( *string* )**

Specifies the arguments to be passed to the stop program when instructed to stop the service.

**STOPCMD( *string* )**

Specifies the name of the executable program to run when the service is requested to stop. You must specify a fully qualified path name to the executable program.

Replaceable inserts can be used for any of the STARTCMD, STARTARG, STOPCMD, STOPARG, STDOUT or STDERR strings, for more information, see Replaceable inserts on service definitions.

Working with services

**ALTER SMDS:** 

Use the MQSC command ALTER SMDS to alter the parameters of existing IBM MQ definitions relating to one or more shared message data sets associated with a specific application structure. It is only supported when the CFSTRUCT definition is using the option OFFLOAD(SMDS).

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

Parameters not specified in the ALTER SMDS command result in the existing values for those parameters being left unchanged.

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for ALTER SMDS” on page 504

**Synonym:**

## ALTER SMDS

### Parameter descriptions for ALTER SMDS

#### SMDS( *qmgr-name* | \* )

Specify the queue manager for which the shared message data set properties are to be modified, or an asterisk to modify the properties for all data sets associated with the specified CFSTRUCT.

#### CFSTRUCT( *structure-name* )

Specify the coupling facility application structure for which the properties of one or more shared message data sets are to be modified.

#### DSBUFS( **number** | **DEFAULT** )

Specify an override value for the number of buffers to be allocated in the specified queue manager or queue managers for accessing shared message data sets for this structure, as a number in the range 1 to 9999, or specify **DEFAULT** to cancel a previous override and resume using the **DSBUFS** value from the **CFSTRUCT** definition. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

When this parameter is altered, any affected queue managers which are already connected to the structure dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager replaces the specified **DSBUFS** parameter with the actual new number of buffers. If the queue manager is not active, the change will come into effect when the queue manager is restarted.

#### DSEXPAND( **YES** | **NO** | **DEFAULT** )

Specify an override value to be used by the specified queue manager or queue managers to control expansion of shared message data sets for this structure.

This parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

**YES** Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used.

**NO** No automatic data set expansion is to take place.

#### **DEFAULT**

Cancels a previous override.

If you used **DEFAULT** to cancel a previous override it resumes using the **DSEXPAND** value from the **CFSTRUCT** definition.

If an expansion attempt fails, the **DSEXPAND** override for the affected queue manager is automatically changed to **NO** to prevent further expansion attempts, but it can be changed back to **YES** using the **ALTER SMDS** command to enable further expansion attempts.

When this parameter is altered, any affected queue managers which are already connected to the structure immediately start using the new parameter value.

**ALTER STGCLASS:** z/OS

Use the MQSC command ALTER STGCLASS to alter the characteristics of a storage class.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

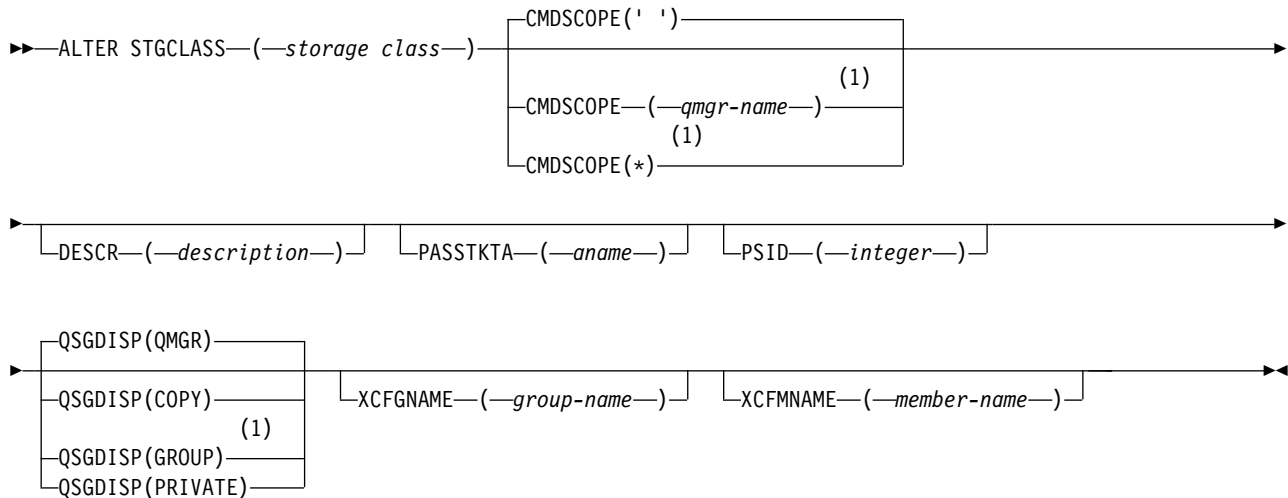

Parameters not specified in the ALTER STGCLASS command result in the existing values for those parameters being left unchanged.

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for ALTER STGCLASS”

**Synonym:** ALT STC

**ALTER STGCLASS**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

**Parameter descriptions for ALTER STGCLASS**

(storage-class)

Name of the storage class.

This name is one to 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

**Note:** Exceptionally, certain all numeric storage class names are allowed, but are reserved for the use of IBM service personnel.

The storage class must not be the same as any other storage class currently defined on this queue manager.

### **CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

### **DESCR( *description* )**

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY STGCLASS command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

### **PASSTKTA( *application name* )**

The application name that is passed to RACF when authenticating the PassTicket specified in the MQIHH header.

### **PSID( *integer* )**

The page set identifier that this storage class is to be associated with.

**Note:** No check is made that the page set has been defined; an error is raised only when you try to put a message to a queue that specifies this storage class (MQRC\_PAGESET\_ERROR).

The string consists of two numeric characters, in the range 00 through 99. See "DEFINE PSID" on page 633.

### **QSGDISP**

Specifies the disposition of the object in the group.

<b>QSGDISP</b>	<b>ALTER</b>
<b>COPY</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.
<b>GROUP</b>	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to refresh local copies on page set zero:  <pre>DEFINE STGCLASS(storage-class) REPLACE QSGDISP(COPY)</pre> <p>The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
<b>PRIVATE</b>	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY). Any object residing in the shared repository is unaffected.
<b>QMGR</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

**XCFGNAME( *group name* )**

If you are using the IMS bridge, this name is the name of the XCF group to which the IMS system belongs. (This name is the group name specified in the IMS parameter list.)

This name is 1 - 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

**XCFMNAME( *member name* )**

If you are using the IMS bridge, this name is the XCF member name of the IMS system within the XCF group specified in XCFGNAME. (This name is the member name specified in the IMS parameter list.)

This name is 1 - 16 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

## ALTER SUB:

Use the MQSC command ALTER SUB to alter the characteristics of an existing subscription.

### Using MQSC commands

For information on how you use MQSC commands, see [Performing local administration tasks using MQSC commands](#).

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

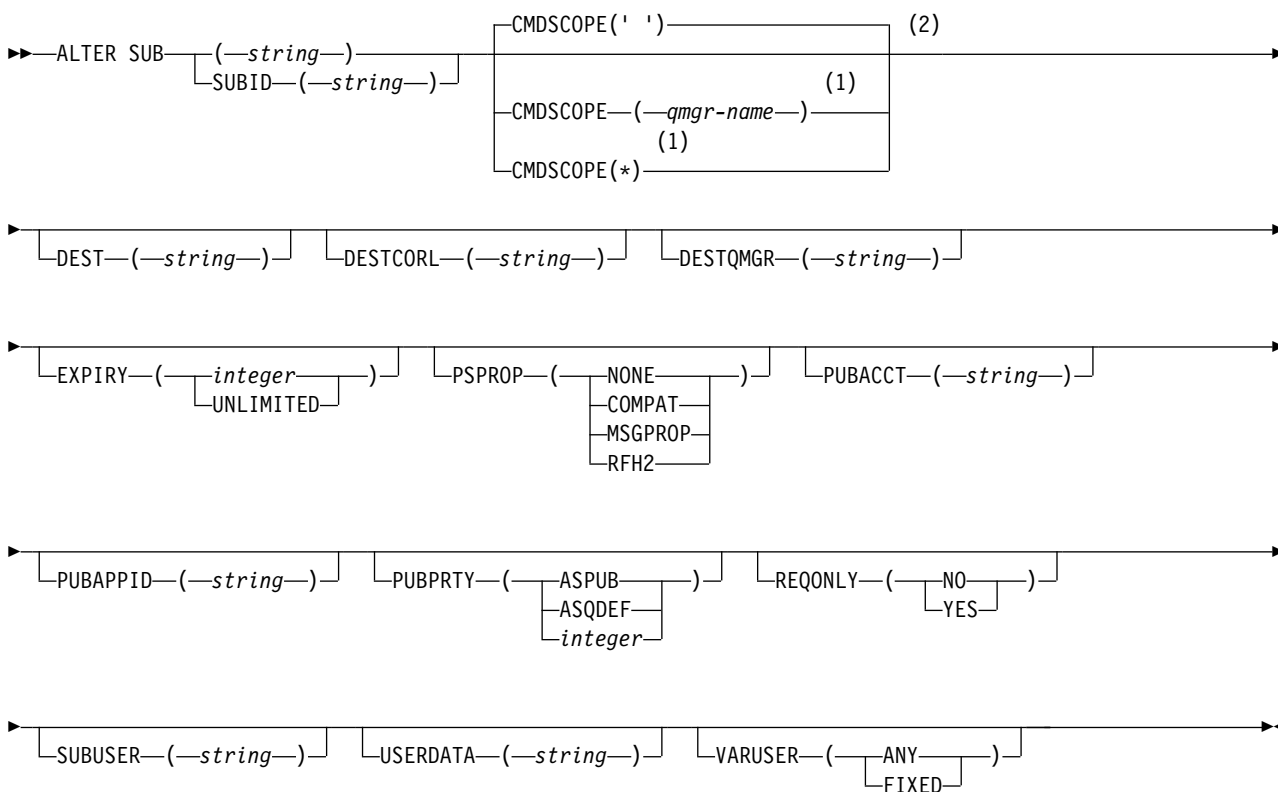

Parameters not specified in the ALTER SUB command result in the existing values for those parameters being left unchanged.

**z/OS** For an explanation of the symbols in the z/OS column, see [Using commands on z/OS](#).

- Syntax diagram
- “Usage notes for ALTER SUB” on page 509
- “Parameter descriptions for ALTER SUB” on page 509

**Synonym:** ALT SUB

### ALTER SUB

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

- 2 Valid only on z/OS.

### Usage notes for ALTER SUB

1. The following are valid forms of the command:  
ALT SUB(*xyz*)  
ALT SUB SUBID(*123*)  
ALT SUB(*xyz*) SUBID(*123*)
2. Although permitted on the DEFINE command, you cannot alter the following fields using DEFINE SUB (REPLACE):
  - TOPICOBJ
  - TOPICSTR
  - WSCHEMA
  - SELECTOR
  - SUBSCOPE
  - DESTCLAS
3. At the time the ALT SUB command processes, no check is performed that the named DEST or DESTQMGR exists. These names are used at publishing time as the *ObjectName* and *ObjectQMGRName* for an MQOPEN call. These names are resolved according to the IBM MQ name resolution rules.
4.  Subscriptions with a SUBTYPE of PROXY cannot be modified. Attempts to modify a proxy subscription by using the PCF interface return MQRCCF\_SUBSCRIPTION\_IN\_USE. MQSC reports the following message:  
AMQ8469: WebSphere MQ subscription SYSTEM.PROXY in use.

### Parameter descriptions for ALTER SUB

(*string*)

A mandatory parameter. Specifies the unique name for this subscription, see **SUBNAME** property.

#### **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is processed when the queue manager is a member of a queue-sharing group.

' ' The command is processed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is processed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is processed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

**DEST**( *string* )

The destination for messages published to this subscription; this parameter is the name of a queue.

**DESTCORL**( *string* )

The *CorrelId* used for messages published to this subscription.

A blank value (default) results in a system generated correlation identifier being used.

If set to ' 00 ' (48 zeros) the **CorrelId** set by the publishing application will be maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

**DESTQMGR**( *string* )

The destination queue manager for messages published to this subscription. You must define the channels to the remote queue manager, for example, the XMITQ, and a sender channel. If you do not, messages do not arrive at the destination.

**EXPIRY**

The time to expiry of the subscription object from the creation date and time.

( *integer* )

The time to expiry, in tenths of a second, from the creation date and time.

**UNLIMITED**

There is no expiry time. This is the default option supplied with the product.

**PSPROP**

The manner in which publish subscribe related message properties are added to messages sent to this subscription.

**NONE**

Do not add publish subscribe properties to the message.

**COMPAT**

Publish subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

**MSGPROP**

Publish subscribe properties are added as message properties.

**RFH2** Publish subscribe properties are added within an MQRFH version 2 header.

**PUBACCT**( *string* )

Accounting token passed by the subscriber, for propagation into messages published to this subscription in the *AccountingToken* field of the MQMD.

**PUBAPPID**( *string* )

Identity data passed by the subscriber, for propagation into messages published to this subscription in the *ApplIdentityData* field of the MQMD.

**PUBPRTY**

The priority of the message sent to this subscription.

**ASPub**

Priority of the message sent to this subscription is taken from the priority supplied in the published message.

**ASQDEF**

Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

( *integer* )

An integer providing an explicit priority for messages published to this subscription.

**REQONLY**

Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

**NO** All publications on the topic are delivered to this subscription.

**YES** Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO\_PUBLICATIONS\_ON\_REQUEST.

**SUBLEVEL( *integer* )**

The level within the subscription hierarchy at which this subscription is made. The range is zero through 9.

**SUBUSER( *string* )**

Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

**USERDATA( *string* )**

Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription as a message property.

**V 8.0.0.7** From IBM MQ Version 8.0.0, Fix Pack 7, an IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant `JMS_IBM_SUBSCRIPTION_USER_DATA` in the `JmsConstants` interface with the method `javax.jms.Message.getStringProperty(java.lang.String)`. For more information, see Retrieval of user subscription data.

**VARUSER**

Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

**ANY** Any user can connect to and takeover ownership of the subscription.

**FIXED**

Takeover by another **USERID** is not permitted.

**ALTER TOPIC:**

Use **ALTER TOPIC** to alter the parameters of an existing IBM MQ topic object.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

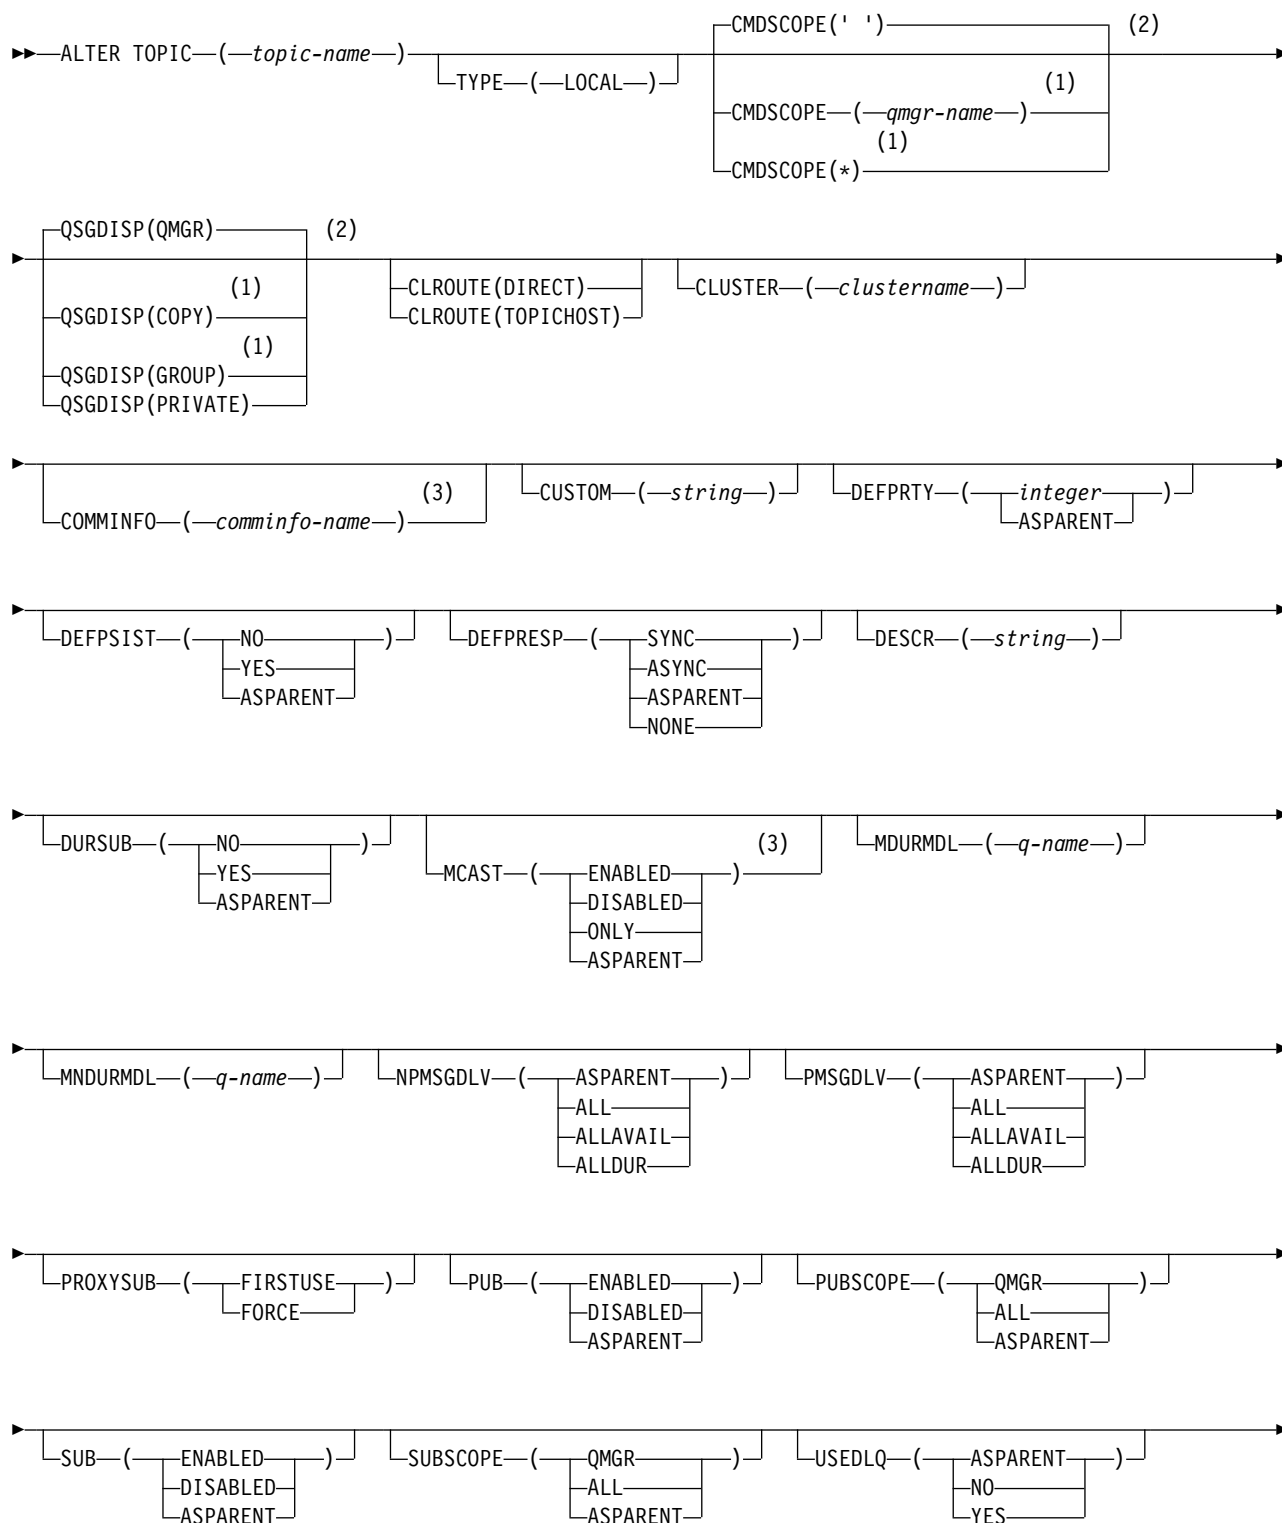

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

Parameters not specified in the **ALTER TOPIC** command result in the existing values for those parameters being left unchanged.

- Syntax diagram
- “Usage notes for **ALTER TOPIC**” on page 513
- “Parameter descriptions for **ALTER TOPIC**” on page 513

**Synonym:** ALT TOPIC

## ALTER TOPIC

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.

**Usage notes for ALTER TOPIC**

- Successful completion of the command does not mean that the action completed. To check for true completion, see the ALTER TOPIC step in Checking that async commands for distributed networks have finished.

**Parameter descriptions for ALTER TOPIC**

*(topic-name)*

Name of the IBM MQ topic definition (see Rules for naming IBM MQ objects ). The maximum length is 48 characters.

The name must not be the same as any other topic definition currently defined on this queue manager (unless REPLACE is specified).

**CLROUTE**

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

**DIRECT**

When you configure a direct routed clustered topic on a queue manager, all queue managers in the cluster become aware of all other queue managers in the cluster. When performing publish and subscribe operations, each queue manager can connect direct to any other queue manager in the cluster.

**TOPICHOST**

When you use topic host routing, all queue managers in the cluster become aware of the cluster queue managers that host the routed topic definition (that is, the queue managers on which you have defined the topic object). When performing publish and subscribe operations, queue managers in the cluster connect only to these topic host queue managers, and not directly to each other. The topic host queue managers are responsible for routing publications from queue managers on which publications are published to queue managers with matching subscriptions.

After a topic object has been clustered (through setting the **CLUSTER** property) you cannot change the value of the **CLROUTE** property. The object must be un-clustered (**CLUSTER** set to ' ') before you can change the value. Un-clustering a topic converts the topic definition to a local topic, which results in a period during which publications are not delivered to subscriptions on remote queue managers; this should be considered when performing this change. See The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager. If you try to change the value of the **CLROUTE** property while it is clustered, the system generates an MQRCCF\_CLROUTE\_NOT\_ALTERABLE exception.

See also Routing for publish/subscribe clusters: Notes® on behavior and Designing publish/subscribe clusters.

**CLUSTER**

The name of the cluster to which this topic belongs. Setting this parameter to a cluster that this queue manager is a member of makes all queue managers in the cluster aware of this topic. Any

publication to this topic or a topic string below it put to any queue manager in the cluster is propagated to subscriptions on any other queue manager in the cluster. For more details, see Distributed publish/subscribe networks.

' ' If no topic object above this topic in the topic tree has set this parameter to a cluster name, then this topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers. If a topic node higher in the topic tree has a cluster name set, publications and subscriptions to this topic are also propagated throughout the cluster.

*string* The topic belongs to this cluster. It is not recommended that this is set to a different cluster from a topic object above this topic object in the topic tree. Other queue managers in the cluster will honor this object's definition unless a local definition of the same name exists on those queue managers.

To prevent all subscriptions and publications being propagated throughout a cluster, leave this parameter blank on the system topics SYSTEM.BASE.TOPIC and SYSTEM.DEFAULT.TOPIC, except in special circumstances, for example to support migration.

#### **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

#### **COMMINFO**(*comminfo-name*)

The name of the communication information object associated with this topic object.

#### **CUSTOM** ( *string* )

The custom attribute for new features.

 This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name and value pairs have the form NAME(VALUE). Single quotation marks must be escaped with another single quotation mark.

#### **CAPEXPY** ( *integer* )

The maximum time, expressed in tenths of a second, until a message published to a topic which inherits properties from this object, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

*integer* The value must be in the range one through to 999 999 999.

#### **NOLIMIT**

There is no limit on the expiry time of messages put to this topic.

**ASPARENT**

The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

Specifying a value for CAPEXPY that is not valid, does not cause the command to fail. Instead, the default value is used.

**DEFPRTY( *integer* )**

The default priority of messages published to the topic.

( *integer* )

The value must be in the range zero (the lowest priority), through to the MAXPRTY queue manager parameter (MAXPRTY is 9).

**ASPARENT**

The default priority is based on the setting of the closest parent administrative topic object in the topic tree.

**DEFPSIST**

Specifies the message persistence to be used when applications specify the MQPER\_PERSISTENCE\_AS\_TOPIC\_DEF option.

**ASPARENT**

The default persistence is based on the setting of the closest parent administrative topic object in the topic tree.

**NO** Messages on this queue are lost during a restart of the queue manager.

**YES** Messages on this queue survive a restart of the queue manager.

On z/OS, N and Y are accepted as synonyms of NO and YES.

**DEFRESP**

Specifies the put response to be used when applications specify the MQPMO\_RESPONSE\_AS\_DEF option.

**ASPARENT**

The default put response is based on the setting of the closest parent administrative topic object in the topic tree.

**SYNC** Put operations to the queue that specify MQPMO\_RESPONSE\_AS\_Q\_DEF are issued as if MQPMO\_SYNC\_RESPONSE had been specified instead. Fields in the MQMD and MQPMO are returned by the queue manager to the application.

**ASYNCR**

Put operations to the queue that specify MQPMO\_RESPONSE\_AS\_Q\_DEF are always issued as if MQPMO\_ASYNC\_RESPONSE had been specified instead. Some fields in the MQMD and MQPMO are not returned by the queue manager to the application. However, an improvement in performance might be seen for messages put in a transaction and any non-persistent messages

**DESCR( *string* )**

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY TOPIC command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**DURSUB**

Specifies whether applications are permitted to make durable subscriptions on this topic.

**ASPARENT**

Whether durable subscriptions can be made on this topic is based on the setting of the closest parent administrative topic object in the topic tree.

**NO** Durable subscriptions cannot be made on this topic.

**YES** Durable subscriptions can be made on this topic.

**MCAST**

Specifies whether multicast is allowable in the topic tree. The values are:

**ASPARENT**

The multicast attribute of the topic is inherited from the parent.

**DISABLED**

No multicast traffic is allowed at this node.

**ENABLED**

Multicast traffic is allowed at this node.

**ONLY** Only subscriptions from a multicast capable client are allowed.

**MDURMDL( *string* )**

The name of the model queue to be used for durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects ). The maximum length is 48 characters.

If MDURMDL is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for MDURMDL.

If you use MDURMDL to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.DURABLE

**MNDURMDL( *string* )**

The name of the model queue to be used for non-durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects ). The maximum length is 48 characters.

If MNDURMDL is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for MNDURMDL.

If you use MNDURMDL to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a non-durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.NDURABLE.

**NPMSGDLV**

The delivery mechanism for non-persistent messages published to this topic:

**ASPARENT**

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

**ALL** Non-persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

**ALLAVAIL**

Non-persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

**ALLDUR**

Non-persistent messages must be delivered to all durable subscribers. Failure to deliver a non-persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

**PMSGDLV**

The delivery mechanism for persistent messages published to this topic:

**ASPARENT**

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

**ALL** Persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

**ALLAVAIL**

Persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

**ALLDUR**

Persistent messages must be delivered to all durable subscribers. Failure to deliver a persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

**PROXYSUB**

Controls when a proxy subscription is sent for this topic, or topic strings below this topic, to neighboring queue managers when in a publish/subscribe cluster or hierarchy. For more details, see Subscription performance in publish/subscribe networks.

**FIRSTUSE**

For each unique topic string at or below this topic object, a proxy subscription is asynchronously sent to all neighboring queue managers when a local subscription is created or a proxy subscription is received that is propagated to further directly connected queue managers in a hierarchy.

**FORCE**

A wildcard proxy subscription that matches all topic strings at and below this point in the topic tree is sent to neighboring queue managers even if no local subscriptions exist.

**Note:** The proxy subscription is sent when this value is set on DEFINE or ALTER. When set on a clustered topic, all queue managers in the cluster issue the wildcard proxy subscription to all other queue managers in the cluster.

**PUB** Controls whether messages can be published to this topic.

**ASPARENT**

Whether messages can be published to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

**ENABLED**

Messages can be published to the topic (by suitably authorized applications).

## DISABLED

Messages cannot be published to the topic.

See also Special handling for the **PUB** parameter.

## PUBSCOPE

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

**Note:** You can restrict the behavior on a publication-by-publication basis, using MQPMO\_SCOPE\_QMGR on the Put Message options.

## ASPARENT

Whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster is based on the setting of the first parent administrative node found in the topic tree that relates to this topic.

## QMGR

Publications for this topic are not propagated to connected queue managers.

**ALL** Publications for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

z/OS

## QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

QSGDISP	ALTER
<b>COPY</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.
<b>GROUP</b>	The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command. If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to refresh local copies on page set zero: <pre>DEFINE TOPIC(name) REPLACE QSGDISP(COPY)</pre> <p>The ALTER for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
<b>PRIVATE</b>	The object resides on the page set of the queue manager that executes the command, and was defined with QSGDISP(QMGR) or QSGDISP(COPY). Any object residing in the shared repository is unaffected.
<b>QMGR</b>	The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

**SUB** Controls whether applications are to be permitted to subscribe to this topic.

## ASPARENT

Whether applications can subscribe to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

**ENABLED**

Subscriptions can be made to the topic (by suitably authorized applications).

**DISABLED**

Applications cannot subscribe to the topic.

**SUBSCOPE**

Determines whether this queue manager subscribes to publications in this queue manager or in the network of connected queue managers. If subscribing to all queue managers, the queue manager propagates subscriptions to them as part of a hierarchy or as part of a publish/subscribe cluster.

**Note:** You can restrict the behavior on a subscription-by-subscription basis, using **MQPMO\_SCOPE\_QMGR** on the Subscription Descriptor or **SUBSCOPE(QMGR)** on **DEFINE SUB**. Individual subscribers can override the **SUBSCOPE** setting of ALL by specifying the **MQSO\_SCOPE\_QMGR** subscription option when creating a subscription.

**ASPARENT**

Whether this queue manager subscribes to publications in the same way as the setting of the first parent administrative node found in the topic tree relating to this topic.

**QMGR**

Only publications that are published on this queue manager reach the subscriber.

**ALL** A publication made on this queue manager or on another queue manager reaches the subscriber. Subscriptions for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

**TOPICSTR( *string* )**

The topic string represented by this topic object definition. This parameter is required and cannot contain the empty string.

The topic string must not be the same as any other topic string already represented by a topic object definition.

The maximum length of the string is 10,240 characters.

**TYPE (topic-type)**

If this parameter is used it must follow immediately after the *topic-name* parameter on all platforms  except z/OS.

**LOCAL**

A local topic object.

**USEDLQ**

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

**ASPARENT**

Determines whether to use the dead-letter queue using the setting of the closest administrative topic object in the topic tree.

**NO** Publication messages that cannot be delivered to their correct subscriber queue are treated as a failure to put the message. The MQPUT of an application to a topic fails in accordance with the settings of NPMSGDLV and PMSGDLV.

**YES** When the DEADQ queue manager attribute provides the name of a dead-letter queue, then it is used. If the queue manager does not provide the name of a dead-letter queue, then the behavior is as for NO.

**WILDCARD**

The behavior of wildcard subscriptions with respect to this topic.

## PASSTHRU

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object receive publications made to this topic and to topic strings more specific than this topic.

## BLOCK

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object do not receive publications made to this topic or to topic strings more specific than this topic.

The value of this attribute is used when subscriptions are defined. If you alter this attribute, the set of topics covered by existing subscriptions is not affected by the modification. This scenario applies also if the topology is changed when topic objects are created or deleted; the set of topics matching subscriptions created following the modification of the WILDCARD attribute is created using the modified topology. If you want to force the matching set of topics to be re-evaluated for existing subscriptions, you must restart the queue manager.

## ALTER TRACE: z/OS

Use the MQSC command ALTER TRACE to change the trace events being traced for a particular active queue manager trace. ALTER TRACE stops the specified trace, and restarts it with the altered parameters.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			12CR

Parameters not specified in the ALTER TRACE command result in the existing values for those parameters being left unchanged.

z/OS For an explanation of the symbols in the z/OS column, see “Using commands on z/OS” on page 342.

- Syntax diagram
- “Usage notes” on page 521
- “Parameter descriptions for ALTER TRACE” on page 521
- “Trace parameters” on page 521

**Synonym:** ALT TRACE

## ALTER TRACE

## Trace attrs:

## Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

## Usage notes

Channel initiator traces cannot be altered.

## Parameter descriptions for ALTER TRACE

Specify one of the following trace types:

### GLOBAL

Service data from the entire queue manager (the synonym is G)

**STAT** Statistical data (the synonym is S)

### ACCTG

Accounting data (the synonym is A)

And:

### TNO( *integer* )

The number of the trace to be altered (1 through 32). You can specify only one trace number.

### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' ' The command is executed on the queue manager on which it was entered.

### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

## Trace parameters

### CLASS( *integer* )

The new trace class. See "START TRACE" on page 1019 for a list of allowed classes. A range of classes can be specified as *m:n* (for example, CLASS(01:03)). CLASS(\*) activates all classes.

### COMMENT( *string* )

A comment that is reproduced in the trace output record (except in the resident trace tables).

*string* is any character string. If it includes blanks, commas, or special characters, it must be enclosed between single quotation marks (').

## IFCID( *ifcid* )

Reserved for IBM Service.

## ARCHIVE LOG: z/OS

Use the MQSC command ARCHIVE LOG as part of your backup procedure. It takes a copy of the current active log (or both logs if you are using dual logging).

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

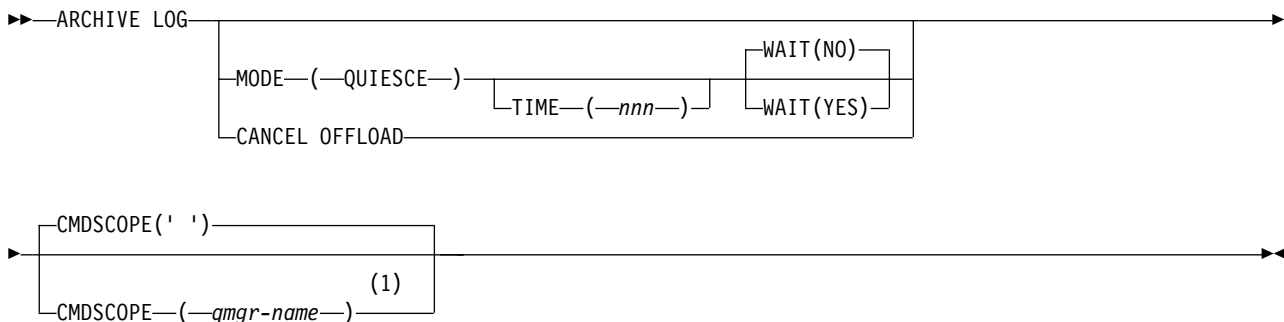

IBM i	UNIX and Linux	Windows	z/OS
			12CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for ARCHIVE LOG”
- “Parameter descriptions for ARCHIVE LOG” on page 523

**Synonym:** ARC LOG

## ARCHIVE LOG

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

### Usage notes for ARCHIVE LOG

In detail, ARCHIVE LOG:

1. Truncates the current active log data sets.
2. Continues logging, switching to the next active log data set.
3. Starts a task to offload the data sets.
4. Archives previous active log data sets not yet archived.

If the MODE(QUIESCE) parameter is used, the ARCHIVE LOG command quiesces (suspends) all user update activity on the current active log before the offload process. Once a system-wide point of consistency is reached (that is, when all currently active update users have reached a commit point), the current active log data set is immediately truncated, and the offload process is initiated. The resulting point of consistency is captured in the current active log before it is offloaded.

Normally, control returns to the user immediately, and the quiescing is done asynchronously. However, if the WAIT(YES) parameter is used, the quiescing is done synchronously, and control does not return to the user until it has finished.

- You cannot issue an ARCHIVE LOG command while a previous ARCHIVE LOG command is in progress.
- You cannot issue an ARCHIVE LOG command when the active log data set is the last available active log data set, because it would use all the available active log data set space, and IBM MQ would halt all processing until an offload had been completed.
- You can issue an ARCHIVE LOG command without the MODE(QUIESCE) option when a STOP QMGR MODE(QUIESCE) is in progress, but not when a STOP QMGR MODE (FORCE) is in progress.
- You can issue a DISPLAY LOG command to discover whether an ARCHIVE LOG command is active. If an ARCHIVE LOG command is active, the DISPLAY command returns message CSQV400I.
- You can issue an ARCHIVE LOG command even if archiving is not being used (that is, OFFLOAD is set to NO in the CSQ6LOGP system parameter macro), or dynamically using the SET LOG command. In this case, the current active log data sets are truncated and logging continues using the next active log data set, but there is no offloading to archive data sets.

### Parameter descriptions for ARCHIVE LOG

All the parameters are optional. If none are specified, the current active log data sets are switched and offloaded immediately.

#### CANCEL OFFLOAD

Cancels any offloading currently in progress and restarts the offload process. The process starts with the oldest active log data set and proceeds through all the active data sets that need offloading.

Use this command only if the offload task does not appear to be working, or if you want to restart a previous offload attempt that failed.

#### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

#### MODE(QUIESCE)

Stops any new update activity on the queue manager, and brings all existing users to a point of consistency after a commit. When this state is reached, or the number of active users is zero, the current active log is archived.

The time that the queue manager waits to reach such a state is limited to the value specified by QUIESCE in the CSQ6ARVP system parameter macro. The value of QUIESCE can be overridden by the TIME parameter of this command. If activity has not quiesced in that time, the command fails; no offload is done, and logging continues with the current active log data set.

## TIME( *nnn* )

Overrides the quiesce time period specified by the QUIESCE value of the CSQ6ARVP system parameter macro.

*nnn* is the time, in seconds, in the range 001 through 999.

To specify the TIME parameter, you must also specify MODE(QUIESCE).

If you specify the TIME parameter, you must specify an appropriate value for the quiesce period. If you make the period too short or too long, one of the following problems might occur:

- The quiesce might not be complete
- IBM MQ lock contention might develop
- A timeout might interrupt the quiesce

**WAIT** Specifies whether IBM MQ is to wait until the quiesce process has finished before returning to the issuer of the ARCHIVE LOG command.

To specify the WAIT parameter, you must also specify MODE(QUIESCE).

**NO** Specifies that control is returned to the issuer when the quiesce process starts. (The synonym is N.) This makes the quiesce process asynchronous to the issuer; you can issue further MQSC commands when the ARCHIVE LOG command returns control to you. This is the default.

**YES** Specifies that control is returned to the issuer when the quiesce process finishes. (The synonym is Y.) This makes the quiesce process synchronous to the issuer; further MQSC commands are not processed until the ARCHIVE LOG command finishes.

## BACKUP CFSTRUCT: z/OS

Use the MQSC command BACKUP CFSTRUCT to initiate a CF application structure backup.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

IBM i	UNIX and Linux	Windows	z/OS
			CR

- Syntax diagram
- "Usage notes for BACKUP CFSTRUCT"
- "Keyword and parameter descriptions for BACKUP CFSTRUCT" on page 525

**Synonym:** None

## BACKUP CFSTRUCT

### Usage notes for BACKUP CFSTRUCT

1. This command is valid only on z/OS when the queue manager is a member of a queue-sharing group.

2. Only persistent shared queue messages are backed up. Non-persistent messages are not backed up and cannot be recovered
3. You can concurrently run separate backups for different application structures on different queue managers within the queue-sharing group. You can also concurrently run separate backups for different application structures on the same queue manager.
4. This command fails if the specified CF structure is defined with either a CFLEVEL less than 3, or with RECOVER set to NO.
5. The command fails if a specified application structure is currently in the process of being backed up by another queue manager within the queue-sharing group.

### Keyword and parameter descriptions for BACKUP CFSTRUCT

#### *structure-name*

The name of the coupling facility (CF) application structure to be backed up. An asterisk (\*) on its own specifies all recoverable CF structures. A trailing asterisk (\*) matches all recoverable structure names with the specified stem followed by zero or more characters. The value (CSQ\*) matches all recoverable CF structures with the specified stem (CSQ) followed by zero or more characters.

#### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

#### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and the command server is enabled.

#### EXCLINT( *integer* )

Specifies a value that defines a number of seconds that are used as an exclusion time. The backup excludes backing-up activity during this exclusion time. The exclusion time starts immediately before the back up starts. For example, if EXCLINT(30) is specified, the backup does not include the last 30 seconds worth of activity for this application-structure before back up started.

The value must be in the range 30 through 600. The default value is 30.

#### CLEAR QLOCAL:

Use the MQSC command CLEAR QLOCAL to clear the messages from a local queue.

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for CLEAR QLOCAL” on page 526

Synonym: CLEAR QL

## CLEAR QLOCAL

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Parameter descriptions for CLEAR QLOCAL

You must specify which local queue you want to clear.

The command fails if either:

- The queue has uncommitted messages that have been put on the queue under syncpoint
- The queue is currently open by an application (with any open options)

If an application has this queue open, or has a queue open that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

*(q-name)*

The name of the local queue to be cleared. The name must be defined to the local queue manager.

#### z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to SHARED.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

#### z/OS QSGDISP

Specifies whether the queue definition is shared. This parameter applies to z/OS only.

#### PRIVATE

Clear only the private queue named *q-name*. The queue is private if it was defined using a command that had the parameters QSGDISP(COPY) or QSGDISP(QMGR). This is the default value.

## SHARED

Clear only the shared queue named *q-name*. The queue is shared if it was defined using a command that had the parameters QSGDISP(SHARED).

## CLEAR TOPICSTR:

Use the MQSC command CLEAR TOPICSTR to clear the retained message which is stored for the specified topic string.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

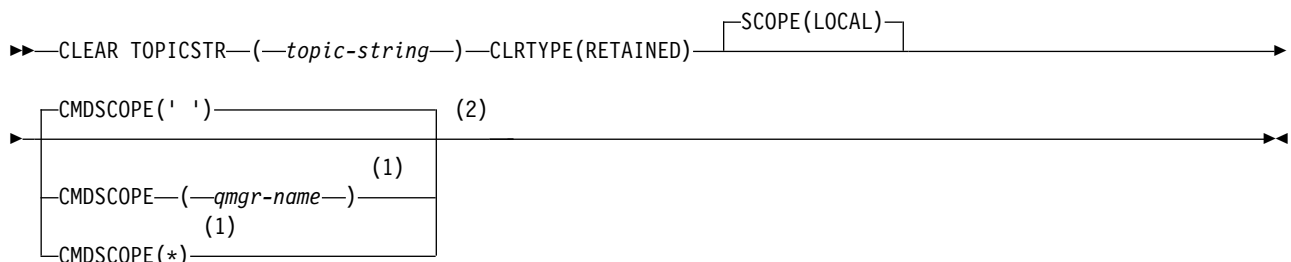

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

**z/OS** For an explanation of the symbols in the z/OS column, see "Using commands on z/OS" on page 342.

- Syntax diagram
- Usage notes for CLEAR TOPICSTR
- Parameter descriptions for CLEAR TOPICSTR

**Synonym:** None.

## CLEAR TOPICSTR

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Usage notes for CLEAR TOPICSTR

1. If the topic string specified has no retained message the command will complete successfully. You can find out whether a topic string has a retained message by using the DISPLAY TPSTATUS command. The RETAINED field shows whether there is a retained message.
2. The topic-string input parameter on this command must match the topic you want to act on. You are advised to keep the character strings in your topic strings as characters that can be used from location issuing the command. If you issue commands using MQSC, you will have fewer characters available to you than if you are using an application submitting PCF messages, such as the IBM MQ Explorer.
3. You might need to use CLEAR TOPICSTR to remove a retained publication from a publish/subscribe cluster. For example:

- If you accidentally configure a retained publication, and then need to remove it from all cluster queue managers, you issue this command on all members of the cluster.
- In a direct routed publish/subscribe cluster, if you move a publishing application to a new queue manager and the previous queue manager holds no subscriptions for the affected topic string, you need to ensure that the previous queue manager does not resend the old retained publication to other members of the cluster. To do this, wait until the application has published on the new queue manager, then issue this command on the previous queue manager to remove the retained publication held there.

See also Design considerations for retained publications in publish/subscribe clusters

### Parameter descriptions for CLEAR TOPICSTR

You must specify which topic string you want to remove the retained publication from.

*(topic-string)*

The topic string to be cleared. This string can represent several topics to be cleared by using wildcards as shown in the following table:

Special Character	Behavior
#	Wildcard, multiple topic level
+	Wildcard, single topic level

**Note:** the '+' and '#' are not treated as wildcards if they are mixed in with other characters (including themselves) within a topic level. In the following string, the '#' and '+' characters are treated as ordinary characters.

level0/level1/#+/level3/level#

To illustrate the effect of wildcards, the following example is used.

Clearing the following topic:

/a/b/#/z

clears the following topics:

/a/b/z

/a/b/c/z

/a/b/c/y/z

### CLRTYPE

This is a mandatory parameter.

The value must be:

#### RETAINED

Remove the retained publication from the specified topic string.

z/OS

### CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the name of the local queue manager, if the shared queue object definition has its queue-sharing group disposition attribute QSGDISP set to SHARED.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

#### SCOPE

The scope of the deletion of retained messages.

The value can be:

#### LOCAL

The retained message is removed from the specified topic string at the local queue manager only. This is the default value.

#### DEFINE AUTHINFO:

Use the MQSC command DEFINE AUTHINFO to define an authentication information object. These objects contain the definitions required to perform certificate revocation checking using OCSP or Certificate Revocation Lists (CRLs) on LDAP servers, and the definitions required to enable user ID and password checking.

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

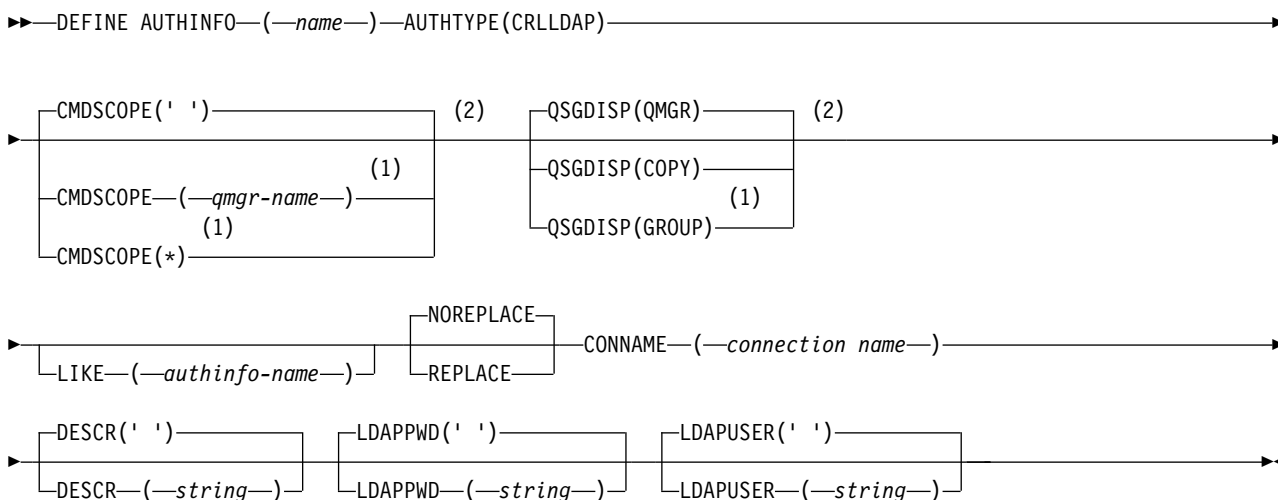

- “Usage notes for DEFINE AUTHINFO” on page 532
- “Parameter descriptions for DEFINE AUTHINFO” on page 533
- Syntax diagram for TYPE(CRLLDAP)
- Syntax diagram for TYPE(OCSP)
- Syntax diagram for TYPE(IDPWOS)
- Syntax diagram for TYPE(IDPWLDAP)

**Synonym:** DEF AUTHINFO

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

#### Syntax diagram for TYPE(CRLLDAP)

## DEFINE AUTHINFO

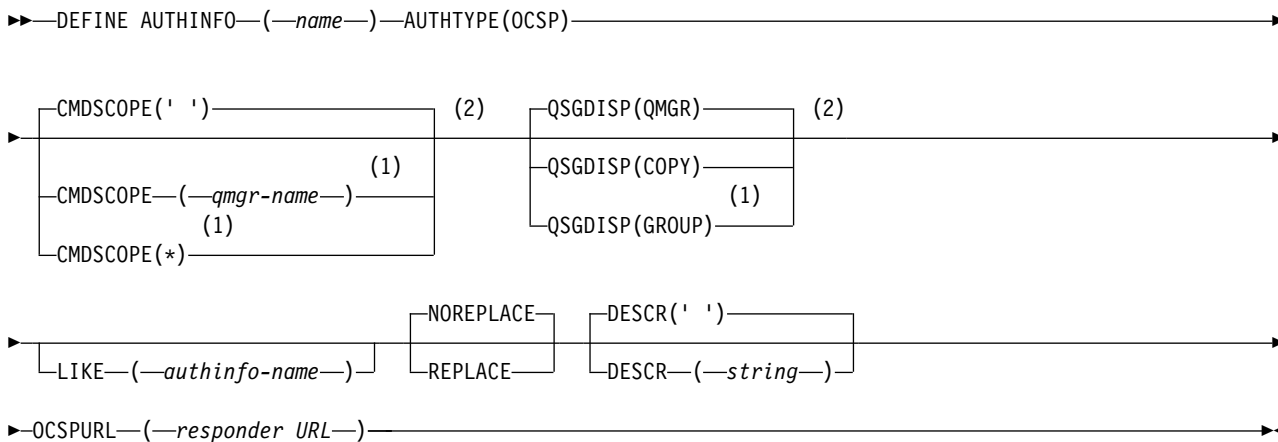

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 2 Valid only on z/OS.

### Syntax diagram for TYPE(OCSP)

## DEFINE AUTHINFO

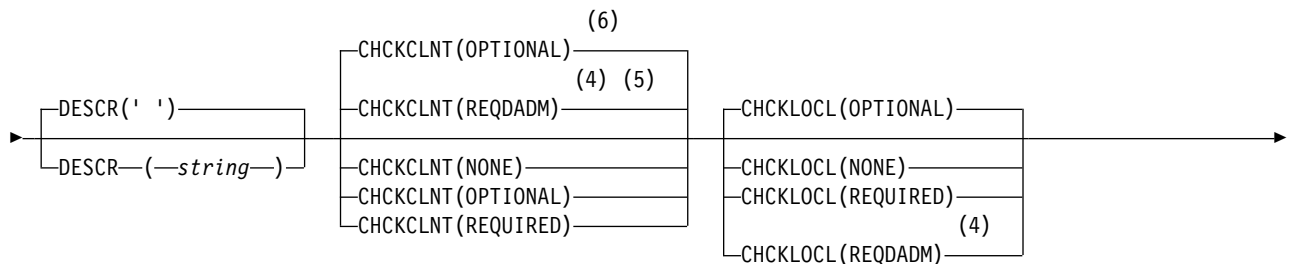

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 2 Valid only on z/OS.

### Syntax diagram for TYPE(IDPWOS)

## DEFINE AUTHINFO

►► DEFINE AUTHINFO—(—name—)—AUTHTYPE(IDPWOS)—————►

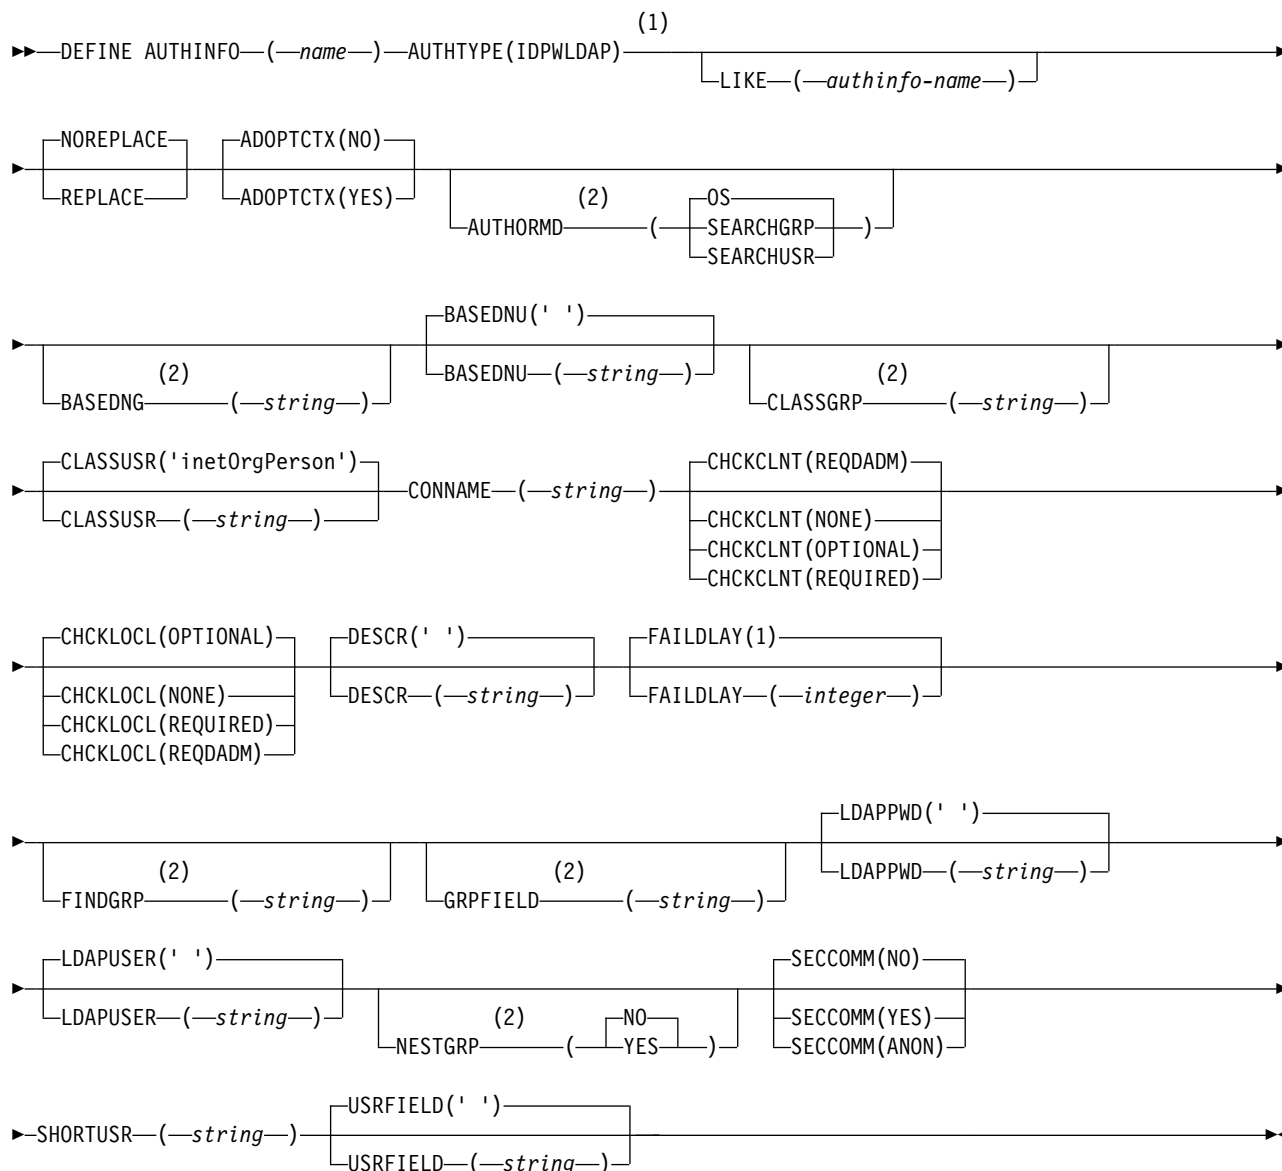

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS and PAM value can be set only on UNIX platforms.
- 4 Not valid on IBM MQ for z/OS.
- 5 Default for platforms other than z/OS.
- 6 Default for z/OS.

### Syntax diagram for TYPE(IDPWLDAP)

## DEFINE AUTHINFO

### Notes:

- 1 Not valid on IBM MQ for z/OS.
- 2 Not valid on Windows.

### Usage notes for DEFINE AUTHINFO

On IBM i, authentication information objects of AUTHTYPE(CRLLDAP) and AUTHTYPE(OCSP) are only used for channels of type CLNTCONN through use of the AMQCLCHL.TAB. Certificates are defined by Digital Certificate Manager for each certificate authority, and are verified against the LDAP servers.

**Attention:** After running the DEFINE AUTHINFO command, you must restart the queue manager. If you do not restart the queue manager, the setmqaut command does not return the correct result.

## Parameter descriptions for DEFINE AUTHINFO

**name** Name of the authentication information object. This parameter is required.

The name must not be the same as any other authentication information object name currently defined on this queue manager (unless REPLACE or ALTER is specified). See Rules for naming IBM MQ objects.

### ADOPTCTX

Whether to use the presented credentials as the context for this application. This means that they are used for authorization checks, shown on administrative displays, and appear in messages.

**YES** The user ID presented in the MQCSP structure, which has been successfully validated by password, is adopted as the context to use for this application. Therefore, this user ID will be the credentials checked for authorization to use IBM MQ resources.

If the user ID presented is an LDAP user ID, and authorization checks are done using operating system user IDs, the SHORTUSR associated with the user entry in LDAP will be adopted as the credentials for authorization checks to be done against.

**NO** Authentication will be performed on the user ID and password presented in the MQCSP structure, but then the credentials will not be adopted for further use. Authorization will be performed using the user ID the application is running under.

This attribute is only valid for an AUTHTYPE of IDPWOS and IDPWLDP.

### V8.0.0.3 AUTHENMD

Authentication method. Whether to use the operating system or Pluggable Authentication Method (PAM) to authenticate user passwords.

**OS** Use the traditional UNIX platforms password verification method.

#### PAM

Use the PAM to authenticate the user password.

You can set the PAM value only on UNIX and Linux platforms.

Changes to this attribute are effective only after you run the REFRESH SECURITY TYPE(CONNAUTH) command.

This attribute is valid only for an AUTHTYPE of IDPWOS.

### V8.0.0.2 AUTHORMD

Authorization Method.

**OS** Use operating system groups to determine permissions associated with a user.

This is how IBM MQ has previously worked, and is the default value.

#### SEARCHGRP

A group entry in the LDAP repository contains an attribute listing all the users belonging to that group. Membership is indicated by the attribute defined in FINDGRP. This value is typically *member* or *uniqueMember*.

#### SEARCHUSR

A user entry in the LDAP repository contains an attribute listing all the groups to which the specified user belongs. The attribute to query is defined by the FINDGRP value, typically *memberOf*.

Many LDAP servers use an attribute of the group object to determine group membership and you should, therefore, set this value to *SEARCHGRP*.

Microsoft Active Directory typically stores group memberships as a user attribute. The IBM Tivoli Directory Server supports both methods.

In general, retrieving memberships through a user attribute will be faster than searching for groups that list the user as a member.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2** , and is not applicable to Windows platforms.

## **AUTHTYPE**

The type of authentication information.

### **CRLLDAP**

Certificate Revocation List checking is done using LDAP servers.

### **IDPWLDAP**

Connection authentication user ID and password checking is done using an LDAP server.

**Attention:** This option is not available on IBM MQ for z/OS

### **IDPWOS**

Connection authentication user ID and password checking is done using the operating system.

**OCSP** Certificate revocation checking is done using OCSP.

An authentication information object with **AUTHTYPE(OCSP)** does not apply for use on IBM i or z/OS queue managers. However, it can be specified on those platforms to be copied to the client channel definition table (CCDT) for client use.

This parameter is required.

You cannot define an authentication information object as **LIKE** one with a different **AUTHTYPE**. You cannot alter the **AUTHTYPE** of an authentication information object after you have created it.

## **V 8.0.0.2 BASEDNG**

Base DN for groups

In order to be able to find group names, this parameter must be set with the base DN to search for groups in the LDAP server.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2** , and is not applicable to Windows platforms.

## **BASEDNU( base DN )**

In order to be able to find the short user name attribute (see **SHORTUSR** ) this parameter must be set with the base DN to search for users within the LDAP server.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

## **CHKCLNT**

This attribute determines the authentication requirements for client applications, and is valid only for an **AUTHTYPE** of *IDPWOS* or *IDPWLDAP* . The possible values are:

**NONE** No user ID and password checks are made. If any user ID or password is supplied by a client application, the credentials are ignored.

### **OPTIONAL**

Client applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the **MQCSP** structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

## REQUIRED

All client applications must provide a user ID and password in the MQCSP structure. This user ID and password is authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

## REQDADM

All client applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the **OPTIONAL** setting.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

**Note:** The REQDADM value for the **CHCKCLNT** attribute is irrelevant if the authentication type is LDAP. This is because there is no concept of privileged user id when using LDAP user accounts. LDAP user accounts and groups must be assigned permission explicitly.

 (This setting is not allowed on z/OS systems.)

## Important:

1. This attribute can be overridden by the **CHCKCLNT** attribute of the **CHLAUTH** rule that matches the client connection. The **CONNAUTH AUTHINFO CHCKCLNT** attribute on the queue manager therefore determines the default client checking behavior for client connections that do not match a **CHLAUTH** rule, or where the **CHLAUTH** rule matched has **CHCKCLNT ASQMGR**.
2. If you select **NONE** and the client connection matches a **CHLAUTH** record with **CHCKCLNT REQUIRED** (or **REQDADM** on platforms other than z/OS), the connection fails. You receive message **AMQ9793** on platforms other than z/OS, and message **CSQX793E** on z/OS.
3. This parameter is valid only with **TYPE (USERMAP)**, **TYPE (ADDRESSMAP)** and **TYPE (SSLPEERMAP)**, and only when **USERSRC** is not set to **NOACCESS**.
4. This parameter applies only to inbound connections that are server-connection channels.

## CHCKLOCL

This attribute determines the authentication requirements for locally bound applications, and is valid only for an **AUTHTYPE** of **IDPWOS** or **IDPWLDAP**. The possible values are:

**NONE** No user ID and password checks are made. If any user ID or password is supplied by a locally bound application, the credentials are ignored.

## OPTIONAL

Locally bound applications are not required to provide a user ID and password.

Any applications that do provide a user ID and password in the MQCSP structure have them authenticated by the queue manager against the password store indicated by the **AUTHTYPE**.

The connection will only be allowed to continue if the user ID and password are valid.

This option might be useful during migration, for example.

## REQUIRED

All locally bound applications must provide a user ID and password in the MQCSP structure. This user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

▶ **z/OS** If your user ID has UPDATE access to the BATCH profile in the MQCONN class, you can treat **CHKLOCL(REQUIRED)** as if it is **CHKLOCL(OPTIONAL)**. That is, you do not have to supply a password, but if you do, the password must be the correct one. See Using **CHKLOCL** on locally bound applications.

#### REQDADM

All locally bound applications using a privileged user ID must provide a user ID and password in the MQCSP structure. Any locally bound applications using a non-privileged user ID are not required to provide a user ID and password and are treated as with the OPTIONAL setting.

Any provided user ID and password will be authenticated by the queue manager against the password store indicated by the **AUTHTYPE**. The connection will only be allowed to continue if the user ID and password are valid.

▶ **z/OS** (This setting is not allowed on z/OS systems.)

#### ▶ **V 8.0.0.2** CLASSGRP

The LDAP object class used for group records in the LDAP repository.

If the value is blank, *groupOfNames* is used.

Other commonly used values include *groupOfUniqueNames* or *group*.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* ▶ **V 8.0.0.2**, and is not applicable to Windows platforms.

#### CLASSUSR( *LDAP class name* )

The LDAP object class used for user records in the LDAP repository.

If blank, the value defaults to *inetOrgPerson*, which is generally the value needed.

For Microsoft Active Directory, the value you require is often *user*.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

#### ▶ **z/OS** CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

#### CONNNAME( *connection name* )

The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running, with an optional port number.

This parameter is valid only for **AUTHTYPE(CRLLDAP)**, when it is mandatory.

If you specify the connection name as an IPv6 address, only systems with an IPv6 stack are able to resolve this address. If the AUTHINFO object is part of the CRL namelist of the queue manager, ensure that any clients using the client channel table generated by the queue manager can resolve the connection name.

On z/OS, if a CONNAME is to resolve to an IPv6 network address, a level of z/OS that supports IPv6 for connection to an LDAP server is required.

The syntax for CONNAME is the same as for channels. For example,

```
conname(' hostname ( nnn )')
```

where *nnn* is the port number.

The maximum length for the field is 264 characters on IBM i, UNIX systems, and Windows, and 48 characters on z/OS.

This attribute is valid only for an **AUTHTYPE** of *CRLLDAP* and *IDPWLDAP*, when the attribute is mandatory.

When used with an **AUTHTYPE** of *IDPWLDAP*, this can be a comma separated list of connection names.

#### **DESCR**( *string* )

Plain-text comment. It provides descriptive information about the authentication information object when an operator issues the DISPLAY AUTHINFO command (see “DISPLAY AUTHINFO” on page 715 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

#### **FAILDLAY**( *delay time* )

When a user ID and password are provided for connection authentication, and the authentication fails due to the user ID or password being incorrect, this is the delay, in seconds, before the failure is returned to the application.

This can aid in avoiding busy loops from an application that simply retries, continuously, after receiving a failure.

The value must be in the range 0 - 60 seconds. The default value is 1.

This attribute is only valid for an **AUTHTYPE** of *IDPWOS* and *IDPWLDAP* .

#### **V 8.0.0.2 FINDGRP**

Name of the attribute used within an LDAP entry to determine group membership.

When AUTHORMD = *SEARCHGRP*, the **FINDGRP** attribute is typically set to *member* or *uniqueMember*.

When AUTHORMD = *SEARCHUSR*, the **FINDGRP** attribute is typically set to *memberOf*.

When the **FINDGRP** attribute is left blank:

- If AUTHORMD = *SEARCHGRP*, the **FINDGRP** attribute defaults to *memberOf*.
- If AUTHORMD = *SEARCHUSR*, the **FINDGRP** attribute defaults to *member*.

#### **V 8.0.0.2 GRPFIELD**

LDAP attribute that represents a simple name for the group.

If the value is blank, commands like setmqaut must use a qualified name for the group. The value can either be a full DN, or a single attribute.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2**, and is not applicable to Windows platforms.

#### **LDAPPWD**( *LDAP password* )

The password associated with the Distinguished Name of the user who is accessing the LDAP server. Its maximum size is 32 characters.

This attribute is valid only for an **AUTHTYPE** of *CRLLDAP* and *IDPWLDAP*.

On z/OS, the LDAPPWD used for accessing the LDAP server might not be the one defined in the AUTHINFO object. If more than one AUTHINFO object is placed in the namelist referred to by the QMGR parameter SSLCRLNL, the LDAPPWD in the first AUTHINFO object is used for accessing all LDAP Servers.

#### **LDAPUSER**( *LDAP user* )

The Distinguished Name of the user who is accessing the LDAP server. (See the SSLPEER parameter for more information about distinguished names.)

This attribute is valid only for an **AUTHTYPE** of *CRLLDAP* and *IDPWLDAP*.

The maximum size for the user name is 1024 characters on IBM i, UNIX systems, and Windows, and 256 characters on z/OS.

On z/OS, the LDAPUSER used for accessing the LDAP Server might not be the one defined in the AUTHINFO object. If more than one AUTHINFO object is placed in the namelist referred to by the QMGR parameter SSLCRLNL, the LDAPUSER in the first AUTHINFO object is used for accessing all LDAP Servers.

On IBM i, UNIX systems, and Windows, the maximum accepted line length is defined to be BUFSIZ, which can be found in stdio.h.

#### **LIKE**( *authinfo-name* )

The name of an authentication information object, with parameters that are used to model this definition.

**z/OS** On z/OS, the queue manager searches for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

#### **Note:**

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified. However, the group object defined is used as a LIKE object.

#### **V 8.0.0.2** **NESTGRP**

Group nesting.

**NO** Only the initially discovered groups are considered for authorization.

#### **YES**

The group list is searched recursively to enumerate all the groups to which a user belongs.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* **V 8.0.0.2**, and is not applicable to Windows platforms.

#### **OCSPURL**( *Responder URL* )

The URL of the OCSP responder used to check for certificate revocation. This value must be an HTTP URL containing the host name and port number of the OCSP responder. If the OCSP responder is using port 80, which is the default for HTTP, then the port number can be omitted. HTTP URLs are defined in RFC 1738.

This field is case sensitive. It must start with the string `http://` in lowercase. The rest of the URL might be case sensitive, depending on the OCSP server implementation. To preserve case, use single quotation marks to specify the OCSPURL parameter value, for example:

```
OCSPURL ('http://ocsp.example.ibm.com')
```

This parameter is applicable only for AUTHTYPE(OCSP), when it is mandatory.

**z/OS QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	DEFINE
<b>COPY</b>	The object is defined on the page set of the queue manager that executes the command using the QSGDISP(GROUP) object of the same name as the 'LIKE' object.
<b>GROUP</b>	The object definition resides in the shared repository. GROUP is allowed only if the queue manager is in a queue-sharing group. If the definition is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to make or refresh local copies on page set zero:  <pre>DEFINE AUTHINFO(name) REPLACE QSGDISP(COPY)</pre> <p>The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
<b>PRIVATE</b>	Not permitted.
<b>QMGR</b>	The object is defined on the page set of the queue manager that executes the command.

**REPLACE and NOREPLACE**

Whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. This parameter is optional. Any object with a different disposition is not changed.

**REPLACE**

The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

**NOREPLACE**

The definition must not replace any existing definition of the same name.

**SECCOMM**

Whether connectivity to the LDAP server should be done securely using SSL/TLS

**YES** Connectivity to the LDAP server is made securely using SSL/TLS.

The certificate used is the default certificate for the queue manager, named in CERTLABL on the queue manager object, or if that is blank, the one described in Digital certificate labels, understanding the requirements.

The certificate is located in the key repository specified in SSLKEYR on the queue manager object. A cipherspec will be negotiated that is supported by both IBM MQ and the LDAP server.

If the queue manager is configured to use SSLFIPS(YES) or SUITEB cipher specs, then this is taken account of in the connection to the LDAP server as well.

**ANON**

Connectivity to the LDAP server is made securely using SSL/TLS just as for SECCOMM(YES) with one difference.

No certificate is sent to the LDAP server; the connection will be made anonymously. To use this setting, ensure that the key repository specified in SSLKEYR, on the queue manager object, does not contain a certificate marked as the default.

**NO** Connectivity to the LDAP server does not use SSL/TLS.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

**SHORTUSR( LDAP field name )**

A field in the user record to be used as a short user name in IBM MQ.

This field must contain values of 12 characters or less. This short user name is used for the following purposes:

- If LDAP authentication is enabled, but LDAP authorization is not enabled, this is used as an operating system user ID for authorization checks. In this case, the attribute must represent an operating system user ID.
- If LDAP authentication and authorization are both enabled, this is used as the user ID carried with the message in order for the LDAP user name to be rediscovered when the user ID inside the message needs to be used.

For example, on another queue manager, or when writing report messages. In this case, the attribute does not need to represent an operating system user ID, but must be a unique string. An employee serial number is an example of a good attribute for this purpose.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP* and is mandatory.

**USRFIELD( LDAP field name )**

If the user ID provided by an application for authentication does not contain a qualifier for the field in the LDAP user record, that is, it does not contain an '=' sign, this attribute identifies the field in the LDAP user record that is used to interpret the provided user ID.

This field can be blank. If this is the case, any unqualified user IDs use the SHORTUSR parameter to interpret the provided user ID.

The contents of this field will be concatenated with an '=' sign, together with the value provided by the application, to form the full user ID to be located in an LDAP user record. For example, the application provides a user of fred and this field has the value cn, then the LDAP repository will be searched for cn=fred.

This attribute is valid only for an **AUTHTYPE** of *IDPWLDAP*.

## DEFINE BUFFPOOL: z/OS

Use the MQSC command DEFINE BUFFPOOL to define a buffer pool that is used for holding messages in main storage.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			1

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes”
- “Parameter descriptions for DEFINE BUFFPOOL”

**Synonym:** DEF BP

### DEFINE BUFFPOOL

### Usage notes

1. Specify DEFINE BUFFPOOL commands in a data set identified by the CSQINP1 DD concatenation in the queue manager started task procedure.
2. Use the DISPLAY USAGE TYPE(PAGESET) command to display buffer pool information (see “DISPLAY USAGE” on page 938 ).
3. Use the ALTER BUFFPOOL command to dynamically change the settings of a predefined buffer pool (see “ALTER BUFFPOOL” on page 357 ).

### Parameter descriptions for DEFINE BUFFPOOL

If more than one DEFINE BUFFPOOL command is issued for the same buffer pool, only the last one is processed.

(*buf-pool-id*)

Buffer pool identifier.

This parameter is an integer in the range zero through 15. If OPMODE is set to OPMODE=(NEWFUNC, 800), this parameter is an integer in the range zero through 99.

**BUFFERS**( *integer* )

This parameter is required and is the number of 4096 byte buffers to be used in this buffer pool.

If the value of the LOCATION parameter is BELOW, the minimum value of buffers is 100 and the maximum value is 500,000. If the value of the LOCATION parameter is ABOVE then valid values are in the range of 100 to 999999999 (nine nines). The storage used for buffers in a buffer pool

with LOCATION ABOVE is obtained in multiples of 4MB. Therefore specifying a BUFFERS value which is a multiple of 1024 will make the most efficient use of storage. See Buffers and buffer pools for guidance on the number of buffers you can define in each buffer pool.

When defining a buffer pool care should be taken to ensure that there is sufficient storage available for it either above or below the bar. For more information, see Address space storage.

#### **LOCATION(LOC)( BELOW or ABOVE )**

The LOCATION or LOC parameter specifies where the memory used by the specified buffer pool is located.

LOCATION and LOC are synonyms and either, but not both, can be used.

This memory location can be either ABOVE (64 bit) or BELOW (31 bit) the bar. Valid values for this parameter are BELOW or ABOVE, with BELOW being the default.

ABOVE can only be specified if OPMODE(NEWFUNC, 800) is in effect. BELOW can be specified regardless of OPMODE(NEWFUNC, 800) being used and has the same effect as not specifying the LOCATION parameter.

When altering a buffer pool, you should take care to make sure that there is sufficient storage available if increasing the number of buffers, or changing the LOCATION value. Switching the location of the buffer pool can be a CPU and I/O intensive task. You should perform this task when the queue manager is not being heavily utilized.

For more information, see Address space storage.

#### **PAGECLAS( 4KB or FIXED4KB )**

Optional parameter that describes the type of virtual storage pages used for backing the buffers in the buffer pool.

This attribute applies to all buffers in the buffer pool, including any that are added later as a result of using the ALTER BUFFPOOL command. The default value is 4KB, which means that pageable 4KB pages are used to back the buffers in the pool.

4KB is the only valid value if the buffer pool has its location attribute set to BELOW. If the buffer pool has its LOCATION attribute set to ABOVE, it is also possible to specify FIXED4KB. This means that fixed 4KB pages, which are permanently in real storage and will never be paged out to auxiliary storage, are used to back the buffers in the buffer pool.

FIXED4KB can only be specified if OPMODE(NEWFUNC, 800) is in effect whereas 4KB can be specified regardless of the setting of OPMODE(NEWFUNC, 800).

The PAGECLAS attribute of a buffer pool can be altered at any time. However, the alteration only takes place when the buffer pool switches location from above the bar, to below the bar, or the other way round. Otherwise, the value is stored in the log of the queue manager and is applied when the queue manager next restarts.

When you specify PAGECLAS(FIXED4KB) the whole buffer pool is backed by page-fixed 4KB pages, so ensure that there is sufficient real storage available on the LPAR. Otherwise, the queue manager might not start up, or other address spaces might be impacted; for more information, see Address space storage.

See IBM MQ Support Pac MP16: IBM MQ for z/OS - Capacity planning & tuning for advice on when to use the FIXED4KB value of the PAGECLAS attribute.

#### **REPLACE/NOREPLACE**

Optional attribute describing whether this definition of a buffer pool overrides any definition that might already be contained in the log of the queue manager.

##### **REPLACE**

This definition of the buffer pool overrides the definition stored in the log of the queue

manager, if there is one. If the definition in the log of the queue manager is different from this definition, the differences are discarded and message CSQP064I is issued.

### NOREPLACE

This is the default value, and provides the same behavior as with previous releases of IBM MQ. If there is a definition of the buffer pool in the log of the queue manager that is used, and this definition is ignored.

**Attention:** The queue manager records the current buffer pool settings in checkpoint log records. These buffer pool settings are automatically restored when a queue manager is later restarted. This restoration occurs after processing of the CSQINP1 data set. Therefore, if you have used ALTER BUFFPOOL since the buffer pool was last defined, any DEFINE BUFFPOOL command in CSQINP1 has been ignored at restart, unless the REPLACE attribute has been specified.

### Switching from OPMODE=(NEWFUNC,800) to OPMODE=(COMPAT,800)

When you switch from OPMODE=(NEWFUNC,800) to OPMODE=(COMPAT,800) the following occurs:

1. Any buffer pools with an id greater than 15 are marked as suspended. This means that these buffer pools cannot be used, deleted, or altered until OPMODE=(NEWFUNC,800) is specified again. Information about the buffer pools is kept in check point log records until OPMODE=(NEWFUNC,800) is specified again.

Any page set that uses a suspended buffer pool is also suspended. Information about the suspended page set is also kept in check point records.

While suspended, any object definitions or messages in the page set are unavailable. An attempt to use a queue or topic which uses the suspended page set results in an MQRC\_PAGESET\_ERROR message

While suspended, a page set can be associated with a different buffer pool by using the FORMAT function of the utility program CSQUTIL, specifying TYPE(REPLACE). You can then issue a **DEFINE PSID** command to bring the page set back into use with a different buffer pool.

**Note:** All units of recovery that involved the suspended page set, except units that are indoubt, will have been backed out by the queue manager when the page set was last used. Indoubt units of recovery can be resolved when the page set is again in use by the queue manager.

2. Any buffer pools with an id of 15 or less that have their LOCATION attribute set to ABOVE, will have the LOCATION attribute switched to BELOW, and their PAGECLAS attribute set to 4KB.

### DEFINE CFSTRUCT: z/OS

Use the MQSC command DEFINE CFSTRUCT to define queue manager CF level capability, message offload environment, and backup and recovery parameters for a coupling facility application structure.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

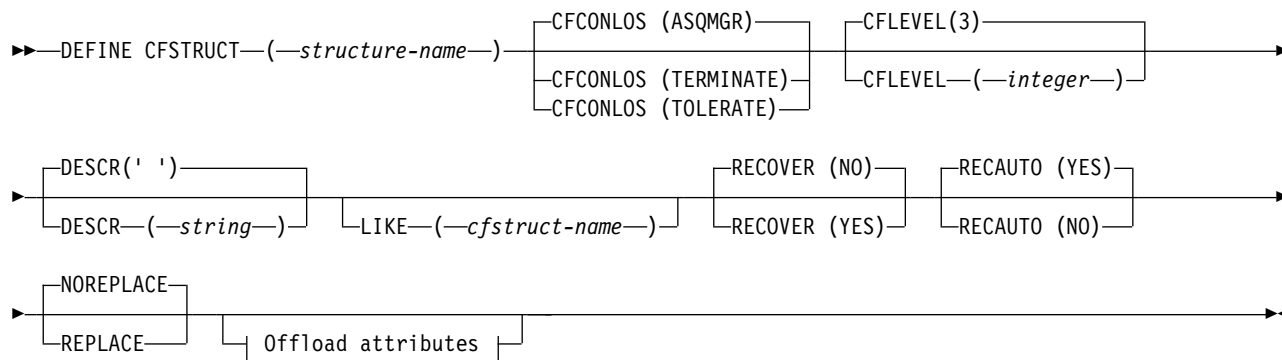

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

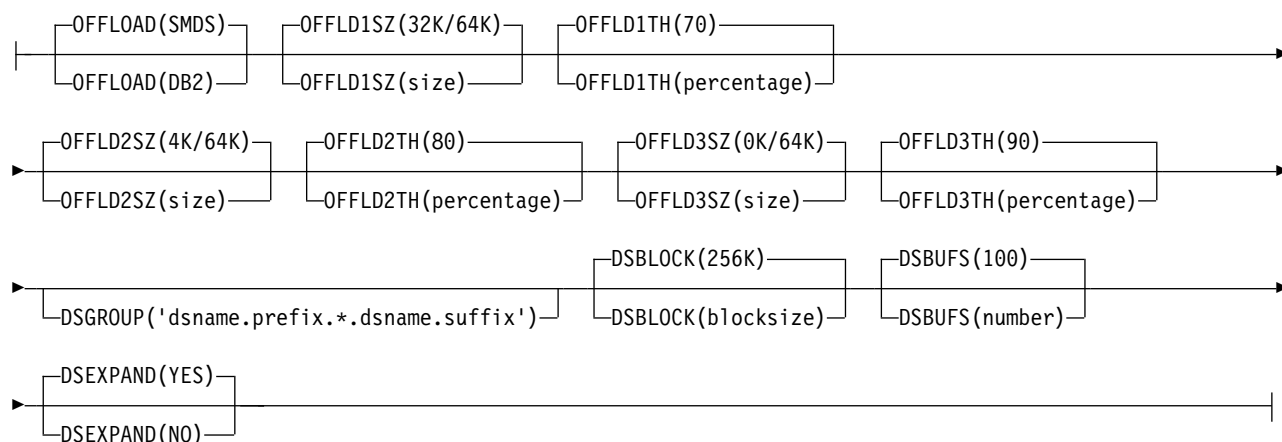

- Syntax diagram
- “Usage notes for DEFINE CFSTRUCT” on page 544
- “Parameter descriptions for DEFINE CFSTRUCT” on page 544

Synonym: DEF CFSTRUCT

## DEFINE CFSTRUCT

### Offload attributes:

### Usage notes for DEFINE CFSTRUCT

1. This command is valid only on z/OS when the queue manager is a member of a queue-sharing group.
2. This command cannot specify the CF administration structure (CSQ\_ADMIN).
3. Before any newly defined CF structure can be used by any queues, the structure must be defined in the Coupling Facility Resource Management (CFRM) policy data set.
4. Only CF structures with RECOVER(YES) defined can be backed up and recovered.

### Parameter descriptions for DEFINE CFSTRUCT

(structure-name)

Name of the coupling facility application structure that has queue manager CF level capability and backup and recovery parameters you want to define. This parameter is required.

The name:

- Cannot have more than 12 characters.
- Must start with an uppercase letter (A through Z).
- Can include only the characters A through Z and 0 through 9.

The name of the queue-sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue-sharing group is always four characters, padded with

@ symbols if necessary. For example, if you use a queue-sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue-sharing group (in this case NY03CSQ\_ADMIN) cannot be used for storing messages.

## CFCONLOS

This parameter specifies the action to be taken when a queue manager loses connectivity to the CF structure. The value can be:

### ASQMGR

The action taken is based on the setting of the CFCONLOS queue manager attribute.

### TERMINATE

The queue manager ends when connectivity to the structure is lost.

### TOLERATE

The queue manager tolerates loss of connectivity to the structure without terminating.

This parameter is only valid from CFLEVEL(5).

## CFLEVEL( *integer* )

Specifies the functional capability level for this CF application structure. Value can be one of the following:

**1** A CF structure that can be "auto-created" by a queue manager at command level 520.

**2** A CF structure at command level 520 that can only be created or deleted by a queue manager at command level 530 or greater.

**3**

A CF structure at command level 530. This CFLEVEL is required if you want to use persistent messages on shared queues (if RECOVER(YES) is set), or for message grouping (when a local queue is defined with INDXTYPE(GROUPID)), or both.

You can only increase the value of CFLEVEL to 3 if all the queue managers in the queue-sharing group are at command level 530 or greater - this is to ensure that there are no latent command level 520 connections to queues referencing the structure.

You can only decrease the value of CFLEVEL from 3 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

**4**

This CFLEVEL supports all the CFLEVEL(3) functions. CFLEVEL(4) allows queues defined with CF structures at this level to have messages with a length greater than 63 KB.

Only a queue manager with a command level of 600 or above can connect to a CF structure at CFLEVEL(4).

You can only increase the value of CFLEVEL to 4 if all the queue managers in the queue-sharing group are at command level 600 or greater.

You can only decrease the value of CFLEVEL from 4 if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

**5**

This CFLEVEL supports all functions for CFLEVEL(4). In addition, CFLEVEL(5) enables the following new functions. If altering an existing CFSTRUCT to CFLEVEL(5), you must review other attributes as indicated:

- queues defined with CF structures at this level can have message data offloaded to either shared message data sets (SMDS), or Db2, under control of the OFFLOAD attribute. The offload threshold and size parameters (such as OFFLD1TH, and OFFLD1SZ) determine whether any particular messages are offloaded given its size and current CF structure utilization. If using SMDS offload, the DSGROUP, DSBUFS, DSEXPAND and DSBLOCK attributes are respected.
- structures at CFLEVEL(5) allow the queue manager to tolerate a loss of connectivity to the CF structure. The CFCONLOS attribute determines queue manager behavior when a loss of connectivity is detected, and the RECAUTO attribute controls subsequent automatic structure recovery behavior.
- messages containing IBM MQ message properties are stored in a different format on shared queues in a CFLEVEL(5) structure. This format leads to internal processing optimizations. Additional application migration capabilities are also available and these are enabled via the queue PROPCTL attribute.

Only a queue manager with a command level of 710 or above can connect to a CF structure at CFLEVEL(5).

**Note:**

You can only increase the value of CFLEVEL to 5 if all the queue managers in the queue-sharing group are at command level 710 or greater and have IBM WebSphere MQ Version 7.1.0 new functions enabled with OPMODE

You can decrease the value of CFLEVEL from 5 if all the queues that reference the CF structure are both empty, that is the queues, and CF structure have no messages or uncommitted activity, and are closed.

**DESCR( *string* )**

Plain-text comment that provides descriptive information about the object when an operator issues the DISPLAY CFSTRUCT command.

The string should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**LIKE( *cfstruct-name* )**

The name of a CFSTRUCT object, with attributes used to model this definition.

The initial values of all attributes are copied from the object, except any DSGROUP attribute is ignored because each structure requires its own unique value.

**OFFLOAD**

Specify whether offloaded message data is to be stored in a group of shared message data sets or in Db2.

**SMDS**

Offload messages from coupling facility to shared message data set (SMDS). This value is the default assumption when a new structure is defined with CFLEVEL(5).

**Db2** Offload messages from coupling facility to Db2. This value is the default assumption when an existing structure is increased to CFLEVEL(5) using DEFINE with the REPLACE option.

Offloading messages using Db2 has significant performance impact. If you want to use the offload rules as a means of increasing capacity, the SMDS option should be specified or assumed.

This parameter is only valid from CFLEVEL(5). At CFLEVEL(4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

**Note:**

If you change the offload technique (from Db2 to SMDS or the other way) then all new messages will be written using the new method but any existing large messages stored using the previous technique can still be retrieved. The relevant Db2 message table or shared message data sets will continue to be used until the queue managers have detected that there are no further messages stored in the old format.

If SMDS is specified or assumed, then the DSGROUP parameter is also required. It can be specified either on the same command or on a previous DEFINE or ALTER command for the same structure.

**OFFLD1TH(percentage) OFFLD1SZ(size)**

**OFFLD2TH(percentage) OFFLD2SZ(size)**

**OFFLD3TH(percentage) OFFLD3SZ(size)**

Specify rules for when messages smaller than the maximum coupling facility entry size are to be offloaded to external storage (shared message data sets or Db2 tables) instead of being stored in the application structure. These rules can be used to increase the effective capacity of the structure. The offloaded message still requires an entry in the coupling facility containing message control information, and a descriptor referring to the offloaded message data, but the amount of structure space required is less than the amount that would be needed to store the whole message.

If the message data is very small (of the order of 100 bytes) it might fit into the same coupling facility entry as the message control information, without needing additional data elements. In this case, no space can be saved, so any offload rules are ignored and the message data is not offloaded. The actual number varies, depending whether more than the default headers are used, or if message properties are being stored.

Messages exceeding the maximum coupling facility entry size (63.75 KB including control information) are always offloaded as they cannot be stored in a coupling facility entry. Messages where the message body exceeds 63 KB are also offloaded to ensure that enough space is available for the control information. Additional rules to request offloading of smaller messages can be specified using these pairs of keywords. Each rule indicates that when the usage of the structure (in either elements or entries) exceeds the specified threshold percentage value, the message data will be offloaded if the total size of the coupling facility entry required to store the whole message (including message data, headers and descriptors) exceeds the specified size value. The minimal set of headers and descriptors require approximately 400 bytes, however this could be greater if other headers or properties are added. This figure would also be greater if an MQMD version greater than 1 is used.

**percentage**

The usage threshold percentage value is an integer in the range 0 (meaning this rule always applies) to 100 (meaning this rule only applies when the structure is full). For example, OFFLD1TH(75) OFFLD1SZ(32K) means that when the structure is over 75% full, messages greater than 32 kilobytes in size are offloaded.

**size**

The message size value should be specified as an integer followed by K, giving the number of kilobytes in the range **0K** to **64K**. As messages exceeding 63.75 KB are always offloaded, the value 64K is allowed as a simple way to indicate that the rule is not being used.

In general, the smaller the numbers, the more messages are offloaded.

A message is offloaded if any offload rule matches. The normal convention is that a later rule would be for a higher usage level and a smaller message size than an earlier one, but no check is made for consistency or redundancy between the rules.

When structure ALTER processing is active, the number of used elements or entries can temporarily exceed the reported total number, giving a percentage exceeding 100, because the new elements or entries are made available during ALTER processing but the total is only updated when the ALTER completes. At such times, a rule specifying 100 for the threshold may temporarily take effect. If a rule is not intended to be used at all, it should specify 64K for the size.

The default values assumed for the offload rules when defining a new structure at CFLEVEL(5) or upgrading an existing structure to CFLEVEL(5) depend on the OFFLOAD method option. For OFFLOAD(SMDS), the default rules specify increasing amounts of offloading as the structure becomes full. This increases the effective structure capacity with minimal performance impact. For OFFLOAD( Db2 ), the default rules have the same threshold values as for SMDS but the size values are set to 64K so that the rules never apply and messages are offloaded only if they are too large to be stored in the structure, as for CFLEVEL(4).

For OFFLOAD(SMDS) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(32K)
- OFFLD2TH(80) OFFLD2SZ(4K)
- OFFLD3TH(90) OFFLD3SZ(0K)

For OFFLOAD( Db2 ) the defaults are:

- OFFLD1TH(70) OFFLD1SZ(64K)
- OFFLD2TH(80) OFFLD2SZ(64K)
- OFFLD3TH(90) OFFLD3SZ(64K)

If the OFFLOAD method option is changed from Db2 to SMDS or back when the current offload rules all match the default values for the old method, the offload rules are switched to the default values for the new method. However, if any of the rules have been changed, the current values are kept when switching method.

These parameters are only valid from CFLEVEL(5). At CFLEVEL(4) any message offloading is always to Db2, and only applies to messages greater than the maximum coupling facility entry size.

## DSGROUP

For OFFLOAD(SMDS), specify the generic data set name to be used for the group of shared message data sets associated with this structure (one for each queue manager), with exactly one asterisk indicating where the queue manager name should be inserted to form the specific data set name.

### **dsname.prefix.\*.dsname.suffix**

The value must be a valid data set name when the asterisk is replaced by a queue manager name of up to four characters.

The entire parameter value must be enclosed in quotation marks.

This parameter cannot be changed after any data sets have been activated for the structure.

If SMDS is specified or assumed, then the DSGROUP parameter must also be specified.

This parameter is only valid from CFLEVEL(5).

## DSBLOCK

For OFFLOAD(SMDS), specify the logical block size, which is the unit in which shared message data set space is allocated to individual queues.

8K  
16K  
32K  
64K  
128K  
256K  
512K

**1M** Each message is written starting at the next page within the current block and is allocated further blocks as needed. A larger size decreases space management requirements and reduces I/O for large messages, but increases buffer space requirements and disk space requirements for small queues.

This parameter cannot be changed after any data sets have been activated for the structure.

This parameter is only valid from CFLEVEL(5).

## **DSBUFS**

For OFFLOAD(SMDS), specify the number of buffers to be allocated in each queue manager for accessing shared message data sets, as a number in the range 1 - 9999. The size of each buffer is equal to the logical block size. SMDS buffers are allocated in memory objects residing in z/OS 64-bit storage (above the bar).

### **number**

This parameter can be overridden for individual queue managers using the DSBUFS parameter on ALTER SMDS.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSBUFS override value) dynamically increase or decrease the number of data set buffers being used for this structure to match the new value. If the specified target value cannot be reached, the affected queue manager adjusts the DSBUFS parameter associated with its own individual SMDS definition (as for the ALTER SMDS command) to match the actual new number of buffers.

This parameter is only valid from CFLEVEL(5).

## **DSEXPAND**

For OFFLOAD(SMDS), this parameter controls whether the queue manager should expand a shared message data set when it becomes nearly full, and further blocks are required in the data set.

**YES** Expansion is supported.

Each time expansion is required, the data set is expanded by the secondary allocation specified when the data set was defined. If no secondary allocation was specified, or it was specified as zero, then a secondary allocation amount of approximately 10% of the existing size is used

**NO** No automatic data set expansion is to take place.

This parameter can be overridden for individual queue managers using the DSEXPAND parameter on ALTER SMDS.

If an expansion attempt fails, the DSEXPAND override for the affected queue manager is automatically changed to NO to prevent further expansion attempts, but it can be changed back to YES using the ALTER SMDS command to enable further expansion attempts.

When this parameter is altered, any queue managers which are already connected to the structure (and which do not have an individual DSEXPAND override value) immediately start using the new parameter value.

This parameter is only valid from CFLEVEL(5).

## RECOVER

Specifies whether CF recovery is supported for the application structure. Values are:

**NO** CF application structure recovery is not supported. (The synonym is **N**.)

**YES** CF application structure recovery is supported. (The synonym is **Y**.)

You can only set RECOVER(YES) if the structure has a CFLEVEL of 3 or higher. Set RECOVER(YES) if you intend to use persistent messages.

You can only change RECOVER(NO) to RECOVER(YES) if all the queue managers in the queue-sharing group are at command level 530 or greater; this is to ensure that there are no latent command level 520 connections to queues referencing the CFSTRUCT.

You can only change RECOVER(YES) to RECOVER(NO) if all the queues that reference the CF structure are both empty (have no messages or uncommitted activity) and closed.

## RECAUTO

Specifies the automatic recovery action to be taken when a queue manager detects that the structure is failed or when a queue manager loses connectivity to the structure and no systems in the SysPlex have connectivity to the Coupling Facility that the structure is allocated in. Values can be:

**YES** The structure and associated shared message data sets which also need recovery will be automatically recovered (The synonym is **Y**.)

**NO** The structure will not be automatically recovered. (The synonym is **N**.)

This parameter has no effect for structures defined with RECOVER(NO).

This parameter is only valid from a CFLEVEL(5)

## REPLACE and NOREPLACE

Defines whether the existing definition is to be replaced with this one. This parameter is optional.

### REPLACE

The definition should replace any existing definition of the same name. If a definition does not exist, one is created. If you use the REPLACE option, all queues that use this CF structure must be empty and closed.

### NOREPLACE

The definition should not replace any existing definition of the same name.

## DEFINE CHANNEL:

Use the MQSC command **DEFINE CHANNEL** to define a new channel, and set its parameters.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

Synonym: DEF CHL

- “Usage notes” on page 551

- “Parameter descriptions for DEFINE CHANNEL”

### Usage notes

- For CLUSSDR channels, you can specify the REPLACE option only for manually created channels.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE CHANNEL step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for DEFINE CHANNEL

The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

**SDR** “Sender channel” on page 586

**SVR** “Server channel” on page 589

**RCVR** “Receiver channel” on page 593

**RQSTR** “Requester channel” on page 595

**CLNTCONN**  
“Client-connection channel” on page 598

**SVRCONN**  
“Server-connection channel” on page 601

**CLUSSDR**  
“Cluster-sender channel” on page 603

**CLUSRCVR**  
“Cluster-receiver channel” on page 606

**V 8.0.0.4 AMQP**  
“AMQP channel” on page 610

## AFFINITY

Use the channel affinity attribute when client applications connect multiple times using the same queue manager name. With the attribute, you can choose whether the client uses the same client channel definition for each connection. This attribute is intended to be used when multiple applicable channel definitions are available.

### PREFERRED

The first connection in a process reading a client channel definition table (CCDT) creates a list of applicable definitions. The list is based on the weightings, with any applicable CLNTWGHT (0) definitions first and in alphabetic order. Each connection in the process

attempts to connect using the first definition in the list. If a connection is unsuccessful the next definition is used. Unsuccessful non- CLNTWGHT (0) definitions are moved to the end of the list. CLNTWGHT (0) definitions remain at the start of the list and are selected first for each connection. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT was modified since the list was created. Each client process with the same host name creates the same list.

**NONE** The first connection in a process reading a CCDT creates a list of applicable definitions. All connections in a process select an applicable definition based on the weighting with any applicable CLNTWGHT (0) definitions selected first in alphabetic order. For C, C++ and .NET (including fully managed .NET) clients the list is updated if the CCDT was modified since the list was created.

For example, suppose that we had the following definitions in the CCDT:

```
CHLNAME(A) QMNAME (QM1) CLNTWGHT(3)
CHLNAME(B) QMNAME (QM1) CLNTWGHT(4)
CHLNAME(C) QMNAME (QM1) CLNTWGHT(4)
```

The first connection in a process creates its own ordered list based on the weightings. So it might, for example, create the ordered list CHLNAME(B), CHLNAME(A), CHLNAME(C).

For AFFINITY(PREFERRED), each connection in the process attempts to connect using CHLNAME(B). If a connection is unsuccessful the definition is moved to the end of the list which now becomes CHLNAME(A), CHLNAME(C), CHLNAME(B). Each connection in the process then attempts to connect using CHLNAME(A).

For AFFINITY(NONE), each connection in the process attempts to connect using one of the three definitions selected at random based on the weightings.

If sharing conversations is enabled with a non-zero channel weighting and AFFINITY(NONE), multiple connections do not have to share an existing channel instance. They can connect to the same queue manager name using different applicable definitions rather than sharing an existing channel instance.

#### **distributed** **V 8.0.0.4** **AMQPKA( integer )**

The keep alive time for an AMQP channel in seconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a `amqp:resource-limit-exceeded` AMQP error condition.

This parameter is valid only for channels with a channel type ( `CHLTYPE` ) of `AMQP`

#### **BATCHHB ( integer )**

Specifies whether batch heartbeats are to be used. The value is the length of the heartbeat in milliseconds.

Batch heartbeats allow a sending channel to verify that the receiving channel is still active just before committing a batch of messages. If the receiving channel is not active, the batch can be backed out rather than becoming in-doubt, as would otherwise be the case. By backing out the batch, the messages remain available for processing so they could, for example, be redirected to another channel.

If the sending channel received a communication from the receiving channel within the batch heartbeat interval, the receiving channel is assumed to be still active. If not, a 'heartbeat' is sent to the receiving channel to check.

The value must be in the range 0 - 999999. A value of zero indicates that batch heart beats are not used.

This parameter is valid for channels with a channel type ( `CHLTYPE` ) of only `SDR`, `SVR`, `CLUSDR`, and `CLUSRCVR`.

#### **BATCHINT ( integer )**

The minimum amount of time, in milliseconds, that a channel keeps a batch open.

The batch is terminated when one of the following conditions is met:

- BATCHSZ messages are sent.
- BATCHLIM kilobytes are sent.
- The transmission queue is empty and BATCHINT is exceeded.

The value must be in the range 0 - 999999999. Zero means that the batch is terminated as soon as the transmission queue becomes empty (or the BATCHSZ limit is reached).

This parameter is valid for channels with a channel type ( CHLTYPE ) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

### **BATCHLIM ( *integer* )**

The limit, in kilobytes, of the amount of data that can be sent through a channel before taking a sync point. A sync point is taken after the message that caused the limit to be reached flows across the channel. A value of zero in this attribute means that no data limit is applied to batches over this channel.

The batch is terminated when one of the following conditions is met:

- BATCHSZ messages are sent.
- BATCHLIM kilobytes are sent.
- The transmission queue is empty and BATCHINT is exceeded.

This parameter is valid for channels with a channel type ( CHLTYPE ) of only SDR, SVR, CLUSSDR, and CLUSRCVR.

The value must be in the range 0 - 999999. The default value is 5000.

This parameter is supported on all platforms.

### **BATCHSZ ( *integer* )**

The maximum number of messages that can be sent through a channel before taking a sync point.

The maximum batch size used is the lowest of the following values:

- The BATCHSZ of the sending channel.
- The BATCHSZ of the receiving channel.
-  On z/OS, three less than the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
- On distributed platforms, the maximum number of uncommitted messages allowed at the sending queue manager (or one if this value is zero or less).
-  On z/OS, three less than the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).
- On distributed platforms, the maximum number of uncommitted messages allowed at the receiving queue manager (or one if this value is zero or less).

While non-persistent messages sent over an NPMSPEED (FAST) channel are delivered to a queue immediately (without waiting for a complete batch), the messages still contribute to the batch size for a channel and, therefore, cause confirm flows to occur when BATCHSZ messages have flowed.

If the batch flows are causing a performance impact when moving only non-persistent messages, and NPMSPEED is set to FAST, you should consider setting the BATCHSZ to the maximum permissible value of 9999, and BATCHLIM to zero.

Additionally, setting BATCHINT to a high value, for example, 999999999 keeps each batch "open" for longer, even if there are no new messages waiting on the transmission queue.

The above settings minimize the frequency of confirm flows, but be aware that if any persistent messages are moved over a channel with these settings, there will be significant delays in the delivery of those persistent messages only.

The maximum number of uncommitted messages is specified by the MAXUMSGS parameter of the ALTER QMGR command. This parameter is valid only for channels with a channel type ( CHLTYPE ) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

The value must be in the range 1 - 9999.

## CERTLABL

Certificate label for this channel to use.

The label identifies which personal certificate in the key repository is sent to the remote peer. If this attribute is blank, the certificate is determined by the queue manager **CERTLABL** parameter.

Note that inbound channels (including receiver, cluster-receiver, unqualified server, and server-connection channels) only send the configured certificate if the IBM MQ version of the remote peer fully supports certificate label configuration, and the channel is using a TLS CipherSpec.

See Interoperability of Elliptic Curve and RSA CipherSpecs for further information.

In all other cases, the queue manager **CERTLABL** parameter determines the certificate sent. In particular, the following only ever receive the certificate configured by the **CERTLABL** parameter of the queue manager, regardless of the channel-specific label setting:

- All current Java and JMS clients.
- Versions of IBM MQ prior to Version 8.0.

You do not need to run the REFRESH SECURITY TYPE(SSL) command if you make any changes to CERTLABL on a channel. However, you must run a REFRESH SECURITY TYPE(SSL) command if you make any changes to CERTLABL on the queue manager.

**Note:** It is an error to inquire, or set, this attribute for cluster-sender channels. If you attempt to do so, you receive the error MQRCCF\_WRONG\_CHANNEL\_TYPE. However, the attribute is present in cluster-sender channel objects (including MQCD structures) and a channel auto-definition (CHAD) exit might set it programmatically if required.

*(channel-name)*

The name of the new channel definition.

This parameter is required on all types of channel. On CLUSSDR channels, it can take a different form to the other channel types. If your convention for naming CLUSSDR channels includes the name of the queue manager, you can define a CLUSSDR channel using the + QMNAME + construction. After connection to the matching CLUSRCVR channel, IBM MQ substitutes the correct repository queue manager name in place of + QMNAME + in the CLUSSDR channel definition. This facility applies to AIX, HP-UX, IBM i, Linux, Solaris, and Windows only; see Components of a cluster.

The name must not be the same as any existing channel defined on this queue manager, unless REPLACE or ALTER is specified. On z/OS, CLNTCONN channel names can duplicate others.

The maximum length of the string is 20 characters, and the string must contain only valid characters; see Rules for naming IBM MQ objects.

## CHLTYPE

Channel type. This parameter is required. It must follow immediately after the *(channel-name)* parameter  on all platforms except z/OS.

**SDR**    Sender channel

**SVR**    Server channel

**RCVR**   Receiver channel

**RQSTR** Requester channel

**CLNTCONN**

Client-connection channel

**SVRCONN**

Server-connection channel

**CLUSDR**

CLUSDR channel.

**CLUSRCVR**

Cluster-receiver channel.

**V8.0.0.4 AMQP**

AMQP channel

**Note:** If you are using the REPLACE option, you cannot change the channel type.

**CLNTWGHT**

Set the client channel weighting attribute to select a client channel definition at random based on its weighting when more than one suitable definition is available. Specify a value in the range 0 - 99.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetic order. To enable random load balancing the value can be in the range 1 - 99, where 1 is the lowest weighting and 99 is the highest.

If a client application issues MQCONN with a queue manager name of \**name* a client channel definition can be selected at random. The chosen definition is randomly selected based on the weighting. Any applicable CLNTWGHT (0) definitions selected are selected first in alphabetic order. Randomness in the selection of client connection definitions is not guaranteed.

For example, suppose that we had the following two definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(2)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(4)
```

A client MQCONN with queue manager name \*GRP1 would choose one of the two definitions based on the weighting of the channel definition. (A random integer 1 - 6 would be generated. If the integer was in the range 1 through 2, address1 would be used otherwise address2 would be used). If this connection was unsuccessful the client would then use the other definition.

The CCDT might contain applicable definitions with both zero and non-zero weighting. In this situation, the definitions with zero weighting are chosen first and in alphabetic order. If these connections are unsuccessful the definitions with non-zero weighting are chosen based on their weighting.

For example, suppose that we had the following four definitions in the CCDT:

```
CHLNAME(TO.QM1) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address1) CLNTWGHT(1)
CHLNAME(TO.QM2) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address2) CLNTWGHT(2)
CHLNAME(TO.QM3) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address3) CLNTWGHT(0)
CHLNAME(TO.QM4) CHLTYPE(CLNTCONN) QMNAME(GRP1) CONNAME(address4) CLNTWGHT(0)
```

A client MQCONN with queue manager name \*GRP1 would first choose definition T0.QM3. If this connection was unsuccessful the client would then choose definition T0.QM4. If this connection was also unsuccessful the client would then randomly choose one of the remaining two definitions based on their weighting.

CLNTWGHT is supported for all transport protocols.

**CLUSNL ( *nname* )**

The name of the namelist that specifies a list of clusters to which the channel belongs.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *CLUSSDR* and *CLUSRCVR* channels. Only one of the resultant values of *CLUSTER* or *CLUSNL* can be nonblank, the other must be blank.

#### **CLUSTER ( *clustername* )**

The name of the cluster to which the channel belongs. The maximum length is 48 characters conforming to the rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *CLUSSDR* and *CLUSRCVR* channels. Only one of the resultant values of *CLUSTER* or *CLUSNL* can be nonblank, the other must be blank.

#### **CLWLPRTY ( *integer* )**

Specifies the priority of the channel for the purposes of cluster workload distribution. The value must be in the range 0 - 9 where 0 is the lowest priority and 9 is the highest.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *CLUSSDR* and *CLUSRCVR* channels.

For more information about this attribute, see *CLWLPRTY* channel attribute.

#### **CLWLRANK ( *integer* )**

Specifies the rank of the channel for the purposes of cluster workload distribution. The value must be in the range 0 - 9 where 0 is the lowest rank and 9 is the highest.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *CLUSSDR* and *CLUSRCVR* channels.

For more information about this attribute, see *CLWLRANK* channel attribute.

#### **CLWLWGHT ( *integer* )**

Specifies the weighting to be applied to a channel so that the proportion of messages sent down the channel can be controlled by workload management. The value must be in the range 1 - 99 where 1 is the lowest rank and 99 is the highest.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *CLUSSDR* and *CLUSRCVR* channels.

For more information about this attribute, see *CLWLWGHT* channel attribute.

#### **z/OS CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

*CMDSCOPE* must either be left blank, or if *QSGDISP* is set to *GROUP*, the local queue manager name.

' ' The command is executed on the queue manager on which it was entered.

##### *QmgrName*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered. To do so, you must be using a shared queue environment, and the command server must be enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

#### **COMPHDR**

The list of header data compression techniques supported by the channel.

For SDR, SVR, CLUSSDR, CLUSRCVR, and CLNTCONN channels, the values must be specified in order of preference. The first compression technique in the list that is supported by the remote end of the channel is used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel. The message exit can alter the compression technique on a per message basis. Compression alters the data passed to send and receive exits.

**NONE** No header data compression is performed.

**SYSTEM** Header data compression is performed.

## COMPMSG

The list of message data compression techniques supported by the channel.

For SDR, SVR, CLUSSDR, CLUSRCVR, and CLNTCONN channels, the values must be specified in order of preference. The first compression technique in the list that is supported by the remote end of the channel is used.

The mutually supported compression techniques of the channel are passed to the message exit of the sending channel. The message exit can alter the compression technique on a per message basis. Compression alters the data passed to send and receive exits.

**NONE** No message data compression is performed.

**RLE** Message data compression is performed using run-length encoding.

### ZLIBFAST

Message data compression is performed using ZLIB encoding with speed prioritized.

 On z/OS systems with zEDC Express facility enabled, compression can be offloaded to zEDC Express.

### ZLIBHIGH

Message data compression is performed using ZLIB encoding with compression prioritized.

**ANY** Any compression technique supported by the queue manager can be used. This value is only valid for RCVR, RQSTR, and SVRCONN channels.

## CONNNAME ( *string* <, *string* > )

Connection name.

For CLUSRCVR channels, CONNNAME relates to the local queue manager, and for other channels it relates to the target queue manager.

 On z/OS, CONNNAME is mandatory for CLUSRCVR channels. In addition, whether you specify CONNNAME, or the name is generated for you, the CONNNAME produced must be a valid connection name for the local queue manager, otherwise the full repository is not able to make a connection back to the local queue manager.

 On z/OS, the maximum length of the string is 48 characters.

On distributed platforms, the maximum length of the string is 264 characters

A workaround to the 48 character limit might be one of the following suggestions:

- Set up your DNS servers so that you use, for example, host name of myserver instead of myserver.location.company.com, ensuring you can use the short host name.
- Use IP addresses.

Specify CONNNAME as a comma-separated list of names of machines for the stated TRPTYPE. Typically only one machine name is required. You can provide multiple machine names to configure multiple connections with the same properties. The connections are usually tried in the order they are specified in the connection list until a connection is successfully established. The order is modified for clients if the CLNTWGHT attribute is provided. If no connection is

successful, the channel attempts the connection again, as determined by the attributes of the channel. With client channels, a connection-list provides an alternative to using queue manager groups to configure multiple connections. With message channels, a connection list is used to configure connections to the alternative addresses of a multi-instance queue manager.

CONNNAME is required for channels with a channel type ( CHLTYPE ) of SDR, RQSTR, CLNTCONN, and CLUSSDR. It is optional for SVR channels, and for CLUSRCVR channels of TRPTYPE(TCP), and is not valid for RCVR or SVRCONN channels.

Providing multiple connection names in a list was first supported in IBM WebSphere MQ Version 7.0.1. It changes the syntax of the CONNNAME parameter. Earlier clients and queue managers connect using the first connection name in the list, and do not read the rest of the connection names in the list. In order for the earlier clients and queue managers to parse the new syntax, you must specify a port number on the first connection name in the list. Specifying a port number avoids problems when connecting to the channel from a client or queue manager that is running at a level earlier than IBM WebSphere MQ Version 7.0.1.

On AIX, HP-UX, IBM i, Linux, Solaris, and Windows platforms, the TCP/IP connection name parameter of a cluster-receiver channel is optional. If you leave the connection name blank, IBM MQ generates a connection name for you, assuming the default port and using the current IP address of the system. You can override the default port number, but still use the current IP address of the system. For each connection name leave the IP name blank, and provide the port number in parentheses; for example:

(1415)

The generated CONNNAME is always in the dotted decimal (IPv4) or hexadecimal (IPv6) form, rather than in the form of an alphanumeric DNS host name.

**Tip:** If you are using any of the special characters in your connection name (for example, parentheses) you must enclose the string in single quotation marks.

The value you specify depends on the transport type ( TRPTYPE ) to be used:

## LU62

- ▶ **z/OS** On z/OS, there are two forms in which to specify the value:

### Logical unit name

The logical unit information for the queue manager, comprising the logical unit name, TP name, and optional mode name. Logical unit name can be specified in one of three forms:

Form	Example
luname	IGY12355
luname/TPname	IGY12345/APING
luname/TPname/modename	IGY12345/APINGD/#INTER

For the first form, the TP name and mode name must be specified for the TPNAME and MODENAME parameters; otherwise these parameters must be blank.

**Note:** For CLNTCONN channels, only the first form is allowed.

### Symbolic name

The symbolic destination name for the logical unit information for the queue manager, as defined in the side information data set. The TPNAME and MODENAME parameters must be blank.

**Note:** For CLUSRCVR channels, the side information is on the other queue managers in the cluster. Alternatively, it can be a name that a channel auto-definition exit can resolve into the appropriate logical unit information for the local queue manager.

The specified or implied LU name can be that of a VTAM generic resources group.

- On AIX, HP-UX, IBM i, Linux, Solaris, and Windows , CONNAME is the name of the CPI-C communications side object. Alternatively, if the TPNAME is not blank, CONNAME is the fully qualified name of the partner logical unit  ; see Configuration parameters for an LU 6.2 connection.

## NetBIOS

A unique NetBIOS name (limited to 16 characters).

**SPX** The 4-byte network address, the 6-byte node address, and the 2-byte socket number. These values must be entered in hexadecimal, with a period separating the network and node addresses. The socket number must be enclosed in brackets, for example:

```
CONNAME ('0a0b0c0d.804abcde23a1(5e86)')
```

**TCP** Either the host name, or the network address of the remote machine (or the local machine for CLUSRCVR channels). This address can be followed by an optional port number, enclosed in parentheses.

If the CONNAME is a host name, the host name is resolved to an IP address.

The IP stack used for communication depends on the value specified for CONNAME and the value specified for LOCLADDR. See LOCLADDR for information about how this value is resolved.

 On z/OS, the connection name can include the IP\_name of an z/OS dynamic DNS group or a Network Dispatcher input port. Do not include the IP\_name or input port for channels with a channel type ( CHLTYPE ) of CLUSSDR.

On AIX, HP-UX, Linux, IBM i, Solaris, Windows  , and z/OS, you do not always need to specify the network address of your queue manager. If you define a channel with a channel type ( CHLTYPE ) of CLUSRCVR that is using TCP/IP, IBM MQ generates a CONNAME for you. It assumes the default port and uses the current IPv4 address of the system. If the system does not have an IPv4 address, the current IPv6 address of the system is used.

**Note:** If you are using clustering between IPv6 -only and IPv4 -only queue managers, do not specify an IPv6 network address as the CONNAME for CLUSRCVR channels. A queue manager that is capable only of IPv4 communication is unable to start a CLUSSDR channel definition that specifies the CONNAME in IPv6 hexadecimal form. Consider, instead, using host names in a heterogeneous IP environment.

## CONVERT

Specifies whether the sending message channel agent attempts conversion of the application message data, if the receiving message channel agent cannot perform this conversion.

**NO** No conversion by sender

**YES** Conversion by sender

 On z/OS, N and Y are accepted as synonyms of NO and YES.

This parameter is valid only for channels with a channel type ( CHLTYPE ) of SDR, SVR, CLUSSDR, or CLUSRCVR.

## DEFCDISP

Specifies the default channel disposition of the channel.

**PRIVATE**

The intended disposition of the channel is as a private channel.

**FIXSHARED**

The intended disposition of the channel is as a shared channel associated with a specific queue manager.

**SHARED** The intended disposition of the channel is as a shared channel.

This parameter does not apply to channels with a channel type ( *CHLTYPE* ) of *CLNTCONN*, *CLUSSDR*, or *CLUSRCVR*.

**DEFRECON**

Specifies whether a client connection automatically reconnects a client application if its connection breaks.

**NO** Unless overridden by *MQCONN*, the client is not reconnected automatically.

**YES** Unless overridden by *MQCONN*, the client reconnects automatically.

**QMGR** Unless overridden by *MQCONN*, the client reconnects automatically, but only to the same queue manager. The *QMGR* option has the same effect as *MQCNO\_RECONNECT\_Q\_MGR*.

**DISABLED**

Reconnection is disabled, even if requested by the client program using the *MQCONN* MQI call.

Table 94. Automatic reconnection depends on the values set in the application and in the channel definition

DEFRECON	Reconnection options set in the application			
	MQCNO_RECONNECT	MQCNO_RECONNECT_Q_MGR	MQCNO_RECONNECT_AS_DEF	MQCNO_RECONNECT_DISABLED
NO	YES	QMGR	NO	NO
YES	YES	QMGR	YES	NO
QMGR	YES	QMGR	QMGR	NO
DISABLED	NO	NO	NO	NO

**DESCR ( *string* )**

Plain-text comment. It provides descriptive information about the channel when an operator issues the **DISPLAY CHANNEL** command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If the information is sent to another queue manager they might be translated incorrectly. The characters must be in the coded character set identifier (CCSID) of the local queue manager.

**DISCINT ( *integer* )**

The minimum time in seconds for which the channel waits for a message to arrive on the transmission queue. The waiting period starts after a batch ends. After the end of the waiting period, if there are no more messages, the channel is ended. A value of zero causes the message channel agent to wait indefinitely.

The value must be in the range 0 - 999 999.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *SVRCONN*, *SDR*, *SVR*, *CLUSSDR*, or *CLUSRCVR*.

For *SVRCONN* channels using the TCP protocol, *DISCINT* has a different interpretation. It is the minimum time in seconds for which the *SVRCONN* instance remains active without any communication from its partner client. A value of zero disables this disconnect processing. The

SVRCONN inactivity interval applies only between IBM MQ API calls from a client, so no client is disconnected during an extended MQGET with wait call. This attribute is ignored for SVRCONN channels using protocols other than TCP.

### HBINT ( *integer* )

HBINT specifies the approximate time between heartbeat flows sent by a message channel agent (MCA). The flows are sent when there are no messages on the transmission queue.

Heartbeat flows unblock the receiving MCA, which is waiting for messages to arrive or for the disconnect interval to expire. When the receiving MCA is unblocked, it can disconnect the channel without waiting for the disconnect interval to expire. Heartbeat flows also free any storage buffers that are allocated for large messages. They also close any queues that are left open at the receiving end of the channel.

The value is in seconds and must be in the range 0 - 999999. A value of zero means that no heartbeat flows are to be sent. The default value is 300. To be most useful, the value needs to be less than the disconnect interval value.

For SVRCONN and CLNTCONN channels, heartbeats can flow from both the server side as well as the client side independently. If no data is transferred across the channel during the heartbeat interval, the CLNTCONN MQI agent sends a heartbeat flow. The SVRCONN MQI agent responds to it with another heartbeat flow. The flows happen irrespective of the state of the channel. For example, irrespective of whether it is inactive while making an API call, or is inactive waiting for client user input. The SVRCONN MQI agent is also capable of initiating a heartbeat to the client, again irrespective of the state of the channel. The SVRCONN and CLNTCONN MQI agents are prevented from heart beating to each other at the same time. The server heartbeat is flowed if no data is transferred across the channel for the heartbeat interval plus 5 seconds.

For server-connection and client-connection channels working in the channel mode before IBM WebSphere MQ Version 7.0, heartbeats flow only when a server MCA is waiting for an MQGET command with the WAIT option specified, which it has issued on behalf of a client application.

For more information, see Heartbeat interval (HBINT).

### KAINT ( *integer* )

The value passed to the communications stack for keepalive timing for this channel.

For this attribute to be effective, TCP/IP keepalive must be enabled both in the queue manager and in TCP/IP.

**z/OS** On z/OS, enable TCP/IP keepalive in the queue manager by issuing the ALTER QMGR TCPKEEP(YES) command. If the TCPKEEP queue manager parameter is NO, the value is ignored, and the keepalive facility is not used.

On distributed platforms, TCP/IP keepalive is enabled when the KEEPALIVE=YES parameter is specified in the TCP stanza. Modify the TCP stanza in the distributed queuing configuration file, qm.ini, or through the IBM MQ Explorer.

Keepalive must also be switched on within TCP/IP itself. Refer to your TCP/IP documentation for information about configuring keepalive. On AIX, use the **no** command. On HP-UX, use the **ndd** command. On Windows, edit the registry.

**z/OS** On z/OS, update your TCP/IP PROFILE data set and add or change the INTERVAL parameter in the TCPCONFIG section.

**z/OS** Although this parameter is available on all platforms, its setting is implemented only on z/OS.

On distributed platforms, you can access and modify the parameter, but it is only stored and forwarded; there is no functional implementation of the parameter. This functionality is useful in a clustered environment where a value set in a cluster-receiver channel definition on Solaris, for example, flows to (and is implemented by) z/OS queue managers that are in, or join, the cluster.

On distributed platforms, if you need the functionality provided by the KAIN parameter, use the Heartbeat Interval ( HBINT ) parameter, as described in HBINT.

( *integer* )

The KeepAlive interval to be used, in seconds, in the range 1 through 99999.

**0** The value used is that specified by the INTERVAL statement in the TCP profile configuration data set.

**AUTO** The KeepAlive interval is calculated based upon the negotiated heartbeat value as follows:

- If the negotiated HBINT is greater than zero, keepalive interval is set to that value plus 60 seconds.
- If the negotiated HBINT is zero, the keepalive value used is that specified by the INTERVAL statement in the TCP/IP PROFILE configuration data set.

If AUTO is specified for KAIN, and it is a server-connection channel, the TCP INTERVAL value is used instead for the keepalive interval.

In this case, KAIN is zero in DISPLAY CHSTATUS; it would be non-zero if an integer had been coded instead of AUTO.

This parameter is valid for all channel types. It is ignored for channels with a TRPTYPE other than TCP or SPX.

**LIKE** ( *channel-name* )

The name of a channel. The parameters of this channel are used to model this definition.

If you do not set LIKE, and do not set a parameter field related to the command, its value is taken from one of the default channels. The default values depend upon the channel type:

**SYSTEM.DEF.SENDER**

Sender channel

**SYSTEM.DEF.SERVER**

Server channel

**SYSTEM.DEF.RECEIVER**

Receiver channel

**SYSTEM.DEF.REQUESTER**

Requester channel

**SYSTEM.DEF.SVRCONN**

Server-connection channel

**SYSTEM.DEF.CLNTCONN**

Client-connection channel

**SYSTEM.DEF.CLUSSDR**

CLUSSDR channel

**SYSTEM.DEF.CLUSRCVR**

Cluster-receiver channel

**SYSTEM.DEF.AMQP**

AMQP channel

This parameter is equivalent to defining the following object:

LIKE(SYSTEM.DEF.SENDER)

for a SDR channel, and similarly for other channel types.

These default channel definitions can be altered by the installation to the default values required.

**z/OS** On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object and channel type you are defining.

**Note:**

1. QSGDISP(GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified. However, the group object defined is used as a LIKE object.

**LOCLADDR ( *string* )**

LOCLADDR is the local communications address for the channel. For channels other than AMQP channels, use this parameter if you want a channel to use a particular IP address, port, or port range for outbound communications. LOCLADDR might be useful in recovery scenarios where a channel is restarted on a different TCP/IP stack. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 stack on a dual-stack system. You can also use LOCLADDR to force a channel to use a dual-mode stack on a single-stack system.

**Note:** AMQP channels do not support the same format of LOCLADDR as other IBM MQ channels. For the format supported by AMQ, see the next parameter AMQP: LOCLADDR.

For channels other than AMQP channels, the LOCLADDR parameter is valid only for channels with a transport type ( TRPTYPE ) of TCP. If TRPTYPE is not TCP, the data is ignored and no error message is issued.

The value is the optional IP address, and optional port or port range used for outbound TCP/IP communications. The format for this information is as follows:

```
LOCLADDR([ip-addr][(low-port[,high-port])][, [ip-addr][(low-port[,high-port])]])
```

The maximum length of LOCLADDR, including multiple addresses, is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

Note, that you can set LOCLADDR for a C client using the Client Channel Definition Table (CCDT).

All the parameters are optional. Omitting the ip-addr part of the address is useful to enable the configuration of a fixed port number for an IP firewall. Omitting the port number is useful to select a particular network adapter without having to identify a unique local port number. The TCP/IP stack generates a unique port number.

Specify [, [ip-addr][(low-port[,high-port])]] multiple times for each additional local address. Use multiple local addresses if you want to specify a specific subset of local network adapters. You can also use [, [ip-addr][(low-port[,high-port])]] to represent a particular local network address on different servers that are part of a multi-instance queue manager configuration.

**ip-addr**

ip-addr is specified in one of three forms:

**IPv4 dotted decimal**

For example 192.0.2.1

**IPv6 hexadecimal notation**

For example 2001:DB8:0:0:0:0:0:0

**Alphanumeric host name form**

For example WWW.EXAMPLE.COM

**low-port and high-port**

low-port and high-port are port numbers enclosed in parentheses.

The following table shows how the LOCLADDR parameter can be used:

Table 95. Examples of how the LOCLADDR parameter can be used

LOCLADDR	Meaning
9.20.4.98	Channel binds to this address locally
9.20.4.98, 9.20.4.99	Channel binds to either IP address. The address might be two network adapters on one server, or a different network adapter on two different servers in a multi-instance configuration.
9.20.4.98(1000)	Channel binds to this address and port 1000 locally
9.20.4.98(1000,2000)	Channel binds to this address and uses a port in the range 1000 - 2000 locally
(1000)	Channel binds to port 1000 locally
(1000,2000)	Channel binds to port in range 1000 - 2000 locally

This parameter is valid only for channels with a channel type ( CHLTYPE ) of SDR, SVR, RQSTR, CLNTCONN, CLUSSDR, OR CLUSRCVR.

On CLUSSDR channels, the IP address and port to which the outbound channel binds, is a combination of fields. It is a concatenation of the IP address, as defined in the LOCLADDR parameter, and the port range from the cluster cache. If there is no port range in the cache, the port range defined in the LOCLADDR parameter is used.

► **z/OS** This port range does not apply to z/OS systems.

Even though this parameter is similar in form to CONNAME, it must not be confused with it. The LOCLADDR parameter specifies the characteristics of the local communications, whereas the CONNAME parameter specifies how to reach a remote queue manager.

When a channel is started, the values specified for CONNAME and LOCLADDR determine the IP stack to be used for communication; see Table 3 and Local Address ( LOCLADDR ).

If the TCP/IP stack for the local address is not installed or configured, the channel does not start and an exception message is generated.

► **z/OS** For example, on z/OS systems, the message is "CSQO015E: Command issued but no reply received." The message indicates that the connect() request specifies an interface address that is not known on the default IP stack. To direct the connect() request to the alternative stack, specify the **LOCLADDR** parameter in the channel definition as either an interface on the alternative stack, or a DNS host name. The same specification also works for listeners that might not use the default stack. To find the value to code for **LOCLADDR**, run the **NETSTAT HOME** command on the IP stacks that you want to use as alternatives.

Table 96. How the IP stack to be used for communication is determined

Protocols supported	CONNAME	LOCLADDR	Action of channel
IPv4 only	IPv4 address <sup>1</sup>		Channel binds to IPv4 stack
	IPv6 address <sup>2</sup>		Channel fails to resolve CONNAME
	IPv4 and 6 host name <sup>3</sup>		Channel binds to IPv4 stack
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	Any address <sup>4</sup>	IPv6 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel fails to resolve CONNAME
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv4 stack

Table 96. How the IP stack to be used for communication is determined (continued)

Protocols supported	CONNNAME	LOCLADDR	Action of channel
IPv4 and IPv6	IPv4 address		Channel binds to IPv4 stack
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to stack determined by IPADDRV
	IPv4 address	IPv4 address	Channel binds to IPv4 stack
	IPv6 address	IPv4 address	Channel fails to resolve CONNNAME
	IPv4 and 6 host name	IPv4 address	Channel binds to IPv4 stack
	IPv4 address	IPv6 address	Channel maps CONNNAME to IPv6 <sup>5</sup>
	IPv6 address	IPv6 address	Channel binds IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel binds to IPv4 stack
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to stack determined by IPADDRV
IPv6 only	IPv4 address		Channel maps CONNNAME to IPv6 <sup>5</sup>
	IPv6 address		Channel binds to IPv6 stack
	IPv4 and 6 host name		Channel binds to IPv6 stack
	Any address	IPv4 address	Channel fails to resolve LOCLADDR
	IPv4 address	IPv6 address	Channel maps CONNNAME to IPv6 <sup>5</sup>
	IPv6 address	IPv6 address	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv6 address	Channel binds to IPv6 stack
	IPv4 address	IPv4 and 6 host name	Channel maps CONNNAME to IPv6 <sup>5</sup>
	IPv6 address	IPv4 and 6 host name	Channel binds to IPv6 stack
	IPv4 and 6 host name	IPv4 and 6 host name	Channel binds to IPv6 stack

**Notes:**

1. IPv4 address. An IPv4 host name that resolves only to an IPv4 network address or a specific dotted notation IPv4 address, for example 1.2.3.4. This note applies to all occurrences of ' IPv4 address' in this table.
2. IPv6 address. An IPv6 host name that resolves only to an IPv6 network address or a specific hexadecimal notation IPv6 address, for example 4321:54bc. This note applies to all occurrences of ' IPv6 address' in this table.
3. IPv4 and 6 host name. A host name that resolves to both IPv4 and IPv6 network addresses. This note applies to all occurrences of ' IPv4 and 6 host name' in this table.
4. Any address. IPv4 address, IPv6 address, or IPv4 and 6 host name. This note applies to all occurrences of 'Any address' in this table.
5. Maps IPv4 CONNNAME to IPv4 mapped IPv6 address. IPv6 stack implementations that do not support IPv4 mapped IPv6 addressing fail to resolve the CONNNAME. Mapped addresses might require protocol translators in order to be used. The use of mapped addresses is not recommended.

**AMQP: LOCLADDR ( *ip-addr* )**

**Note:** For the format of LOCLADDR that other IBM MQ channels use, see the previous parameter LOCLADDR.

For AMQP channels, LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of LOCLADDR is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

#### **ip-addr**

ip-addr is a single network address, specified in one of three forms:

##### **IPv4 dotted decimal**

For example 192.0.2.1

##### **IPv6 hexadecimal notation**

For example 2001:DB8:0:0:0:0:0:0

##### **Alphanumeric host name form**

For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

#### **LONGRTY ( *integer* )**

The LONGRTY parameter specifies the maximum number of further attempts that are made by a SDR, SVR, or CLUSSDR channel to connect to a remote queue manager. The interval between attempts is specified by LONGTMR. The LONGRTY parameter takes effect if the count specified by SHORTRTY is exhausted.

If this count is exhausted without success, an error is logged to the operator, and the channel stops. In this circumstance, the channel must be restarted with a command. It is not started automatically by the channel initiator.

The LONGRTY value must be in the range 0 - 9999999.

This parameter is valid only for channels with a channel type ( CHLTYPE ) of SDR, SVR, CLUSSDR, or CLUSRCVR.

A channel attempts to reconnect if it fails to connect initially, whether it is started automatically by the channel initiator or by an explicit command. It also tries to connect again if the connection fails after the channel successfully connecting. If the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

#### **LONGTMR ( *integer* )**

For LONGRTY, LONGTMR is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate; zero means that another connection attempt is made as soon as possible.

The interval between attempting to reconnect might be extended if the channel has to wait to become active.

The LONGTMR value must be in the range 0 - 9999999.

**Note:** For implementation reasons, the maximum LONGTMR value is 999,999; values exceeding this maximum are treated as 999,999. Similarly, the minimum interval between attempting to reconnect is 2 seconds. Values less than this minimum are treated as 2 seconds.

This parameter is valid only for channels with a channel type ( CHLTYPE ) of SDR, SVR, CLUSSDR, or CLUSRCVR.

#### **MAXINST ( *integer* )**

The maximum number of simultaneous instances of an individual SVRCONN channel or AMQP channel that can be started.

The value must be in the range 0 - 999999999.

A value of zero prevents all client access on this channel.

New instances of SVRCONN channels cannot start if the number of running instances equals or exceeds the value of this parameter. If MAXINST is changed to less than the number of instances of the SVRCONN channel that are currently running, the number of running instances is not affected.

If an AMQP client attempts to connect to an AMQP channel, and the number of connected clients has reached MAXINST, the channel closes the connection with a close frame. The close frame contains the following message: `amqp:resource-limit-exceeded`. If a client connects with an ID that is already connected (that is, it performs a client-takeover), and the client is permitted to take over the connection, the takeover will succeed regardless of whether the number of connected clients has reached MAXINST.

This parameter is valid only for channels with a channel type ( `CHLTYPE` ) of SVRCONN or of AMQP.

#### **MAXINSTC ( *integer* )**

The maximum number of simultaneous individual SVRCONN channels that can be started from a single client. In this context, connections that originate from the same remote network address are regarded as coming from the same client.

The value must be in the range 0 - 999999999.

A value of zero prevents all client access on this channel.

If you reduce the value of MAXINSTC to less than the number of instances of the SVRCONN channel that is currently running from an individual client, the running instances are not affected. New SVRCONN instances from that client cannot start until the client is running fewer instances than the value of MAXINSTC.

This parameter is valid only for channels with a channel type ( `CHLTYPE` ) of SVRCONN.

#### **MAXMSGL ( *integer* )**

Specifies the maximum message length that can be transmitted on the channel. This parameter is compared with the value for the partner and the actual maximum used is the lower of the two values. The value is ineffective if the MQCB function is being executed and the channel type ( `CHLTYPE` ) is SVRCONN.

The value zero means the maximum message length for the queue manager; see ALTER QMGR MAXMSGL.

On AIX, HP-UX, IBM i, Linux, Solaris, and Windows, specify a value in the range zero to the maximum message length for the queue manager.

 On z/OS, specify a value in the range 0 - 104857600 bytes (100 MB).

Note that by adding the digital signature and key to the message, IBM MQ Advanced Message Security increases the length of the message.

#### **MCANAME ( *string* )**

Message channel agent name.

This parameter is reserved, and if specified must be set to blanks (maximum length 20 characters).

#### **MCTYPE**

Specifies whether the message-channel-agent program on an outbound message channel runs as a thread or a process.

##### **PROCESS**

The message channel agent runs as a separate process.

**THREAD** The message channel agent runs as a separate thread

In situations where a threaded listener is required to service many incoming requests, resources can become strained. In this case, use multiple listener processes and target incoming requests at specific listeners though the port number specified on the listener.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of SDR, SVR, RQSTR, CLUSSDR, or CLUSRCVR. It is supported only on AIX, HP-UX, IBM i, Linux, Solaris, and Windows.

▶ **z/OS** On z/OS, it is supported only for channels with a channel type of CLUSRCVR. When specified in a CLUSRCVR definition, MCAUSER is used by a remote machine to determine the corresponding CLUSSDR definition.

### **MCAUSER ( *string* )**

Message channel agent user identifier.

**Note:** An alternative way of providing a user ID for a channel to run under is to use channel authentication records. With channel authentication records, different connections can use the same channel while using different credentials. If both MCAUSER on the channel is set and channel authentication records are used to apply to the same channel, the channel authentication records take precedence. The MCAUSER on the channel definition is only used if the channel authentication record uses USERSRC(CHANNEL). For more details, see Channel authentication records

This parameter interacts with PUTAUT ; see PUTAUT.

If MCAUSER is nonblank, a user identifier is used by the message channel agent for authorization to access IBM MQ resources. If PUTAUT is DEF, authorization includes authorization to put the message to the destination queue for RCVR or RQSTR channels.

If it is blank, the message channel agent uses its default user identifier.

The default user identifier is derived from the user ID that started the receiving channel. The possible values are:

▶ **z/OS** **z/OS,**

The user ID assigned to the channel-initiator started task by the z/OS started-procedures table.

### **TCP/IP, distributed platforms**

The user ID from the inetd.conf entry, or the user that started the listener.

### **SNA, distributed platforms**

The user ID from the SNA server entry. In the absence of the user ID from the SNA server entry, the user from the incoming attach request, or the user that started the listener.

### **NetBIOS or SPX**

The user ID that started the listener.

The maximum length of the string is 64 characters on Windows and 12 characters on other platforms. On Windows, you can optionally qualify a user identifier with the domain name in the format user@domain.

This parameter is not valid for channels with a channel type ( *CHLTYPE* ) of SDR, SVR, CLNTCONN, CLUSSDR.

### **MODENAME ( *string* )**

LU 6.2 mode name (maximum length 8 characters).

This parameter is valid only for channels with a transport type ( *TRPTYPE* ) of LU62. If TRPTYPE is not LU62, the data is ignored and no error message is issued.

If specified, this parameter must be set to the SNA mode name unless the CONNAME contains a side-object name. If CONNAME is a side-object name it must be set to blanks. The actual name is then taken from the CPI-C Communications Side Object, or APPC side information data set

▶ **z/OS** ; see Configuration parameters for an LU 6.2 connection.

This parameter is not valid for channels with a channel type ( *CHLTYPE* ) of RCVR or SVRCONN.

## MONCHL

Controls the collection of online monitoring data for channels:

- QMGR** Collect monitoring data according to the setting of the queue manager parameter MONCHL.
- OFF** Monitoring data collection is turned off for this channel.
- LOW** If the value of the queue manager MONCHL parameter is not NONE, online monitoring data is turned on. Data is collected at a low rate for this channel.
- MEDIUM** If the value of the queue manager MONCHL parameter is not NONE, online monitoring data is turned on. Data is collected at a medium rate for this channel.
- HIGH** If the value of the queue manager MONCHL parameter is not NONE, online monitoring data is turned on. Data is collected at a high rate for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

For cluster channels, the value of this parameter is not replicated in the repository and, therefore, not used in the auto-definition of CLUSSDR channels. For auto-defined CLUSSDR channels, the value of this parameter is taken from the queue manager attribute MONACLS. This value might then be overridden in the channel auto-definition exit.

## MRDATA ( *string* )

Channel message-retry exit user data. The maximum length is 32 characters.

This parameter is passed to the channel message-retry exit when it is called.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of RCVR, RQSTR, or CLUSRCVR.

## MREXIT ( *string* )

Channel message-retry exit name.

The format and maximum length of the name is the same as for MSGEXIT, however you can specify only one message-retry exit.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of RCVR, RQSTR, or CLUSRCVR.

## MRRTY ( *integer* )

The number of times the channel tries again before it decides it cannot deliver the message.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of MRRTY is passed to the exit to use. The number of attempts to redeliver the message is controlled by the exit, and not by this parameter.

The value must be in the range 0 - 999999999. A value of zero means that no attempts to redeliver the message are tried.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of RCVR, RQSTR, or CLUSRCVR.

## MRTMR ( *integer* )

The minimum interval of time that must pass before the channel can try the MQPUT operation again. The time interval is in milliseconds.

This parameter controls the action of the MCA only if the message-retry exit name is blank. If the exit name is not blank, the value of MRTMR is passed to the exit to use. The number of attempts to redeliver the message is controlled by the exit, and not by this parameter.

The value must be in the range 0 - 999999999. A value of zero means that if the value of MRRTY is greater than zero, the channel reattempts delivery as soon as possible.

This parameter is valid only for channels with a channel type ( `CHLTYPE` ) of `RCVR`, `RQSTR`, or `CLUSRCVR`.

### MSGDATA ( *string* )

User data for the channel message exit. The maximum length is 32 characters.

This data is passed to the channel message exit when it is called.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

**z/OS** On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first message exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of message exit data for each channel.

**Note:** This parameter is accepted but ignored for `SVRCONN` and `CLNTCONN` channels.

### MSGEXIT ( *string* )

Channel message exit name.

If `MSGEXIT` is nonblank the exit is called at the following times:

- Immediately after a `SDR` or `SVR` channel retrieves a message from the transmission queue.
- Immediately before a `RQSTR` channel puts a message on destination queue.
- When the channel is initialized or ended.

The exit is passed the entire application message and transmission queue header for modification.

`MSGEXIT` is accepted and ignored by `CLNTCONN` and `SVRCONN` channels. `CLNTCONN` or `SVRCONN` channels do not call message exits.

The format and maximum length of the exit name depends on the platform; see Table 97.

If the `MSGEXIT`, `MREXIT`, `SCYEXIT`, `SENDEXIT`, and `RCVEXIT` parameters are all left blank, the channel user exit is not invoked. If any of these parameters is nonblank, the channel exit program is called. You can enter text string for these parameters. The maximum length of the string is 128 characters.

Table 97. Message exit format and length

Platform	Exit name format	Maximum length	Comment
AIX, HP-UX, Linux, and Solaris	<i>libraryname(functionname)</i>	128	You can specify the name of more than one exit program. Specify multiple strings separated by commas. However, the total number of characters specified must not exceed 999.
Windows	<i>dllname(functionname)</i>	128	<ol style="list-style-type: none"> <li>1. You can specify the name of more than one exit program. Specify multiple strings separated by commas. However, the total number of characters specified must not exceed 999.</li> <li>2. <i>dllname</i> is specified without the suffix ( <code>.DLL</code> ).</li> </ol>

Table 97. Message exit format and length (continued)

Platform	Exit name format	Maximum length	Comment
IBM i	<i>programe libname</i>	20	<ol style="list-style-type: none"> <li>You can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.</li> <li><i>program name</i> occupies the first 10 characters and <i>libname</i> the second 10 characters. If necessary, both fields are padded to the right with blanks.</li> </ol>
z/OS OS	<i>LoadModuleName</i>	8	<ol style="list-style-type: none"> <li>You can specify the names of up to eight exit programs by specifying multiple strings separated by commas.</li> <li>128 characters are allowed for exit names for CLNTCONN channels, subject to a maximum total length including commas of 999.</li> </ol>

### NETPRTY ( *integer* )

The priority for the network connection. Distributed queuing chooses the path with the highest priority if there are multiple paths available. The value must be in the range 0 - 9; 0 is the lowest priority.

This parameter is valid only for CLUSRCVR channels.

### NPMSPEED

The class of service for nonpersistent messages on this channel:

**FAST** Fast delivery for nonpersistent messages; messages might be lost if the channel is lost. Messages are retrieved using MQGMO\_SYNCPOINT\_IF\_PERSISTENT and so are not included in the batch unit of work.

**NORMAL** Normal delivery for nonpersistent messages.

If the value of NPMSPEED differs between the sender and receiver, or either one does not support it, NORMAL is used.

This parameter is valid only for channels with a CHLTYPE of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

### PASSWORD ( *string* )

Password used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent. The maximum length is 12 characters.

This parameter is valid only for channels with a channel type ( CHLTYPE ) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR. On z/OS, it is supported only for channels with a channel type ( CHLTYPE ) of CLNTCONN.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

### V8.0.0.4 PORT ( *integer* )

The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672. If you are already using port 5672, you can specify a different port.

### PROPCTL

Property control attribute; see **PROPCTL** channel options.

PROPCTL specifies what happens to message properties when a message is sent to another queue manager; see

This parameter is applicable to SDR, SVR, CLUSSDR, and CLUSRCVR channels.

This parameter is optional.

Permitted values are:

**COMPAT** COMPAT allows applications which expect JMS-related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

Message properties	Result
The message contains a property with a prefix of mcd., jms., usr. or mqext.	If the Support value is MQPD_SUPPORT_OPTIONAL, all optional message properties are placed in one or more MQRFH2 headers. This rule does not apply to properties in the message descriptor or extension, which remain in the same place. Optional message properties are moved into the message data before the message is sent to the remote queue manager.
The message does not contain a property with a prefix of mcd., jms., usr. or mqext.	All message properties, except properties in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the Support field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.
The message contains one or more properties where the Support field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL. Other fields of the property descriptor are set to non-default values.	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the content='properties' attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to a Version 6 or prior queue manager.

**NONE** All properties of the message, except properties in the message descriptor or extension, are removed from the message. The properties are removed before the message is sent to the remote queue manager.

If the message contains a property where the Support field of the property descriptor is not set to MQPD\_SUPPORT\_OPTIONAL then the message is rejected with reason MQRC\_UNSUPPORTED\_PROPERTY. The error is reported in accordance with the report options set in the message header.

**ALL** All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except properties in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

## PUTAUT

PUTAUT specifies which user identifiers are used to establish authority for a channel. It specifies the user identifier to put messages to the destination queue using a message channel, or to run an MQI call using an MQI channel.

**DEF** The default user ID is used.

▶ **z/OS** On z/OS, DEF might involve using both the user ID received from the network and that derived from MCAUSER.

**CTX** The user ID from the *UserIdentifier* field of the message descriptor is used.

▶ **z/OS** On z/OS, CTX might involve also using the user ID received from the network or that derived from MCAUSER, or both.

▶ **z/OS ONLYMCA**

The user ID derived from MCAUSER is used. Any user ID received from the network is not used. This value is supported only on z/OS.

▶ **z/OS ALTMCA**

The user ID from the *UserIdentifier* field of the message descriptor is used. Any user ID received from the network is not used. This value is supported only on z/OS.

▶ **z/OS** On z/OS, the user IDs that are checked, and how many user IDs are checked, depends on the setting of the MQADMIN RACF class hlq.RESLEVEL profile. Depending on the level of access the user ID of the channel initiator has to hlq.RESLEVEL, zero, one, or two user IDs are checked. ▶ **z/OS** To see how many user IDs are checked, see RESLEVEL and the channel initiator connection. For more information about which user IDs are checked, see User IDs used by the channel initiator.

On distributed platforms, this parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, or CLUSRCVR.

▶ **z/OS** On z/OS, this parameter is valid only for channels with a channel type (CHLTYPE) of RCVR, RQSTR, CLUSRCVR, or SVRCONN. CTX and ALTMCA are not valid for SVRCONN channels.

### QMNAME ( *string* )

Queue manager name.

For CLNTCONN channels, QMNAME is the name of a queue manager to which an IBM MQ MQI client application can request connection. QMNAME is not necessarily the same as the name of the queue manager on which the channel is defined; see Queue manager groups in the CCDT.

For channels of other types, the QMNAME parameter is not valid.

▶ **z/OS QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command using the QSGDISP(GROUP) object of the same name as the LIKE object.
GROUP	The object definition resides in the shared repository but only if the queue manager is in a queue-sharing group. If the definition is successful, the following command is generated. The command is sent to all active queue managers in the queue-sharing group to make or refresh local copies on page set zero: DEFINE CHANNEL(channel-name) CHLTYPE(type) REPLACE QSGDISP(COPY)  The <b>DEFINE</b> command for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

### RCVDATA ( *string* )

Channel receive exit user data (maximum length 32 characters).

This parameter is passed to the channel receive exit when it is called.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

▶ **z/OS** On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first receive exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of receive exit data for each channel.

## **RCVEXIT ( *string* )**

Channel receive exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before the received network data is processed.  
The exit is given the complete transmission buffer as received. The contents of the buffer can be modified as required.
- At initialization and termination of the channel.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

▶ **z/OS** On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one receive exit name for each channel.

The format and maximum length of the name is the same as for MSGEXIT.

## **REPLACE and NOREPLACE**

Replace the existing definition with this one, or not. This parameter is optional.

▶ **z/OS** On z/OS it must have the same disposition. Any object with a different disposition is not changed.

### **REPLACE**

The definition replaces any existing definition of the same name. If a definition does not exist, one is created. REPLACE does not alter the channel status.

### **NOREPLACE**

The definition does not replace any existing definition of the same name.

## **SCYDATA ( *string* )**

Channel security exit user data (maximum length 32 characters).

This parameter is passed to the channel security exit when it is called.

## **SCYEXIT ( *string* )**

Channel security exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately after establishing a channel.  
Before any messages are transferred, the exit is able to instigate security flows to validate connection authorization.
- Upon receipt of a response to a security message flow.

Any security message flows received from the remote processor on the remote queue manager are given to the exit.

- At initialization and termination of the channel.

The format and maximum length of the name is the same as for MSGEXIT but only one name is allowed.

### SENDDATA ( *string* )

Channel send exit user data. The maximum length is 32 characters.

This parameter is passed to the channel send exit when it is called.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify data for more than one exit program by specifying multiple strings separated by commas. The total length of the field must not exceed 999 characters.

On IBM i, you can specify up to 10 strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

**z/OS** On z/OS, you can specify up to eight strings, each of length 32 characters. The first string of data is passed to the first send exit specified, the second string to the second exit, and so on.

On other platforms, you can specify only one string of send exit data for each channel.

### SENDEXIT ( *string* )

Channel send exit name.

If this name is nonblank, the exit is called at the following times:

- Immediately before data is sent out on the network.  
The exit is given the complete transmission buffer before it is transmitted. The contents of the buffer can be modified as required.
- At initialization and termination of the channel.

On AIX, HP-UX, Linux, Solaris, and Windows, you can specify the name of more than one exit program by specifying multiple strings separated by commas. However, the total number of characters specified must not exceed 999.

On IBM i, you can specify the names of up to 10 exit programs by specifying multiple strings separated by commas.

**z/OS** On z/OS, you can specify the names of up to eight exit programs by specifying multiple strings separated by commas.

On other platforms, you can specify only one send exit name for each channel.

The format and maximum length of the name is the same as for MSGEXIT.

### SEQWRAP ( *integer* )

When this value is reached, sequence numbers wrap to start again at 1.

This value is nonnegotiable and must match in both the local and remote channel definitions.

The value must be in the range 100 - 999999999.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of SDR, SVR, RCVR, RQSTR, CLUSSDR, or CLUSRCVR.

### SHARECNV ( *integer* )

Specifies the maximum number of conversations that can be sharing each TCP/IP channel instance. A SHARECNV value of:

- 1 Specifies no sharing of conversations over a TCP/IP channel instance. Client heart

beating is available whether in an MQGET call or not. Read ahead and client asynchronous consumption are also available, and channel quiescing is more controllable.

**0** Specifies no sharing of conversations over a TCP/IP channel instance.

The value must be in the range zero through 999999999.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *CLNTCONN* or *SVRCONN*. If the *CLNTCONN SHARECNV* value does not match the *SVRCONN SHARECNV* value, the lower of the two values is used. This parameter is ignored for channels with a transport type ( *TRPTYPE* ) other than TCP.

All the conversations on a socket are received by the same thread.

High *SHARECNV* limits have the advantage of reducing queue manager thread usage. If many conversations sharing a socket are all busy, there is a possibility of delays. The conversations contend with one another to use the receiving thread. In this situation, a lower *SHARECNV* value is better.

The number of shared conversations does not contribute to the *MAXINST* or *MAXINSTC* totals.

**Note:** You should restart the client for this change to take effect.

### **SHORTRTY ( *integer* )**

*SHORTRTY* specifies the maximum number of attempts that are made by a *SDR*, *SVR*, or *CLUSDR* channel to connect to the remote queue manager, at intervals specified by *SHORTTMR*. After the number of attempts is exhausted, the channel tries to reconnect using to the schedule defined by *LONGRTY*.

The value must be in the range 0 - 999999999.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *SDR*, *SVR*, *CLUSDR*, or *CLUSRCVR*.

A channel attempts to reconnect if it fails to connect initially, whether it is started automatically by the channel initiator or by an explicit command. It also tries to connect again if the connection fails after the channel successfully connecting. If the cause of the failure is such that more attempts are unlikely to be successful, they are not attempted.

### **SHORTTMR ( *integer* )**

For *SHORTRTY*, *SHORTTMR* is the maximum number of seconds to wait before reattempting connection to the remote queue manager.

The time is approximate. From IBM MQ Version 8.0, zero means that another connection attempt is made as soon as possible.

The interval between attempting to reconnect might be extended if the channel has to wait to become active.

The value must be in the range 0 - 999999999.

**Note:** For implementation reasons, the maximum *SHORTTMR* value is 999,999; values exceeding this maximum are treated as 999,999. From IBM MQ Version 8.0, if *SHORTTMR* is set to 1 then the minimum interval between attempting to connect is 2 seconds.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of *SDR*, *SVR*, *CLUSDR*, or *CLUSRCVR*.

### **SSLCAUTH**

*SSLCAUTH* defines whether IBM MQ requires a certificate from the SSL client. The SSL client is the initiating end of the channel. *SSLCAUTH* is applied to the SSL server, to determine the behavior required of the client. The SSL server is the end of the channel that receives the initiation flow.

This parameter is valid only for channels with a channel type ( CHLTYP ) of RCVR, SVRCONN, CLUSRCVR, SVR, OR RQSTR.

The parameter is used only for channels with SSLCIPH specified. If SSLCIPH is blank, the data is ignored and no error message is issued.

**REQUIRED**

IBM MQ requires and validates a certificate from the SSL client.

**OPTIONAL**

The peer SSL client system might still send a certificate. If it does, the contents of this certificate are validated as normal.

**SSLCIPH (string)**

SSLCIPH specifies the CipherSpec that is used on the channel. The maximum length is 32 characters. This parameter is valid on all channel types which use transport type TRPTYPE(TCP). If the SSLCIPH parameter is blank, no attempt is made to use SSL on the channel.

Specify the name of the CipherSpec you are using. The CipherSpecs that can be used with IBM MQ SSL support are shown in the following table. The SSLCIPH values must specify the same CipherSpec on both ends of the channel.

**Note:**   On  IBM MQ for z/OS;  IBM i; you can also specify the two digit hexadecimal code of a CipherSpec, whether or not it appears in the table. On IBM i, installation of AC3 is a prerequisite for the use of SSL.

Platform support <sup>1</sup>	CipherSpec name	Protocol used	Data integrity	Encryption algorithm	Encryption bits	FIPS <sup>2</sup>	Suite B

Platform support <sup>1</sup>	CipherSpec name	Protocol used	Data integrity	Encryption algorithm	Encryption bits	FIPS <sup>2</sup>	Suite B
<p><b>Notes:</b></p> <ol style="list-style-type: none"> <li>If no specific platform is noted, the CipherSpec is available on all platforms.</li> <li>Specifies whether the CipherSpec is FIPS-certified on a FIPS-certified platform. See Federal Information Processing Standards (FIPS) for an explanation of FIPS.</li> <li>This CipherSpec cannot be used to secure a connection from the MQ Explorer to a queue manager unless the appropriate unrestricted policy files are applied to the JRE used by the Explorer.</li> <li>Following a recommendation by NIST, GCM CipherSpecs now have a restriction which means that after 2022 TLS records are sent, using the same session key, the connection will be terminated with message AMQ9288. To prevent this error from happening: avoid using GCM Ciphers, enable secret key reset, or start your IBM MQ queue manager with the environment variable GSK_ENFORCE_GCM_RESTRICTION=GSK_FALSE set. <b>Important:</b> The GCM restriction is active, regardless of the FIPS mode being used.</li> <li>The CipherSpecs listed as supported on IBM i apply to Versions 7.2 and 7.3 of IBM i.</li> </ol>							

When you request a personal certificate, you specify a key size for the public and private key pair. The key size that is used during the SSL handshake can depend on the size stored in the certificate and on the CipherSpec:

- On  z/OS, Windows, UNIX and Linux systems, when a CipherSpec name includes \_EXPORT, the maximum handshake key size is 512 bits. If either of the certificates exchanged during the SSL handshake has a key size greater than 512 bits, a temporary 512-bit key is generated for use during the handshake.
- On Windows, UNIX and Linux systems, when a CipherSpec name includes \_EXPORT1024, the handshake key size is 1024 bits.
- Otherwise the handshake key size is the size stored in the certificate.

### SSLPEER (*string*)

Specifies the certificate filter used by the peer queue manager or client at the other end of the channel. The filter is used to compare with the distinguished name of the certificate. A “distinguished name” is the identifier of the SSL certificate. If the distinguished name in the certificate received from the peer does not match the SSLPEER filter, the channel does not start.

**Note:** An alternative way of restricting connections into channels by matching against the SSL or TLS Subject distinguished name, is to use channel authentication records. With channel authentication records, different SSL or TLS subject distinguished name patterns can be applied to the same channel. Both SSLPEER and a channel authentication record can be applied to the same channel. If so, the inbound certificate must match both patterns in order to connect. For more information, see Channel authentication records.

SSLPEER is optional. If it is not specified, the distinguished name of the peer is not checked at channel startup. The distinguished name from the certificate is still written into the SSLPEER definition held in memory, and passed to the security exit. If SSLCIPH is blank, the data is ignored and no error message is issued.

This parameter is valid for all channel types.

The SSLPEER value is specified in the standard form used to specify a distinguished name. For example:

```
SSLPEER('SERIALNUMBER=4C:D0:49:D5:02:5F:38,CN="H1_C_FR1",O=IBM,C=GB')
```

You can use a semi-colon as a separator instead of a comma.

The possible attribute types supported are:

*Table 98. Attribute types supported by SSLPEER.*

A two column table describing the attributes supported by the SSLPEER parameter

Attribute	Description
SERIALNUMBER	Certificate serial number
MAIL	Email address
E	Email address (Deprecated in preference to MAIL)
UID or USERID	User identifier
CN	Common Name
T	Title
OU	Organizational Unit name
DC	Domain component
O	Organization name
STREET	Street / First line of address
L	Locality name
ST (or SP or S)	State or Province name
PC	Postal code / zipcode
C	Country
UNSTRUCTUREDNAME	Host name
UNSTRUCTUREDADDRESS	IP address
DNQ	Distinguished name qualifier

IBM MQ accepts only uppercase letters for the attribute types.

If any of the unsupported attribute types are specified in the SSLPEER string, an error is output either when the attribute is defined, or at run time. When the error is output depends on which platform you are running on. An error implies that the SSLPEER string does not match the distinguished name of the flowed certificate.

If the distinguished name of the flowed certificate contains multiple organizational unit (OU) attributes, and SSLPEER specifies that these attributes are to be compared, they must be defined in descending hierarchical order. For example, if the distinguished name of the flowed certificate contains the OUs OU=Large Unit, OU=Medium Unit, OU=Small Unit, specifying the following SSLPEER values works:

```
('OU=Large Unit,OU=Medium Unit')
('OU=*,OU=Medium Unit,OU=Small Unit')
('OU=*,OU=Medium Unit')
```

but specifying the following SSLPEER values fails:

```
('OU=Medium Unit,OU=Small Unit')
('OU=Large Unit,OU=Small Unit')
('OU=Medium Unit')
('OU=Small Unit, Medium Unit, Large Unit')
```

As indicated in these examples, attributes at the low end of the hierarchy can be omitted. For example, ('OU=Large Unit,OU=Medium Unit') is equivalent to ('OU=Large Unit,OU=Medium Unit,OU=\*')

If two DNs are equal in all respects except for their domain component (DC) values, almost the same matching rules apply as for OUs. The exception is that with DC values, the left-most DC is the lowest-level and most specific, and the comparison ordering differs accordingly.

Any or all the attribute values can be generic, either an asterisk \* on its own, or a stem with initiating or trailing asterisks. Asterisks allow the SSLPEER to match any distinguished name value, or any value starting with the stem for that attribute. You can specify an asterisk at the beginning or end of any attribute value in the DN on the certificate. If you do so, you can still check for an exact match with SSLPEER. Specify \\* to check for an exact match. For example, if you have an attribute of CN='Test\*' in the DN of the certificate, you use the following command to check for an exact match:

```
SSLPEER('CN=Test\*')
```

The maximum length of the parameter is 1024 bytes on Windows, IBM i, UNIX and Linux platforms

► **z/OS** The maximum length of the parameter is 256 bytes on z/OS.

Channel authentication records provide greater flexibility when using SSLPEER and support 1024 bytes on all platforms.

## STATCHL

Controls the collection of statistics data for channels:

**QMGR** The value of the STATCHL parameter of the queue manager is inherited by the channel.

**OFF** Statistics data collection is turned off for this channel.

**LOW** If the value of the STATCHL parameter of the queue manager is not NONE, statistics data collection is turned on. Data is collected at a low rate for this channel.

**MEDIUM** If the value of the STATCHL parameter of the queue manager is not NONE, statistics data collection is turned on. Data is collected at a medium rate for this channel.

**HIGH** If the value of the STATCHL parameter of the queue manager is not NONE, statistics data collection is turned on. Data is collected at a high rate for this channel.

Changes to this parameter take effect only on channels started after the change occurs.

► **z/OS** On z/OS, this parameter simply turns on statistics data collection, regardless of the value you select. Specifying LOW, MEDIUM, or HIGH makes no difference to your results.

For cluster channels, the value of this parameter is not replicated in the repository and therefore is not used in the auto-definition of CLUSSDR channels. For auto-defined CLUSSDR channels, the value of this parameter is taken from the attribute STATACLS of the queue manager. This value might then be overridden in the channel auto-definition exit.

## TPNAME ( *string* )

LU 6.2 transaction program name (maximum length 64 characters).

This parameter is valid only for channels with a transport type ( TRPTYPE ) of LU62.

Set this parameter to the SNA transaction program name, unless the CONNAME contains a side-object name in which case set it to blanks. The actual name is taken instead from the CPI-C Communications Side Object, or the APPC side information data set. ► **z/OS** See Configuration parameters for an LU 6.2 connection

On Windows SNA Server, ► **z/OS** and in the side object on z/OS, the TPNAME is wrapped to uppercase.

This parameter is not valid for channels with a channel type ( `CHLTYPE` ) of RCVR.

#### ► V 8.0.0.4 TPROOT

The topic root for an AMQP channel. The default value for TPROOT is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other MQ pub/sub applications. Alternatively, AMQP clients can publish and subscribe under a different topic prefix, specified in the TPROOT attribute.

This parameter is valid only for channels with a channel type ( `CHLTYPE` ) of AMQP

#### TRPTYPE

Transport type to be used.

On AIX, HP-UX, Linux, IBM i, Solaris, Windows ► `z/OS` , and `z/OS`, this parameter is optional because, if you do not enter a value, the value specified in the SYSTEM.DEF. *channel-type* definition is used. If the channel is initiated from the other end, no check is made that the correct transport type is specified.

► `z/OS` On `z/OS`, if the SYSTEM.DEF. *channel-type* definition does not exist, the default is LU62.

This parameter is required on all other platforms.

**LU62** SNA LU 6.2

#### NETBIOS

NetBIOS (supported only on Windows, and DOS).

► `z/OS` This attribute also applies to `z/OS` for defining client-connection channels that connect to servers on the platforms supporting NetBIOS.

**SPX** Sequenced packet exchange (supported only on Windows, and DOS).

► `z/OS` This attribute also applies to `z/OS` for defining client-connection channels that connect to servers on the platforms supporting SPX.

**TCP** Transmission Control Protocol - part of the TCP/IP protocol suite

#### ► V 8.0.0.4 USECLTID

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

#### USEDLQ

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

**NO** Messages that cannot be delivered by a channel are treated as a failure. The channel either discards the message, or the channel ends, in accordance with the NPMSPEED setting.

**YES** When the DEADQ queue manager attribute provides the name of a dead-letter queue, then it is used, else the behavior is as for NO. YES is the default value.

#### USERID ( *string* )

Task user identifier. The maximum length is 12 characters.

This parameter is used by the message channel agent when attempting to initiate a secure LU 6.2 session with a remote message channel agent.

On distributed platforms this parameter is valid only for channels with a channel type (CHLTYPE) of SDR, SVR, RQSTR, CLNTCONN, or CLUSSDR.

► `z/OS` On `z/OS`, it is supported only for CLNTCONN channels.

Although the maximum length of the parameter is 12 characters, only the first 10 characters are used.

On the receiving end, if passwords are encrypted and the LU 6.2 software is using a different encryption method, the channel fails to start. The error is diagnosed as invalid security details. You can avoid invalid security details by modifying the receiving SNA configuration to either:

- Turn off password substitution, or
- Define a security user ID and password.

### XMITQ ( *string* )

Transmission queue name.

The name of the queue from which messages are retrieved. See Rules for naming IBM MQ objects.

This parameter is valid only for channels with a channel type ( *CHLTYPE* ) of SDR or SVR. For these channel types, this parameter is required.

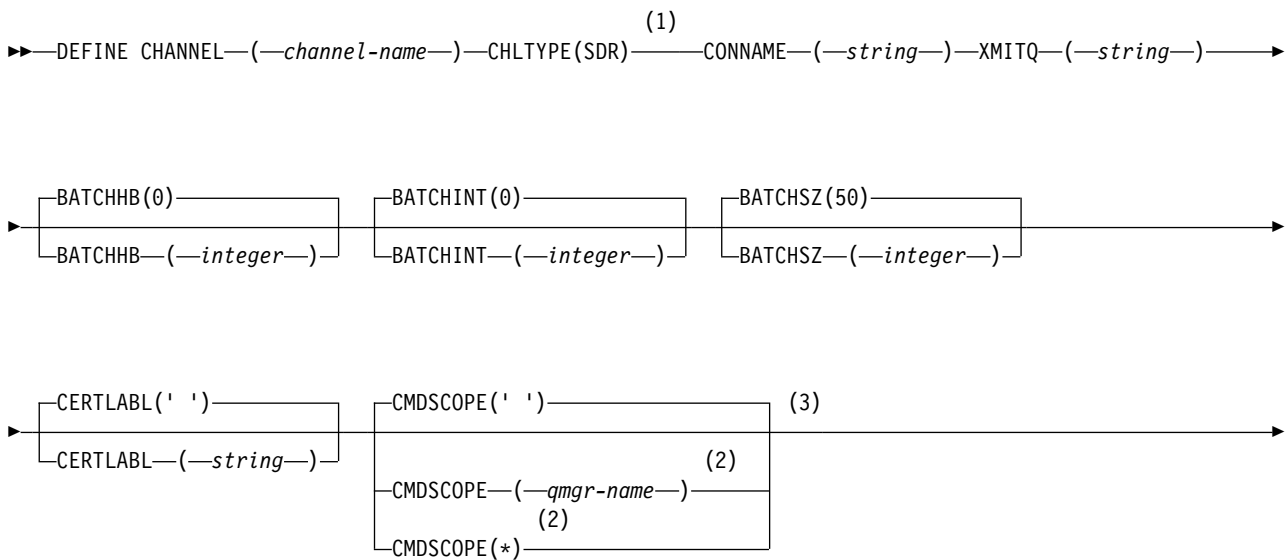

There is a separate syntax diagram for each type of channel:

*Sender channel:*

Syntax diagram for a sender channel when using the DEFINE CHANNEL command.

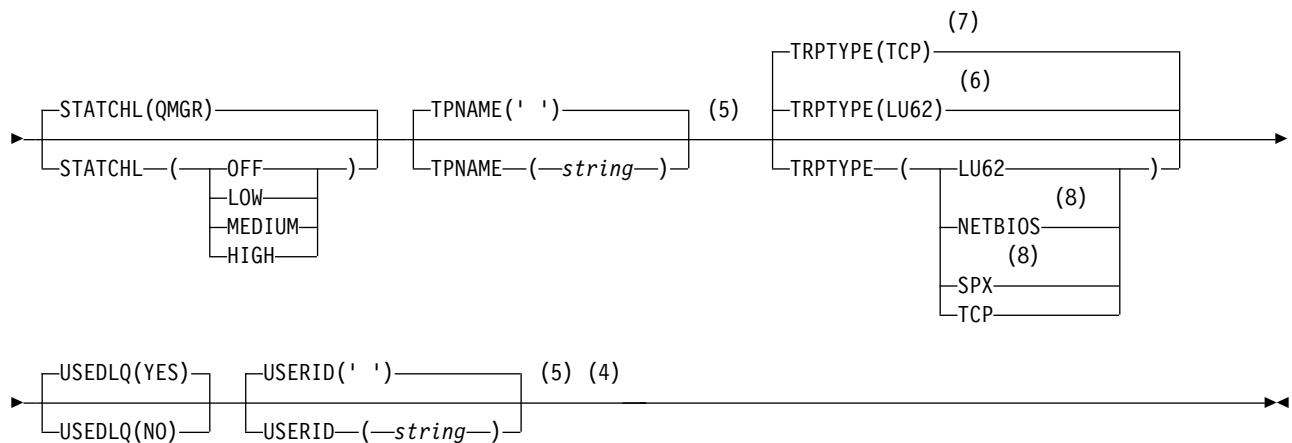

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

### DEFINE CHANNEL

**Notes:**

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Default for z/OS.
- 7 Default for distributed platforms.
- 8 Valid only on Windows.

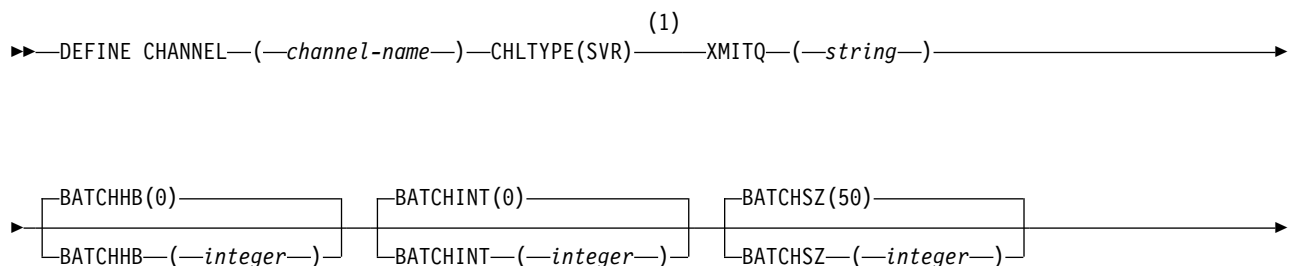

The parameters are described in “DEFINE CHANNEL” on page 550.

*Server channel:*

Syntax diagram for a server channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

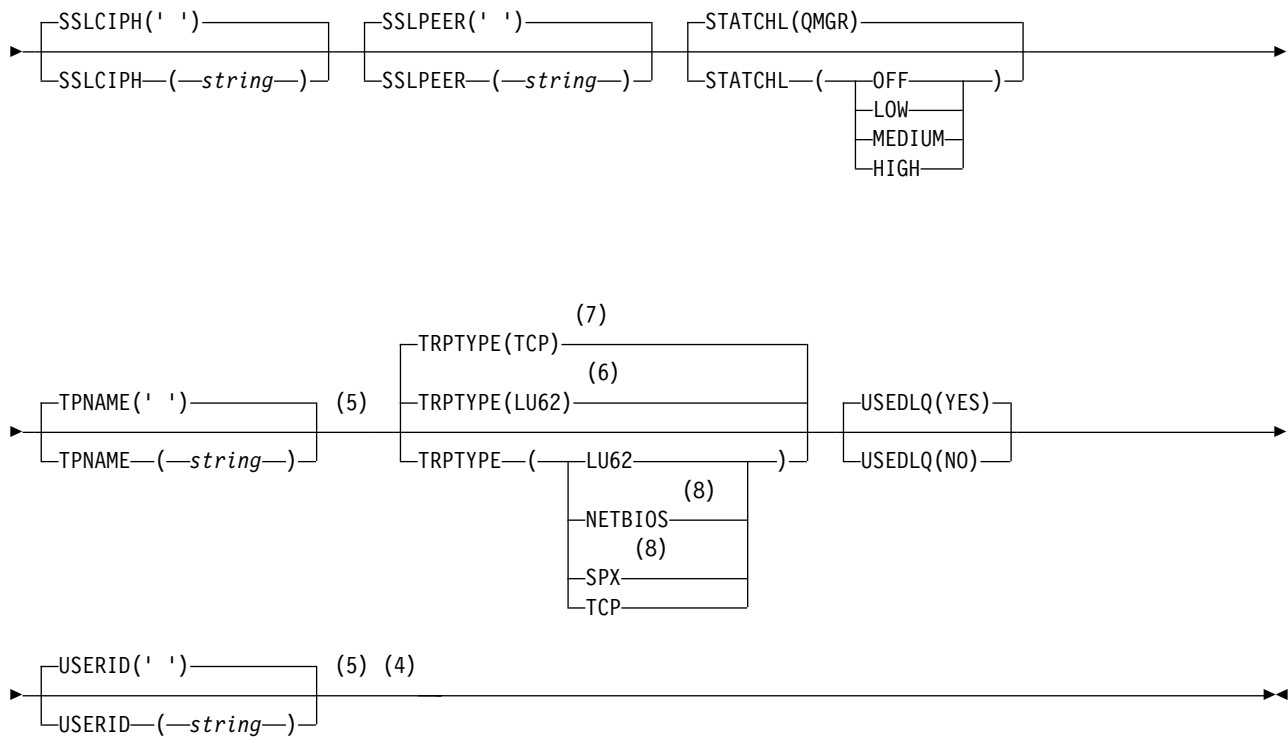

**DEFINE CHANNEL**

**Notes:**

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Default for z/OS.
- 7 Default for distributed platforms.
- 8 Valid only on Windows.

The parameters are described in "DEFINE CHANNEL" on page 550.

Receiver channel:

Syntax diagram for a receiver channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "How to read railroad diagrams" on page 176.

## DEFINE CHANNEL

**Notes:**

- 1 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 2 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Default for z/OS.
- 5 Default for distributed platforms.
- 6 Valid only on Windows.

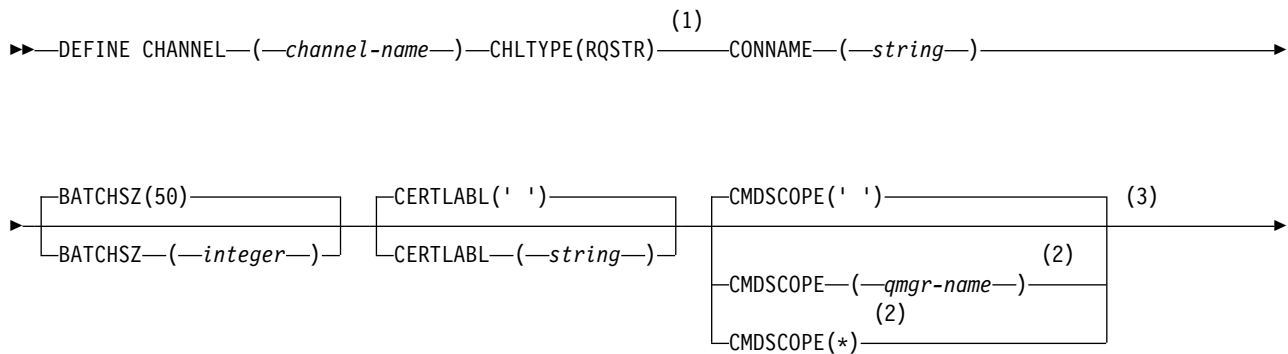

The parameters are described in “DEFINE CHANNEL” on page 550.

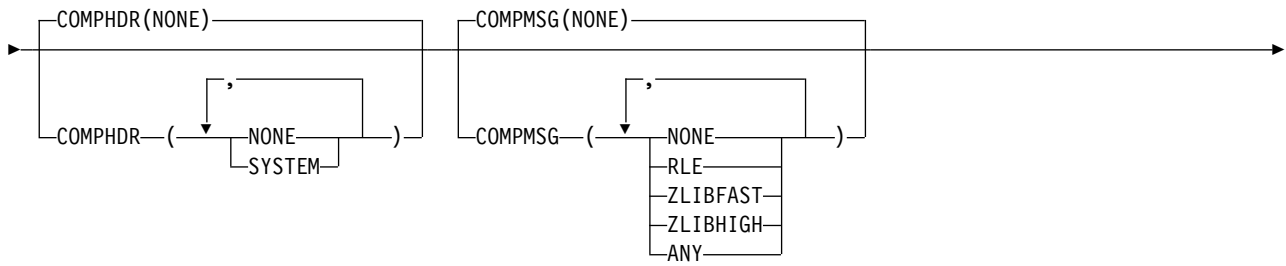

*Requester channel:*

Syntax diagram for a requester channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

**DEFINE CHANNEL**

### Notes:

- 1 This parameter must follow immediately after the channel name **z/OS** except on z/OS.
- 2 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Default for z/OS.
- 7 Default for distributed platforms.
- 8 Valid only on Windows.

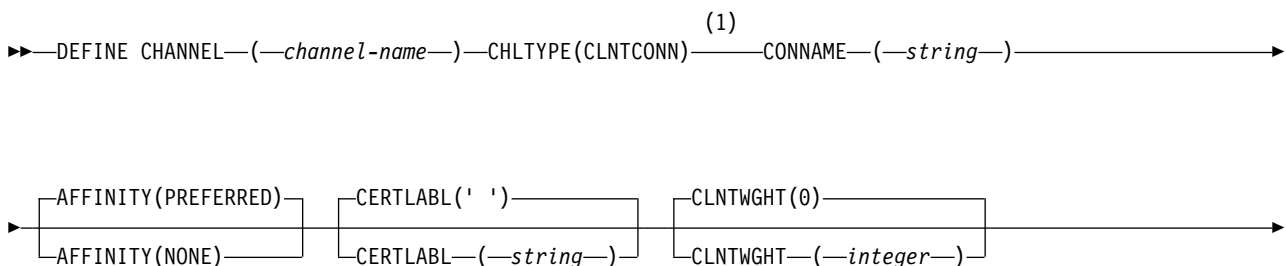

The parameters are described in “DEFINE CHANNEL” on page 550.

*Client-connection channel:*

Syntax diagram for a client-connection channel when using the DEFINE CHANNEL command.

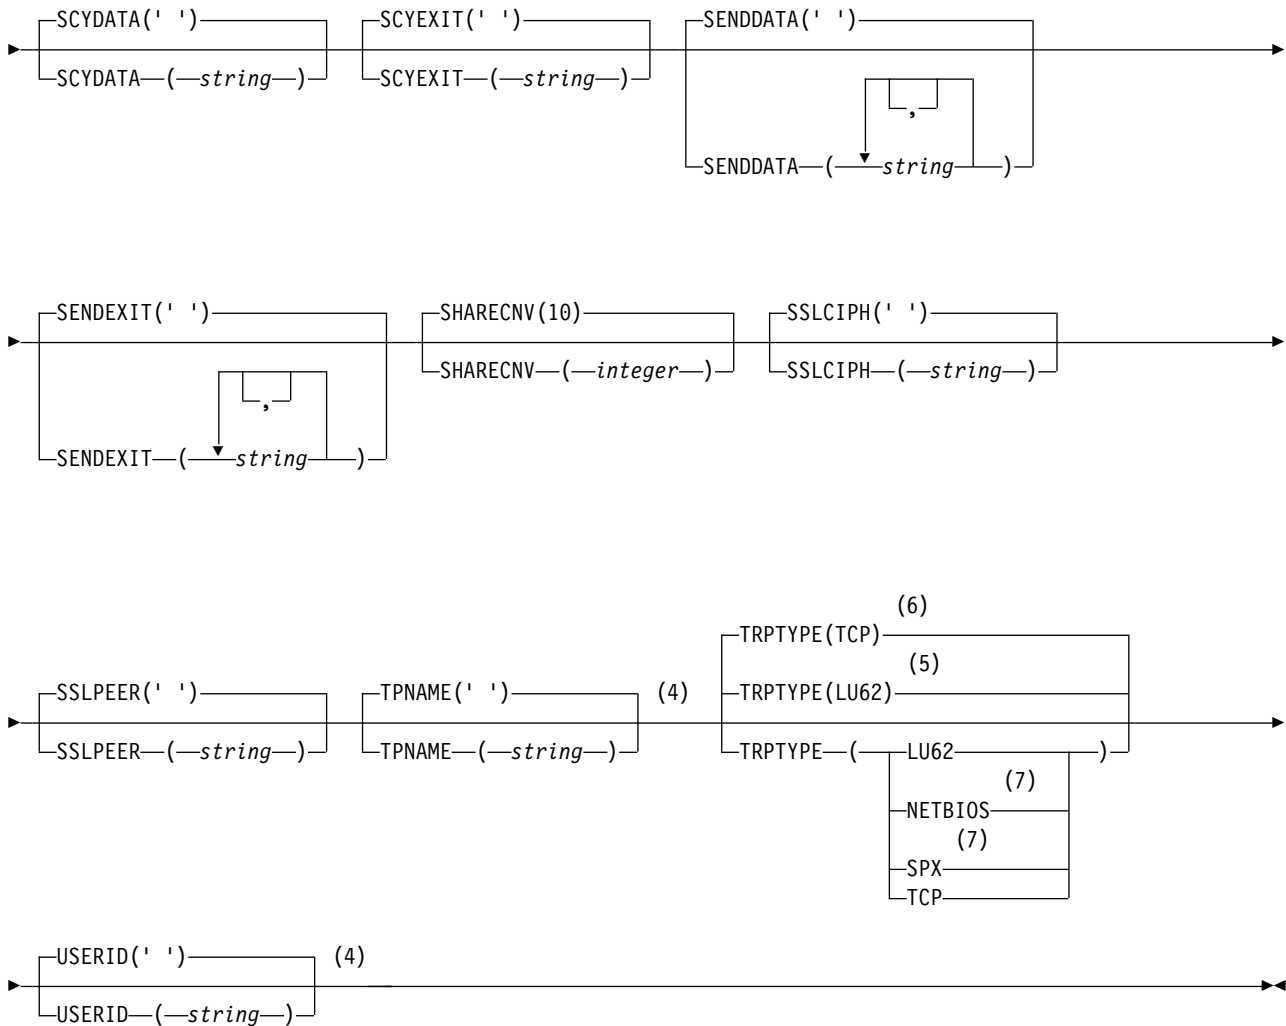

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

### DEFINE CHANNEL

**Notes:**

- 1 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 2 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Valid only if TRPTYPE is LU62.
- 5 Default for z/OS.
- 6 Default for distributed platforms.
- 7 Valid only for clients to be run on DOS or Windows.

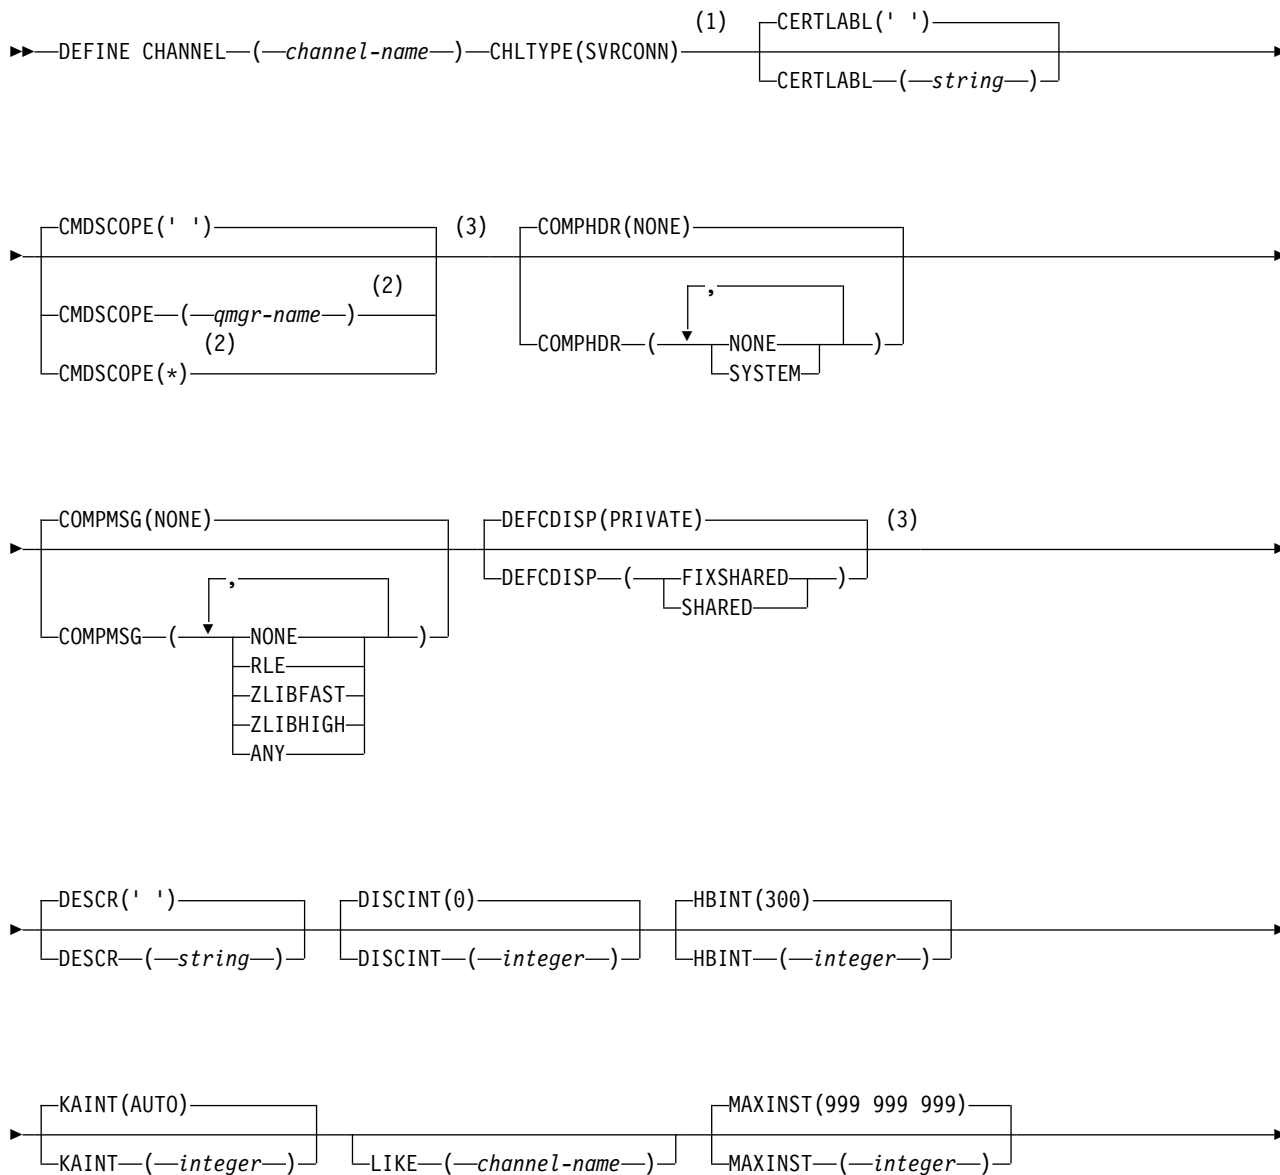

The parameters are described in “DEFINE CHANNEL” on page 550.

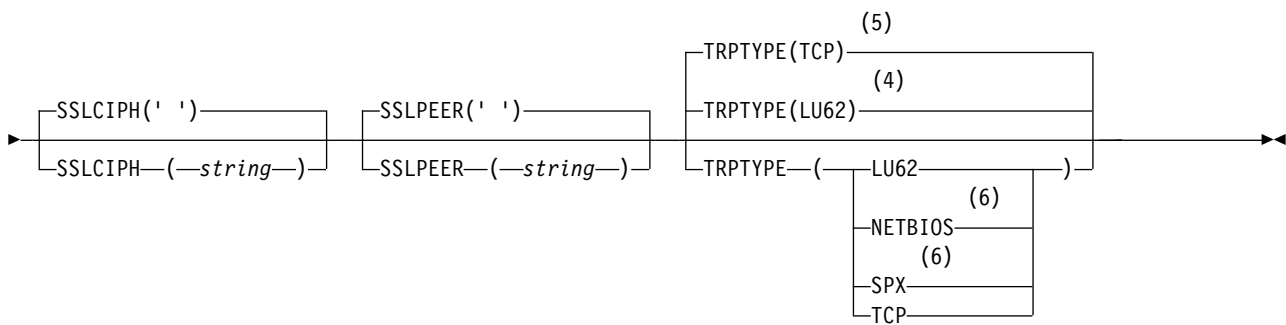

Server-connection channel:

Syntax diagram for a server-connection channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "How to read railroad diagrams" on page 176.

## DEFINE CHANNEL

**Notes:**

- 1 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 2 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Default for z/OS.
- 5 Default for distributed platforms.
- 6 Valid only for clients to be run on Windows.

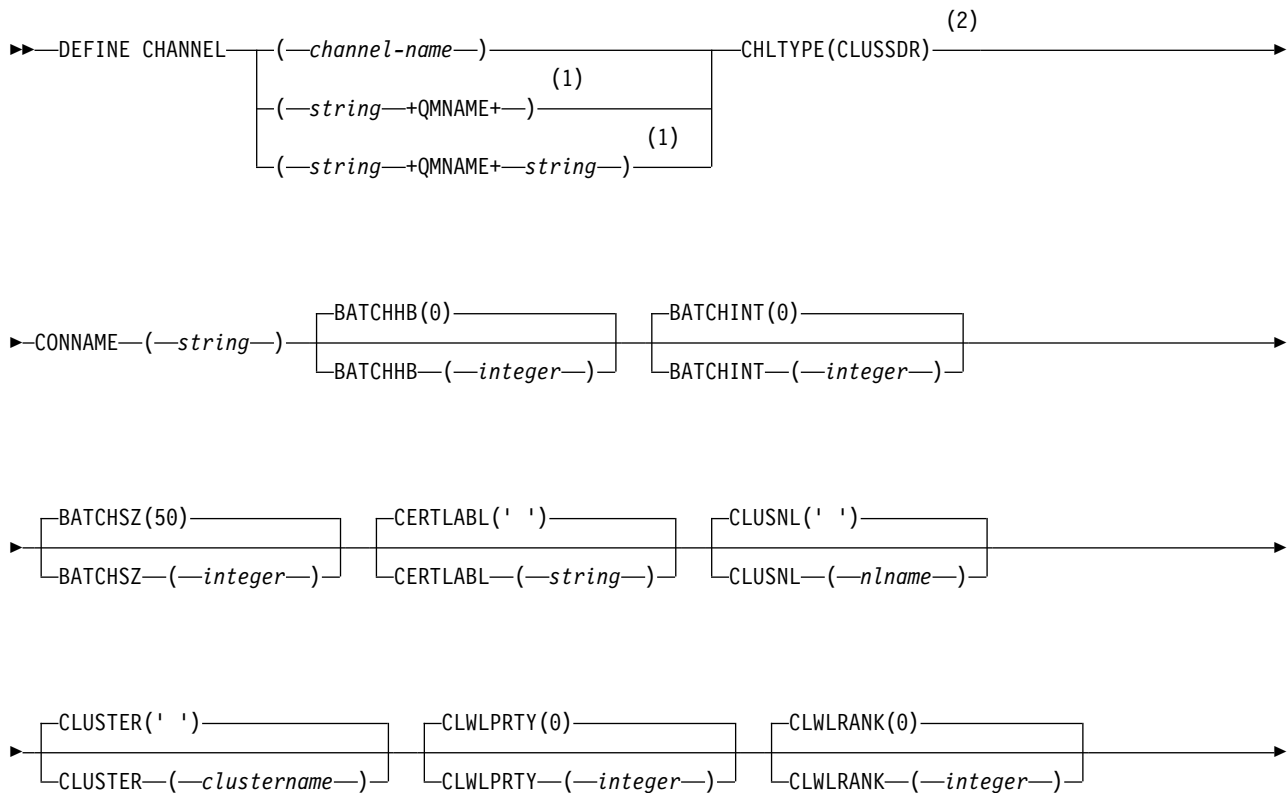

The parameters are described in “DEFINE CHANNEL” on page 550.

*Cluster-sender channel:*

Syntax diagram for a cluster-sender channel when using the DEFINE CHANNEL command.

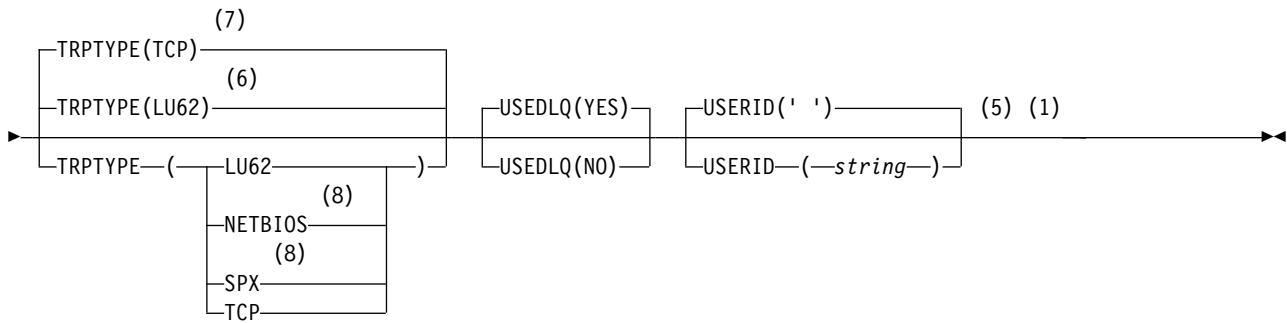

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

**DEFINE CHANNEL**

**Notes:**

- 1 Not valid on z/OS.
- 2 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 3 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 4 Valid only on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Default for z/OS.
- 7 Default for distributed platforms.
- 8 Valid only on Windows.

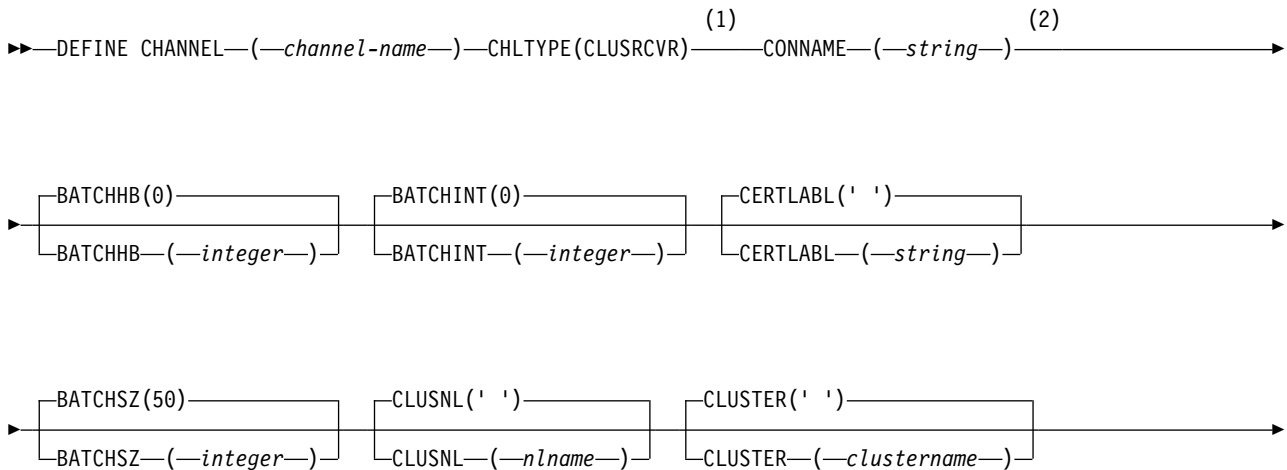

The parameters are described in "DEFINE CHANNEL" on page 550.

*Cluster-receiver channel:*

Syntax diagram for a cluster-receiver channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See "How to read railroad diagrams" on page 176.

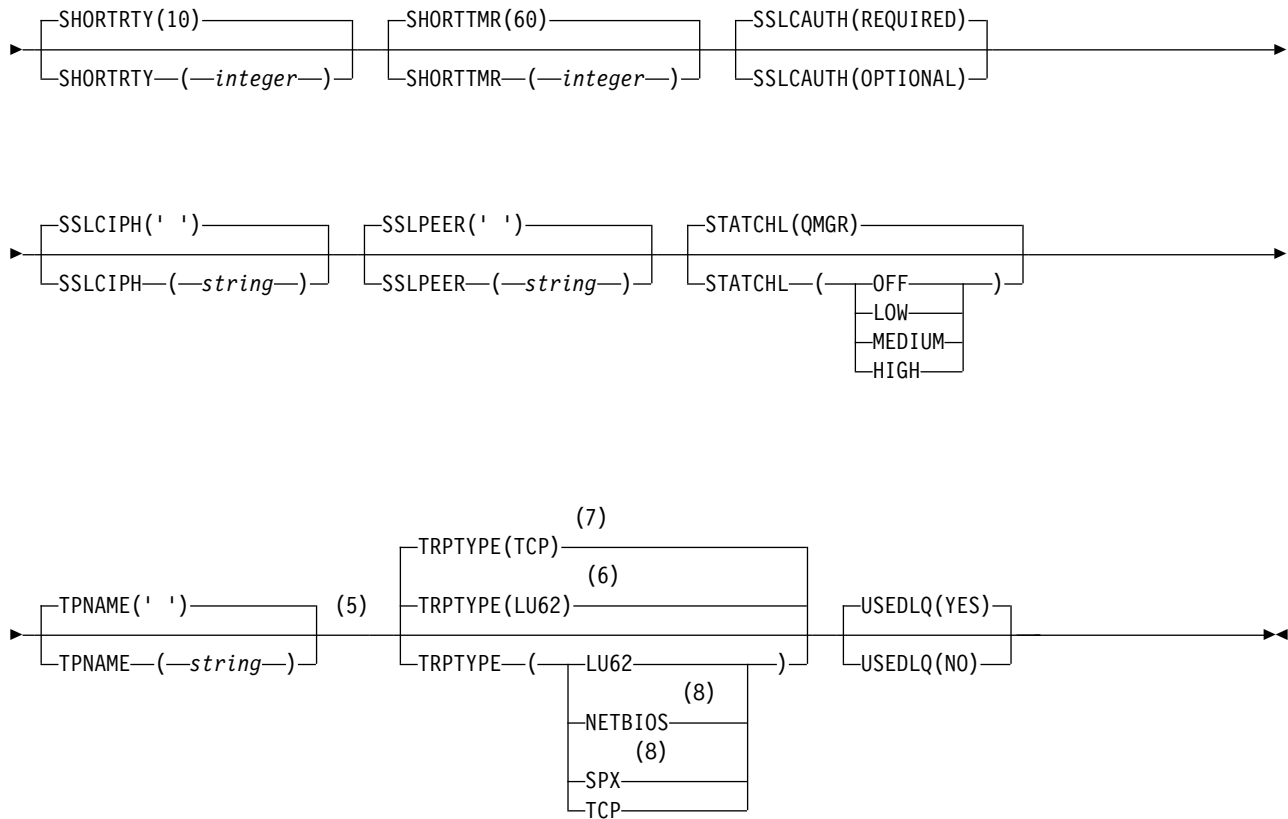

**DEFINE CHANNEL**

**Notes:**

- 1 This parameter must follow immediately after the channel name z/OS except on z/OS.
- 2 This parameter is optional if TRPTYPE is TCP.
- 3 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 4 Valid only on z/OS.
- 5 Valid only if TRPTYPE is LU62.
- 6 Default for z/OS.
- 7 Default for distributed platforms.
- 8 Valid only on Windows.

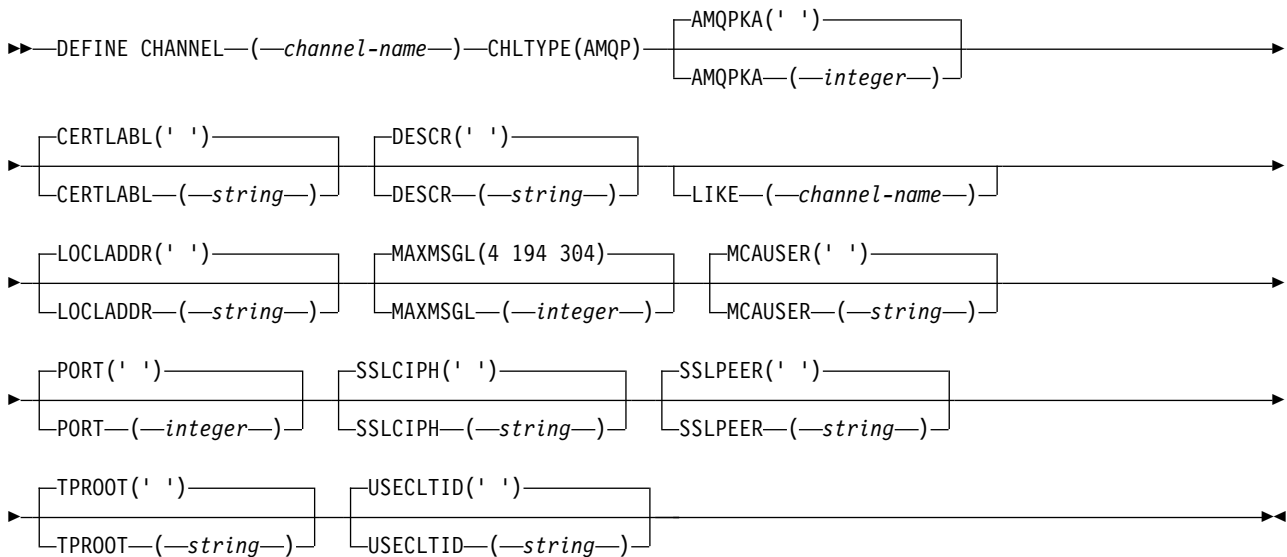

The parameters are described in “DEFINE CHANNEL” on page 550.

AMQP channel: **distributed** **V8.0.0.4**

Syntax diagram for an AMQP channel when using the DEFINE CHANNEL command.

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

### DEFINE CHANNEL

The parameters are described in “DEFINE CHANNEL” on page 550.

### DEFINE CHANNEL (MQTT):

Syntax diagram for a telemetry channel when using the **DEFINE CHANNEL** command.

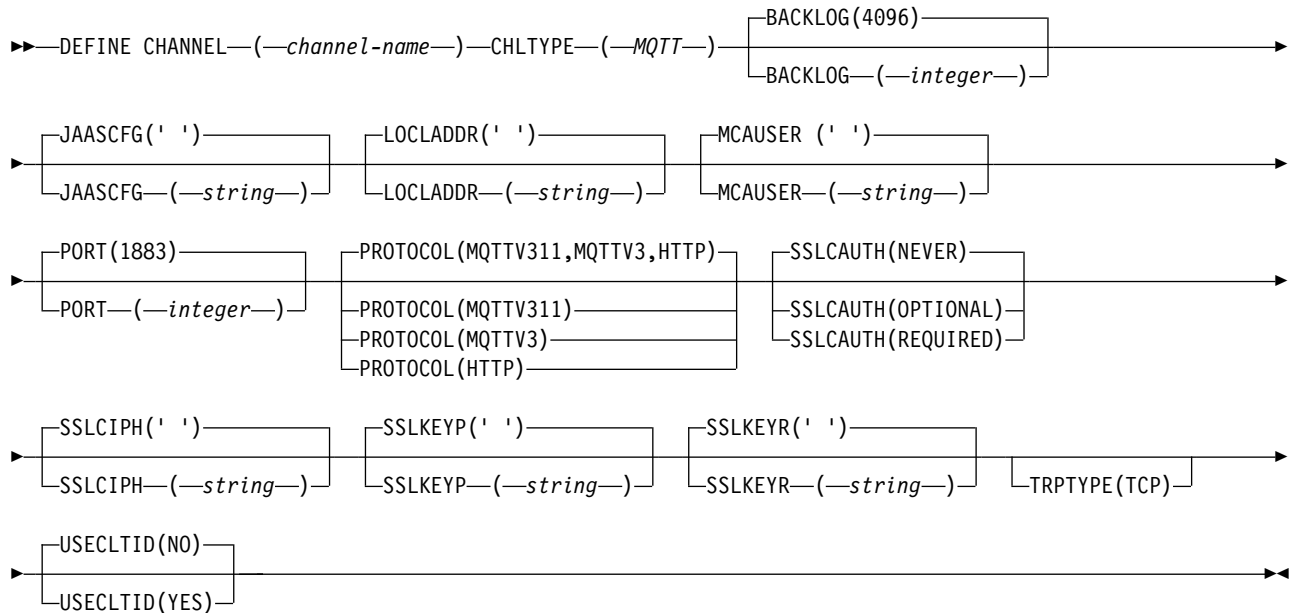

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	AIX and Linux	Windows	z/OS
	✓	✓	

**Note:** For the telemetry server, AIX is the only supported UNIX platform.

## DEFINE CHANNEL ( MQTT )

### Usage notes

The telemetry (MQXR) service must be running when you issue this command. For instructions on how to start the telemetry (MQXR) service, see [Configuring a queue manager for telemetry on Linux](#) or [Configuring a queue manager for telemetry on Windows](#).

### Parameter descriptions for DEFINE CHANNEL (MQTT)

*(channel-name)*

The name of the new channel definition.

The name must not be the same as any existing channel defined on this queue manager (unless REPLACE or ALTER is specified).

The maximum length of the string is 20 characters, and the string must contain only valid characters; see [Rules for naming IBM MQ objects](#).

### BACKLOG ( integer )

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed.

The value is in the range 0 - 999999999.

The default value is 4096.

### CHLTYPE

Channel type. MQTT (telemetry) channel.

### JAASCFG ( string )

The name of a stanza in the JAAS configuration file.

See [Authenticating an MQTT client Java app with JAAS](#)

### LOCLADDR ( ip-addr )

LOCLADDR is the local communications address for the channel. Use this parameter if you want to force the client to use a particular IP address. LOCLADDR is also useful to force a channel to use an IPv4 or IPv6 address if a choice is available, or to use a particular network adapter on a system with multiple network adapters.

The maximum length of LOCLADDR is MQ\_LOCAL\_ADDRESS\_LENGTH.

If you omit LOCLADDR, a local address is automatically allocated.

#### **ip-addr**

ip-addr is a single network address, specified in one of three forms:

##### **IPv4 dotted decimal**

For example 192.0.2.1

##### **IPv6 hexadecimal notation**

For example 2001:DB8:0:0:0:0:0:0

##### **Alphanumeric host name form**

For example WWW.EXAMPLE.COM

If an IP address is entered, only the address format is validated. The IP address itself is not validated.

#### **MCAUSER ( *string* )**

Message channel agent user identifier.

The maximum length of the string is 64 characters on Windows and 12 characters on other platforms. On Windows, you can optionally qualify a user identifier with the domain name in the format user@domain.

If this parameter is nonblank, and **USECLNTID** is set to N0, then this user identifier is used by the telemetry service for authorization to access IBM MQ resources.

If this parameter is blank, and **USECLNTID** is set to N0, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

#### **PORT ( *integer* )**

The port number on which the telemetry (MQXR) service accepts client connections. The default port number for a telemetry channel is 1883; and the default port number for a telemetry channel secured using SSL is 8883. Specifying a port value of 0 causes MQTT to dynamically allocate an available port number.

#### **PROTOCOL**

The following communication protocols are supported by the channel:

##### **V8.0.0.3 MQTTV311**

The channel accepts connections from clients using the protocol defined by the MQTT Version 3.1.1 Oasis standard. The functionality provided by this protocol is almost identical to that provided by the pre-existing MQTTV3 protocol.

**MQTTV3** The channel accepts connections from clients using the MQTT V3.1 Protocol Specification from mqtt.org.

**HTTP** The channel accepts HTTP requests for pages, or WebSockets connections to IBM MQ Telemetry.

To accept connections from clients using different protocols, specify the acceptable values as a comma-delimited list. For example if you specify MQTTV3,HTTP the channel accepts connections from clients using either MQTTV3 or HTTP. If you specify no client protocols, the channel accepts connections from clients using any of the supported protocols.

**V8.0.0.3** If you are using IBM MQ Version 8.0.0, Fix Pack 3 or later, and your configuration includes an MQTT channel that was last modified in an earlier version of IBM MQ, you must explicitly change the protocol setting to prompt the channel to use the MQTTV311 option. This is so even if the channel does not specify any client protocols, because the specific protocols to use with the channel are stored at the time the channel is configured, and previous versions of the product have no awareness of the MQTTV311 option. To prompt a channel in this state to use the MQTTV311 option, explicitly add the option then save your changes. The channel definition is now aware of the option. If you subsequently change the settings again, and specify no client protocols, the MQTTV311 option is still included in the stored list of supported protocols.

## SSLCAUTH

Defines whether IBM MQ requires a certificate from the SSL client. The initiating end of the channel acts as the SSL client, so this parameter applies to the end of the channel that receives the initiation flow, which acts as the SSL server.

**NEVER** IBM MQ never requests a certificate from the SSL client.

### REQUIRED

IBM MQ requires and validates a certificate from the SSL client.

### OPTIONAL

IBM MQ lets the SSL client decide whether to provide a certificate. If the client sends a certificate, the contents of this certificate are validated as normal.

## SSLCIPH (*string*)

When SSLCIPH is used with a telemetry channel, it means “SSL Cipher Suite”. The SSL cipher suite is the one supported by the JVM that is running the telemetry (MQXR) service. If the SSLCIPH parameter is blank, no attempt is made to use SSL on the channel.

If you plan to use SHA-2 cipher suites, see System requirements for using SHA-2 cipher suites with MQTT channels.

## SSLKEYP (*string*)

The passphrase for the Secure Sockets Layer (SSL) key repository.

## SSLKEYR (*string*)

The full path name of the Secure Sockets Layer (SSL) key repository file, the store for digital certificates and their associated private keys. If you do not specify a key file, SSL is not used.

The maximum length of the string is 256 characters. On UNIX and Linux, the name is of the form *pathname/keyfile* and on Windows *pathname\keyfile*, where *keyfile* is specified without the suffix *.kdb*, and identifies a Java keystore file.

## TRPTYPE (*string*)

The transmission protocol to be used:

### TCP

TCP/IP.

## USECLTID

Decide whether you want to use the MQTT client ID for the new connection as the IBM MQ user ID for that connection. If this property is specified, the user name supplied by the client is ignored.

If you set this parameter to YES, then **MCAUSER** must be blank.

If **USECLNTID** is set to NO, and **MCAUSER** is blank, then the user name flowed in the MQTT CONNECT Packet is used. See MQTT client identity and authorization.

**Related reference:**

“ALTER CHANNEL (MQTT)” on page 417

Syntax diagram for a telemetry channel when using the **ALTER CHANNEL** command.

**Related information:**

Telemetry channel configuration for MQTT client authentication using SSL

Telemetry channel configuration for channel authentication using SSL

CipherSpecs and CipherSuites

System requirements for using SHA-2 cipher suites with MQTT channels

**DEFINE COMMINFO:**

Use the MQSC command DEFINE COMMINFO to define a new communication information object. These objects contain the definitions required for Multicast messaging.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

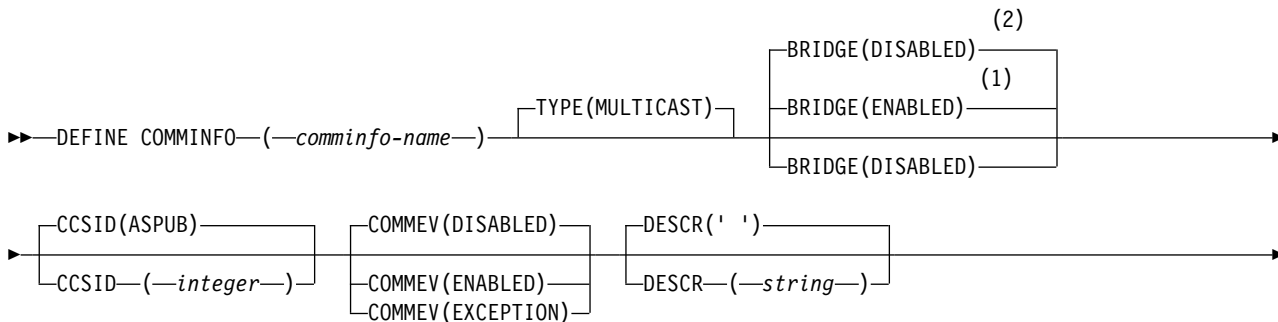

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions for DEFINE COMMINFO” on page 615

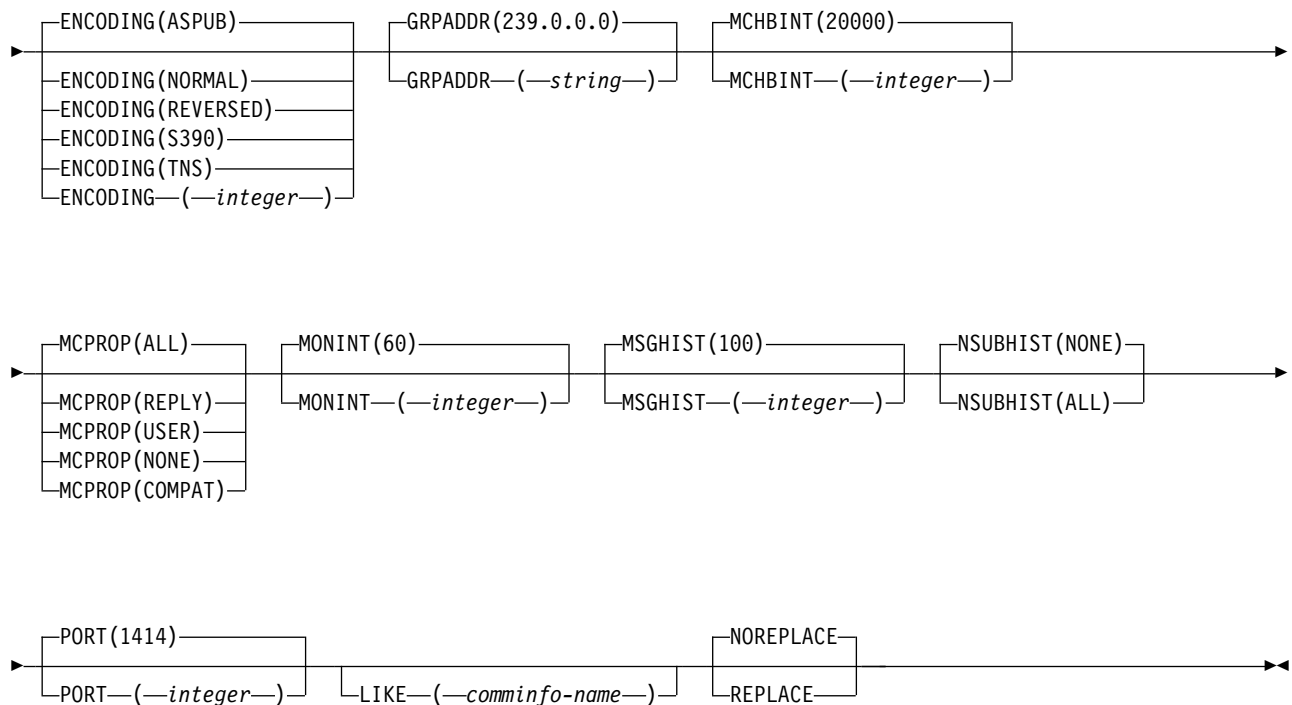

**Synonym:** DEF COMMINFO

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

**DEFINE COMMINFO**

#### Notes:

- 1 Default for platforms other than IBM i.
- 2 Default for IBM i.

#### Parameter descriptions for DEFINE COMMINFO

(*comminfo name*)

Name of the communications information object. This is required.

The name must not be the same as any other communications information object name currently defined on this queue manager. See Rules for naming IBM MQ objects.

**TYPE** The type of the communications information object. The only type supported is MULTICAST.

#### BRIDGE

Controls whether publications from applications not using Multicast are bridged to applications using Multicast. Bridging does not apply to topics that are marked as **MCAST(ONLY)**. As these topics can only be Multicast traffic, it is not applicable to bridge to the queue's publish/subscribe domain.

#### DISABLED

Publications from applications not using Multicast are not bridged to applications that do use Multicast. This is the default for IBM i.

#### ENABLED

Publications from applications not using Multicast are bridged to applications that do use Multicast. This is the default for platforms other than IBM i.

**CCSID**( *integer* )

The coded character set identifier that messages are transmitted on. Specify a value in the range 1 through 65535.

The CCSID must specify a value that is defined for use on your platform, and use a character set that is appropriate to the platform. If you use this parameter to change the CCSID, applications that are running when the change is applied continue to use the original CCSID. Because of this, you must stop and restart all running applications before you continue. This includes the command server and channel programs. To do this, stop and restart the queue manager after making the change.

The default value is ASPUB which means that the coded character set is taken from the one that is supplied in the published message.

## COMMEV

Controls whether event messages are generated for Multicast handles that are created using this COMMINFO object. Events will only be generated if they are enabled using the **MONINT** parameter.

### DISABLED

Event messages are not generated for Multicast handles that are created using the COMMINFO object. This is the default value.

### ENABLED

Event messages are generated for Multicast handles that are created using the COMMINFO object.

### EXCEPTION

Event messages are written if the message reliability is below the reliability threshold. The reliability threshold is set to 90 by default.

## DESCR( *string* )

Plain-text comment. It provides descriptive information about the communication information object when an operator issues the DISPLAY COMMINFO command (see "DISPLAY COMMINFO" on page 798 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

## ENCODING

The encoding that the messages are transmitted in.

### ASPUB

The encoding of the message is taken from the one that is supplied in the published message. This is the default value.

### REVERSED

### NORMAL

### S390

### TNS

### *encoding*

## GRPADDR

The group IP address or DNS name.

It is the administrator's responsibility to manage the group addresses. It is possible for all multicast clients to use the same group address for every topic; only the messages that match outstanding subscriptions on the client are delivered. Using the same group address can be inefficient because every client must examine and process every multicast packet in the network.

It is more efficient to allocate different IP group addresses to different topics or sets of topics, but this requires careful management, especially if other non-MQ multicast applications are in use on the network. The default value is 239.0.0.0.

#### **MCHBINT**

The heartbeat interval is measured in milliseconds, and specifies the frequency at which the transmitter notifies any receivers that there is no further data available. The value is in the range 0 to 999 999. The default value is 2000 milliseconds.

#### **MCPROP**

The multicast properties control how many of the MQMD properties and user properties flow with the message.

##### **All**

All user properties and all the fields of the MQMD are transported.

##### **Reply**

Only user properties, and MQMD fields that deal with replying to the messages, are transmitted. These properties are:

- MsgType
- MessageId
- CorrelId
- ReplyToQ
- ReplyToQmgr

##### **User**

Only the user properties are transmitted.

##### **NONE**

No user properties or MQMD fields are transmitted.

##### **COMPAT**

This value causes the transmission of the message to be done in a compatible mode to RMM. This allows some inter-operation with the current XMS applications and Broker RMM applications.

#### **MONINT( *integer* )**

How frequently, in seconds, that monitoring information is updated. If events messages are enabled, this parameter also controls how frequently event messages are generated about the status of the Multicast handles created using this COMMINFO object.

A value of 0 means that there is no monitoring.

The default value is 60.

#### **MSGHIST**

This value is the amount of message history in kilobytes that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

The value is in the range 0 to 999 999 999. A value of 0 gives the least level of reliability. The default value is 100.

#### **NSUBHIST**

The new subscriber history controls whether a subscriber joining a publication stream receives as much data as is currently available, or receives only publications made from the time of the subscription.

##### **NONE**

A value of NONE causes the transmitter to transmit only publication made from the time of the subscription. This is the default value.

**ALL**

A value of ALL causes the transmitter to retransmit as much history of the topic as is known. In some circumstances this can give a similar behavior to retained publications.

**Note:** Using the value of ALL might have a detrimental effect on performance if there is a large topic history because all the topic history is retransmitted.

**PORT( *integer* )**

The port number to transmit on. The default port number is 1414.

**LIKE( *authinfo-name* )**

The name of a communication information object, with parameters that are used to model this definition.

If this field is not complete, and you do not complete the parameter fields related to the command, the values are taken from the default definition for an object of this type.

This default communication information object definition can be altered by the installation to the default values required.

**REPLACE and NOREPLACE**

Whether the existing definition is to be replaced with this one. This is optional. The default is NOREPLACE. Any object with a different disposition is not changed.

**REPLACE**

The definition replaces an existing definition of the same name. If a definition does not exist, one is created.

**NOREPLACE**

The definition does not replace an existing definition of the same name.

**DEFINE LISTENER:**

Use the MQSC command DEFINE LISTENER to define a new IBM MQ listener definition, and set its parameters.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

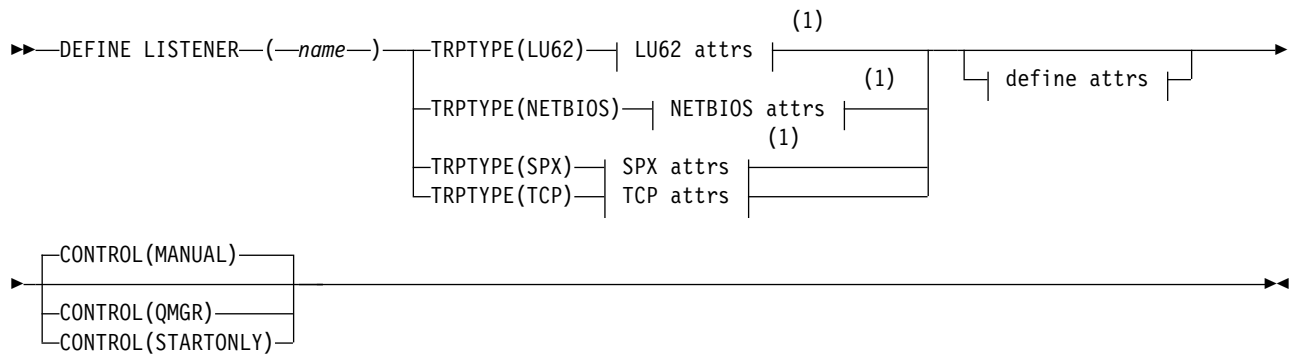

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions for DEFINE LISTENER” on page 620

**Synonym:** DEF LSTR

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

## DEFINE LISTENER

### LU62 attrs:

### NETBIOS attrs:

### SPX attrs:

### TCP attrs:

### Define attrs:

### Notes:

- 1 Valid only on Windows.

- 2 When the BACKLOG attribute is left unchanged or when it is explicitly set to zero, the attribute is stored as zero by default in the listener object created by the **DEFINE LISTENER** command. However, when the listener is started, the default backlog value takes effect. For information about the default value of the BACKLOG attribute, see Using the TCP listener backlog option.

### Parameter descriptions for DEFINE LISTENER

*(listener-name)*

Name of the IBM MQ listener definition (see Rules for naming IBM MQ objects ). This is required.

The name must not be the same as any other listener definition currently defined on this queue manager (unless REPLACE is specified).

**ADAPTER**( *integer* )

The adapter number on which NetBIOS listens. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**BACKLOG**( *integer* )

The number of concurrent connection requests that the listener supports.

**COMMANDS**( *integer* )

The number of commands that the listener can use. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**CONTROL**( *string* )

Specifies how the listener is to be started and stopped.:

#### **MANUAL**

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the START LISTENER and STOP LISTENER commands.

#### **QMGR**

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

#### **STARTONLY**

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

**DESCR**( *string* )

Plain-text comment. It provides descriptive information about the listener when an operator issues the DISPLAY LISTENER command (see "DISPLAY LISTENER" on page 816 ).

It should contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**IPADDR**( *string* )

IP address for the listener specified in IPv4 dotted decimal, IPv6 hexadecimal notation, or alphanumeric host name form. If you do not specify a value for this parameter, the listener listens on all configured IPv4 and IPv6 stacks.

**LIKE**( *listener-name* )

The name of a listener, with parameters that are used to model this definition.

This parameter applies only to the DEFINE LISTENER command.

If this field is not filled in, and you do not complete the parameter fields related to the command, the values are taken from the default definition for listeners on this queue manager. This is equivalent to specifying:

LIKE(SYSTEM.DEFAULT.LISTENER)

A default listener is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

**LOCLNAME( *string* )**

The NetBIOS local name that the listener uses. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**NTBNAMES( *integer* )**

The number of names that the listener can use. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**PORT( *integer* )**

The port number for TCP/IP. This is valid only when TRPTYPE is TCP. It must not exceed 65535.

**SESSIONS( *integer* )**

The number of sessions that the listener can use. This parameter is valid only on Windows when TRPTYPE is NETBIOS.

**SOCKET( *integer* )**

The SPX socket on which to listen. This is valid only if TRPTYPE is SPX.

**TPNAME( *string* )**

The LU 6.2 transaction program name (maximum length 64 characters). This parameter is valid only on Windows when TRPTYPE is LU62.

**TRPTYPE( *string* )**

The transmission protocol to be used:

**LU62**

SNA LU 6.2. This is valid only on Windows.

**NETBIOS**

NetBIOS. This is valid only on Windows.

**SPX**

Sequenced packet exchange. This is valid only on Windows.

**TCP**

TCP/IP.

## DEFINE LOG: z/OS

Use the MQSC command DEFINE LOG to add a new active log data set in the ring of active logs.

### Using MQSC commands

For information on how you use MQSC commands, see *Performing local administration tasks using MQSC commands*.

IBM i	UNIX and Linux	Windows	z/OS
			CR

z/OS For an explanation of the symbols in the z/OS column, see *Using commands on z/OS*.

The named data set is dynamically allocated to the running queue manager, added to either the COPY1 or COPY2 active log and the BSDS updated with the information so it is retained over a queue manager restart. The data set is added to the active log ring in a position such that it will be the next active log used when the current active log fills and an active log switch occurs.

- Syntax diagram
- “Usage note for DEFINE LOG”
- “Parameter descriptions for DEFINE LOG”

**Synonym:** DEF LOG

### DEFINE LOG

#### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.

#### Usage note for DEFINE LOG

If a log data set has to be added because there is no more log space and the queue manager is waiting, you must issue the command from the z/OS console, and not through the command server.

#### Parameter descriptions for DEFINE LOG

(name)

The name of the new log data set. This is required and is the name of a VSAM linear data set which will have already been defined by Access Method Services (and, optionally, formatted by utility CSQJUFMT). This is allocated dynamically to the queue manager.

The maximum length of the string is 44 characters. The string must conform to z/OS data set naming conventions.

#### COPY

Specifies the number of an active log ring to which to add the new log data set. This is either 1 or 2 and is required.

## CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

## DEFINE MAXSMGS: z/OS

Use the MQSC command DEFINE MAXSMGS to define the maximum number of messages that a task can get or put within a single unit of recovery.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes”
- “Parameter descriptions for DEFINE MAXSMGS” on page 624

**Synonym:** DEF MAXSM

## DEFINE MAXSMGS

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.

### Usage notes

1. This command is valid only on z/OS and is retained for compatibility with earlier releases, although it can no longer be issued from the CSQINP1 initialization input data set. You should use the MAXUMSGS parameter of the ALTER QMGR command instead.
2. You can issue the DEFINE MAXSMGS command to change the number of messages allowed. Once a value is set, it is preserved during a queue manager restart.

## Parameter descriptions for DEFINE MAXSMGS

(integer)

The maximum number of messages that a task can get or put within a single unit of recovery. This value must be an integer in the range 1 through 999999999. The default value is 10000.

The number includes any trigger messages and report messages generated within the same unit of recovery.

## CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

## DEFINE NAMELIST:

Use the MQSC command DEFINE NAMELIST to define a list of names. This is most commonly a list of cluster names or queue names.

## Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

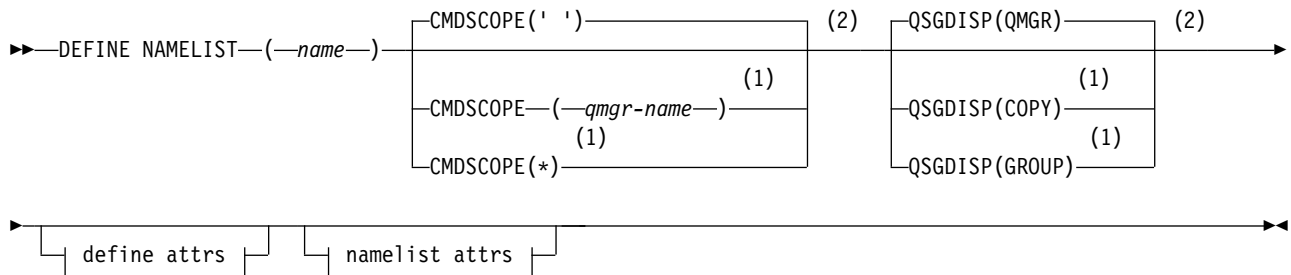

▶ **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes” on page 625
- “Parameter descriptions for DEFINE NAMELIST” on page 625

**Synonym:** DEF NL

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

## DEFINE NAMELIST

### Define attrs:

### Namelist attrs:

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Usage notes

- On UNIX systems, the command is valid only on AIX, HP-UX, Linux and Solaris.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE NAMELIST step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for DEFINE NAMELIST

(*name*)

Name of the list.

The name must not be the same as any other namelist name currently defined on this queue manager (unless REPLACE or ALTER is specified). See Rules for naming IBM MQ objects.

#### z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of specifying \* is the same as entering the command on every queue manager in the queue-sharing group.

#### **DESCR**( *string* )

Plain-text comment. It provides descriptive information about the namelist when an operator issues the DISPLAY NAMELIST command (see "DISPLAY NAMELIST" on page 826 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

#### **LIKE**( *namelist-name* )

The name of a namelist, with parameters that are used to model this definition.

If this field is not completed and you do not complete the parameter fields related to the command, the values are taken from the default definition for namelists on this queue manager.

Not completing this parameter is equivalent to specifying:

LIKE(SYSTEM.DEFAULT.NAMELIST)

A default namelist definition is provided, but it can be altered by the installation to the default values required. See Rules for naming IBM MQ objects.

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

#### **Note:**

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

#### **NAMES**( *name, ...* )

List of names.

The names can be of any type, but must conform to the rules for naming IBM MQ objects, with a maximum length of 48 characters.

An empty list is valid: specify NAMES(). The maximum number of names in the list is 256.

#### **NLTYPE**

Indicates the type of names in the namelist.

This parameter is valid only on z/OS.

#### **NONE**

The names are of no particular type.

#### **QUEUE or Q**

A namelist that holds a list of queue names.

#### **CLUSTER**

A namelist that is associated with clustering, containing a list of the cluster names.

**AUTHINFO**

This namelist is associated with SSL and contains a list of authentication information object names.

Namelists used for clustering must have NLTYPE(CLUSTER) or NLTYPE(NONE).

Namelists used for SSL must have NLTYPE(AUTHINFO).

**z/OS** **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	DEFINE
<b>COPY</b>	The object is defined on the page set of the queue manager that executes the command using the QSGDISP(GROUP) object of the same name as the 'LIKE' object.
<b>GROUP</b>	The object definition resides in the shared repository but only if the queue manager is in a queue-sharing group. If the definition is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to make or refresh local copies on page set zero:  <pre>DEFINE NAMELIST(name) REPLACE QSGDISP(COPY)</pre> <p>The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
<b>PRIVATE</b>	Not permitted.
<b>QMGR</b>	The object is defined on the page set of the queue manager that executes the command.

**REPLACE and NOREPLACE**

Whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. Any object with a different disposition is not changed.

**REPLACE**

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

**NOREPLACE**

The definition does not replace any existing definition of the same name.

## DEFINE PROCESS:

Use the MQSC command DEFINE PROCESS to define a new IBM MQ, process definition, and set its parameters.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

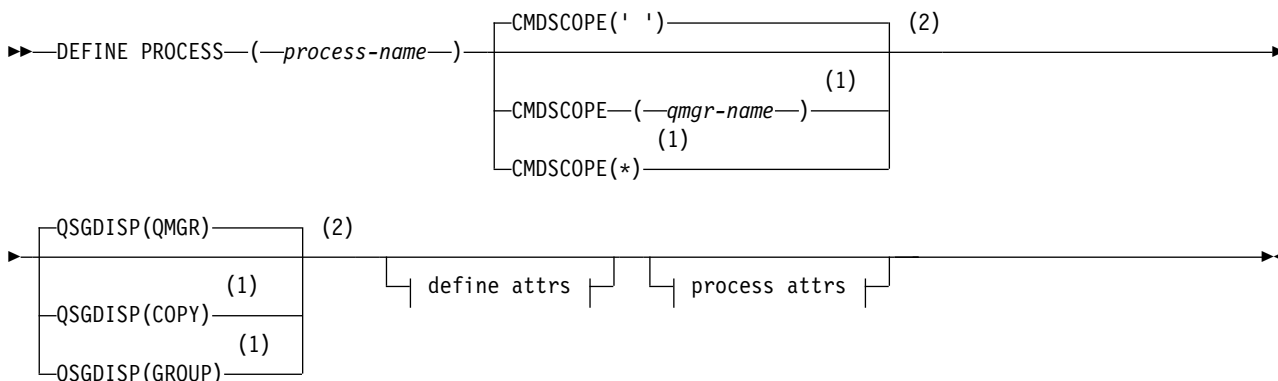

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DEFINE PROCESS” on page 629

**Synonym:** DEF PRO

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

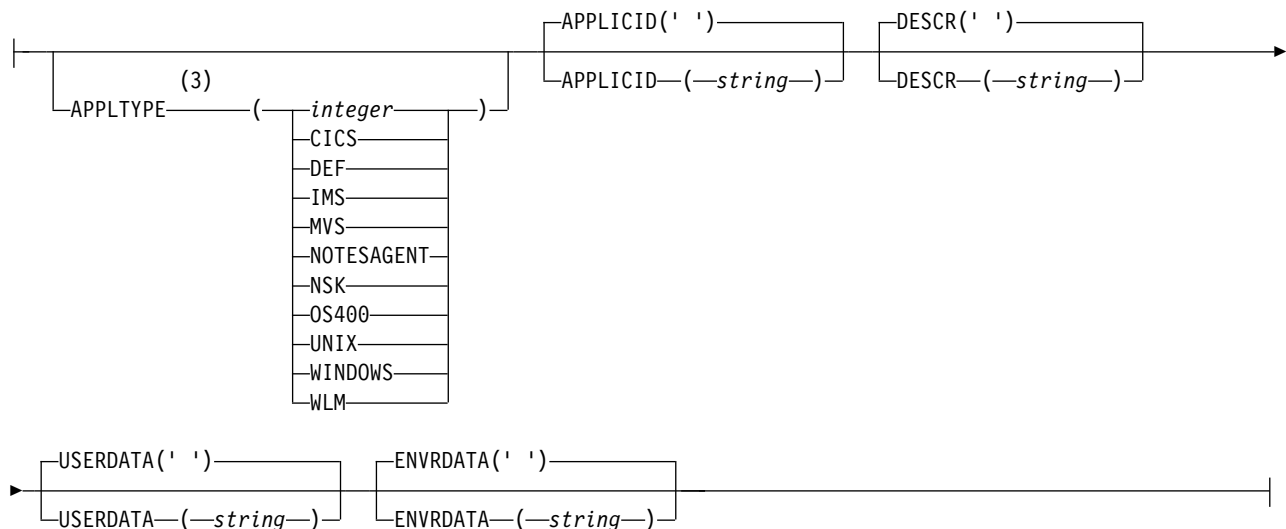

## DEFINE PROCESS

### Define attrs:

### Process attrs:

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 The default depends on the platform, and can be changed by your installation.

**Parameter descriptions for DEFINE PROCESS**

(*process-name*)

Name of the IBM MQ process definition (see Rules for naming IBM MQ objects ). *process-name* is required.

The name must not be the same as any other process definition currently defined on this queue manager (unless REPLACE is specified).

**APPLICID( *string* )**

The name of the application to be started. The name might typically be a fully qualified file name of an executable object. Qualifying the file name is particularly important if you have multiple IBM MQ installations, to ensure the correct version of the application is run. The maximum length is 256 characters.

For a CICS application the name is a CICS transaction ID.

▶ **z/OS** For an IMS application, it is an IMS transaction ID.

▶ **z/OS** On z/OS, for distributed queuing, it must be **CSQX START**.

**APPLTYPE( *string* )**

The type of application to be started. Valid application types are:

**integer**

A system-defined application type in the range zero through 65 535 or a user-defined application type in the range 65 536 through 999 999 999.

For certain values in the system range, a parameter from the following list can be specified instead of a numeric value:

**CICS** Represents a CICS transaction.

▶ **z/OS** **IMS**

Represents an IMS transaction.

▶ **z/OS** **MVS**

Represents a z/OS application (batch or TSO).

**NOTESAGENT**

Represents a Lotus Notes agent.

**NSK** Represents an HP Integrity NonStop Server application.

▶ **IBM i** **OS400**

Represents an IBM i application.

**UNIX** Represents a UNIX application.

**WINDOWS**

Represents a Windows application.

▶ **z/OS** **WLM**

Represents a z/OS workload manager application.

**DEF** Specifying DEF causes the default application type for the platform at which the command is interpreted to be stored in the process definition. This default cannot be changed by the installation. If the platform supports clients, the default is interpreted as the default application type of the server.

Only use application types (other than user-defined types) that are supported on the platform at which the command is run:

- ▶ **z/OS** On z/OS, CICS, IMS, MVS, UNIX, WINDOWS, WLM, and DEF are supported
- On IBM i, OS400, CICS, and DEF are supported
- On UNIX systems, UNIX, WINDOWS, CICS, and DEF are supported
- On Windows, WINDOWS, UNIX, CICS, and DEF are supported

▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

In a shared queue environment, you can provide a different queue manager name from the one you are using to enter the command. The command server must be enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect is the same as entering the command on every queue manager in the queue-sharing group.

**DESCR**( *string* )

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY PROCESS command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** Use characters from the coded character set identifier (CCSID) for this queue manager. Other characters might be translated incorrectly if the information is sent to another queue manager.

## ENVRDATA( *string* )

A character string that contains environment information pertaining to the application to be started. The maximum length is 128 characters.

The meaning of ENVRDATA is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ appends ENVRDATA to the parameter list passed to the started application. The parameter list consists of the MQTMC2 structure, followed by one blank, followed by ENVRDATA with trailing blanks removed.

### Notes:

1.  On z/OS, ENVRDATA is not used by the trigger-monitor applications provided by IBM MQ.
2.  On z/OS, if APPLTYPE is WLM, the default values for the ServiceName and ServiceStep fields in the work information header (MQWIH) can be supplied in ENVRDATA. The format must be:  
SERVICENAME=servname,SERVICESTEP=stepname

where:

**SERVICENAME=**  
is the first 12 characters of ENVRDATA.

**servname**  
is a 32-character service name. It can contain embedded blanks or any other data, and have trailing blanks. It is copied to the MQWIH as is.

**SERVICESTEP=**  
is the next 13 characters of ENVRDATA.

**stepname**  
is a 1 - 8 character service step name. It is copied as-is to the MQWIH, and padded to eight characters with blanks.

If the format is incorrect, the fields in the MQWIH are set to blanks.

3. On UNIX systems, ENVRDATA can be set to the ampersand character to make the started application run in the background.

## LIKE( *process-name* )

The name of an object of the same type, with parameters that are used to model this definition.

If this field is not provided, the values of fields you do not provide are taken from the default definition for this object.

Using LIKE is equivalent to specifying:

LIKE(SYSTEM.DEFAULT.PROCESS)

A default definition for each object type is provided. You can alter the provided defaults to the default values required. See Rules for naming IBM MQ objects.

 On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

### Note:

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

## QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command. It uses the QSGDISP(GROUP) object of the same name as the 'LIKE' object.
GROUP	The object definition resides in the shared repository. GROUP is allowed only if the queue manager is in a queue-sharing group. If the definition is successful, the following command is generated. <pre>DEFINE PROCESS(process-name) REPLACE QSGDISP(COPY)</pre> <p>The command is sent to all active queue managers in the queue-sharing group to attempt to make or refresh local copies on page set zero. The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

## REPLACE and NOREPLACE

Whether the existing definition  (and on z/OS, with the same disposition) is to be replaced with this one. REPLACE is optional. Any object with a different disposition is not changed.

### REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

### NOREPLACE

The definition does not replace any existing definition of the same name.

## USERDATA( *string* )

A character string that contains user information pertaining to the application defined in the APPLICID that is to be started. The maximum length is 128 characters.

The meaning of USERDATA is determined by the trigger-monitor application. The trigger monitor provided by IBM MQ simply passes USERDATA to the started application as part of the parameter list. The parameter list consists of the MQTMC2 structure (containing USERDATA), followed by one blank, followed by ENVRDATA with trailing blanks removed.

For IBM MQ message channel agents, the format of this field is a channel name of up to 20 characters. See Managing objects for triggering for information about what APPLICID to provide to message channel agents.

For Microsoft Windows, the character string must not contain double quotation marks if the process definition is going to be passed to **runmqtrm**.

## DEFINE PSID: z/OS

Use the MQSC command DEFINE PSID to define a page set and associated buffer pool.

### Using MQSC commands

For information on how you use MQSC commands, see [Performing local administration tasks using MQSC commands](#).

IBM i	UNIX and Linux	Windows	z/OS
			1CR

z/OS For an explanation of the symbols in the z/OS column, see [Using commands on z/OS](#).

- Syntax diagram
- “Usage notes for DEFINE PSID”
- “Parameter descriptions for DEFINE PSID” on page 634

**Synonym:** DEF PSID

### DEFINE PSID

### Usage notes for DEFINE PSID

The command can be used in two ways:

1. **At restart, from the CSQINP1 initialization input data set, to specify your standard page sets:**
  - You cannot specify the DSN keyword if issuing the command from CSQINP1.
  - If more than one DEFINE PSID command is issued for the same page set, only the last one is processed.
2. **While the queue manager is running, to dynamically add a page set:**
  - The command must specify the DSN keyword and can be issued from either of the following:
    - The z/OS console.
    - The command server and command queue by means of CSQUTIL, CSQINPX, or applications.
  - The page set identifier (that is the PSID number) may have previously been used by a queue manager. It should therefore be freshly formatted by a FORMAT(RECOVER) statement in CSQUTIL, or formatted by with a FORMAT(REPLACE) in CSQUTIL.
  - You cannot dynamically add page set zero.
  - The BUFFPOOL parameter can specify a currently unused buffer pool. If the buffer pool was defined in CSQINP1 but not used by any PSID, then the number of buffers specified there is created if the required virtual storage is available. If this is not available, or if the buffer pool was not defined in CSQINP1, the queue manager attempts to allocate 1000 buffers. If this is not possible, 100 buffers are allocated.

- You should update your queue manager started task procedure JCL and your CSQINP1 initialization input data set to include the new page set.

One of the messages CSQP042I or CSQP041E is output when the command is complete.

You can use ALTER PSID to dynamically change the expansion method.

You can use the DISPLAY USAGE TYPE(PAGESET) command to display information about page sets (see "DISPLAY USAGE" on page 938 ).

### Parameter descriptions for DEFINE PSID

*(psid-number)*

Identifier of the page set. This is required.

A one-to-one relationship exists between page sets and the VSAM data sets used to store the pages. The identifier consists of a number in the range 00 through 99. It is used to generate a *ddname*, which references the VSAM LDS data set, in the range CSQP0000 through CSQP0099.

The identifier must not be the same as any other page set identifier currently defined on this queue manager.

### BUFFPOOL( *integer* )

The buffer pool number (in the range zero through 15). If OPMODE is set to OPMODE=(NEWFUNC, 800), this number is in the range zero through 99. This is optional. The default is zero.

If the buffer pool has not already been created by a DEFINE BUFFPOOL command, the buffer pool is created with 1000 buffers, and a LOCATION value of BELOW.

If the psid-number is zero, the buffer pool number must be in the range 0 to 15, otherwise the command fails, and the queue manager does not start.

### DSN( *data set name* )

The name of a cataloged VSAM LDS data set. This is optional. There is no default.

### EXPAND

Controls how the queue manager should expand a page set when it becomes nearly full, and further pages are required in a page set.

**USER** The secondary extent size that was specified when the page set was defined is used. If no secondary extent size was specified, or it was specified as zero, no dynamic page set expansion can take place if page set data set is non-striped.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set. Only one extent is required to reach this size.

### SYSTEM

A secondary extent size that is approximately 10 per cent of the current size of the page set is used. It can be rounded up depending on the characteristics of the DASD.

### NONE

No further page set expansion is to take place.

## DEFINE queues:

Use the MQSC **DEFINE** command to define a local, model, or remote queue, or a queue alias, reply-to queue alias, or a queue-manager alias.

## Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

This section contains the following commands:

- “DEFINE QALIAS” on page 658
- “DEFINE QLOCAL” on page 659
- “DEFINE QMODEL” on page 663
- “DEFINE QREMOTE” on page 666

Define a reply-to queue or queue-manager alias with the “DEFINE QREMOTE” on page 666 command.

These commands are supported on the following platforms:

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

► **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

## Usage notes for DEFINE queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE queues step in Checking that async commands for distributed networks have finished.
- For local queues
  1. ► **z/OS** You can define a local queue with QSGDISP(SHARED) even though another queue manager in the queue-sharing group already has a local version of the queue. However, when you try to access the locally defined queue, it fails with reason code MQRC\_OBJECT\_NOT\_UNIQUE (2343). A local version of the queue with the same name can be of type QLOCAL, QREMOTE, or QALIAS and has the disposition, QSGDISP(QMGR).

To resolve the conflict, you must delete one of the queues using the **DELETE** command. If the queue you want to delete contains messages, use the PURGE option or remove the messages first using the **MOVE** command.

For example, to delete the QSGDISP(LOCAL) version, which contains messages, and copy those messages to the QSGDISP(SHARED) version, then issue the following commands:

```
MOVE QLOCAL(Queue.1) QSGDISP(PRIVATE) TOQLOCAL(Queue.1) TYPE(ADD)
DELETE QLOCAL(Queue.1) QSGDISP(QMGR)
```
- For alias queues:
  1. DEFINE QALIAS( *aliasqueue* ) TARGET( *otherqname* ) CLUSTER( *c* ) advertises the queue *otherqname* by the name *aliasqueue*.
  2. DEFINE QALIAS( *aliasqueue* ) TARGET( *otherqname* ) allows a queue advertised by the name *otherqname* to be used on this queue manager by the name *aliasqueue*.
  3. TARGTYPE and TARGET are not cluster attributes, that is, they are not shared in a cluster environment.
- For remote queues:

1. `DEFINE QREMOTE( rqueue ) RNAME( otherq ) RQMNAME( otherqm ) CLUSTER( cl )` advertises this queue manager as a store and forward gateway to which messages for queue *rqueue* can be sent. It has no effect as a reply-to queue alias, except on the local queue manager.  
`DEFINE QREMOTE( otherqm ) RNAME() RQMNAME( anotherqm ) XMITQ( xq ) CLUSTER` advertises this queue manager as a store and forward gateway to which messages for *anotherqm* can be sent.
2. `RQMNAME` can itself be the name of a cluster queue manager within the cluster. You can map the advertised queue manager name to another name locally. The pattern is the same as with `QALIAS` definitions.
3. It is possible for the values of `RQMNAME` and `QREMOTE` to be the same if `RQMNAME` is itself a cluster queue manager. If this definition is also advertised using a `CLUSTER` attribute, do not choose the local queue manager in the cluster workload exit. If you do so, a cyclic definition results.
4. Remote queues do not have to be defined locally. The advantage of doing so is that applications can refer to the queue by a simple, locally defined name. If you do then the queue name is qualified by the name of the queue manager on which the queue resides. Using a local definition means that applications do not need to be aware of the real location of the queue.
5. A remote queue definition can also be used as a mechanism for holding a queue manager alias definition, or a reply-to queue alias definition. The name of the definition in these cases is:
  - The queue manager name being used as the alias for another queue manager name (queue manager alias), or
  - The queue name being used as the alias for the reply-to queue (reply-to queue alias).

#### Parameter descriptions for `DEFINE QUEUE` and `ALTER QUEUE`

Table 99 shows the parameters that are relevant for each type of queue. There is a description of each parameter after the table.

Table 99. `DEFINE` and `ALTER QUEUE` parameters

Parameter	Local queue	Model queue	Alias queue	Remote queue
ACCTQ	✓	✓

Table 99. DEFINE and ALTER QUEUE parameters (continued)

Parameter	Local queue	Model queue	Alias queue	Remote queue
TRIGMPRI	✓	✓		
TRIGTYPE	✓	✓		
USAGE	✓	✓		
XMITQ				✓

*queue-name*

Local name of the queue, except the remote queue where it is the local definition of the remote queue.

The name must not be the same as any other queue name of any queue type currently defined on this queue manager, unless you specify **REPLACE** or **ALTER**. See Rules for naming IBM MQ objects.

**ACCTQ**

Specifies whether accounting data collection is to be enabled for the queue. On z/OS, the data collected is class 3 accounting data (thread-level and queue-level accounting). In order for accounting data to be collected for this queue, accounting data for this connection must also be enabled. Turn on accounting data collection by setting either the **ACCTQ** queue manager attribute, or the options field in the MQCNO structure on the MQCONN call.

**QMGR** The collection of accounting data is based on the setting of the **ACCTQ** parameter on the queue manager definition.

**ON** Accounting data collection is enabled for the queue unless the **ACCTQ** queue manager parameter has a value of NONE. On z/OS systems, you must switch on class 3 accounting using the **START TRACE** command.

**OFF** Accounting data collection is disabled for the queue.

**BOQNAME** ( *queue-name* )

The excessive backout requeue name.

This parameter is supported only on local and model queues.

Use this parameter to set or change the back out queue name attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS transfers a message that is backed out the maximum number of times to this queue. The maximum is specified by the **BOTHRESH** attribute.

**BOTHRESH** ( *integer* )

The backout threshold.

This parameter is supported only on local and model queues.

Use this parameter to set or change the value of the back out threshold attribute of a local or model queue. Apart from allowing its value to be queried, the queue manager does nothing based on the value of this attribute. IBM MQ classes for JMS use the attribute to determine how many times back a message out. When the value is exceeded the message is transferred to the queue named by the **BOQNAME** attribute.

Specify a value in the range 0 - 999,999,999.

▶ **z/OS** **CFSTRUCT** ( *structure-name* )

Specifies the name of the coupling facility structure where you want messages stored when you use shared queues.

This parameter is supported only on z/OS for local and model queues.

The name:

- Cannot have more than 12 characters
- Must start with an uppercase letter (A - Z)
- Can include only the characters A - Z and 0 - 9

The name of the queue-sharing group to which the queue manager is connected is prefixed to the name you supply. The name of the queue-sharing group is always four characters, padded with @ symbols if necessary. For example, if you use a queue-sharing group named NY03 and you supply the name PRODUCT7, the resultant coupling facility structure name is NY03PRODUCT7. The administrative structure for the queue-sharing group (in this case NY03CSQ\_ADMIN) cannot be used for storing messages.

For ALTER QLOCAL, ALTER QMODEL, DEFINE QLOCAL with **REPLACE**, and DEFINE QMODEL with **REPLACE** the following rules apply:

- On a local queue with **QSGDISP** ( SHARED ), **CFSTRUCT** cannot change.  
If you change either the **CFSTRUCT** or **QSGDISP** value you must delete and redefine the queue. To preserve any of the messages on the queue you must offload the messages before you delete the queue. Reload the messages after you redefine the queue, or move the messages to another queue.
- On a model queue with **DEFTYPE** ( SHAREDYN ), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

For DEFINE QLOCAL with **NOREPLACE** and DEFINE QMODEL with **NOREPLACE**, the coupling facility structure:

- On a local queue with **QSGDISP** ( SHARED ) or a model queue with a **DEFTYPE** ( SHAREDYN ), **CFSTRUCT** cannot be blank.
- On a local queue with a **QSGDISP** other than SHARED, or a model queue with a **DEFTYPE** other than SHAREDYN, the value of **CFSTRUCT** does not matter.

**Note:** Before you can use the queue, the structure must be defined in the coupling facility Resource Management (CFRM) policy data set.

#### **CLCHNAME** ( *channel name* )

This parameter is supported only on transmission queues.

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

You can also set the transmission queue attribute CLCHNAME attribute to a cluster-sender channel manually. Messages that are destined for the queue manager connected by the cluster-sender channel are stored in the transmission queue that identifies the cluster-sender channel. They are not stored in the default cluster transmission queue. If you set the CLCHNAME attribute to blanks, the channel switches to the default cluster transmission queue when the channel restarts. The default queue is either SYSTEM.CLUSTER.TRANSMIT. *ChannelName* or SYSTEM.CLUSTER.TRANSMIT.QUEUE, depending on the value of the queue manager DEFCLXQ attribute.

By specifying asterisks, "\*" \* "", in CLCHNAME, you can associate a transmission queue with a set of cluster-sender channels. The asterisks can be at the beginning, end, or any number of places in the middle of the channel name string. CLCHNAME is limited to a length of 48 characters, MQ\_OBJECT\_NAME\_LENGTH. A channel name is limited to 20 characters: MQ\_CHANNEL\_NAME\_LENGTH. If you specify an asterisk you must also set the SHARE attribute so that multiple channels can concurrently access the transmission queue.

► **z/OS** If you specify a "" \* "" in CLCHNAME, to obtain a channel profile name, you must specify the channel profile name within quotation marks. If you do not specify the generic channel name within quotation marks you receive message CSQ9030E.

The default queue manager configuration is for all cluster-sender channels to send messages from a single transmission queue, SYSTEM.CLUSTER.TRANSMIT.QUEUE. The default configuration can be changed by modified by changing the queue manager attribute, DEFCLXQ. The default value of the attribute is SCTQ. You can change the value to CHANNEL. If you set the DEFCLXQ attribute to CHANNEL, each cluster-sender channel defaults to using a specific cluster transmission queue, SYSTEM.CLUSTER.TRANSMIT. *ChannelName*.

► **z/OS** On z/OS, if this parameter is set, the queue:

- Must be shareable, by specifying the queue attribute SHARE.
- Must be indexed on the correlation ID by specifying INDXTYPE(CORRELID).
- Must not be a dynamic or a shared queue.

### **CLUSNL** ( *namelist name* )

The name of the namelist that specifies a list of clusters to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be nonblank; you cannot specify a value for both.

On local queues, this parameter cannot be set for transmission, SYSTEM.CHANNEL. *xx*, SYSTEM.CLUSTER. *xx*, or SYSTEM.COMMAND. *xx* queues ► **z/OS** , and on z/OS only, for SYSTEM.QSG. *xx* queues.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS.

### **CLUSTER** ( *cluster name* )

The name of the cluster to which the queue belongs.

This parameter is supported only on alias, local, and remote queues.

The maximum length is 48 characters conforming to the rules for naming IBM MQ objects. Changes to this parameter do not affect instances of the queue that are already open.

Only one of the resultant values of **CLUSNL** or **CLUSTER** can be nonblank; you cannot specify a value for both.

On local queues, this parameter cannot be set for transmission, SYSTEM.CHANNEL. *xx*, SYSTEM.CLUSTER. *xx*, or SYSTEM.COMMAND. *xx* queues ► **z/OS** , and on z/OS only, for SYSTEM.QSG. *xx* queues.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS.

### **CLWLPRTY** ( *integer* )

Specifies the priority of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest priority and 9 is the highest. For more information about this attribute, see CLWLPRTY queue attribute.

### **CLWLRANK** ( *integer* )

Specifies the rank of the queue for the purposes of cluster workload distribution. This parameter is valid only for local, remote, and alias queues. The value must be in the range zero through 9 where zero is the lowest rank and 9 is the highest. For more information about this attribute, see CLWLRANK queue attribute.

## CLWLUSEQ

Specifies the behavior of an MQPUT operation when the target queue has a local instance and at least one remote cluster instance. The parameter has no effect when the MQPUT originates from a cluster channel. This parameter is valid only for local queues.

**QMGR** The behavior is as specified by the **CLWLUSEQ** parameter of the queue manager definition.

**ANY** The queue manager is to treat the local queue as another instance of the cluster queue for the purposes of workload distribution.

**LOCAL** The local queue is the only target of the MQPUT operation.

z/OS

## CMDSCOPE

This parameter applies to z/OS only. It specifies where the command is run when the queue manager is a member of a queue-sharing group.

**CMDSCOPE** must be blank, or the local queue manager, if **QSGDISP** is set to GROUP or SHARED.

' ' The command is run on the queue manager on which it was entered.

### *QmgrName*

The command is run on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can specify another name, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

## CUSTOM ( *string* )

The custom attribute for new features.

**V8.0.0.4** This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name and value pairs have the form NAME(VALUE). Single quotation marks must be escaped with another single quotation mark.

## CAPEXPY ( *integer* )

The maximum time, expressed in tenths of a second, until a message put using an object handle with this object in the resolution path, becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

*integer* The value must be in the range one through to 999 999 999.

## NOLIMIT

There is no limit on the expiry time of messages put using this object. This is the default value.

Specifying a value for CAPEXPY that is not valid, does not cause the command to fail. Instead the default value is used.

Note that existing messages in the queue, prior to a change in **CAPEXPY**, are not affected by the change (that is, their expiry time remains intact). Only new messages that are put into the queue after the change in **CAPEXPY** have the new expiry time.

## DEFBIND

Specifies the binding to be used when the application specifies MQ00\_BIND\_AS\_Q\_DEF on the MQOPEN call, and the queue is a cluster queue.

**OPEN** The queue handle is bound to a specific instance of the cluster queue when the queue is opened.

**NOTFIXED**

The queue handle is not bound to any instance of the cluster queue. The queue manager selects a specific queue instance when the message is put using MQPUT. It changes that selection later, if the need arises.

**GROUP** Allows an application to request that a group of messages is allocated to the same destination instance.

Multiple queues with the same name can be advertised in a queue manager cluster. An application can send all messages to a single instance, MQOO\_BIND\_ON\_OPEN. It can allow a workload management algorithm to select the most suitable destination on a per message basis, MQOO\_BIND\_NOT\_FIXED. It can allow an application to request that a “group” of messages be all allocated to the same destination instance. The workload balancing reselects a destination between groups of messages, without requiring an MQCLOSE and MQOPEN of the queue.

The MQPUT1 call always behaves as if NOTFIXED is specified.

This parameter is valid only on AIX, HP-UX, Linux, IBM i, Solaris, and Windows , and z/OS.

**DEFPRESP**

Specifies the behavior to be used by applications when the put response type, within the MQPMO options, is set to MQPMO\_RESPONSE\_AS\_Q\_DEF.

**SYNC** Put operations to the queue specifying MQPMO\_RESPONSE\_AS\_Q\_DEF are issued as if MQPMO\_SYNC\_RESPONSE is specified instead.

**ASYN** Put operations to the queue specifying MQPMO\_RESPONSE\_AS\_Q\_DEF are issued as if MQPMO\_ASYNC\_RESPONSE is specified instead; see MQPMO options (MQLONG).

**DEFPRTY ( integer )**

The default priority of messages put on the queue. The value must be in the range 0 - 9. Zero is the lowest priority, through to the **MAXPRTY** queue manager parameter. The default value of **MAXPRTY** is 9.

**DEFPSIST**

Specifies the message persistence to be used when applications specify the MQPER\_PERSISTENCE\_AS\_Q\_DEF option.

**NO** Messages on this queue are lost across a restart of the queue manager.

**YES** Messages on this queue survive a restart of the queue manager.

 On z/OS, N and Y are accepted as synonyms of NO and YES.

**DEFREADA**

Specifies the default read ahead behavior for non-persistent messages delivered to the client. Enabling read ahead can improve the performance of client applications consuming non-persistent messages.

**NO** Non-persistent messages are not read ahead unless the client application is configured to request read ahead.

**YES** Non-persistent messages are sent to the client before an application requests them. Non-persistent messages can be lost if the client ends abnormally or if the client does not delete all the messages it is sent.

**DISABLED**

Read ahead of non-persistent messages is not enabled for this queue. Messages are not sent ahead to the client regardless of whether read ahead is requested by the client application.

**DEFSOPT**

The default share option for applications opening this queue for input:

**EXCL** The open request is for exclusive input from the queue

**SHARED**

The open request is for shared input from the queue

**DEFTYPE**

Queue definition type.

This parameter is supported only on model queues.

**PERMDYN**

A permanent dynamic queue is created when an application issues an MQOPEN MQI call with the name of this model queue specified in the object descriptor ( MQOD).

▶ **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

▶ **z/OS** **SHAREDYN**

This option is available on z/OS only.

A permanent dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor ( MQOD).

The dynamic queue has a disposition of SHARED.

**TEMPDYN**

A temporary dynamic queue is created when an application issues an MQOPEN API call with the name of this model queue specified in the object descriptor ( MQOD).

▶ **z/OS** On z/OS, the dynamic queue has a disposition of QMGR.

Do not specify this value for a model queue definition with a **DEFPSIST** parameter of YES.

If you specify this option, do not specify **INDXTYPE** ( MSGTOKEN ).

**DESCR** ( *string* )

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY QUEUE command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** Use characters that are in the coded character set identifier (CCSID) of this queue manager. If you do not do so and if the information is sent to another queue manager, they might be translated incorrectly.

**DISTL**

**DISTL** sets whether distribution lists are supported by the partner queue manager.

**YES** Distribution lists are supported by the partner queue manager.

**NO** Distribution lists are not supported by the partner queue manager.

**Note:** You do not normally change this parameter, because it is set by the MCA. However you can set this parameter when defining a transmission queue if the distribution list capability of the destination queue manager is known.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows.

**FORCE**

This parameter applies only to the ALTER command on alias, local and remote queues.

Specify this parameter to force completion of the command in the following circumstances.

For an alias queue, if both of the following are true:

- The **TARGQ** parameter is specified

- An application has this alias queue open

For a local queue, if both of the following are true:

- The **NOSHARE** parameter is specified
- More than one application has the queue open for input

**FORCE** is also needed if both of the following are true:

- The **USAGE** parameter is changed
- Either one or more messages are on the queue, or one or more applications have the queue open

Do not change the **USAGE** parameter while there are messages on the queue; the format of messages changes when they are put on a transmission queue.

For a remote queue, if both of the following are true:

- The **XMITQ** parameter is changed
- One or more applications has this queue open as a remote queue

**FORCE** is also needed if both of the following are true:

- Any of the **RNAME**, **RQMNAME**, or **XMITQ** parameters are changed
- One or more applications has a queue open that resolved through this definition as a queue manager alias

**Note:** **FORCE** is not required if this definition is in use as a reply-to queue alias only.

If **FORCE** is not specified in the circumstances described, the command is unsuccessful.

**GET** Specifies whether applications are to be permitted to get messages from this queue:

**ENABLED**

Messages can be retrieved from the queue, by suitably authorized applications.

**DISABLED**

Applications cannot retrieve messages from the queue.

This parameter can also be changed using the MQSET API call.

**HARDENBO & NOHARDENBO**

Specifies whether hardening is used to ensure that the count of the number of times that a message is backed out is accurate.

This parameter is supported only on local and model queues and you can set this parameter on distributed platforms, but it is ineffective..

**HARDENBO**

The count is hardened.

**NOHARDENBO**

The count is not hardened.

**Note:**  This parameter affects only IBM MQ for z/OS.

 **INDXTYPE**

The type of index maintained by the queue manager to expedite MQGET operations on the queue. For shared queues, the type of index determines the type of MQGET operations that can be used.

This parameter is supported only on local and model queues.

Messages can be retrieved using a selection criterion only if an appropriate index type is maintained, as the following table shows:

Retrieval selection criterion	Index type required	
	Shared queue	Other queue
None (sequential retrieval)	Any	Any
Message identifier	MSGID or NONE	Any
Correlation identifier	CORRELID	Any
Message and correlation identifiers	MSGID or CORRELID	Any
Group identifier	GROUPID	Any
Grouping	GROUPID	GROUPID
Message token	Not allowed	MSGTOKEN

where the value of **INDXTYPE** parameter has the following values:

**NONE** No index is maintained. Use **NONE** when messages are typically retrieved sequentially or use both the message identifier and the correlation identifier as a selection criterion on the **MQGET** call.

**MSGID** An index of message identifiers is maintained. Use **MSGID** when messages are typically retrieved using the message identifier as a selection criterion on the **MQGET** call with the correlation identifier set to **NULL**.

**CORRELID**

An index of correlation identifiers is maintained. Use **CORRELID** when messages are typically retrieved using the correlation identifier as a selection criterion on the **MQGET** call with the message identifier set to **NULL**.

**GROUPID**

An index of group identifiers is maintained. Use **GROUPID** when messages are retrieved using message grouping selection criteria.

**Note:**

1. You cannot set **INDXTYPE** to **GROUPID** if the queue is a transmission queue.
2. The queue must use a CF structure at **CFLEVEL(3)**, to specify a shared queue with **INDXTYPE ( GROUPID )**.

**z/OS MSGTOKEN**

An index of message tokens is maintained. Use **MSGTOKEN** when the queue is a WLM-managed queue that you are using with the Workload Manager functions of z/OS.

**Note:** You cannot set **INDXTYPE** to **MSGTOKEN** if:

- The queue is a model queue with a definition type of **SHAREDYN**
- The queue is a temporary dynamic queue
- The queue is a transmission queue
- You specify **QSGDISP ( SHARED )**

For queues that are not shared and do not use grouping or message tokens, the index type does not restrict the type of retrieval selection. However, the index is used to expedite **GET** operations on the queue, so choose the type that corresponds to the most common retrieval selection.

If you are altering or replacing an existing local queue, you can change the **INDXTYPE** parameter only in the cases indicated in the following table:

Queue type		NON-SHARED			SHARED	
Queue state		Uncommitted activity	No uncommitted activity, messages present	No uncommitted activity, and empty	Open or messages present	Not open, and empty
Change INDXTYPE from:	To:	Change allowed?				
NONE	MSGID	No	Yes	Yes	No	Yes
NONE	CORRELID	No	Yes	Yes	No	Yes
NONE	MSGTOKEN	No	No	Yes	-	-
NONE	GROUPLD	No	No	Yes	No	Yes
MSGID	NONE	No	Yes	Yes	No	Yes
MSGID	CORRELID	No	Yes	Yes	No	Yes
MSGID	MSGTOKEN	No	No	Yes	-	-
MSGID	GROUPLD	No	No	Yes	No	Yes
CORRELID	NONE	No	Yes	Yes	No	Yes
CORRELID	MSGID	No	Yes	Yes	No	Yes
CORRELID	MSGTOKEN	No	No	Yes	-	-
CORRELID	GROUPLD	No	No	Yes	No	Yes
MSGTOKEN	NONE	No	Yes	Yes	-	-
MSGTOKEN	MSGID	No	Yes	Yes	-	-
MSGTOKEN	CORRELID	No	Yes	Yes	-	-
MSGTOKEN	GROUPLD	No	No	Yes	-	-
GROUPLD	NONE	No	No	Yes	No	Yes
GROUPLD	MSGID	No	No	Yes	No	Yes
GROUPLD	CORRELID	No	No	Yes	No	Yes
GROUPLD	MSGTOKEN	No	No	Yes	-	-

This parameter is supported only on z/OS. On other platforms, all queues are automatically indexed.

**INITQ** (*string*)

The local name of the initiation queue on this queue manager, to which trigger messages relating to this queue are written; see Rules for naming IBM MQ objects.

This parameter is supported only on local and model queues.

**LIKE** (*qtype-name*)

The name of a queue, with parameters that are used to model this definition.

If this field is not completed, the values of undefined parameter fields are taken from one of the following definitions. The choice depends on the queue type:

Queue type	Definition
Alias queue	SYSTEM.DEFAULT.ALIAS.QUEUE
Local queue	SYSTEM.DEFAULT.LOCAL.QUEUE
Model queue	SYSTEM.DEFAULT.MODEL.QUEUE
Remote queue	SYSTEM.DEFAULT.REMOTE.QUEUE

For example, not completing this parameter is equivalent to defining the following value of **LIKE** for an alias queue:

```
LIKE(SYSTEM.DEFAULT.ALIAS.QUEUE)
```

If you require different default definitions for all queues, alter the default queue definitions instead of using the **LIKE** parameter.

► **z/OS** On z/OS, the queue manager searches for an object with the name and queue type you specify with a disposition of QMGR, COPY, or SHARED. The disposition of the **LIKE** object is not copied to the object you are defining.

**Note:**

1. **QSGDISP** ( GROUP ) objects are not searched.
2. **LIKE** is ignored if **QSGDISP** ( COPY ) is specified.

**MAXDEPTH** ( *integer* )

The maximum number of messages allowed on the queue.

This parameter is supported only on local and model queues.

On AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS, specify a value in the range zero through 999999999.

This parameter is valid only on AIX, HP-UX, Linux, Solaris, and Windows ► **z/OS** , and z/OS.

On any other IBM MQ platform, specify a value in the range zero through 640000.

Other factors can still cause the queue to be treated as full, for example, if there is no further hard disk space available.

If this value is reduced, any messages that are already on the queue that exceed the new maximum remain intact.

**MAXMSGL** ( *integer* )

The maximum length (in bytes) of messages on this queue.

This parameter is supported only on local and model queues.

On AIX, HP-UX, Linux, Solaris, and Windows, specify a value in the range zero to the maximum message length for the queue manager. See the **MAXMSGL** parameter of the ALTER QMGR command, ALTER QMGR MAXMSGL.

► **z/OS** On z/OS, specify a value in the range zero through 100 MB (104 857 600 bytes).

Message length includes the length of user data and the length of headers. For messages put on the transmission queue, there are additional transmission headers. Allow an additional 4000 bytes for all the message headers.

If this value is reduced, any messages that are already on the queue with length that exceeds the new maximum are not affected.

Applications can use this parameter to determine the size of buffer for retrieving messages from the queue. Therefore, the value can be reduced only if it is known that this reduction does not cause an application to operate incorrectly.

Note that by adding the digital signature and key to the message, IBM MQ Advanced Message Security increases the length of the message.

## MONQ

Controls the collection of online monitoring data for queues.

This parameter is supported only on local and model queues.

**QMGR** Collect monitoring data according to the setting of the queue manager parameter **MONQ**.

**OFF** Online monitoring data collection is turned off for this queue.

**LOW** If the value of the **MONQ** parameter of the queue manager is not **NONE**, online monitoring data collection is turned on for this queue.

### MEDIUM

If the value of the **MONQ** parameter of the queue manager is not **NONE**, online monitoring data collection is turned on for this queue.

**HIGH** If the value of the **MONQ** parameter of the queue manager is not **NONE**, online monitoring data collection is turned on for this queue.

There is no distinction between the values **LOW**, **MEDIUM**, and **HIGH**. These values all turn data collection on, but do not affect the rate of collection.

When this parameter is used in an **ALTER** queue command, the change is effective only when the queue is next opened.

## MSGDLVSQ

Message delivery sequence.

This parameter is supported only on local and model queues.

### PRIORITY

Messages are delivered (in response to **MQGET** API calls) in first-in-first-out (FIFO) order within priority.

**FIFO** Messages are delivered (in response to **MQGET** API calls) in FIFO order. Priority is ignored for messages on this queue.

The message delivery sequence parameter can be changed from **PRIORITY** to **FIFO** while there are messages on the queue. The order of the messages already on the queue is not changed. Messages added to the queue later take the default priority of the queue, and so might be processed before some of the existing messages.

If the message delivery sequence is changed from **FIFO** to **PRIORITY**, the messages put on the queue while the queue was set to **FIFO** take the default priority.

**Note:**  If **INDXTYPE** ( **GROUPID** ) is specified with **MSGDLVSQ** ( **PRIORITY** ), the priority in which groups are retrieved is based on the priority of the first message within each group. The priorities 0 and 1 are used by the queue manager to optimize the retrieval of messages in logical order. The first message in each group must not use these priorities. If it does, the message is stored as if it was priority two.

## NPMCLASS

The level of reliability to be assigned to non-persistent messages that are put to the queue:

**NORMAL** Non-persistent messages are lost after a failure, or queue manager shutdown. These messages are discarded on a queue manager restart.

**HIGH** The queue manager attempts to retain non-persistent messages on this queue over a queue manager restart or switch over.

 You cannot set this parameter on z/OS.

## PROCESS ( *string* )

The local name of the IBM MQ process.

This parameter is supported only on local and model queues.

This parameter is the name of a process instance that identifies the application started by the queue manager when a trigger event occurs; see Rules for naming IBM MQ objects.

The process definition is not checked when the local queue is defined, but it must be available for a trigger event to occur.

If the queue is a transmission queue, the process definition contains the name of the channel to be started. This parameter is optional for transmission queues on AIX, HP-UX, IBM i, Linux, Solaris, and Windows  z/OS, and z/OS. If you do not specify it, the channel name is taken from the value specified for the **TRIGDATA** parameter.

## PROPCTL

Property control attribute. The attribute is optional. It is applicable to local, alias, and model queues.

**PROPCTL** options are as follows. The options do not affect message properties in the MQMD or MQMD extension.

### ALL

Set ALL so that an application can read all the properties of the message either in MQRFH2 headers, or as properties of the message handle.

The ALL option enables applications that cannot be changed to access all the message properties from MQRFH2 headers. Applications that can be changed, can access all the properties of the message as properties of the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

### COMPAT

Set COMPAT so that unmodified applications that expect JMS-related properties to be in an MQRFH2 header in the message data continue to work as before. Applications that can be changed, can access all the properties of the message as properties of the message handle.

If the message contains a property with a prefix of *mcd.*, *jms.*, *usr.*, or *mqext.*, all message properties are delivered to the application. If no message handle is supplied, properties are returned in an MQRFH2 header. If a message handle is supplied, all properties are returned in the message handle.

If the message does not contain a property with one of those prefixes, and the application does not provide a message handle, no message properties are returned to the application. If a message handle is supplied, all properties are returned in the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

### FORCE

Force all applications to read message properties from MQRFH2 headers.

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the `MQGMO` structure on the `MQGET` call is ignored. Properties of the message are not accessible using the message handle.

In some cases, the format of data in MQRFH2 headers in the received message might be different to the format in the message when it was sent.

#### **NONE**

If a message handle is supplied, all the properties are returned in the message handle.

All message properties are removed from the message body before it is delivered to the application.

**PUT** Specifies whether messages can be put on the queue.

#### **ENABLED**

Messages can be added to the queue (by suitably authorized applications).

#### **DISABLED**

Messages cannot be added to the queue.

This parameter can also be changed using the MQSET API call.

#### **QDEPTHHI** ( *integer* )

The threshold against which the queue depth is compared to generate a Queue Depth High event.

This parameter is supported only on local and model queues.  For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events ( IBM MQ for z/OS ).

This event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDPHIEV** parameter.

The value is expressed as a percentage of the maximum queue depth ( **MAXDEPTH** parameter), and must be in the range zero through 100 and no less than **QDEPTHLO**.

#### **QDEPTHLO** ( *integer* )

The threshold against which the queue depth is compared to generate a Queue Depth Low event.

This parameter is supported only on local and model queues.  For more information about the effect that shared queues on z/OS have on this event; see Shared queues and queue depth events ( IBM MQ for z/OS ).

This event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDPLOEV** parameter.

The value is expressed as a percentage of the maximum queue depth ( **MAXDEPTH** parameter), and must be in the range zero through 100 and no greater than **QDEPTHHI**.

#### **QDPHIEV**

Controls whether Queue Depth High events are generated.

This parameter is supported only on local and model queues.

A Queue Depth High event indicates that an application put a message on a queue resulting in the number of messages on the queue becoming greater than or equal to the queue depth high threshold. See the **QDEPTHHI** parameter.

**Note:** The value of this parameter can change implicitly  , and shared queues on z/OS affect the event. See the description of Queue Depth High.

#### **ENABLED**

Queue Depth High events are generated

**DISABLED**

Queue Depth High events are not generated

**QDPLOEV**

Controls whether Queue Depth Low events are generated.

This parameter is supported only on local and model queues.

A Queue Depth Low event indicates that an application retrieved a message from a queue resulting in the number of messages on the queue becoming less than or equal to the queue depth low threshold. See the **QDEPTHLO** parameter.

**Note:** The value of this parameter can change implicitly , and shared queues on z/OS affect the event. For more information about this event, see Queue Depth Low.

**ENABLED**

Queue Depth Low events are generated

**DISABLED**

Queue Depth Low events are not generated

**QDPMAXEV**

Controls whether Queue Full events are generated.

This parameter is supported only on local and model queues.

A Queue Full event indicates that a put to a queue was rejected because the queue is full. The queue depth reached its maximum value.

**Note:** The value of this parameter can change implicitly , and shared queues on z/OS affect the event. For more information about this event, see Queue Full.

**ENABLED**

Queue Full events are generated

**DISABLED**

Queue Full events are not generated

 **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

Table 100. **QSGDISP** parameters.

Definitions of the **QSGDISP** parameters when defining a queue.

<b>QSGDISP</b>	<b>DEFINE</b>
COPY	<p>The object is defined on the page set of the queue manager that executes the command using the QSGDISP(GROUP) object of the same name as the LIKE object.</p> <p>For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.</p>
GROUP	<p>The object definition resides in the shared repository but only if there is a shared queue manager environment. If the definition is successful, the following command is generated. The command is sent to all active queue managers to attempt to make or refresh local copies on page set zero:</p> <pre>DEFINE QUEUE(q-name) REPLACE QSGDISP(COPY)</pre> <p>The <b>DEFINE</b> command for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>

Table 100. QSGDISP parameters (continued).

Definitions of the QSGDISP parameters when defining a queue.

QSGDISP	DEFINE
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command. For local queues, messages are stored on the page sets of each queue manager and are available only through that queue manager.
SHARED	<p>This option applies only to local queues. The object is defined in the shared repository. Messages are stored in the coupling facility and are available to any queue manager in the queue-sharing group. You can specify SHARED only if:</p> <ul style="list-style-type: none"> <li>• CFSTRUCT is nonblank</li> <li>• INDXTYPE is not MSGTOKEN</li> <li>• The queue is not: <ul style="list-style-type: none"> <li>– SYSTEM.CHANNEL.INITQ</li> <li>– SYSTEM.COMMAND.INPUT</li> </ul> </li> </ul> <p>If the queue is clustered, a command is generated. The command is sent to all active queue managers in the queue-sharing group to notify them of this clustered, shared queue.</p>

## QSVCI EV

Controls whether Service Interval High or Service Interval OK events are generated.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

A Service Interval High event is generated when a check indicates that no messages were retrieved from the queue for at least the time indicated by the QSVCI NT parameter.

A Service Interval OK event is generated when a check indicates that messages were retrieved from the queue within the time indicated by the QSVCI NT parameter.

**Note:** The value of this parameter can change implicitly. For more information, see the description of the Service Interval High and Service Interval OK events in Queue Service Interval High and Queue Service Interval OK.

**HIGH** Service Interval High events are generated

**OK** Service Interval OK events are generated

**NONE** No service interval events are generated

## QSVCI NT ( integer )

The service interval used for comparison to generate Service Interval High and Service Interval OK events.

This parameter is supported only on local and model queues and is ineffective if it is specified on a shared queue.

See the QSVCI EV parameter.

The value is in units of milliseconds, and must be in the range zero through 999999999.

## REPLACE & NOREPLACE

This option controls whether any existing definition  , and on IBM MQ for z/OS of the same disposition, is to be replaced with this one.

**Note:**  Any object with a different disposition is not changed.

## REPLACE

If the object does exist, the effect is like issuing the **ALTER** command without the **FORCE** parameter and with all the other parameters specified. In particular, note that any messages that are on the existing queue are retained.

There is a difference between the **ALTER** command without the **FORCE** parameter, and the **DEFINE** command with the **REPLACE** parameter. The difference is that **ALTER** does not change unspecified parameters, but **DEFINE** with **REPLACE** sets all the parameters. If you use **REPLACE**, unspecified parameters are taken either from the object named on the **LIKE** parameter, or from the default definition, and the parameters of the object being replaced, if one exists, are ignored.

The command fails if both of the following are true:

- The command sets parameters that would require the use of the **FORCE** parameter if you were using the **ALTER** command
- The object is open

The **ALTER** command with the **FORCE** parameter succeeds in this situation.

If **SCOPE(CELL)** is specified on UNIX and Linux systems, or Windows, and there is already a queue with the same name in the cell directory, the command fails, even if **REPLACE** is specified.

## NOREPLACE

The definition must not replace any existing definition of the object.

## RETINTVL ( *integer* )

The number of hours from when the queue was defined, after which the queue is no longer needed. The value must be in the range 0 - 999,999,999.

This parameter is supported only on local and model queues.

The CRDATE and CRTIME can be displayed using the **DISPLAY QUEUE** command.

This information is available for use by an operator or a housekeeping application to delete queues that are no longer required.

**Note:** The queue manager does not delete queues based on this value, nor does it prevent queues from being deleted if their retention interval is not expired. It is the responsibility of the user to take any required action.

## RNAME ( *string* )

Name of remote queue. This parameter is the local name of the queue as defined on the queue manager specified by **RQMNAME**.

This parameter is supported only on remote queues.

- If this definition is used for a local definition of a remote queue, **RNAME** must not be blank when the open occurs.
- If this definition is used for a queue manager alias definition, **RNAME** must be blank when the open occurs.

In a queue manager cluster, this definition applies only to the queue manager that made it. To advertise the alias to the whole cluster, add the **CLUSTER** attribute to the remote queue definition.

- If this definition is used for a reply-to queue alias, this name is the name of the queue that is to be the reply-to queue.

The name is not checked to ensure that it contains only those characters normally allowed for queue names; see Rules for naming IBM MQ objects.

## RQMNAME ( *string* )

The name of the remote queue manager on which the queue **RNAME** is defined.

This parameter is supported only on remote queues.

- If an application opens the local definition of a remote queue, **RQMNAME** must not be blank or the name of the local queue manager. When the open occurs, if **XMITQ** is blank there must be a local queue of this name, which is to be used as the transmission queue.
- If this definition is used for a queue manager alias, **RQMNAME** is the name of the queue manager that is being aliased. It can be the name of the local queue manager. Otherwise, if **XMITQ** is blank, when the open occurs there must be a local queue of this name, which is to be used as the transmission queue.
- If **RQMNAME** is used for a reply-to queue alias, **RQMNAME** is the name of the queue manager that is to be the reply-to queue manager.

The name is not checked to ensure that it contains only those characters normally allowed for IBM MQ object names; see Rules for naming IBM MQ objects.

## SCOPE

Specifies the scope of the queue definition.

This parameter is supported only on alias, local, and remote queues.

**QMGR** The queue definition has queue manager scope. This means that the definition of the queue does not extend beyond the queue manager that owns it. You can open a queue for output that is owned by another queue manager in either of two ways:

1. Specify the name of the owning queue manager.
2. Open a local definition of the queue on the other queue manager.

**CELL** The queue definition has cell scope. Cell scope means that the queue is known to all the queue managers in the cell. A queue with cell scope can be opened for output merely by specifying the name of the queue. The name of the queue manager that owns the queue need not be specified.

If there is already a queue with the same name in the cell directory, the command fails. The **REPLACE** option does not affect this situation.

This value is valid only if a name service supporting a cell directory is configured.

**Restriction:** The DCE name service is no longer supported.

This parameter is valid only on UNIX and Linux systems, and Windows.

## SHARE and NOSHARE

Specifies whether multiple applications can get messages from this queue.

This parameter is supported only on local and model queues.

**SHARE** More than one application instance can get messages from the queue.

### NOSHARE

Only a single application instance can get messages from the queue.

## STATQ

Specifies whether statistics data collection is enabled:

**QMGR** Statistics data collection is based on the setting of the **STATQ** parameter of the queue manager.

**ON** If the value of the **STATQ** parameter of the queue manager is not NONE, statistics data collection for the queue is enabled.

**OFF** Statistics data collection for the queue is disabled.

If this parameter is used in an **ALTER** queue command, the change is effective only for connections to the queue manager made after the change to the parameter.

This parameter is valid only on IBM i, UNIX and Linux systems, and Windows.

▶ z/OS

### **STGCLASS** ( *string* )

The name of the storage class.

This parameter is supported only on local and model queues.

This parameter is an installation-defined name.

This parameter is valid on z/OS only ▶ z/OS ; see Storage classes.

The first character of the name must be uppercase A through Z, and subsequent characters either uppercase A through Z or numeric 0 through 9.

**Note:** You can change this parameter only if the queue is empty and closed.

If you specify **QSGDISP** ( SHARED ) or **DEFTYPE** ( SHAREDYN ), this parameter is ignored.

### **TARGET** ( *string* )

The name of the queue or topic object being aliased; See Rules for naming IBM MQ objects. The object can be a queue or a topic as defined by **TARGETYPE**. The maximum length is 48 characters.

This parameter is supported only on alias queues.

This object needs to be defined only when an application process opens the alias queue.

This parameter is a synonym of the parameter **TARGQ** ; **TARGQ** is retained for compatibility. If you specify **TARGET**, you cannot also specify **TARGQ**.

### **TARGETYPE** ( *string* )

The type of object to which the alias resolves.

**QUEUE** The alias resolves to a queue.

**TOPIC** The alias resolves to a topic.

### **TRIGDATA** ( *string* )

The data that is inserted in the trigger message. The maximum length of the string is 64 bytes.

This parameter is supported only on local and model queues.

For a transmission queue on AIX, HP-UX, IBM i, Linux, Solaris, and Windows ▶ z/OS , and z/OS, you can use this parameter to specify the name of the channel to be started.

This parameter can also be changed using the MQSET API call.

### **TRIGDPTH** ( *integer* )

The number of messages that have to be on the queue before a trigger message is written, if **TRIGTYPE** is DEPTH. The value must be in the range 1 - 999,999,999.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

### **TRIGGER & NOTRIGGER**

Specifies whether trigger messages are written to the initiation queue, named by the **INITQ** parameter, to trigger the application, named by the **PROCESS** parameter:

#### **TRIGGER**

Triggering is active, and trigger messages are written to the initiation queue.

#### **NOTRIGGER**

Triggering is not active, and trigger messages are not written to the initiation queue.

This parameter is supported only on local and model queues.

This parameter can also be changed using the MQSET API call.

### **TRIGMPRI** ( *integer* )

The message priority number that triggers this queue. The value must be in the range zero through to the **MAXPRTY** queue manager parameter; see “DISPLAY QMGR” on page 839 for details.

This parameter can also be changed using the MQSET API call.

### **TRIGTYPE**

Specifies whether and under what conditions a trigger message is written to the initiation queue. The initiation queue is (named by the **INITQ** parameter.

This parameter is supported only on local and model queues.

**FIRST** Whenever the first message of priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue arrives on the queue.

**EVERY** Every time a message arrives on the queue with priority equal to or greater than the priority specified by the **TRIGMPRI** parameter of the queue.

**DEPTH** When the number of messages with priority equal to or greater than the priority specified by **TRIGMPRI** is equal to the number indicated by the **TRIGDPH** parameter.

**NONE** No trigger messages are written.

This parameter can also be changed using the MQSET API call.

### **USAGE**

Queue usage.

This parameter is supported only on local and model queues.

#### **NORMAL**

The queue is not a transmission queue.

**XMITQ** The queue is a transmission queue, which is used to hold messages that are destined for a remote queue manager. When an application puts a message to a remote queue, the message is stored on the appropriate transmission queue. It stays there, awaiting transmission to the remote queue manager.

If you specify this option, do not specify values for **CLUSTER** and **CLUSNL**.

 Additionally, on z/OS, do not specify **INDXTYPE** ( **MSGTOKEN** ) or **INDXTYPE** ( **GROUPID** ).

### **XMITQ** ( *string* )

The name of the transmission queue to be used for forwarding messages to the remote queue. **XMITQ** is used with either remote queue or queue manager alias definitions.

This parameter is supported only on remote queues.

If **XMITQ** is blank, a queue with the same name as **RQMNAME** is used as the transmission queue.

This parameter is ignored if the definition is being used as a queue manager alias and **RQMNAME** is the name of the local queue manager.

It is also ignored if the definition is used as a reply-to queue alias definition.

## DEFINE QALIAS:

Use DEFINE QALIAS to define a new alias queue, and set its parameters.

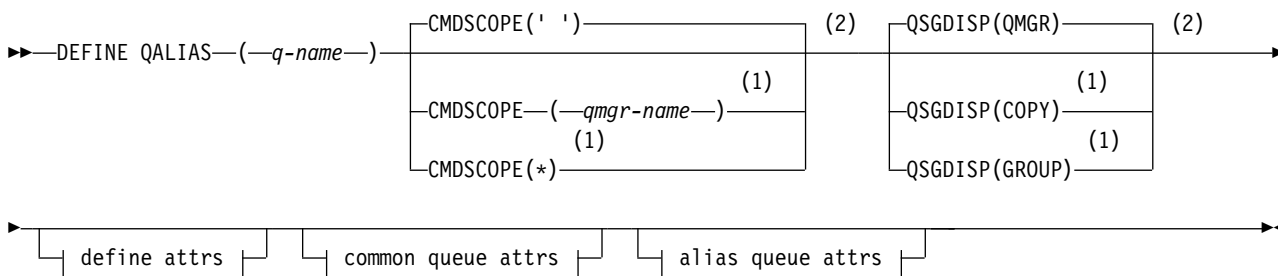

**Note:** An alias queue provides a level of indirection to another queue or a topic object. If the alias refers to a queue, it must be another local or remote queue, defined at this queue manager, or a clustered alias queue defined on another queue manager. It cannot be another alias queue on this queue manager. If the alias refers to a topic, it must be a topic object defined at this queue manager.

- Syntax diagram
- “Usage notes for DEFINE queues” on page 635
- “Parameter descriptions for DEFINE QUEUE and ALTER QUEUE” on page 636

**Synonym:** DEF QA

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

## DEFINE QALIAS

### Define attrs:

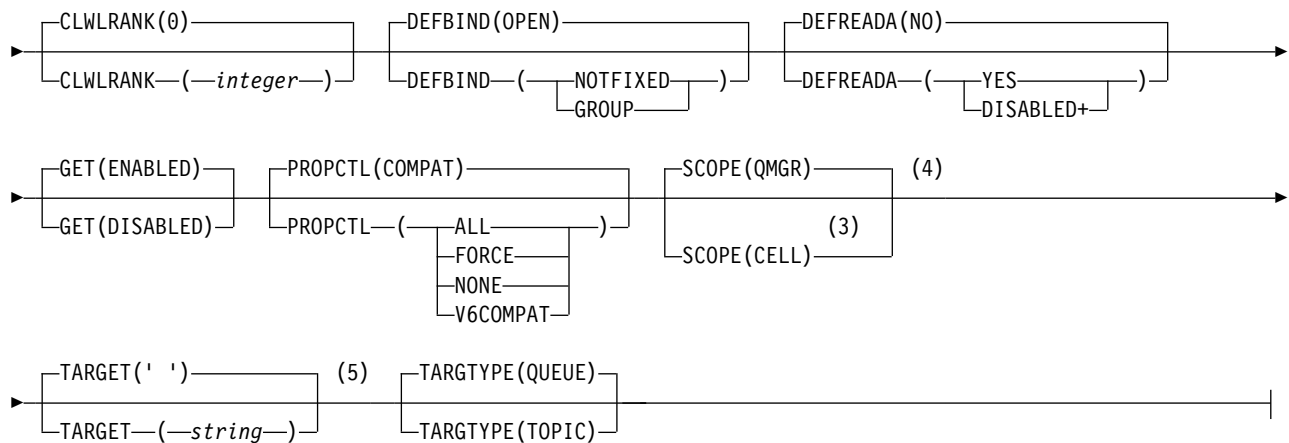

### Common queue attrs:

### Alias queue attrs:

**Notes:**

- 1 Valid only on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on UNIX and Linux systems, and Windows.
- 4 Not valid on z/OS.
- 5 The TARGQ parameter is available for compatibility with previous releases. It is a synonym of TARGET; you cannot specify both parameters.

*DEFINE QLOCAL:*

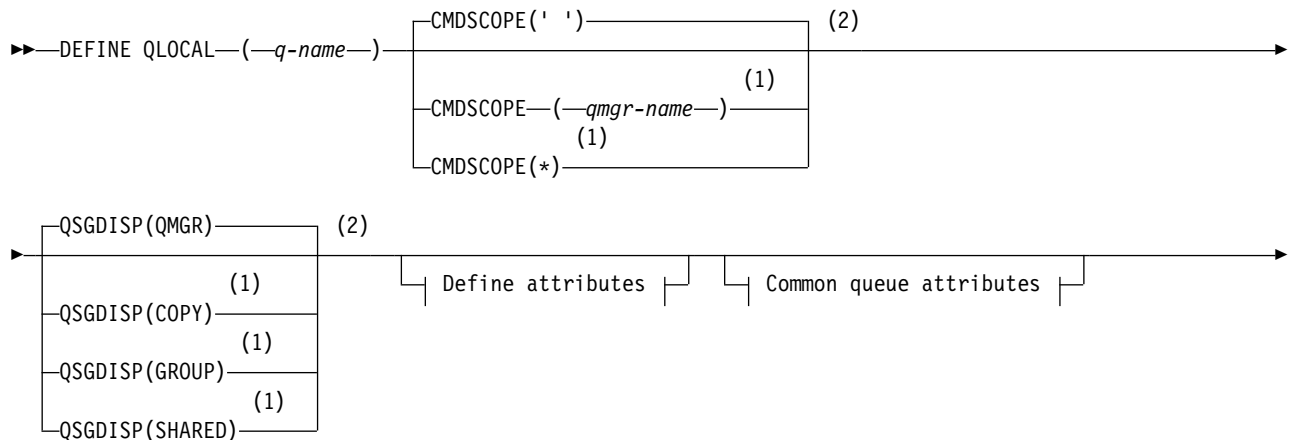

Use **DEFINE QLOCAL** to define a new local queue, and set its parameters.

- Syntax diagram
- “Usage notes for DEFINE queues” on page 635
- “Parameter descriptions for DEFINE QUEUE and ALTER QUEUE” on page 636

**Synonym: DEF QL**

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

**DEFINE QLOCAL**

**Define attributes:**

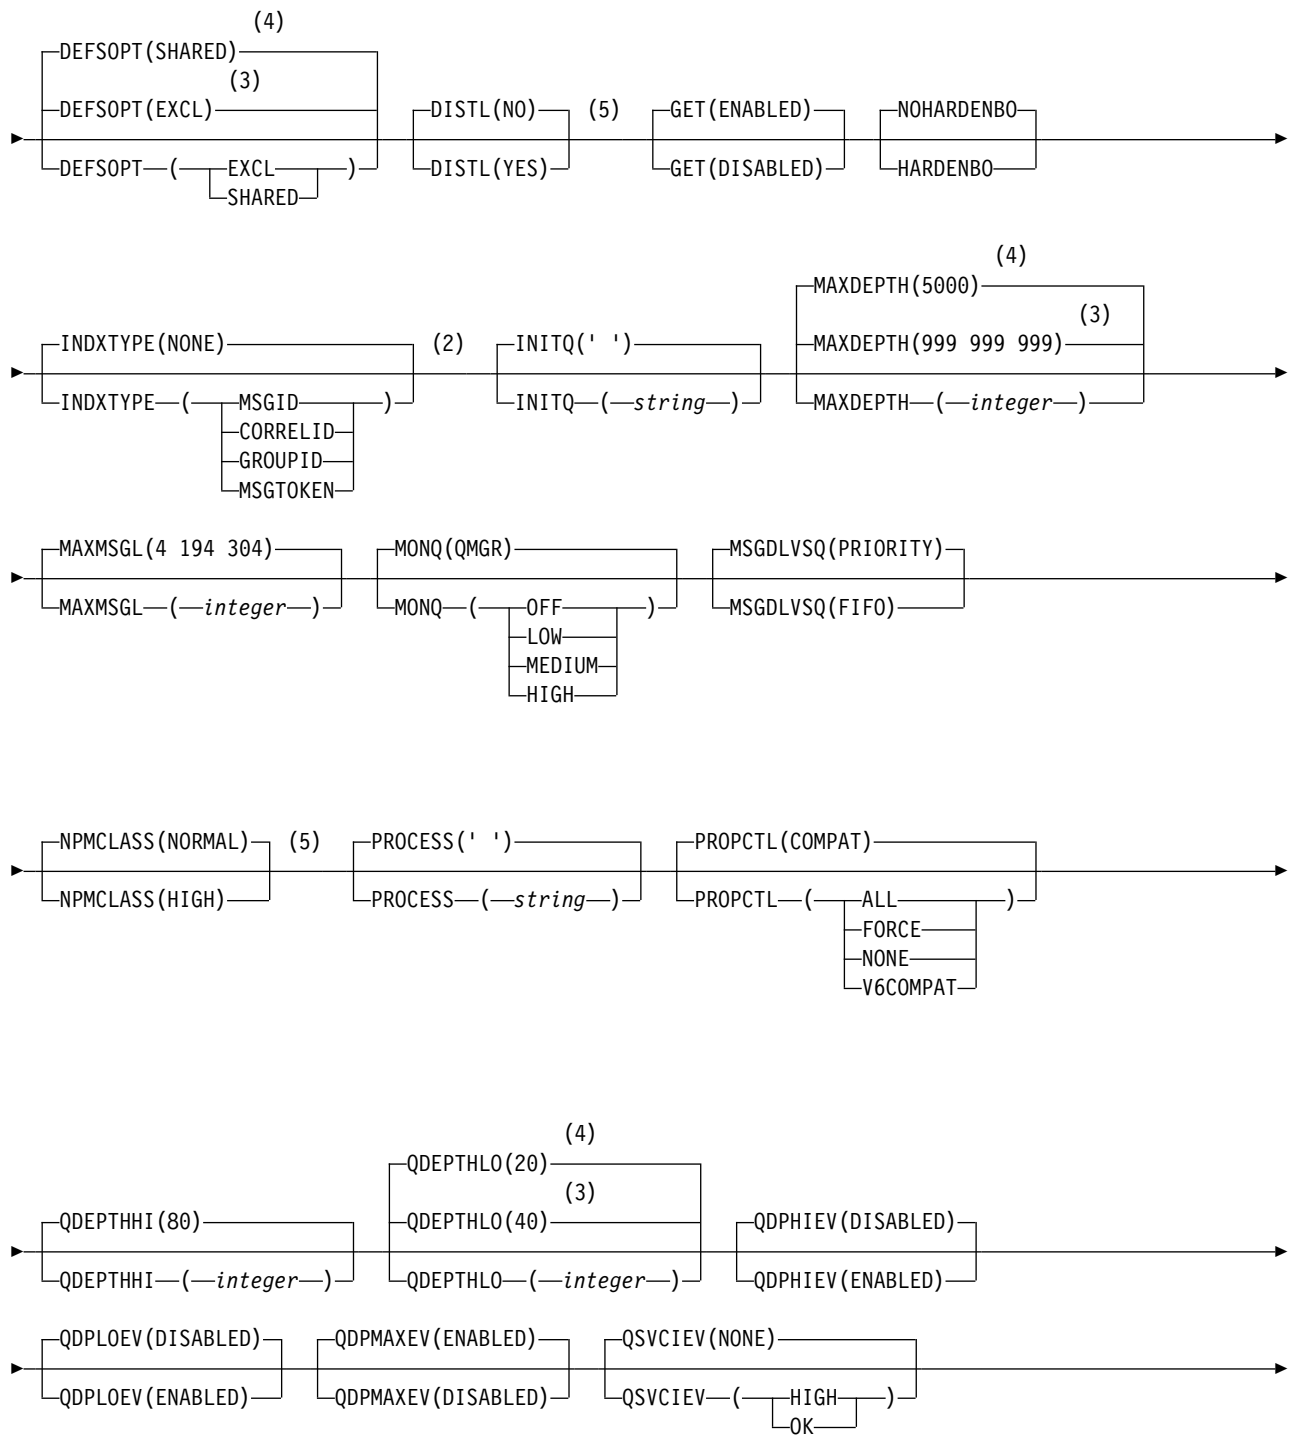

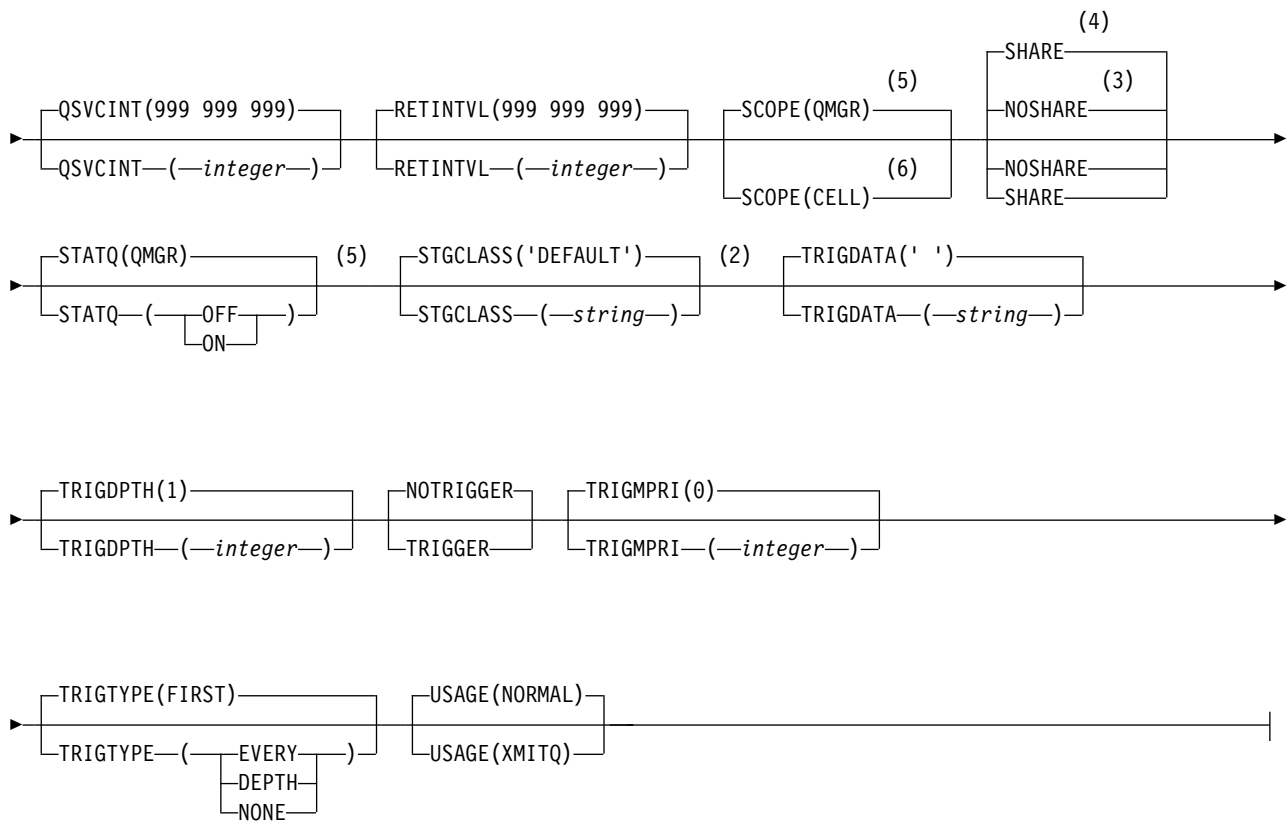

**Common queue attributes:**

**Local queue attributes:**

**Notes:**

- 1 Valid only on z/OS and when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Default for z/OS.
- 4 Default for distributed platforms.
- 5 Not valid on z/OS.
- 6 Valid only on UNIX, Linux, and Windows systems.

## DEFINE QMODEL:

Use **DEFINE QMODEL** to define a new model queue, and set its parameters.

A model queue is not a real queue, but a collection of attributes that you can use when creating dynamic queues with the MQOPEN API call.

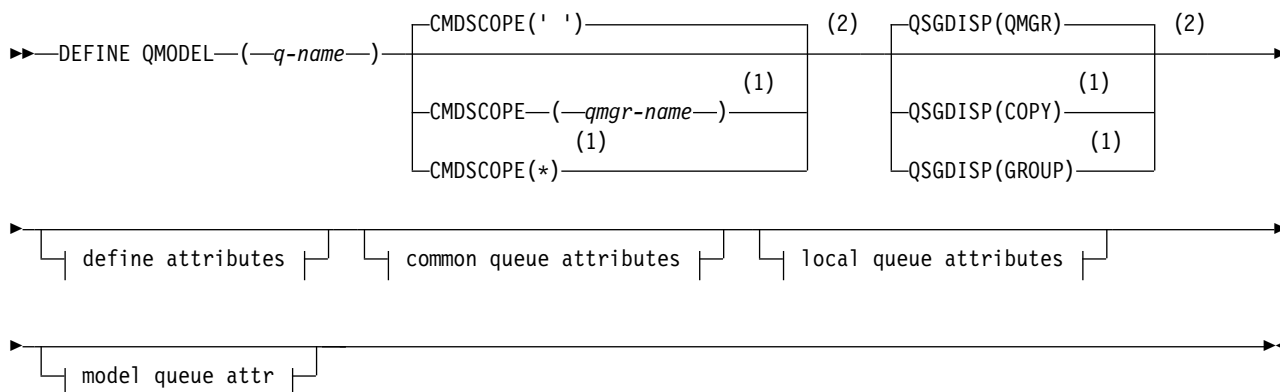

When it has been defined, a model queue (like any other queue) has a complete set of applicable attributes, even if some of these are defaults.

- Syntax diagram
- “Usage notes for DEFINE queues” on page 635
- “Parameter descriptions for DEFINE QUEUE and ALTER QUEUE” on page 636

### Synonym: DEF QM

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

## DEFINE QMODEL

### Define attributes:

### Common queue attributes:

### Local queue attributes:

**Model queue attr:**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Used only on z/OS.
- 3 Not valid on z/OS.
- 4 Default for z/OS.
- 5 Default for distributed platforms.

## DEFINE QREMOTE:

Use DEFINE QREMOTE to define a new local definition of a remote queue, a queue manager alias, or a reply-to queue alias, and to set its parameters.

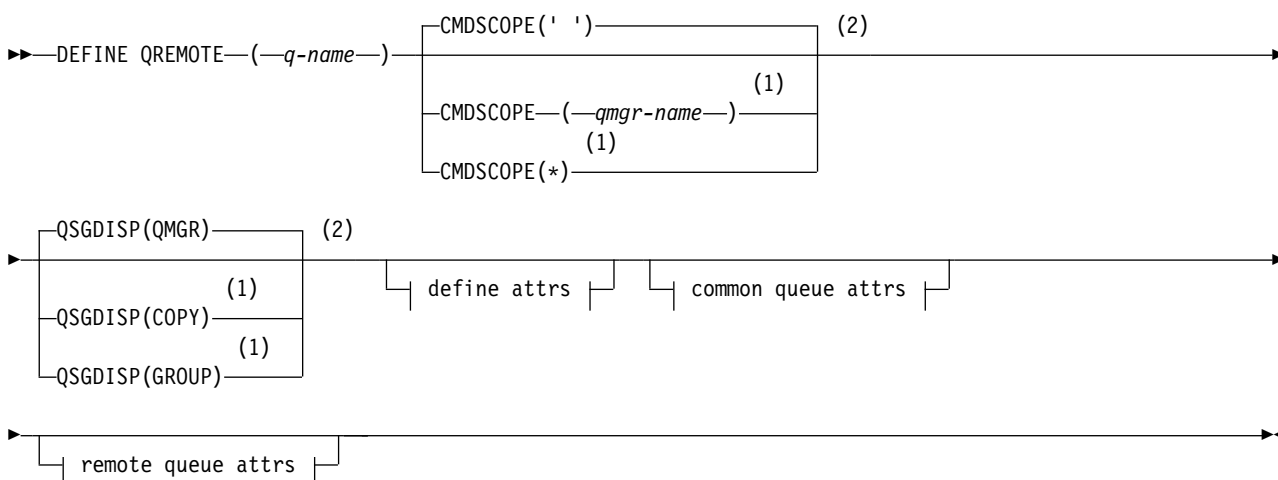

A remote queue is one that is owned by another queue manager that application processes connected to this queue manager need to access.

- Syntax diagram
- “Usage notes for DEFINE queues” on page 635
- “Parameter descriptions for DEFINE QUEUE and ALTER QUEUE” on page 636

**Synonym:** DEF QR

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

## DEFINE QREMOTE

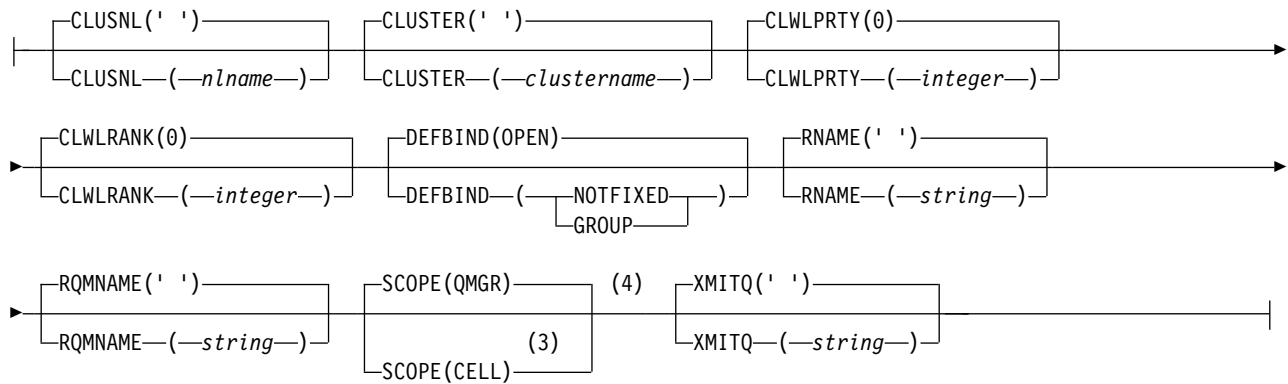

### Define attrs:

### Common queue attrs:

**Remote queue attrs:**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Valid only on UNIX and Linux systems, and Windows.
- 4 Not valid on z/OS.

**DEFINE SERVICE:**

Use the MQSC command DEFINE SERVICE to define a new IBM MQ service definition, and set its parameters.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Usage notes” on page 668
- “Parameter descriptions for DEFINE SERVICE” on page 668

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

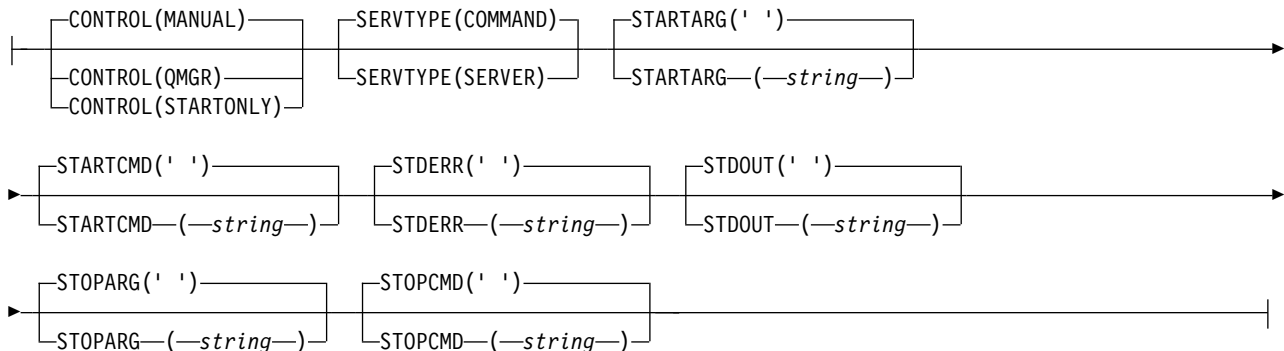

**DEFINE SERVICE**

## Define attrs:

## Service attrs:

## Usage notes

A service is used to define the user programs that are to be started and stopped when the queue manager is started and stopped. You can also start and stop these programs by issuing the START SERVICE and STOP SERVICE commands.

**Attention:** This command allows a user to run an arbitrary command with mqm authority. If granted rights to use this command, a malicious or careless user could define a service which damages your systems or data, for example, by deleting essential files.

For more information about services, see Services.

## Parameter descriptions for DEFINE SERVICE

The parameter descriptions apply to the ALTER SERVICE and DEFINE SERVICE commands, with the following exceptions:

- The **LIKE** parameter applies only to the DEFINE SERVICE command.
- The **NOREPLACE** and **REPLACE** parameter applies only to the DEFINE SERVICE command.

(*service-name*)

Name of the IBM MQ service definition (see Rules for naming IBM MQ objects ).

The name must not be the same as any other service definition currently defined on this queue manager (unless REPLACE is specified).

## CONTROL(*string*)

Specifies how the service is to be started and stopped:

### MANUAL

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the START SERVICE and STOP SERVICE commands.

### QMGR

The service being defined is to be started and stopped at the same time as the queue manager is started and stopped.

**STARTONLY**

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

**DESCR( *string* )**

Plain-text comment. It provides descriptive information about the service when an operator issues the DISPLAY SERVICE command (see "DISPLAY SERVICE" on page 889 ).

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**LIKE( *service-name* )**

The name of a service the parameters of which are used to model this definition.

This parameter applies only to the DEFINE SERVICE command.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for services on this queue manager. Not completing this parameter is equivalent to specifying:

LIKE(SYSTEM.DEFAULT.SERVICE)

A default service is provided but it can be altered by the installation of the default values required. See Rules for naming IBM MQ objects.

**REPLACE and NOREPLACE**

Whether the existing definition is to be replaced with this one.

This parameter applies only to the DEFINE SERVICE command.

**REPLACE**

The definition must replace any existing definition of the same name. If a definition does not exist, one is created.

**NOREPLACE**

The definition should not replace any existing definition of the same name.

**SERVTYPE**

Specifies the mode in which the service is to run:

**COMMAND**

A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

**SERVER**

A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the DISPLAY SVSTATUS command.

**STARTARG( *string* )**

Specifies the arguments to be passed to the user program at queue manager startup.

**STARTCMD( *string* )**

Specifies the name of the program which is to run. You must specify a fully qualified path name to the executable program.

**STDERR( *string* )**

Specifies the path to a file to which the standard error (stderr) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stderr by the service program is discarded.

### STDOUT( *string* )

Specifies the path to a file to which the standard output (stdout) of the service program is redirected. If the file does not exist when the service program is started, the file is created. If this value is blank then any data written to stdout by the service program is discarded.

### STOPARG( *string* )

Specifies the arguments to be passed to the stop program when instructed to stop the service.

### STOPCMD( *string* )

Specifies the name of the executable program to run when the service is requested to stop. You must specify a fully qualified path name to the executable program.

Replaceable inserts can be used for any of the STARTCMD, STARTARG, STOPCMD, STOPARG, STDOUT or STDERR strings, for more information, see Replaceable inserts on service definitions.

### Related information:

Working with services

### DEFINE STGCLASS: z/OS

Use the MQSC command DEFINE STGCLASS to define a storage class to page set mapping.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

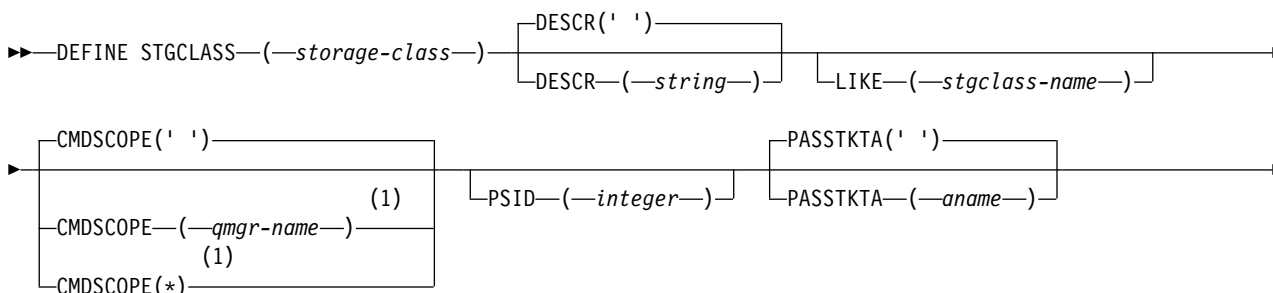

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DEFINE STGCLASS” on page 671
- “Parameter descriptions for DEFINE STGCLASS” on page 671

**Synonym:** DEF STC

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

### DEFINE STGCLASS

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

**Usage notes for DEFINE STGCLASS**

1. The resultant values of XCFGNAME and XCFMNAME must either both be blank or both be nonblank.
2. You can change a storage class only if it is not being used by any queues. To determine whether any queues are using the storage class, you can use the following command: class, you can use the following command:

```
DISPLAY QUEUE(*) STGCLASS(ABC) PSID(n)
```

where 'ABC' is the name of the storage class, and *n* is the identifier of the page set that the storage class is associated with.

This command gives a list of all queues that reference the storage class, and have an active association to page set *n*, and therefore identifies the queues that are actually preventing the change to the storage class. If you do not specify the PSID, you just get a list of queues that are potentially stopping the change.

See the DISPLAY QUEUE PSID command for more information about active association of a queue to a page set.

**Parameter descriptions for DEFINE STGCLASS**

*(storage-class)*

Name of the storage class.

This name is one to 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

**Note:** Exceptionally, certain all numeric storage class names are allowed, but are reserved for the use of IBM service personnel.

The storage class must not be the same as any other storage class currently defined on this queue manager.

**CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active

queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

**DESCR**( *description* )

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY STGCLASS command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager

**LIKE**( *stgclass-name* )

The name of an object of the same type, with parameters that are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for this object.

Not completing this parameter is equivalent to specifying:

LIKE(SYSTEMST)

This default storage class definition can be altered by your installation to the default values required.

The queue manager searches for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

**Note:**

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

**PASSTKTA**( *application name* )

The application name that is passed to RACF when authenticating the PassTicket specified in the MQIIH header.

**PSID**( *integer* )

The page set identifier that this storage class is to be associated with.

**Note:** No check is made that the page set has been defined; an error is raised only when you try to put a message to a queue that specifies this storage class (MQRC\_PAGESET\_ERROR).

The string consists of two numeric characters, in the range 00 through 99. See "DEFINE PSID" on page 633.

**QSGDISP**

Specifies the disposition of the object in the group.

QSGDISP	DEFINE
COPY	The object is defined on the page set of the queue manager that executes the command using the QSGDISP(GROUP) object of the same name as the 'LIKE' object.

QSGDISP	DEFINE
GROUP	<p>The object definition resides in the shared repository but only if the queue manager is in a queue-sharing group. If the definition is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to make or refresh local copies on page set zero:</p> <pre>DEFINE STGCLASS(storage-class) REPLACE QSGDISP(COPY)</pre> <p>The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.</p>
PRIVATE	Not permitted.
QMGR	The object is defined on the page set of the queue manager that executes the command.

### REPLACE and NOREPLACE

Whether the existing definition, and with the same disposition, is to be replaced with this one. Any object with a different disposition is not changed.

#### REPLACE

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

If you use the REPLACE option, all queues that use this storage class must be temporarily altered to use another storage class while the command is issued.

#### NOREPLACE

The definition does not replace any existing definition of the same name.

#### XCFGNAME( *group name* )

If you are using the IMS bridge, this name is the name of the XCF group to which the IMS system belongs. (This name is the group name specified in the IMS parameter list.)

This name is 1 - 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

#### XCFMNAME( *member name* )

If you are using the IMS bridge, this name is the XCF member name of the IMS system within the XCF group specified in XCFGNAME. (This name is the member name specified in the IMS parameter list.)

This name is 1 - 16 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 - 9.

## DEFINE SUB:

Use DEFINE SUB to allow an existing application to participate in a publish/subscribe application by allowing the administrative creation of a durable subscription.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

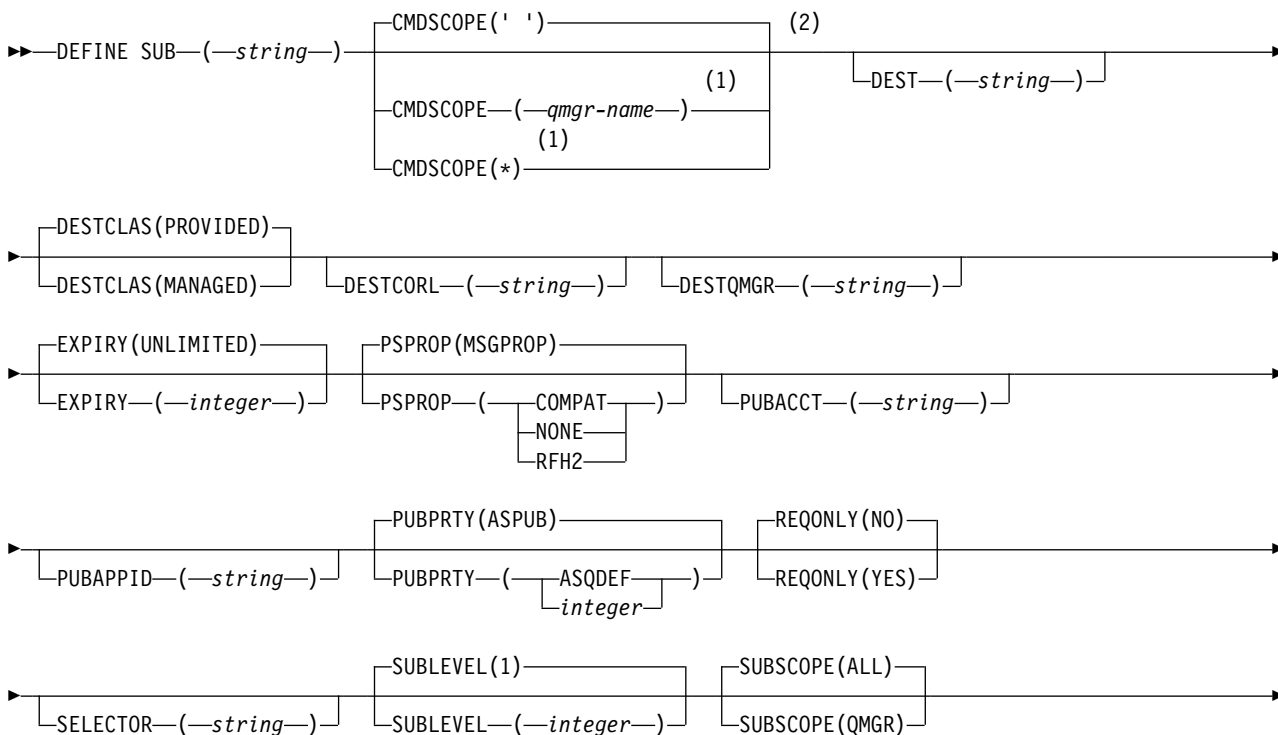

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DEFINE SUB” on page 675
- “Parameter descriptions for DEFINE SUB” on page 676

**Synonym:** DEF SUB

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

## DEFINE SUB

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 At least one of **TOPICSTR** and **TOPICOBJ** must be present on **DEFINE**.

**Usage notes for DEFINE SUB**

- You must provide the following information when you define a subscription:
  - The SUBNAME
  - A destination for messages
  - The topic to which the subscription applies
- You can provide the topic name in the following ways:

**TOPICSTR**

The topic is fully specified as the TOPICSTR attribute.

**TOPICOBJ**

The topic is obtained from the TOPICSTR attribute of the named topic object. The named topic object is retained as the TOPICOBJ attribute of the new subscription. This method is provided to help you enter long topic strings through an object definition.

**TOPICSTR and TOPICOBJ**

The topic is obtained by the concatenation of the TOPICSTR attribute of the named topic object and the value of TOPICSTR (see the MQSUB API specification for concatenation rules). The named topic object is retained as the TOPICOBJ attribute of the new subscription.

- If you specify TOPICOBJ, the parameter must name an IBM MQ topic object. The existence of the named topic object is checked at the time the command processes.
- You can explicitly specify the destination for messages through the use of the DEST and DESTQMGR keywords.
 

You must provide the DEST keyword for the default option of DESTCLAS(PROVIDED); if you specify DESTCLAS(MANAGED), a managed destination is created on the local queue manager, so you cannot specify either the DEST or DESTQMGR attribute.
- On z/OS only, at the time the DEF SUB command processes, no check is performed that the named DEST or DESTQMGR exists.
 

These names are used at publishing time as the *ObjectName* and *ObjectQMgrName* for an MQOPEN call. These names are resolved according to the IBM MQ name resolution rules.
- When a subscription is defined administratively using MQSC or PCF commands, the selector is not validated for invalid syntax. The DEFINE SUB command has no equivalent to the MQRC\_SELECTION\_NOT\_AVAILABLE reason code that can be returned by the MQSUB API call.
- TOPICOBJ, TOPICSTR, WSCHEMA, SELECTOR, SUBSCOPE, and DESTCLAS cannot be changed with DEFINE REPLACE.
- When a publication has been retained, it is no longer available to subscribers at higher levels because it is republished at PubLevel 1.

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE SUB step in Checking that async commands for distributed networks have finished.

## Parameter descriptions for DEFINE SUB

(string)

A mandatory parameter. Specifies the unique name for this subscription, see **SUBNAME** property.

### **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is processed when the queue manager is a member of a queue-sharing group.

' ' The command is processed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is processed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is processed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

**DEST**( string )

The destination for messages published to this subscription; this parameter is the name of a queue.

**DESTCLAS**

System managed destination.

**PROVIDED**

The destination is a queue.

**MANAGED**

The destination is managed.

**DESTCORL**( string )

The *CorrelId* used for messages published to this subscription.

A blank value (default) results in a system generated correlation identifier being used.

If set to ' 00 ' (48 zeros) the **CorrelId** set by the publishing application will be maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

**DESTQMGR**( string )

The destination queue manager for messages published to this subscription. You must define the channels to the remote queue manager, for example, the XMITQ, and a sender channel. If you do not, messages do not arrive at the destination.

**EXPIRY**

The time to expiry of the subscription object from the creation date and time.

( integer )

The time to expiry, in tenths of a second, from the creation date and time.

**UNLIMITED**

There is no expiry time. This is the default option supplied with the product.

**LIKE( *subscription-name* )**

The name of a subscription, the parameters of which are used as a model for this definition.

This parameter applies only to the DEFINE SUB command.

If this field is not supplied, and you do not complete the parameter fields related to the command, the values are taken from the default definition for subscriptions on this queue manager. Not completing this parameter is equivalent to specifying:

LIKE (SYSTEM.DEFAULT.SUB)

**PSPROP**

The manner in which publish subscribe related message properties are added to messages sent to this subscription.

**NONE**

Do not add publish subscribe properties to the message.

**COMPAT**

Publish subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

**MSGPROP**

Publish subscribe properties are added as message properties.

**RFH2** Publish subscribe properties are added within an MQRFH version 2 header.

**PUBACCT( *string* )**

Accounting token passed by the subscriber, for propagation into messages published to this subscription in the *AccountingToken* field of the MQMD.

**PUBAPPID( *string* )**

Identity data passed by the subscriber, for propagation into messages published to this subscription in the *AppIdentityData* field of the MQMD.

**PUBPRTY**

The priority of the message sent to this subscription.

**AS PUB**

Priority of the message sent to this subscription is taken from the priority supplied in the published message.

**AS QDEF**

Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

**(integer)**

An integer providing an explicit priority for messages published to this subscription.

**REPLACE and NOREPLACE**

This parameter controls whether any existing definition is to be replaced with this one.

**REPLACE**

The definition replaces any existing definition of the same name. If a definition does not exist, one is created.

You cannot change TOPICOBJ, TOPICSTR, WSCHEMA, SELECTOR, SUBSCOPE, or DESTCLAS with DEFINE REPLACE.

**NOREPLACE**

The definition does not replace any existing definition of the same name.

## REQONLY

Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

**NO** All publications on the topic are delivered to this subscription.

**YES** Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO\_PUBLICATIONS\_ON\_REQUEST.

## SELECTOR( *string* )

A selector that is applied to messages published to the topic.

## SUBLEVEL( *integer* )

The level within the subscription hierarchy at which this subscription is made. The range is zero through 9.

## SUBSCOPE

Determines whether this subscription is forwarded to other queue managers, so that the subscriber receives messages published at those other queue managers.

**ALL** The subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

## QMGR

The subscription forwards messages published on the topic only within this queue manager.

**Note:** Individual subscribers can only *restrict* **SUBSCOPE**. If the parameter is set to ALL at topic level, then an individual subscriber can restrict it to QMGR for this subscription. However, if the parameter is set to QMGR at topic level, then setting an individual subscriber to ALL has no effect.

## SUBNAME

The application's unique subscription name that is associated with the handle. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. Not all subscriptions will have a subscription name.

## SUBUSER( *string* )

Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

## TOPICOBJ( *string* )

The name of a topic object used by this subscription.

## TOPICSTR( *string* )

Specifies a fully qualified topic name, or a topic set using wildcard characters for the subscription.

## USERDATA( *string* )

Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription as a message property.

► **V 8.0.0.7** From IBM MQ Version 8.0.0, Fix Pack 7, an IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant `JMS_IBM_SUBSCRIPTION_USER_DATA` in the `JmsConstants` interface with the method `javax.jms.Message.getStringProperty(java.lang.String)`. For more information, see Retrieval of user subscription data.

**VARUSER**

Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

**ANY** Any user can connect to and takeover ownership of the subscription.

**FIXED**

Takeover by another **USERID** is not permitted.

**WSHEMA**

The schema to be used when interpreting any wildcard characters in the topic string.

**CHAR**

Wildcard characters represent portions of strings.

**TOPIC**

Wildcard characters represent portions of the topic hierarchy.

**DEFINE TOPIC:**

Use DEFINE TOPIC to define a new IBM MQ administrative topic in a topic tree, and set its parameters.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

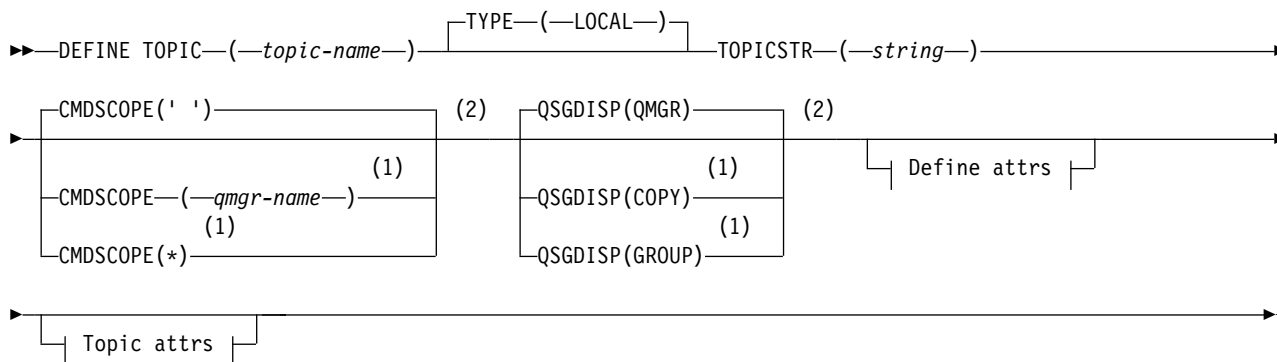

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DEFINE TOPIC” on page 680
- “Parameter descriptions for DEFINE TOPIC” on page 681

**Synonym:** DEF TOPIC

Values shown above the main line in the railroad diagram are the defaults supplied with IBM MQ, but your installation might have changed them. See “How to read railroad diagrams” on page 176.

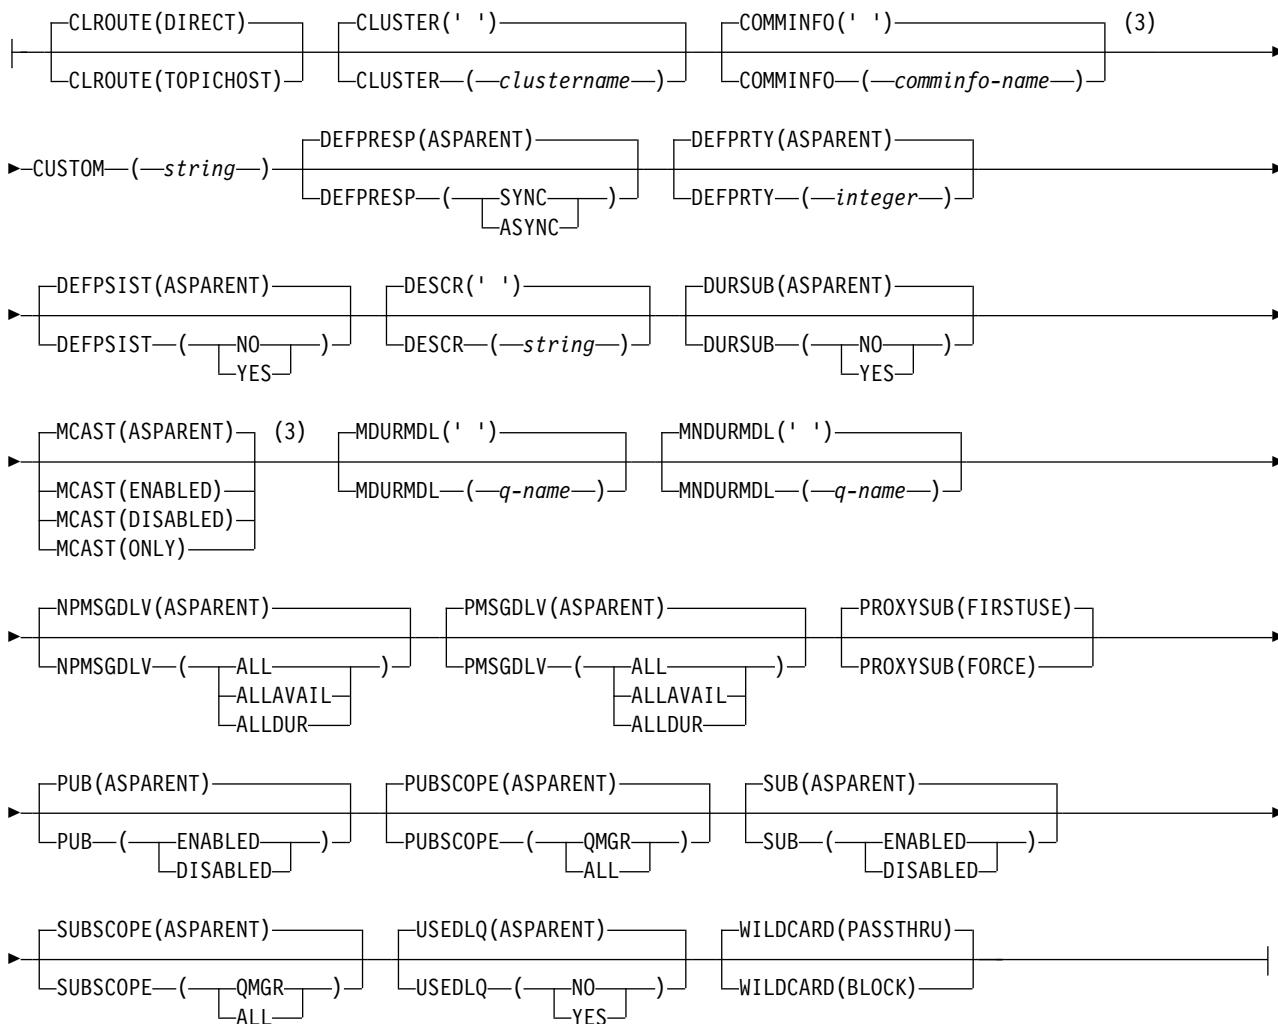

**DEFINE TOPIC**

## Define attrs:

## Topic attrs:

## Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.

## Usage notes for DEFINE TOPIC

- When an attribute has the value ASPARENT, the value is taken from the setting of the first parent administrative node that is found in the topic tree. Administered nodes are based on either locally defined topic objects or remotely defined cluster topics when participating in a publish/subscribe cluster. If the first parent topic object also has the value ASPARENT, the next object is looked for. If every object that is found, when looking up the tree, uses ASPARENT, the values are taken from the

SYSTEM.BASE.TOPIC, if it exists. If SYSTEM.BASE.TOPIC does not exist, the values are the same as the values supplied with IBM MQ in the definition of the SYSTEM.BASE.TOPIC.

- The ASPARENT attribute is applied at each queue manager in the cluster collective by inspecting the set of local definitions and cluster definitions that is visible in the queue manager at the time.
- When a publication is sent to multiple subscribers, the attributes used from the topic object are used consistently for all subscribers that receive the publication. For example, inhibiting publication on a topic is applied for the next application MQPUT to the topic. A publication that is in progress to multiple subscribers completes to all subscribers. This publication does not take note of a change that has happened, part of the way through, to any attribute on the topic.
- Successful completion of the command does not mean that the action completed. To check for true completion, see the DEFINE TOPIC step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for DEFINE TOPIC

*(topic-name)*

Name of the IBM MQ topic definition (see Rules for naming IBM MQ objects ). The maximum length is 48 characters.

The name must not be the same as any other topic definition currently defined on this queue manager (unless REPLACE is specified).

### CLROUTE

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

#### DIRECT

When you configure a direct routed clustered topic on a queue manager, all queue managers in the cluster become aware of all other queue managers in the cluster. When performing publish and subscribe operations, each queue manager can connect direct to any other queue manager in the cluster.

#### TOPICHOST

When you use topic host routing, all queue managers in the cluster become aware of the cluster queue managers that host the routed topic definition (that is, the queue managers on which you have defined the topic object). When performing publish and subscribe operations, queue managers in the cluster connect only to these topic host queue managers, and not directly to each other. The topic host queue managers are responsible for routing publications from queue managers on which publications are published to queue managers with matching subscriptions.

After a topic object has been clustered (through setting the **CLUSTER** property) you cannot change the value of the **CLROUTE** property. The object must be un-clustered (**CLUSTER** set to ' ') before you can change the value. Un-clustering a topic converts the topic definition to a local topic, which results in a period during which publications are not delivered to subscriptions on remote queue managers; this should be considered when performing this change. See The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager. If you try to change the value of the **CLROUTE** property while it is clustered, the system generates an MQRCCF\_CLROUTE\_NOT\_ALTERABLE exception.

See also Routing for publish/subscribe clusters: Notes on behavior and Designing publish/subscribe clusters.

### CLUSTER

The name of the cluster to which this topic belongs. Setting this parameter to a cluster that this queue manager is a member of makes all queue managers in the cluster aware of this topic. Any publication to this topic or a topic string below it put to any queue manager in the cluster is propagated to subscriptions on any other queue manager in the cluster. For more details, see Distributed publish/subscribe networks.

' ' If no topic object above this topic in the topic tree has set this parameter to a cluster

name, then this topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers. If a topic node higher in the topic tree has a cluster name set, publications and subscriptions to this topic are also propagated throughout the cluster.

*string* The topic belongs to this cluster. It is not recommended that this is set to a different cluster from a topic object above this topic object in the topic tree. Other queue managers in the cluster will honor this object's definition unless a local definition of the same name exists on those queue managers.

To prevent all subscriptions and publications being propagated throughout a cluster, leave this parameter blank on the system topics SYSTEM.BASE.TOPIC and SYSTEM.DEFAULT.TOPIC, except in special circumstances, for example to support migration.

#### **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which it was entered, only if you are using a shared queue environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

#### **COMMINFO( *comminfo-name* )**

The name of the Multicast communication information object associated with this topic object.

#### **CUSTOM ( *string* )**

The custom attribute for new features.

 This attribute contains the values of attributes, as pairs of attribute name and value, separated by at least one space. The attribute name and value pairs have the form NAME(VALUE). Single quotation marks must be escaped with another single quotation mark.

#### **CAPEXPY ( *integer* )**

The maximum time, expressed in tenths of a second, until a message published to a topic which inherits properties from this object, remains in the system until it becomes eligible for expiry processing.

For more information on message expiry processing, see Enforcing lower expiration times.

*integer* The value must be in the range one through to 999 999 999.

#### **NOLIMIT**

There is no limit on the expiry time of messages put to this topic.

#### **ASPARENT**

The maximum message expiry time is based on the setting of the closest parent administrative topic object in the topic tree. This is the default value.

Specifying a value for CAPEXPY that is not valid, does not cause the command to fail. Instead, the default value is used.

**DEFPRESP**

Specifies the put response to be used when applications specify the MQPMO\_RESPONSE\_AS\_DEF option.

**ASPARENT**

The default put response is based on the setting of the closest parent administrative topic object in the topic tree.

**SYNC** Put operations to the queue that specify MQPMO\_RESPONSE\_AS\_Q\_DEF are issued as if MQPMO\_SYNC\_RESPONSE had been specified instead. Fields in the MQMD and MQPMO are returned by the queue manager to the application.

**ASYNC**

Put operations to the queue that specify MQPMO\_RESPONSE\_AS\_Q\_DEF are always issued as if MQPMO\_ASYNC\_RESPONSE had been specified instead. Some fields in the MQMD and MQPMO are not returned by the queue manager to the application; but an improvement in performance might be seen for messages put in a transaction and any non-persistent messages

**DEFPRTY( *integer* )**

The default priority of messages published to the topic.

( *integer* )

The value must be in the range zero (the lowest priority), through to the MAXPRTY queue manager parameter (MAXPRTY is 9).

**ASPARENT**

The default priority is based on the setting of the closest parent administrative topic object in the topic tree.

**DEFPSIST**

Specifies the message persistence to be used when applications specify the MQPER\_PERSISTENCE\_AS\_TOPIC\_DEF option.

**ASPARENT**

The default persistence is based on the setting of the closest parent administrative topic object in the topic tree.

**NO** Messages on this queue are lost during a restart of the queue manager.

**YES** Messages on this queue survive a restart of the queue manager.

On z/OS, N and Y are accepted as synonyms of NO and YES.

**DESCR( *string* )**

Plain-text comment. It provides descriptive information about the object when an operator issues the DISPLAY TOPIC command.

It must contain only displayable characters. The maximum length is 64 characters. In a DBCS installation, it can contain DBCS characters (subject to a maximum length of 64 bytes).

**Note:** If characters are used that are not in the coded character set identifier (CCSID) for this queue manager, they might be translated incorrectly if the information is sent to another queue manager.

**DURSUB**

Specifies whether applications are permitted to make durable subscriptions on this topic.

**ASPARENT**

Whether durable subscriptions can be made on this topic is based on the setting of the closest parent administrative topic object in the topic tree.

**NO** Durable subscriptions cannot be made on this topic.

**YES** Durable subscriptions can be made on this topic.

**LIKE( *topic-name* )**

The name of a topic. The topic parameters are used to model this definition.

If this field is not completed, and you do not complete the parameter fields related to the command, the values are taken from the default definition for topics on this queue manager.

Not completing this field is equivalent to specifying:

LIKE(SYSTEM.DEFAULT.TOPIC)

A default topic definition is provided, but it can be altered by the installation to the default values required. See Rules for naming IBM MQ objects.

**z/OS** On z/OS, the queue manager searches page set zero for an object with the name you specify and a disposition of QMGR or COPY. The disposition of the LIKE object is not copied to the object you are defining.

**Note:**

1. QSGDISP (GROUP) objects are not searched.
2. LIKE is ignored if QSGDISP(COPY) is specified.

**MCAST**

Specifies whether multicast is allowable in the topic tree. The values are:

**ASPARENT**

The multicast attribute of the topic is inherited from the parent.

**DISABLED**

No multicast traffic is allowed at this node.

**ENABLED**

Multicast traffic is allowed at this node.

**ONLY** Only subscriptions from a multicast capable client are allowed.

**MDURMDL( *string* )**

The name of the model queue to be used for durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects ). The maximum length is 48 characters.

If MDURMDL is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for MDURMDL.

If you use MDURMDL to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.DURABLE

**MNDURMDL( *string* )**

The name of the model queue to be used for non-durable subscriptions that request that the queue manager manages the destination of its publications (see Rules for naming IBM MQ objects ). The maximum length is 48 characters.

If MNDURMDL is blank, it operates in the same way as ASPARENT values on other attributes. The name of the model queue to be used is based on the closest parent administrative topic object in the topic tree with a value set for MNDURMDL.

If you use MNDURMDL to specify a model queue for a clustered topic, you must ensure that the queue is defined on every queue manager in the cluster where a non-durable subscription using this topic can be made.

The dynamic queue created from this model has a prefix of SYSTEM.MANAGED.NDURABLE.

## **NPMSGDLV**

The delivery mechanism for non-persistent messages published to this topic:

### **ASPARENT**

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

**ALL** Non-persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

### **ALLAVAIL**

Non-persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

### **ALLDUR**

Non-persistent messages must be delivered to all durable subscribers. Failure to deliver a non-persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

## **PMSGDLV**

The delivery mechanism for persistent messages published to this topic:

### **ASPARENT**

The delivery mechanism used is based on the setting of the first parent administrative node found in the topic tree relating to this topic.

**ALL** Persistent messages must be delivered to all subscribers, irrespective of durability for the MQPUT call to report success. If a delivery failure to any subscriber occurs, no other subscribers receive the message and the MQPUT call fails.

### **ALLAVAIL**

Persistent messages are delivered to all subscribers that can accept the message. Failure to deliver the message to any subscriber does not prevent other subscribers from receiving the message.

### **ALLDUR**

Persistent messages must be delivered to all durable subscribers. Failure to deliver a persistent message to any non-durable subscribers does not return an error to the MQPUT call. If a delivery failure to a durable subscriber occurs, no subscribers receive the message and the MQPUT calls fails.

## **PROXYSUB**

Controls when a proxy subscription is sent for this topic, or topic strings below this topic, to neighboring queue managers when in a publish/subscribe cluster or hierarchy. For more details, see Subscription performance in publish/subscribe networks.

### **FIRSTUSE**

For each unique topic string at or below this topic object, a proxy subscription is asynchronously sent to all neighboring queue managers in the following scenarios:

- When a local subscription is created.
- When a proxy subscription is received that must be propagated to further directly connected queue managers.

### **FORCE**

A wildcard proxy subscription that matches all topic strings at and below this point in the topic tree is sent to neighboring queue managers even if no local subscriptions exist.

**Note:** The proxy subscription is sent when this value is set on DEFINE or ALTER. When set on a clustered topic, all queue managers in the cluster issue the wildcard proxy subscription to all other queue managers in the cluster.

**PUB** Controls whether messages can be published to this topic.

**ASPARENT**

Whether messages can be published to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

**ENABLED**

Messages can be published to the topic (by suitably authorized applications).

**DISABLED**

Messages cannot be published to the topic.

See also Special handling for the **PUB** parameter.

**PUBSCOPE**

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

**Note:** You can restrict the behavior on a publication-by-publication basis, using MQPMO\_SCOPE\_QMGR on the Put Message options.

**ASPARENT**

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster. This is based on the setting of the first parent administrative node found in the topic tree that relates to this topic.

**QMGR**

Publications for this topic are not propagated to connected queue managers.

**ALL** Publications for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

**z/OS QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object within the group.

QSGDISP	DEFINE
<b>COPY</b>	The object is defined on the page set of the queue manager that executes the command using the QSGDISP(GROUP) object of the same name as the 'LIKE' object.
<b>GROUP</b>	The object definition resides in the shared repository but only if the queue manager is in a queue-sharing group. If the definition is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to attempt to make or refresh local copies on page set zero:  DEFINE TOPIC(name) REPLACE QSGDISP(COPY)  The DEFINE for the group object takes effect regardless of whether the generated command with QSGDISP(COPY) fails.
<b>PRIVATE</b>	Not permitted.
<b>QMGR</b>	The object is defined on the page set of the queue manager that executes the command.

## REPLACE and NOREPLACE

Determines whether the existing definition (and on z/OS, with the same disposition) is to be replaced with this one. Any object with a different disposition is not changed.

### REPLACE

If the object does exist, the effect is like issuing the ALTER command without the FORCE option and with *all* the other parameters specified.

(The difference between the ALTER command without the FORCE option, and the DEFINE command with the REPLACE option, is that ALTER does not change unspecified parameters, but DEFINE with REPLACE sets *all* the parameters. When you use REPLACE, unspecified parameters are taken either from the object named on the LIKE option, or from the default definition, and the parameters of the object being replaced, if one exists, are ignored.)

The command fails if both of the following are true:

- The command sets parameters that would require the use of the FORCE option if you were using the ALTER command.
- The object is open.

The ALTER command with the FORCE option succeeds in this situation.

### NOREPLACE

The definition must not replace any existing definition of the object.

**SUB** Controls whether applications are to be permitted to subscribe to this topic.

### ASPARENT

Whether applications can subscribe to the topic is based on the setting of the closest parent administrative topic object in the topic tree.

### ENABLED

Subscriptions can be made to the topic (by suitably authorized applications).

### DISABLED

Applications cannot subscribe to the topic.

## SUBSCOPE

Determines whether this queue manager subscribes to publications in this queue manager or in the network of connected queue managers. If subscribing to all queue managers, the queue manager propagates subscriptions to them as part of a hierarchy or as part of a publish/subscribe cluster.

**Note:** You can restrict the behavior on a subscription-by-subscription basis, using **MQPMO\_SCOPE\_QMGR** on the Subscription Descriptor or **SUBSCOPE(QMGR)** on **DEFINE SUB**. Individual subscribers can override the **SUBSCOPE** setting of ALL by specifying the **MQSO\_SCOPE\_QMGR** subscription option when creating a subscription.

### ASPARENT

Whether this queue manager subscribes to publications in the same way as the setting of the first parent administrative node found in the topic tree relating to this topic.

### QMGR

Only publications that are published on this queue manager reach the subscriber.

**ALL** A publication made on this queue manager or on another queue manager reaches the subscriber. Subscriptions for this topic are propagated to hierarchically connected queue managers and to publish/subscribe cluster-connected queue managers.

## TOPICSTR( *string* )

The topic string represented by this topic object definition. This parameter is required and cannot contain the empty string.

The topic string must not be the same as any other topic string already represented by a topic object definition.

The maximum length of the string is 10,240 characters.

**TYPE (topic-type)**

If this parameter is used it must follow immediately after the *topic-name* parameter on all platforms  except z/OS.

**LOCAL**

A local topic object.

**USEDLQ**

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

**ASPARENT**

Determines whether to use the dead-letter queue using the setting of the closest administrative topic object in the topic tree. This value is the default supplied with IBM MQ, but your installation might have changed it.

**NO** Publication messages that cannot be delivered to their correct subscriber queue are treated as a failure to put the message. The MQPUT of an application to a topic fails in accordance with the settings of NPMSGDLV and PMSGDLV.

**YES** When the DEADQ queue manager attribute provides the name of a dead-letter queue, then it is used. If the queue manager does not provide the name of a dead-letter queue, then the behavior is as for NO.

**WILDCARD**

The behavior of wildcard subscriptions with respect to this topic.

**PASSTHRU**

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object receive publications made to this topic and to topic strings more specific than this topic.

**BLOCK**

Subscriptions made to a wildcarded topic less specific than the topic string at this topic object do not receive publications made to this topic or to topic strings more specific than this topic.

The value of this attribute is used when subscriptions are defined. If you alter this attribute, the set of topics covered by existing subscriptions is not affected by the modification. This scenario applies also if the topology is changed when topic objects are created or deleted; the set of topics matching subscriptions created following the modification of the WILDCARD attribute is created using the modified topology. If you want to force the matching set of topics to be re-evaluated for existing subscriptions, you must restart the queue manager.

## DELETE AUTHINFO:

Use MQSC command DELETE AUTHINFO to delete an authentication information object.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

► **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DELETE AUTHINFO”

**Synonym:** None

## DELETE AUTHINFO

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 2 Valid only on z/OS.

### Parameter descriptions for DELETE AUTHINFO

*(name)*

Name of the authentication information object. This is required.

The name must be that of an existing authentication information object.

► **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

**z/OS QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

**COPY** The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

**GROUP**

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to delete local copies on page set zero:

```
DELETE AUTHINFO(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

**QMGR**

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

**DELETE AUTHREC:**

Use the MQSC command DELETE AUTHREC to delete authority records associated with a profile name.

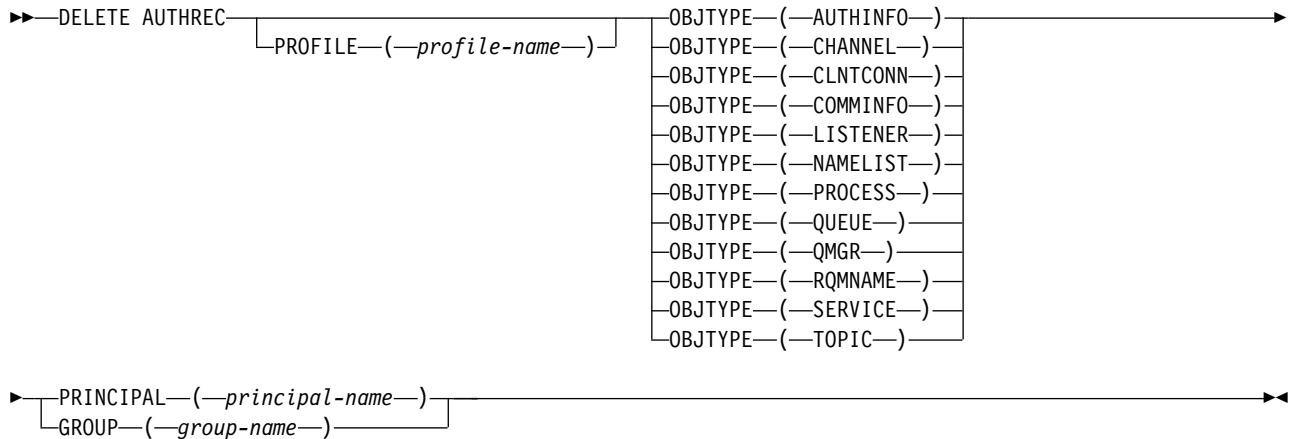

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions” on page 691

## DELETE AUTHREC

### Parameter descriptions

#### PROFILE(*profile-name*)

The name of the object or generic profile for which to remove the authority record. This parameter is required unless the **OBJTYPE** parameter is QMGR, in which case it can be omitted.

#### OBJTYPE

The type of object referred to by the profile. Specify one of the following values:

##### AUTHINFO

Authentication information record

##### CHANNEL

Channel

##### CLNTCONN

Client connection channel

##### COMMINFO

Communication information object

##### LISTENER

Listener

##### NAMELIST

Namelist

##### PROCESS

Process

##### QUEUE

Queue

##### QMGR

Queue manager

##### RQMNAME

Remote queue manager

##### SERVICE

Service

##### TOPIC

Topic

**PRINCIPAL**(*principal-name*)

A principal name. This is the name of a user for whom to remove authority records for the specified profile. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: user@domain.

You must specify either PRINCIPAL or GROUP.

**GROUP**(*group-name*)

A group name. This is the name of the user group for which to remove authority records for the specified profile. You can specify one name only and it must be the name of an existing user group.

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

GroupName@domain  
domain\GroupName

You must specify either PRINCIPAL or GROUP.

**DELETE BUFFPOOL:** z/OS

Use the MQSC command DELETE BUFFPOOL to delete a buffer pool that is used for holding messages in main storage.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage note for DELETE BUFFPOOL”
- “Parameter descriptions for DELETE BUFFPOOL”

**Synonym:** DEL BP

**DELETE BUFFPOOL**

▶▶—DELETE BUFFPOOL—(—*integer*—)—————▶▶

**Usage note for DELETE BUFFPOOL**

- Ensure there are no current page set definitions using the named buffer pool, otherwise the command will fail.
- DELETE BUFFPOOL cannot be issued from CSQINPT.

**Parameter descriptions for DELETE BUFFPOOL**

(*integer*)

This is the number of the buffer pool to be deleted. The value is an integer in the range zero through 15. If OPMODE is set to OPMODE=(NEWFUNC, 800), this parameter is an integer in the range zero through 99.

## DELETE CFSTRUCT: z/OS

Use the MQSC command DELETE CFSTRUCT to delete a CF application structure definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DELETE CFSTRUCT”
- “Keyword and parameter descriptions for DELETE CFSTRUCT”

**Synonym:** None

### DELETE CFSTRUCT

▶▶—DELETE CFSTRUCT—(*—structure-name—*)—————▶▶

#### Usage notes for DELETE CFSTRUCT

1. This command is valid only z/OS when the queue manager is a member of a queue-sharing group.
2. The command fails if there are any queues in existence that reference this CF structure name that are not both empty and closed.
3. The command cannot specify the CF administration structure (CSQ\_ADMIN).
4. The command deletes the Db2 CF structure record only. It does **not** delete the CF structure definition from the CFRM policy data set.
5. CF structures at CFLEVEL(1) are automatically deleted when the last queue on that structure is deleted.

#### Keyword and parameter descriptions for DELETE CFSTRUCT

(*structure-name*)

The name of the CF structure definition to be deleted. The name must be defined within the queue sharing group.

## DELETE CHANNEL:

Use the MQSC command DELETE CHANNEL to delete a channel definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

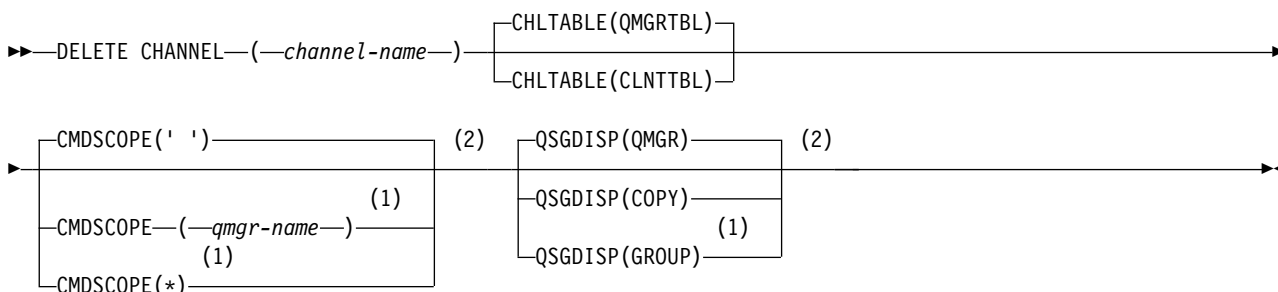

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

► **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes”
- “Parameter descriptions”

**Synonym:** DELETE CHL

## DELETE CHANNEL

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Usage notes

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE CHANNEL step in Checking that async commands for distributed networks have finished.
- ► **z/OS** On z/OS systems, the command fails if the channel initiator and command server have not been started, or the channel status is RUNNING, except client-connection channels, which can be deleted without the channel initiator or command server running.
- ► **z/OS** On z/OS systems, you can only delete cluster-sender channels that have been created manually.

### Parameter descriptions

(channel-name)

The name of the channel definition to be deleted. This is required. The name must be that of an existing channel.

## CHLTABLE

Specifies the channel definition table that contains the channel to be deleted. This is optional.

## QMGRBTBL

The channel table is that associated with the target queue manager. This table does not contain any channels of type CLNTCONN. This is the default.

## CLNTTBL

The channel table for CLNTCONN channels. On z/OS, this is associated with the target queue manager, but separate from the main channel table. On all other platforms, this channel table is normally associated with a queue manager, but can be a system-wide, queue manager independent channel table if you set up a number of environment variables. For more information about setting up environment variables, see Using IBM MQ environment variables.

## z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

## z/OS QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

**COPY** The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

## GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to delete local copies on page set zero:

```
DELETE CHANNEL(channel-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

## QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

## DELETE CHANNEL (MQTT):

Use the MQSC command DELETE CHANNEL to delete an IBM MQ Telemetry channel definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	AIX and Linux	Windows	z/OS
	✓	✓	

**Note:** For the telemetry server, AIX is the only supported UNIX platform.

The DELETE CHANNEL (MQTT) command is only valid for IBM MQ Telemetry channels.

**Synonym:** DELETE CHL

## DELETE CHANNEL

►►—DELETE CHANNEL—(—*channel-name*—)—CHLTYPE—(—MQTT—)—◄◄

### Parameter descriptions

(*channel-name*)

The name of the channel definition to be deleted. This is required. The name must be that of an existing channel.

### CHLTYPE

This parameter is required. There is only one possible value: MQTT.

## DELETE COMMINFO:

Use the MQSC command DELETE COMMINFO to delete a communication information object.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions for DELETE COMMINFO”

**Synonym:** DEL COMMINFO

## DELETE COMMINFO

▶▶—DELETE COMMINFO—(*comminfo name*)—▶▶

### Parameter descriptions for DELETE COMMINFO

(*comminfo name*)

The name of the communications information object to be deleted. This is required.

## DELETE LISTENER:

Use the MQSC command DELETE LISTENER to delete a listener definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Usage notes for DELETE LISTENER” on page 698
- “Keyword and parameter descriptions for DELETE LISTENER” on page 698

**Synonym:** DELETE LSTR

## DELETE LISTENER

▶▶—DELETE LISTENER—(—*listener-name*—)—————▶▶

### Usage notes for DELETE LISTENER

1. The command fails if an application has the specified listener object open, or if the listener is currently running.

### Keyword and parameter descriptions for DELETE LISTENER

(*listener-name*)

The name of the listener definition to be deleted. This is required. The name must be that of an existing listener defined on the local queue manager.

### DELETE NAMELIST:

Use the MQSC command DELETE NAMELIST to delete a namelist definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

▶ **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes”
- “Parameter descriptions for DELETE NAMELIST” on page 699

Synonym: DELETE NL

## DELETE NAMELIST

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Usage notes

- On UNIX systems, the command is valid only on AIX, HP-UX, Linux and Solaris.

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE NAMELIST step in Checking that async commands for distributed networks have finished.

## Parameter descriptions for DELETE NAMELIST

You must specify which namelist definition you want to delete.

*(name)*

The name of the namelist definition to be deleted. The name must be defined to the local queue manager.

If an application has this namelist open, the command fails.

### ▶ z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

### ▶ z/OS **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

**COPY** The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

#### **GROUP**

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to delete local copies on page set zero:

```
DELETE NAMELIST(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

#### **QMGR**

The object definition resides on the page set of the queue manager that executes the

command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

#### DELETE POLICY:

Use the MQSC command DELETE POLICY to delete a security policy.

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions for DELETE POLICY”

#### DELETE POLICY

▶▶—DELETE POLICY—(—*policy-name*—)—————▶▶

#### Parameter descriptions for DELETE POLICY

(*policy-name*)

Specifies the policy name to be deleted.

The name of the policy, or policies, to delete are the same as the name of the queue, or queues, that the policies control.

#### DELETE PROCESS:

Use the MQSC command DELETE PROCESS to delete a process definition.

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

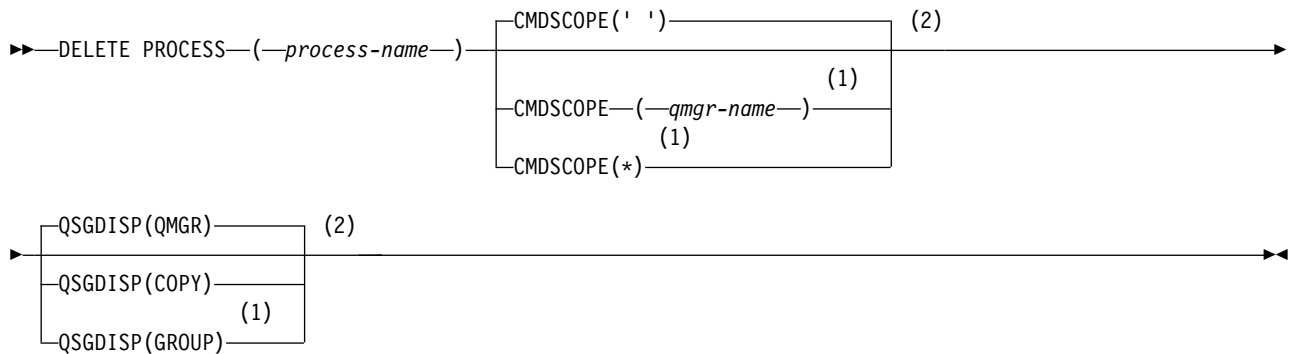

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

▶ **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DELETE PROCESS” on page 701

**Synonym:** DELETE PRO

## DELETE PROCESS

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Parameter descriptions for DELETE PROCESS

You must specify which process definition you want to delete.

(*process-name*)

The name of the process definition to be deleted. The name must be defined to the local queue manager.

If an application has this process open, the command fails.

#### z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

#### z/OS QSGDISP

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

**COPY** The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters

QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

### GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to delete local copies on page set zero:

```
DELETE PROCESS(process-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

### QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

### DELETE PSID:

Use the MQSC command DELETE PSID to delete a page set. This command closes the page set and de-allocates it from the queue manager.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DELETE PSID”
- “Parameter descriptions for DELETE PSID” on page 703

**Synonym:** DEL PSID

### DELETE PSID

▶▶—DELETE PSID—(—psid-number—)—————▶▶

### Usage notes for DELETE PSID

1. The identified page set must have no storage class (STGCLASS) referencing it.
2. If the page set still has buffers in the buffer pool when you issue this command, the command fails and an error message is issued. You cannot delete the page set until 3 checkpoints have been completed since the page set was emptied.

3. If the page set is not to be used again by the queue manager, update the queue manager started task procedure JCL, and remove the corresponding DEFINE PSID command from the CSQINP1 initialization data set. If the page set had a dedicated buffer pool, remove its definitions also from CSQINP1.
4. If you want to reuse the data set again as a page set, format it before doing so.

### Parameter descriptions for DELETE PSID

*(psid-number)*

Identifier of the page set. This is required. You cannot delete page set 0.

### DELETE queues:

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

This section contains the following commands:

- “DELETE QALIAS” on page 705
- “DELETE QLOCAL” on page 706
- “DELETE QMODEL” on page 706
- “DELETE QREMOTE” on page 707

These commands are supported on the following platforms:

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

### Usage notes for DELETE queues

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE queues step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for DELETE queues

*(q-name)*

The name of the queue must be defined to the local queue manager for all the queue types.

For an alias queue this is the local name of the alias queue to be deleted.

For a model queue this is the local name of the model queue to be deleted.

For a remote queue this is the local name of the remote queue to be deleted.

For a local queue this is the name of the local queue to be deleted. You must specify which queue you want to delete.

**Note:** A queue cannot be deleted if it contains uncommitted messages.

If an application has this queue open, or has open a queue that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

If this queue has a SCOPE attribute of CELL, the entry for the queue is also deleted from the cell directory.

## **AUTHREC**

This parameter does not apply to z/OS.

Specifies whether the associated authority record is also deleted:

**YES** The authority record associated with the object is deleted. This is the default.

**NO** The authority record associated with the object is not deleted.

## **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP or SHARED.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\*

The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

## **PURGE and NOPURGE**

Specifies whether any existing committed messages on the queue named by the DELETE command are to be purged for the delete command to work. The default is NOPURGE.

### **PURGE**

The deletion is to go ahead even if there are committed messages on the named queue, and these messages are also to be purged.

### **NOPURGE**

The deletion is not to go ahead if there are any committed messages on the named queue.

## **z/OS** **QSGDISP**

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves). If the object definition is shared, you do not need to delete it on every queue manager that is part of a queue-sharing group. (Queue-sharing groups are available only on IBM MQ for z/OS.)

**COPY** The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

### **GROUP**

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters QSGDISP(SHARED), is not affected by this command.

If the deletion is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to make, or delete, local copies on page set zero:

```
DELETE queue(q-name) QSGDISP(COPY)
```

or, for a local queue only:

```
DELETE QLOCAL(q-name) NOPURGE QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

**Note:** You always get the NOPURGE option even if you specify PURGE. To delete messages on local copies of the queues, you must explicitly issue the command:

```
DELETE QLOCAL(q-name) QSGDISP(COPY) PURGE
```

for each copy.

### QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

### SHARED

This option applies only to local queues.

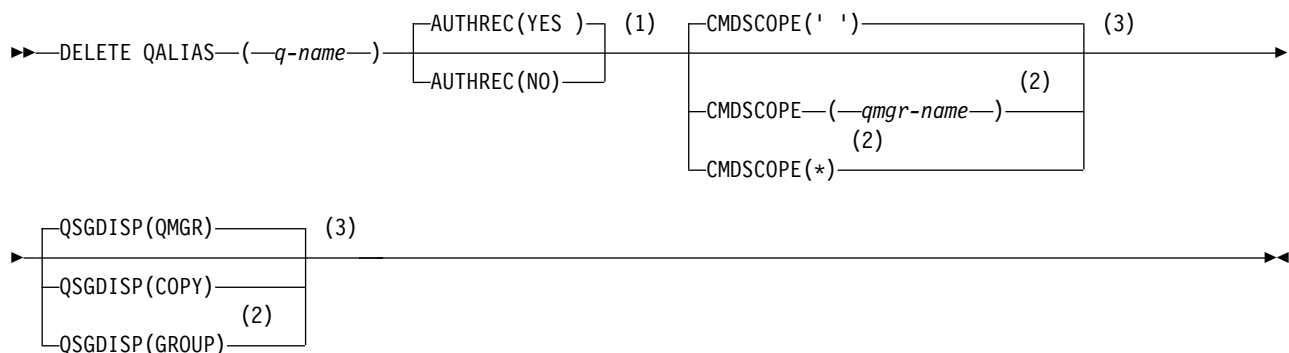

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(SHARED). Any object residing on the page set of the queue manager that executes the command, or any object defined using a command that had the parameters QSGDISP(GROUP), is not affected by this command.

### DELETE QALIAS:

Use DELETE QALIAS to delete an alias queue definition.

**Synonym:** DELETE QA

### DELETE QALIAS

### Notes:

- 1 Not valid on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

3 Valid only on z/OS.

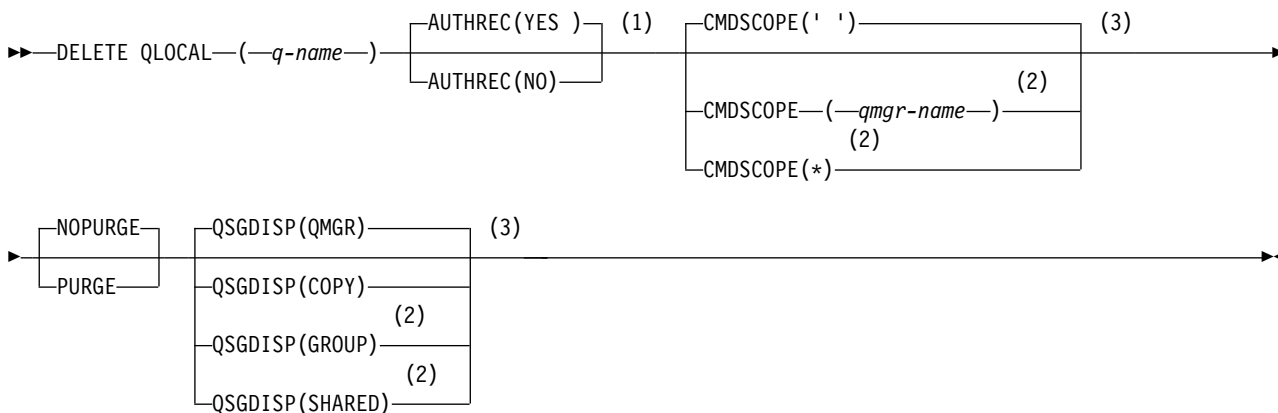

The parameters are described in “DELETE queues” on page 703.

*DELETE QLOCAL:*

Use DELETE QLOCAL to delete a local queue definition. You can specify that the queue must not be deleted if it contains messages, or that it can be deleted even if it contains messages.

**Synonym:** DELETE QL

**DELETE QLOCAL**

**Notes:**

- 1 Not valid on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.

The parameters are described in “DELETE queues” on page 703.

*DELETE QMODEL:*

Use DELETE QMODEL to delete a model queue definition.

**Synonym:** DELETE QM

**DELETE QMODEL**

**Notes:**

- 1 Not valid on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.

The parameters are described in “DELETE queues” on page 703.

*DELETE QREMOTE:*

Use DELETE QREMOTE to delete a local definition of a remote queue. It does not affect the definition of that queue on the remote system.

**Synonym:** DELETE QR

**DELETE QREMOTE**

**Notes:**

- 1 Not valid on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.

The parameters are described in “DELETE queues” on page 703.

## DELETE SERVICE:

Use the MQSC command DELETE SERVICE to delete a service definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Usage notes for DELETE SERVICE”
- “Keyword and parameter descriptions for DELETE SERVICE”

**Synonym:**

## DELETE SERVICE

►►—DELETE SERVICE—(—*service-name*—)—————►►

### Usage notes for DELETE SERVICE

1. The command fails if an application has the specified service object open, or if the service is currently running.

### Keyword and parameter descriptions for DELETE SERVICE

(*service-name*)

The name of the service definition to be deleted. This is required. The name must be that of an existing service defined on the local queue manager.

## DELETE SUB:

Use the MQSC command DELETE SUB to remove a durable subscription from the system. For a managed destination, any unprocessed messages left on the destination are removed.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

► **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- Usage notes for DELETE SUB
- “Parameter descriptions for DELETE SUB” on page 709

**Synonym:** DEL SUB

## DELETE SUB

### Notes:

- 1 Valid only on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

### Usage notes for DELETE SUB

- You can specify either the name, the identifier, or both, of the subscription you want to delete.

Examples of valid forms:

```
DELETE SUB(xyz)
DELETE SUB SUBID(123)
DELETE SUB(xyz) SUBID(123)
```

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE SUB step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for DELETE SUB

#### *subscription-name*

The local name of the subscription definition to be deleted.

#### **z/OS** CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is processed on the queue manager on which it was entered. This is the default value.

#### *qmgr-name*

The command is processed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is processed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

#### **SUBID**( *string* )

The internal, unique key identifying a subscription.

## DELETE STGCLASS: z/OS

Use the MQSC command DELETE STGCLASS to delete a storage class definition.

### Using MQSC commands

For information on how you use MQSC commands, see *Performing local administration tasks using MQSC commands*.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see *Using commands on z/OS*.

- Syntax diagram
- “Parameter descriptions for DELETE STGCLASS”

**Synonym:** DELETE STC

### DELETE STGCLASS

#### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

#### Parameter descriptions for DELETE STGCLASS

You must specify which storage class definition you want to delete.

All queues that use this storage class must be altered to use another storage class.

*(name)*

The name of the storage class definition to be deleted. The name must be defined to the local queue manager.

The command fails unless all queues referencing the storage class are empty and closed.

#### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

### QSGDISP

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

#### COPY

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

#### GROUP

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to delete local copies on page set zero:

```
DELETE STGCLASS(name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

#### QMGR

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

### DELETE TOPIC:

Use DELETE TOPIC to delete an IBM MQ administrative topic node.

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

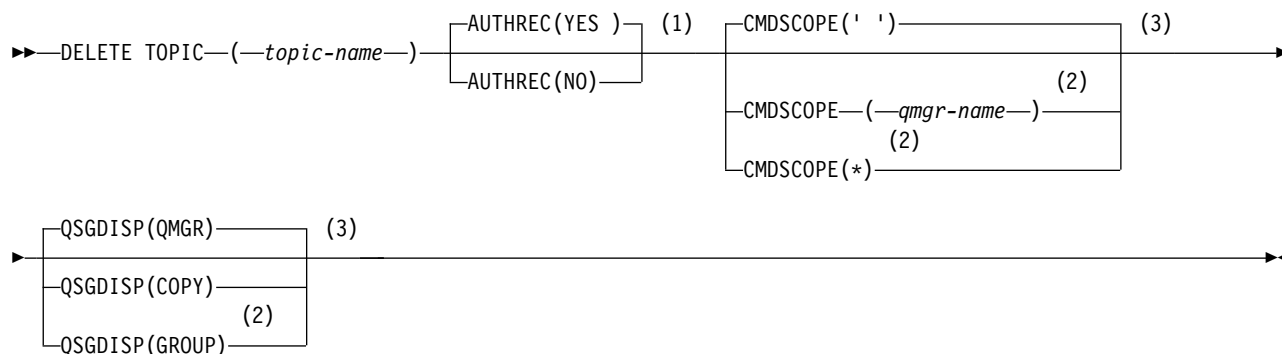

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

▶ **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DELETE TOPIC” on page 712
- “Parameter descriptions for DELETE TOPIC” on page 712

Synonym: None

## DELETE TOPIC

### Notes:

- 1 Not valid on z/OS
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.

### Usage notes for DELETE TOPIC

- Successful completion of the command does not mean that the action completed. To check for true completion, see the DELETE TOPIC step in Checking that async commands for distributed networks have finished.

### Parameter descriptions for DELETE TOPIC

*(topic-name)*

The name of the administrative topic object to be deleted. This parameter is required.

The name must be that of an existing administrative topic object.

#### AUTHREC

This parameter does not apply to z/OS

Specifies whether the associated authority record is also deleted:

**YES** The authority record associated with the object is deleted. This is the default.

**NO** The authority record associated with the object is not deleted.

#### **CMDSCOPE**

This parameter applies to only z/OS and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active

queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

**z/OS** **QSGDISP**

This parameter applies to z/OS only.

Specifies the disposition of the object to which you are applying the command (that is, where it is defined and how it behaves).

**COPY** The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(COPY). Any object residing in the shared repository, or any object defined using a command that had the parameters QSGDISP(QMGR), is not affected by this command.

**GROUP**

The object definition resides in the shared repository. The object was defined using a command that had the parameters QSGDISP(GROUP). Any object residing on the page set of the queue manager that executes the command (except a local copy of the object) is not affected by this command.

If the command is successful, the following command is generated and sent to all active queue managers in the queue-sharing group to make, or delete, local copies on page set zero:

```
DELETE TOPIC(topic-name) QSGDISP(COPY)
```

The deletion of the group object takes effect even if the generated command with QSGDISP(COPY) fails.

**QMGR**

The object definition resides on the page set of the queue manager that executes the command. The object was defined using a command that had the parameters QSGDISP(QMGR). Any object residing in the shared repository, or any local copy of such an object, is not affected by this command.

This is the default value.

**DISPLAY ARCHIVE:** **z/OS**

Use the MQSC command DISPLAY ARCHIVE to display archive system parameters and information.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			12CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY ARCHIVE” on page 714
- “Parameter descriptions for DISPLAY ARCHIVE” on page 714

**Synonym:** DIS ARC

## DISPLAY ARCHIVE

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

### Usage notes for DISPLAY ARCHIVE

1. DISPLAY ARCHIVE returns a report that shows the initial values for the archiving parameters, and the current values as changed by the SET ARCHIVE command.
  - Units in which primary and secondary space allocations are made (ALCUNIT).
  - Prefix for first archive log data set name (ARCPFX1).
  - Prefix for second archive log data set name (ARCPFX2).
  - The retention period of the archive log data set in days (ARCRETN).
  - List of route codes for messages to the operator about archive log data sets (ARCWRTC).
  - Whether to send message to operator and wait for reply before trying to mount an archive log data set (ARCWTOR).
  - Block size of archive log data set (BLKSIZE).
  - Whether archive log data sets are cataloged in the ICF (CATALOG).
  - Whether archive log data sets should be compacted (COMPACT).
  - Primary space allocation for DASD data sets (PRIQTY).
  - Whether archive log data sets are protected by ESM profiles when the data sets are created (PROTECT).
  - Maximum time, in seconds, allowed for quiesce when ARCHIVE LOG with MODE(QUIESCE) specified (QUIESCE).
  - Secondary space allocation for DASD data sets. See the ALCUNIT parameter for the units to be used (SECQTY).
  - Whether the archive data set name should include a time stamp (TSTAMP).
  - Device type or unit name on which the first copy of archive log data sets is stored (UNIT).
  - Device type or unit name on which the second copy of archive log data sets is stored (UNIT2).

It also reports the status of tape units used for archiving.

For more details of these parameters, see "SET ARCHIVE" on page 981.

2. This command is issued internally by IBM MQ at the end of queue manager startup.

### Parameter descriptions for DISPLAY ARCHIVE

#### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

## DISPLAY AUTHINFO:

Use the MQSC command DISPLAY AUTHINFO to display the attributes of an authentication information object.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

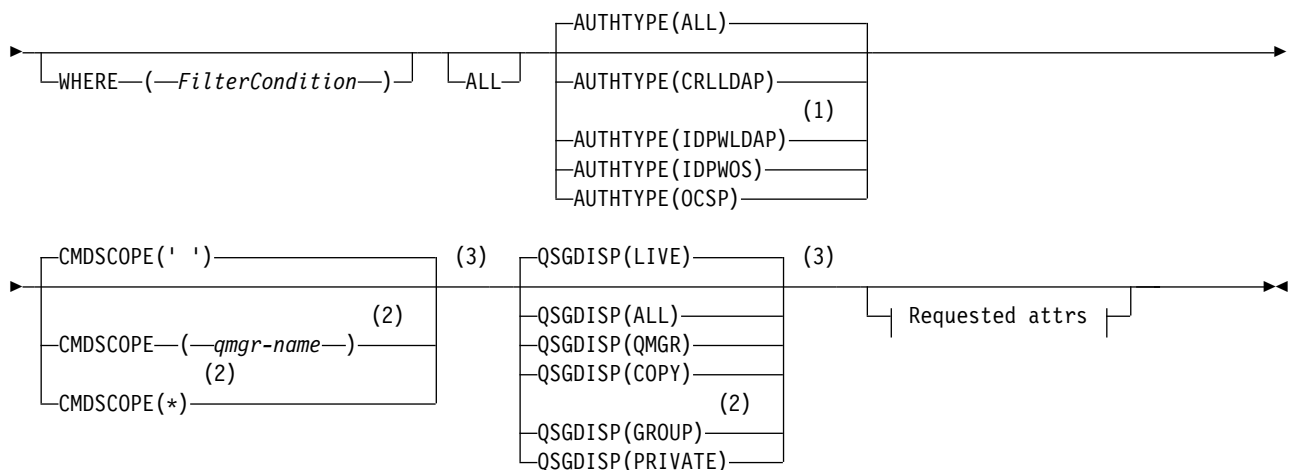

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY AUTHINFO” on page 716
- “Requested parameters” on page 719

**Synonym:** DIS AUTHINFO

## DISPLAY AUTHINFO

►►—DISPLAY AUTHINFO—(—*generic-authentication-information-object-name*—)—————►

## Notes:

- 1 Not valid on IBM MQ for z/OS.
- 2 Valid only when the queue manager is a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.
- 3 Valid only on z/OS.
- 4 Not valid on z/OS and AUTHENMD PAM value valid only on UNIX platforms.
- 5 Not valid on Windows.

## Parameter descriptions for DISPLAY AUTHINFO

(*generic-authentication-information-object-name*)

The name of the authentication information object to be displayed (see Rules for naming IBM MQ objects ). A trailing asterisk (\*) matches all authentication information objects with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all authentication information objects.

## WHERE

Specify a filter condition to display only those authentication information objects that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords.

### *operator*

This is used to determine whether an authentication information object satisfies the filter value on the given filter keyword. The operators are:

<b>LT</b>	Less than
<b>GT</b>	Greater than
<b>EQ</b>	Equal to
<b>NE</b>	Not equal to
<b>LE</b>	Less than or equal to
<b>GE</b>	Greater than or equal to
<b>LK</b>	Matches a generic string that you provide as a <i>filter-value</i>
<b>NL</b>	Does not match a generic string that you provide as a <i>filter-value</i>

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use any of the operators except LK and NL.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value with numeric values. Only a single trailing wildcard character (asterisk) is permitted.

You can only use operators LK or NL for generic values on the DISPLAY AUTHINFO command.

**ALL** Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic name and do not request any specific parameters.

▶ **z/OS** On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

### ▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

## AUTHTYPE

Specifies the authentication information type of the objects for which information is to be displayed. Values are:

### ALL

This is the default value and displays information for objects defined with AUTHTYPE(CRLLDAP) and with AUTHTYPE(OCSP).

### CRLLDAP

Displays information only for objects defined with AUTHTYPE(CRLLDAP).

### IDPWLDAP

Displays information only for objects defined with AUTHTYPE(IDPWLDAP).

### IDPWOS

Displays information only for objects defined with AUTHTYPE(IDPWOS).

### OCSP

Displays information only for objects defined with AUTHTYPE(OCSP).

z/OS

## QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**ALL** Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(LIVE) is specified or defaulted, or if QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

**COPY** Displays information only for objects defined with QSGDISP(COPY).

### GROUP

Displays information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

### PRIVATE

Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

### QMGR

Displays information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

### QMGR

The object was defined with QSGDISP(QMGR).

### GROUP

The object was defined with QSGDISP(GROUP).

**COPY** The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

## Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names and their AUTHTYPEs, and, on z/OS, their QSGDISPs, are displayed.

### ADOPTCTX

Displays the presented credentials as the context for this application.

### ALTDATE

The date on which the definition was last altered, in the form yyyy-mm-dd

### ALTTIME

The time at which the definition was last altered, in the form hh.mm.ss

### ▶ V 8.0.0.3 AUTHENMD

Authentication method. Possible values are:

**OS** Displays the traditional UNIX platforms password verification method permissions.

#### PAM

Displays the Pluggable Authentication Method permissions.

You can set the PAM value only on UNIX and Linux platforms.

### ▶ V 8.0.0.2 AUTHORMD

Authorization method. Possible values are:

**OS** Displays the operating system groups determining permissions

#### SEARCHGRP

Displays a group entry in the LDAP server, containing an attribute listing all the users belonging to that group.

#### SEARCHUSR

Displays a user entry in the LDAP server containing an attribute listing all the groups to which the user belongs.

This attribute is not applicable to Windows platforms.

### AUTHTYPE

The type of the authentication information

### ▶ V 8.0.0.2 BASEDNG

Displays the Base DN for groups.

This attribute is not applicable to Windows platforms.

### BASEDNU

Displays the base distinguished name to search for users within the LDAP server.

### CHCKLOCL or CHCKCLNT

These attributes are valid only for an **AUTHTYPE** of *IDPWOS* or *IDPWLDAP*. The possible values are:

**NONE** Displays all locally bound applications that have no user ID and password authentication.

#### OPTIONAL

Displays the user IDs and passwords provided by an application. Note that it is not mandatory to provide these attributes. This option might be useful during migration, for example.

**REQUIRED**

Displays all applications providing a valid user ID and password.

**REQDADM**

Displays privileged users supplying a valid user ID and password, Non-privileged users are treated as with the OPTIONAL setting. See also the following note.  (This setting is not allowed on z/OS systems.)

 **CLASSGRP**

Displays the LDAP object class for group records.

This attribute is not applicable to Windows platforms.

**CLASSUSR**

Displays the LDAP object class for user records within the LDAP repository.

**CONNAME**

The host name, IPv4 dotted decimal address, or IPv6 hexadecimal notation of the host on which the LDAP server is running. Applies only to objects with AUTHTYPE(CRLLDAP) or AUTHTYPE(IDPWLDAP).

**DESCR**

Description of the authentication information object.

**FAILDLAY**

Delay in seconds before an authentication failure is returned to an application.

 **FINDGRP**

Displays the name of the attribute within an LDAP entry to determine group membership.

This attribute is not applicable to Windows platforms.

 **GRPFIELD**

Displays the LDAP attribute that represents a simple name for the group.

This attribute is not applicable to Windows platforms.

**LDAPPWD**

Password associated with the Distinguished Name of the user on the LDAP server. If nonblank, this is displayed as asterisks  on all platforms except z/OS. Applies only to objects with AUTHTYPE(CRLLDAP) or AUTHTYPE(IDPWLDAP).

**LDAPUSER**

Distinguished Name of the user on the LDAP server. Applies only to objects with AUTHTYPE(CRLLDAP) or AUTHTYPE(IDPWLDAP).

 **NESTGRP**

Displays whether a group is a member of another group..

This attribute is not applicable to Windows platforms.

**OCSPURL**

The URL of the OCSP responder used to check for certificate revocation. Applies only to objects with AUTHTYPE(OCSP).

**SECCOMM**

Displays the method used to connect the LDAP server.

**SHORTUSR**

Displays the user record being used as a short name.

## USRFIELD

Displays the user record being used in the LDAP user record, only if the user ID does not contain a qualifier.

See “Usage notes for DEFINE AUTHINFO” on page 532 for more information about individual parameters.

## DISPLAY AUTHREC:

Use the MQSC command DISPLAY AUTHREC to display the authority records associated with a profile name.

### Using MQSC commands

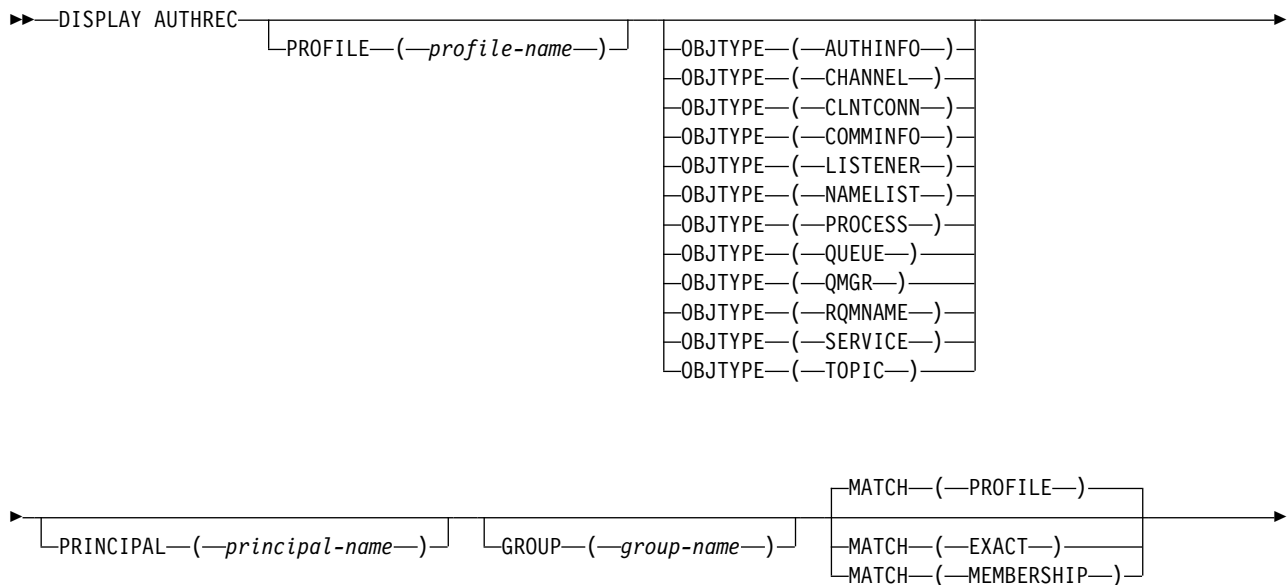

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions” on page 722
- “Requested parameters” on page 723

Synonym: DIS AUTHREC

## DISPLAY AUTHREC

## Parameter descriptions

### **PROFILE**(*profile-name*)

The name of the object or generic profile for which to display the authority records. If you omit this parameter, all authority records that satisfy the values of the other parameters are displayed.

### **OBJTYPE**

The type of object referred to by the profile. Specify one of the following values:

#### **AUTHINFO**

Authentication information record

#### **CHANNEL**

Channel

#### **CLNTCONN**

Client connection channel

#### **COMMINFO**

Communication information object

#### **LISTENER**

Listener

#### **NAMELIST**

Namelist

#### **PROCESS**

Process

#### **QUEUE**

Queue

#### **QMGR**

Queue manager

#### **RQMNAME**

Remote queue manager

#### **SERVICE**

Service

#### **TOPIC**

Topic

If you omit this parameter, authority records for all object types are displayed.

### **PRINCIPAL**(*principal-name*)

A principal name. This is the name of a user for whom to retrieve authorizations to the specified object. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: `user@domain`.

This parameter cannot be specified with **GROUP**.

### **GROUP**(*group-name*)

A group name. This is the name of the user group on which to make the inquiry. You can specify one name only and it must be the name of an existing user group.

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

GroupName@domain  
domain\GroupName

This parameter cannot be specified with PRINCIPAL.

#### **MATCH**

Specify this parameter to control the set of authority records that is displayed. Specify one of the following values:

##### **PROFILE**

Return only those authority records which match the specified profile, principal, and group names. This means that a profile of ABCD results in the profiles ABCD, ABC\*, and AB\* being returned (if ABC\* and AB\* have been defined as profiles). If the profile name is a generic profile, only authority records which exactly match the specified profile name are returned. If a principal is specified, no profiles are returned for any group in which the principal is a member; only the profiles defined for the specified principal or group.

This is the default value.

##### **MEMBERSHIP**

Return only those authority records which match the specified profile, and the entity field of which matches the specified principal and the profiles pertaining to any groups in which the principal is a member that contribute to the cumulative authority for the specified entity.

If this option is specified, the PROFILE and OBJTYPE parameters must also be specified. In addition, either the PRINCIPAL or GROUP parameter must also be supplied. If OBJTYPE(QMGR) is specified, the profile name is optional.

##### **EXACT**

Return only those authority records which exactly match the specified profile name and EntityName. No matching generic profiles are returned unless the profile name is, itself, a generic profile. If a principal is specified, no profiles are returned for any group in which the principal is a member; only the profile defined for the specified principal or group.

#### **SERVCOMP(*service-component*)**

The name of the authorization service for which information is to be displayed.

If you specify this parameter, it specifies the name of the authorization service to which the authorizations apply. If you omit this parameter, the inquiry is made to the registered authorization services in turn in accordance with the rules for chaining authorization services.

#### **ALL**

Specify this parameter to display all of the authorization information available for the entity and the specified profile.

#### **Requested parameters**

You can request the following information about the authorizations:

##### **AUTHLIST**

Specify this parameter to display the list of authorizations.

##### **ENTITY**

Specify this parameter to display the entity name.

##### **ENTTYPE**

Specify this parameter to display the entity type.

## DISPLAY AUTHSERV:

Use the MQSC command DISPLAY AUTHSERV to display information about the level of function supported by the installed authorization services.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
	✓	✓	

- Syntax diagram
- "Parameter descriptions"
- "Requested parameters"

Synonym: DIS AUTHSERV

## DISPLAY AUTHSERV

### Parameter descriptions

**ALL** Specify this parameter to display all the information for each authorization service.

### Requested parameters

You can request the following information for the authorization service:

#### IFVER

Specify this parameter to display the current interface version of the authorization service.

#### UIDSUPP

Specify this parameter to display whether the authorization service supports user IDs.

## DISPLAY CFSTATUS: z/OS

Use the MQSC command DISPLAY CFSTATUS to display the status of one or more CF application structures. This command is valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

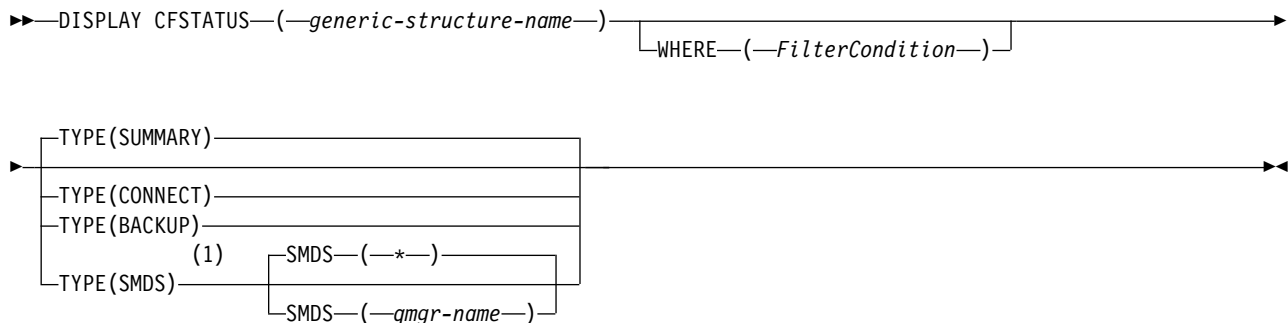

IBM i	UNIX and Linux	Windows	z/OS
			CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Keyword and parameter descriptions for DISPLAY CFSTATUS”
- “Summary status” on page 727
- “Connection status” on page 729
- “Backup status” on page 729
- “SMDS status” on page 730

**Synonym:** DIS CFSTATUS

## DISPLAY CFSTATUS

### Notes:

- 1 This option is only supported when the CFSTRUCT is defined with OFFLOAD(SMDS).

### Keyword and parameter descriptions for DISPLAY CFSTATUS

The name of the application structure for the status information to be displayed must be specified. This can be a specific application structure name or a generic name. By using a generic name, it is possible to display either:

- status information for all application structure definitions
- status information for one or more application structures that match the specified name

The type of status information to be returned can also be specified. This can be:

- summary status information for the application structure in the queue-sharing group

- connection status information for each queue manager in the queue-sharing group for each matching application structure name
- backup status information for each backup taken for each matching application structure defined in the queue-sharing group

*(generic-structure-name)*

The 12-character name of the CF application structure to be displayed. A trailing asterisk (\*) matches all structure names with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all structure names.

The CF structure name must be defined within the queue-sharing group.

The CFSTATUS generic name can be the administration CF structure name (CSQ\_ADMIN) or any generic form of this name. Data for this structure, however, is only displayed when TYPE is set to SUMMARY.

## WHERE

Specify a filter condition to display status information for those CF application structures that satisfy the selection criterion of the filter condition. The filter condition is in three parts:

*filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that is returned by this DISPLAY command. However, you cannot use the TYPE parameter as a filter keyword.

*operator*

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

**CT** Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.

**EX** Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

**CTG** Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.

**EXG** Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, GE, only. However, if the value is one from a possible set of values returnable on a parameter (for example, the value ACTIVE on the STATUS parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string in the QMNAME parameter) with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC\* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

**TYPE** Specifies the type of status information required to be displayed. Values are:

**SUMMARY**

Display summary status information for each application structure. This is the default.

**CONNECT**

Display connection status information for each application structure for each active queue manager.

**BACKUP**

Display backup status information for each application structure.

**SMDS**

Display shared message data set information.

**SMDS**

***qmgr-name***

Specifies the queue manager for which the shared message data set status is to be displayed.

- \* Displays the status for all shared message data sets associated with the specified CFSTRUCT except those which have both STATUS(NOTFOUND) and ACCESS(ENABLED).

**Summary status**

For summary status, the following information is returned for each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

**CFTYPE**

The CF structure type. This is one of the following:

**ADMIN**

This is the CF administration structure.

**APPL**

This is a CF application structure.

**STATUS**

The status of the CF application structure. This is one of the following:

**ACTIVE**

The structure is active.

**FAILED**

The structure has failed.

**NOTFOUND**

The structure is not allocated in the CF, but has been defined to Db2. Check and resolve any messages in the job log about this structure.

**INBACKUP**

The structure is in the process of being backed-up.

**INRECOVER**

The structure is in the process of being recovered.

**UNKNOWN**

The status of the CF structure is not known because, for example, Db2 might be unavailable.

**SIZEMAX** (*size*)

The size in kilobytes of the application structure.

**SIZEUSED** (*integer*)

The percentage of the size of the application structure that is in use. Therefore SIZEUSED(25) would indicate that a quarter of the space allocated to this application structure is in use.

**ENTSMAX** (*integer*)

The number of CF list entries defined for this application structure.

**Note:** The number does not include any entries that are in storage class memory (SCM), and which might have been allocated to the structure.

**ENTSUSED** (*integer*)

The number of CF list entries for this application structure that are in use.

**Note:** The number does not include any entries that are in storage class memory (SCM), and which might have been allocated to the structure.

**FAILTIME** (*time*)

The time that this application structure failed. The format of this field is hh.mm.ss. This parameter is only applicable when the CF structure is in FAILED or INRECOVER state. If the structure is not in a failed state, this is displayed as FAILTIME().

**FAILDATE** (*date*)

The date that this application-structure failed. The format of this field is yyyy-mm-dd. This parameter is only applicable when the CF structure is in FAILED or INRECOVER state. If the structure is not in a failed state, then this is displayed as FAILDATE().

**OFFLDUSE**

This indicates whether offloaded large message data potentially exists in shared message data sets, Db2 or both.

When the offload method is switched, the previous offload method needs to remain available for retrieving and deleting old messages, so the OFFLDUSE status is changed to indicate BOTH. When a queue manager disconnects normally from a structure that has OFFLDUSE(BOTH) it checks whether there still are any messages which were stored using the old offload method. If not, it changes the OFFLDUSE status to match the current offload method and issues message CSQE245I to indicate that the switch is complete.

This parameter is one of the following:

**NONE**

No offloaded large messages are present.

**SMDS**

Offloaded large messages can exist in shared message data sets.

**Db2**

Offloaded large messages can exist in Db2.

**BOTH**

Offloaded large messages can exist both in shared message data sets and in Db2.

**Connection status**

For connection status, the following information is returned for each connection to each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

**QMNAME** (*qmgrname*)

The queue manager name.

**SYSNAME** (*systemname*)

The name of the z/OS image of the queue manager that last connected to the application structure. These can be different across queue managers depending on the customer configuration setup.

**STATUS**

A status indicating whether this queue manager is connected to this application structure. This is one of the following:

**ACTIVE**

The structure is connected to this queue manager.

**FAILED**

The queue manager connection to this structure has failed.

**NONE**

The structure has never been connected to this queue manager.

**UNKNOWN**

The status of the CF structure is not known.

**FAILTIME** (*time*)

The time that this queue manager lost connectivity to this application structure. The format of this field is hh.mm.ss. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILTIME().

**FAILDATE** (*date*)

The date that this queue manager lost connectivity to this application structure. The format of this field is yyyy-mm-dd. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILDATE().

**Backup status**

For backup status, the following information is returned for each structure that satisfies the selection criteria:

- The name of the application structure matching the generic name.
- The type of information returned.

**STATUS**

The status of the CF application structure. This is one of the following:

**ACTIVE**

The structure is active.

**FAILED**

The structure has failed.

**NONE**

The structure is defined as RECOVER(YES), but has never been backed up.

**INBACKUP**

The structure is in the process of being backed-up.

**INRECOVER**

The structure is in the process of being recovered.

**UNKNOWN**

The status of the CF structure is not known.

**QMNAME** (*qmgrname*)

The name of the queue manager that took the last successful backup for this application structure.

**BKUPTIME** (*time*)

The end time of the last successful backup taken for this application structure. The format of this field is hh.mm.ss.

**BKUPDATE** (*date*)

The date of the last successful backup taken for this application structure. The format of this field is yyyy-mm-dd.

**BKUPSIZE** (*size*)

The size in megabytes of the last successful backup taken for this application structure.

**BKUPSRBA** (*hexadecimal*)

This is the backup data set start RBA for the start of the last successful backup taken for this application structure.

**BKUPERBA** (*hexadecimal*)

This is the backup data set end RBA for the end of the last successful backup taken for this application structure.

**LOGS** (*qmgrname-list*)

This is the list of queue managers, the logs of which are required to perform a recovery.

**FAILTIME** (*time*)

The time that this CF structure failed. The format of this field is hh.mm.ss. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILTIME().

**FAILDATE** (*date*)

The date that this CF structure failed. The format of this field is yyyy-mm-dd. This parameter is only applicable when the CF structure is in FAILED state. If the structure is not in a failed state, this is displayed as FAILDATE().

**SMDS status**

The DISPLAY CFSTATUS command with TYPE(SMDS) displays status information relating to one or more shared message data sets associated with a specific application structure.

The following data is returned for each selected data set:

**SMDS**

The queue manager name which owns the shared message data set for which properties are being displayed

**STATUS**

The current status of the shared message data set. This is one of the following:

**NOTFOUND**

The data set has never been used, or the attempt to open it for the first time failed. Check and resolve any messages in the job log about this structure.

**NEW**

The data set is being opened and initialized for the first time, ready to be made active.

**ACTIVE**

The data set is available for normal use.

**FAILED**

The data set is in an unusable state and probably requires recovery.

**INRECOVER**

Data set recovery (using RECOVER CFSTRUCT) is in progress.

**RECOVERED**

The data set has been recovered or otherwise repaired, and is ready for use again, but requires some restart processing the next time it is opened. This restart processing ensures that obsolete references to any deleted messages have been removed from the coupling facility structure before the data set is made available again. The restart processing also rebuilds the data set space map.

**EMPTY**

The data set contains no messages. The data set is put into this state if it is closed normally by the owning queue manager at a time when it does not contain any messages. It can also be put into EMPTY state when the previous data set contents are to be discarded because the application structure has been emptied (using RECOVER CFSTRUCT with TYPE PURGE or, for a nonrecoverable structure only, by deleting the previous instance of the structure). The next time the data set is opened by its owning queue manager, the space map is reset to empty, and the status is changed to ACTIVE. As the previous data set contents are no longer required, a data set in this state can be replaced with a newly allocated data set, for example to change the space allocation or move it to another volume.

**ACCESS**

The current availability state of the shared message data set. This parameter is one of the following:

**ENABLED**

The data set can be used, and no error has been detected since the time that it was enabled. If the data set has STATUS(RECOVERED) it can only be opened by the owning queue manager for restart purposes, but if it has STATUS(ACTIVE) all queue managers can open it.

**SUSPENDED**

The data set is unavailable because of an error.

This occurs specifically when the STATUS is set to FAILED either because of an error accessing the data set, or using the ALTER SMDS command.

The queue manager can try to enable access again automatically if the error might no longer be present, for example when recovery completes, or if the status is manually set to RECOVERED. Otherwise, it can be enabled again by a command in order to retry the action which originally failed.

**DISABLED**

The shared message data set cannot be used because it has been explicitly disabled using a command. It can only be enabled again by using another command to enable it. For more information, see "RESET SMDS" on page 970.

**RCVDATE**

The recovery start date.

If recovery is currently enabled for the data set, this indicates the date when it was activated, in the form yyyy-mm-dd. If recovery is not enabled, this is displayed as RCVDATE().

**RCVTIME**

The recovery start time.

If recovery is currently enabled for the data set, this indicates the time when it was activated, in the form hh.mm.ss. If recovery is not enabled, this is displayed as RCVTIME().

**FAILDATE**

The failure date.

If the data set was put into a failed state, and has not yet been restored to the active state, this indicates the date when the failure was indicated, in the form yyyy-mm-dd. If the data set is in the active state, this is displayed as FAILDATE().

**FAILTIME**

The failure time.

If the data set was put into a failed state and has not yet been restored to the active state, this indicates the time when the failure was indicated, in the form hh.mm.ss. If the data set is in the active state, this is displayed as FAILTIME().

**DISPLAY CFSTRUCT:** z/OS

Use the MQSC command DISPLAY CFSTRUCT to display the attributes of one or more CF application structures. This command is valid only on z/OS when the queue manager is a member of a queue-sharing group.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

OFFLD3TH	(1)
OFFLOAD	
RECAUTO	(1)
RECOVER	

**Notes:**

- 1  For more information about this parameter, see Planning your coupling facility and offload storage environment.

**Usage notes for DISPLAY CFSTRUCT**

1. The command cannot specify the CF administration structure (CSQ\_ADMIN).

**Keyword and parameter descriptions for DISPLAY CFSTRUCT**

The name of the application structure to be displayed must be specified. This can be a specific application structure name or a generic name. By using a generic name, it is possible to display either:

- all application structure definitions
- one or more application structures that match the specified name

( *generic-structure-name* )

The 12-character name of the CF application structure to be displayed. A trailing asterisk (\*) matches all structure names with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all structure names.

The CF structure name must be defined within the queue-sharing group.

## WHERE

Specify a filter condition to display only those CF application structures that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Any parameter that can be used to display attributes for this DISPLAY command.

### *operator*

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the RECOVER parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.  
You can only use operators LK or NL for generic values on the DISPLAY CFSTRUCT command.

**ALL** Specify this to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

## Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the structure names are displayed.

## ALTDATE

The date on which the definition was last altered, in the form yyyy-mm-dd.

## ALTTIME

The time at which the definition was last altered, in the form hh.mm.ss.

**CFCONLOS**

The action to be taken when the queue manager loses connectivity to the CF application structure.

**CFLEVEL**

Indicates the functional capability level for this CF application structure.

**DESCR**

Descriptive comment.

**DSBLOCK**

The logical block size, which is the unit in which shared message data set space is allocated to individual queues.

**DSBUFS**

The number of buffers allocated in each queue manager for accessing shared message data sets.

**DSEXPAND**

Whether the queue manager expands a shared message data set.

**DSGROUP**

The generic data set name to be used for the group of shared message data sets.

**OFFLD1SZ**

Offload rule 1: The message size value specifying an integer followed by K, giving the number of kilobytes.

**OFFLD1TH**

Offload rule 1: The coupling facility structure percentage usage threshold value as an integer.

**OFFLD2SZ**

Offload rule 2: The message size value specifying an integer followed by K, giving the number of kilobytes.

**OFFLD2TH**

Offload rule 2: The coupling facility structure percentage usage threshold value as an integer.

**OFFLD3SZ**

Offload rule 3: The message size value specifying an integer followed by K, giving the number of kilobytes.

**OFFLD3TH**

Offload rule 3: The coupling facility structure percentage usage threshold value as an integer.

**OFFLOAD**

If the CFLEVEL is less than 4, the only value you can display is NONE.

If the CFLEVEL is 4, the only value can display is Db2.

If the CFLEVEL is 5, the values displayed are Db2, SMDS, or BOTH. These values depict whether offloaded message data is stored in a group of shared message data sets, or in Db2, or both.

In addition, the offload rules parameter values for OFFLD1SZ, OFFLD1TH, OFFLD2SZ, OFFLD2TH, OFFLD3SZ, and OFFLD3TH are displayed.

**RECAUTO**

Indicates whether automatic recovery action is taken when a queue manager detects that the structure is failed, or when a queue manager loses connectivity to the structure and no systems in the SysPlex have connectivity to the Coupling Facility that the structure is allocated in. Values are:

**YES**

The structure and associated shared message data sets which also need recovery are automatically recovered.

**NO** The structure is not automatically recovered.

**RECOVER**

Indicates whether CF recovery for the application structure is supported. Values are:

**NO** CF application structure recovery is not supported.

**YES**

CF application structure recovery is supported.

**DISPLAY CHANNEL:**

Use the MQSC command DISPLAY CHANNEL to display a channel definition.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

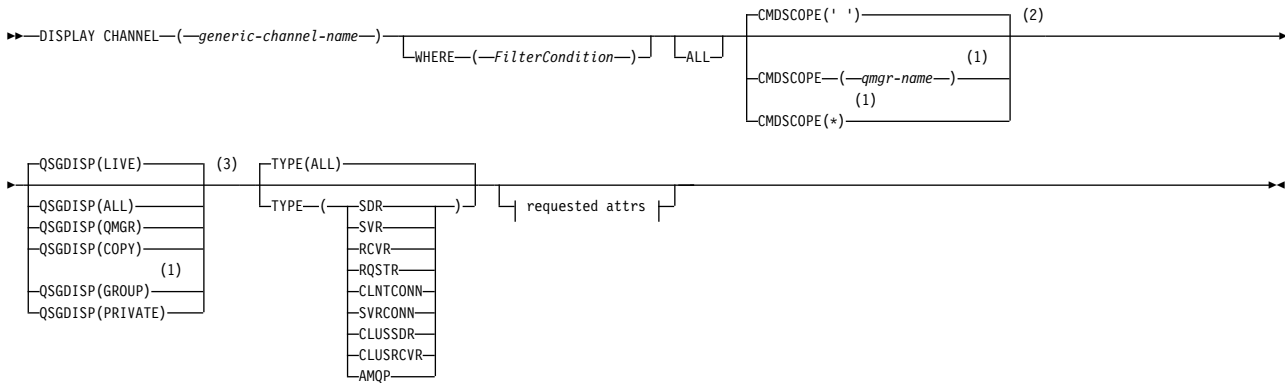

IBM i	UNIX and Linux	Windows	z/OS

## Notes:

- 1 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 2 Not valid for z/OS client-connection channels.
- 3 Valid only on z/OS.
- 4 Valid only for RCVR, RQSTR, CLUSRCVR and (for z/OS only) SVRCONN channel types.
- 5 Not valid on z/OS.

## Usage notes

You can only display cluster-sender channels if they were created manually. See Cluster channels.

The values shown describe the current definition of the channel. If the channel has been altered since it was started, any currently running instance of the channel object might not have the same values as the current definition.

## Parameter descriptions for DISPLAY CHANNEL

You must specify the name of the channel definition you want to display. It can be a specific channel name or a generic channel name. By using a generic channel name, you can display either:

- All channel definitions
- One or more channel definitions that match the specified name

*(generic-channel-name)*

The name of the channel definition to be displayed (see Rules for naming IBM MQ objects ). A trailing asterisk (\*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all channel definitions.

## WHERE

Specify a filter condition to display only those channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, QSGDISP, or MCANAME parameters as filter keywords. You cannot use TYPE (or CHLTYPE) if it is also used to select channels. Channels of a type for which the filter keyword is not a valid attribute are not displayed.

*operator*

This is used to determine whether a channel satisfies the filter value on the given filter keyword. The operators are:

- |           |  |
|-----------|--|
| <b>LT</b> | Less than  |
| <b>GT</b> | Greater than   |
| <b>EQ</b> | Equal to   |
| <b>NE</b> | Not equal to   |
| <b>LE</b> | Less than or equal to  |
| <b>GE</b> | Greater than or equal to   |
| <b>LK</b> | Matches a generic string that you provide as a <i>filter-value</i>   |
| <b>NL</b> | Does not match a generic string that you provide as a <i>filter-value</i>  |
| <b>CT</b> | Contains a specified item. If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which contain the specified item. |

- EX** Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.
- CTG** Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which match the generic string.
- EXG** Does not contain any item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not match the generic string.

#### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the TYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.  
You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC\* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

**ALL** Specify ALL to display the results of querying all the parameters. If ALL is specified, any request for a specific parameter is ignored. The result of querying with ALL is to return the results for all of the possible parameters.

This is the default, if you do not specify a generic name and do not request any specific parameters.

▶ **z/OS** On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms, only requested attributes are displayed.

If no parameters are specified (and the ALL parameter is not specified or defaulted), the default is that the channel names only are displayed.

▶ **z/OS** On z/OS, the CHLTYPE and QSGDISP values are also displayed.

#### ▶ **z/OS** **CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

#### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

z/OS

## QSGDISP

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**ALL** Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

**Note:** In the QSGDISP(LIVE) case, this occurs only where a shared and a non-shared queue have the same name; such a situation should not occur in a well-managed system.

In a shared queue manager environment, use  
DISPLAY CHANNEL(name) CMDSCOPE(\*) QSGDISP(ALL)

to list ALL objects matching

name

in the queue-sharing group without duplicating those in the shared repository.

**COPY** Display information only for objects defined with QSGDISP(COPY).

### GROUP

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

### PRIVATE

Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

### QMGR

Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

### QMGR

The object was defined with QSGDISP(QMGR).

### GROUP

The object was defined with QSGDISP(GROUP).

**COPY** The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

**TYPE** This is optional. It can be used to restrict the display to channels of one type.

The value is one of the following:

**ALL** Channels of all types are displayed (this is the default).

**SDR** Sender channels only are displayed.

**SVR** Server channels only are displayed.

**RCVR**  
Receiver channels only are displayed.

**RQSTR**  
Requester channels only are displayed.

**CLNTCONN**  
Client-connection channels only are displayed.

**SVRCONN**  
Server-connection channels only are displayed.

**CLUSDR**  
Cluster-sender channels only are displayed. )

**CLUSRCVR**  
Cluster-receiver channels only are displayed. )

**V8.0.0.4 AMQP**  
AMQP channels only are displayed.

CHLTYPE( *type* ) can be used as a synonym for this parameter. ,

### Requested parameters

Specify one or more DISPLAY CHANNEL parameters that define the data to be displayed. You can specify the parameters in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, nor is an error raised. The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required. **V8.0.0.4**

Table 101. Parameters that result in data being returned from the DISPLAY CHANNEL command

**Note:**

1. PUTAUT is valid for a channel type of SVRCONN on z/OS only.

**AFFINITY**

The channel affinity attribute.

**PREFERRED**

Subsequent connections in a process attempt to use the same channel definition as the first connection.

**NONE**

All connections in a process select an applicable definition based on the weighting with any applicable CLNTWGHT(0) definitions selected first in alphabetical order.

**ALTDATE**

The date on which the definition was last altered, in the form yyyy-mm-dd.

**ALTTIME**

The time at which the definition was last altered, in the form hh.mm.ss.

**V8.0.0.4 AMQPKA**

The keep alive time for an AMQP channel in seconds.

**AUTOSTART**

Whether an LU 6.2 responder process should be started for the channel.

**BATCHHB**

The batch heartbeating value being used.

**BATCHINT**

Minimum batch duration.

**BATCHLIM**

Batch data limit.

The limit of the amount of data that can be sent through a channel.

**BATCHSZ**

Batch size.

**CERTLABL**

Certificate label.

**CHLTYPE**

Channel type.

The channel type is always displayed if you specify a generic channel name and do not request any other parameters. On z/OS, the channel type is always displayed.

On all platforms other than z/OS, TYPE can be used as a synonym for this parameter.

**CLNTWGHT**

The client channel weighting.

The special value 0 indicates that no random load balancing is performed and applicable definitions are selected in alphabetical order. If random load balancing is performed the value is in the range 1 - 99 where 1 is the lowest weighting and 99 is the highest.

**CLUSTER**

The name of the cluster to which the channel belongs.

**CLUSNL**

The name of the namelist that specifies the list of clusters to which the channel belongs.

**CLWLPRTY**

The priority of the channel for the purposes of cluster workload distribution.

**CLWLRANK**

The rank of the channel for the purposes of cluster workload distribution.

**CLWLWGHT**

The weighting of the channel for the purposes of cluster workload distribution.

**COMPHDR**

The list of header data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference.

**COMPMSG**

The list of message data compression techniques supported by the channel. For sender, server, cluster-sender, cluster-receiver, and client-connection channels, the values specified are in order of preference.

**CONNNAME**

Connection name.

**CONVERT**

Whether sender should convert application message data.

**DEFCDISP**

Specifies the default channel disposition of the channels for which information is to be returned. If this keyword is not present, channels of all default channel dispositions are eligible.

**ALL** Channels of all default channel dispositions are displayed.

This is the default setting.

**PRIVATE**

Only channels where the default channel disposition is PRIVATE are displayed.

**SHARED**

Only channels where the default channel disposition is FIXSHARED or SHARED are displayed.

**Note:** This does not apply to client-connection channel types on z/OS.

**DESCR**

Default client reconnection option.

**DESCR**

Description.

**DISCINT**

Disconnection interval.

**HBINT**

Heartbeat interval.

**KAINT**

KeepAlive timing for the channel.

**LOCLADDR**

Local communications address for the channel.

**LONGRTY**

Long retry count.

**LONGTMR**

Long retry timer.

**MAXINST( *integer* )**

The maximum number of instances of a server-connection channel that are permitted to run simultaneously.

**MAXINSTC( *integer* )**

The maximum number of instances of a server-connection channel, started from a single client, that are permitted to run simultaneously.

**Note:** In this context, connections originating from the same remote network address are regarded as coming from the same client.

**MAXMSGL**

Maximum message length for channel.

**MCANAME**

Message channel agent name.

You cannot use MCANAME as a filter keyword.

**MCTYPE**

Whether message channel agent runs as a separate process or a separate thread.

**MCAUSER**

Message channel agent user identifier.

**MODENAME**

LU 6.2 mode name.

**MONCHL**

Online monitoring data collection.

**MRDATA**

Channel message-retry exit user data.

**MREXIT**

Channel message-retry exit name.

**MRRTY**

Channel message-retry count.

**MRTMR**

Channel message-retry time.

**MSGDATA**

Channel message exit user data.

**MSGEXIT**

Channel message exit names.

**NETPRTY**

The priority for the network connection.

**NPMSPEED**

Nonpersistent message speed.

**PASSWORD**

Password for initiating LU 6.2 session. If nonblank, this is displayed as asterisks  on all platforms except z/OS.

 **PORT**

The port number used to connect an AMQP channel.

**PROPCTL**

Message property control.

Specifies what happens to properties of messages when the message is about to be sent to a V6 or prior queue manager (a queue manager that does not understand the concept of a property descriptor).

This parameter is applicable to Sender, Server, Cluster Sender, and Cluster Receiver channels.

This parameter is optional.

Permitted values are:

**COMPAT**

This is the default value.

Message properties	Result
The message contains a property with a prefix of <b>mcd.</b> , <b>jms.</b> , <b>usr.</b> or <b>mqext.</b>	All optional message properties (where the <b>Support</b> value is MQPD_SUPPORT_OPTIONAL), except those in the message descriptor or extension, are placed in one or more MQRFH2 headers in the message data before the message is sent to the remote queue manager.
The message does not contain a property with a prefix of <b>mcd.</b> , <b>jms.</b> , <b>usr.</b> or <b>mqext.</b>	All message properties, except those in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.
The message contains a property where the <b>Support</b> field of the property descriptor is not set to MQPD_SUPPORT_OPTIONAL	The message is rejected with reason MQRC_UNSUPPORTED_PROPERTY and treated in accordance with its report options.
The message contains one or more properties where the <b>Support</b> field of the property descriptor is set to MQPD_SUPPORT_OPTIONAL but other fields of the property descriptor are set to non-default values	The properties with non-default values are removed from the message before the message is sent to the remote queue manager.
The MQRFH2 folder that would contain the message property needs to be assigned with the <i>content='properties'</i> attribute	The properties are removed to prevent MQRFH2 headers with unsupported syntax flowing to a V6 or prior queue manager.

#### NONE

All properties of the message, except those in the message descriptor or extension, are removed from the message before the message is sent to the remote queue manager.

If the message contains a property where the **Support** field of the property descriptor is not set to MQPD\_SUPPORT\_OPTIONAL then the message is rejected with reason MQRC\_UNSUPPORTED\_PROPERTY and treated in accordance with its report options.

**ALL** All properties of the message are included with the message when it is sent to the remote queue manager. The properties, except those in the message descriptor (or extension), are placed in one or more MQRFH2 headers in the message data.

#### PUTAUT

Put authority.

#### QMNAME

Queue manager name.

#### RESETSEQ

Pending reset sequence number.

This is the sequence number from an outstanding request and it indicates a user RESET CHANNEL command request is outstanding.

A value of zero indicates that there is no outstanding RESET CHANNEL. The value can be in the range 1 - 999999999.

This parameter is not applicable on z/OS.

#### RCVDATA

Channel receive exit user data.

#### RCVEXIT

Channel receive exit names.

#### SCYDATA

Channel security exit user data.

#### SCYEXIT

Channel security exit names.

**SENDDATA**

Channel send exit user data.

**SENDEXIT**

Channel send exit names.

**SEQWRAP**

Sequence number wrap value.

**SHARECNV**

Sharing conversations value.

**SHORTRTY**

Specifies the maximum number of times that the channel is to try allocating a session to its partner.

**SHORTTMR**

Short retry timer.

**SSLCAUTH**

Whether SSL client authentication is required.

**SSLCIPH**

Cipher specification for the SSL connection.

**SSLPEER**

Filter for the Distinguished Name from the certificate of the peer queue manager or client at the other end of the channel.

**STATCHL**

Statistics data collection.

**TPNAME**

LU 6.2 transaction program name.

**V8.0.0.4 TPROOT**

The topic root for an AMQP channel.

**TRPTYPE**

Transport type.

**V8.0.0.4 USECLTID**

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

**USEDLQ**

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

**USERID**

User identifier for initiating LU 6.2 session.

**XMITQ**

Transmission queue name.

For more details of these parameters, see "DEFINE CHANNEL" on page 550.

## DISPLAY CHANNEL (MQTT):

Use the MQSC command DISPLAY CHANNEL (MQTT) to display an IBM MQ Telemetry channel definition.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	AIX and Linux	Windows	z/OS
	✓	✓	

**Note:** For the telemetry server, AIX is the only supported UNIX platform.

- Syntax diagram
- “Parameter descriptions for DISPLAY CHANNEL (MQTT)”
- “Requested parameters” on page 752

Synonym: DIS CHL

## DISPLAY CHANNEL ( MQTT )

### Requested attrs:

DISPLAY CHANNEL (MQTT) command is only valid for IBM MQ Telemetry channels.

### Parameter descriptions for DISPLAY CHANNEL (MQTT)

You must specify the name of the channel definition you want to display. This can be a specific channel name or a generic channel name. By using a generic channel name, you can display either:

- All channel definitions
- One or more channel definitions that match the specified name

*(generic-channel-name)*

The name of the channel definition to be displayed (see Rules for naming IBM MQ objects ). A trailing asterisk (\*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all channel definitions.

#### **CHLTYPE( type )**

The value is always MQTT.

TYPE can be used as a synonym for this parameter.

#### **WHERE**

Specify a filter condition to display only those channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

##### *filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, QSGDISP, or MCANAME parameters as filter keywords. You cannot use TYPE (or CHLTYPE) if it is also used to select channels. Channels of a type for which the filter keyword is not a valid attribute are not displayed.

##### *operator*

This is used to determine whether a channel satisfies the filter value on the given filter keyword. The operators are:

- |            |   |
|------------|---|
| <b>LT</b>  | Less than   |
| <b>GT</b>  | Greater than  |
| <b>EQ</b>  | Equal to  |
| <b>NE</b>  | Not equal to  |
| <b>LE</b>  | Less than or equal to   |
| <b>GE</b>  | Greater than or equal to  |
| <b>LK</b>  | Matches a generic string that you provide as a <i>filter-value</i>  |
| <b>NL</b>  | Does not match a generic string that you provide as a <i>filter-value</i>   |
| <b>CT</b>  | Contains a specified item. If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which contain the specified item.  |
| <b>EX</b>  | Does not contain a specified item. If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which do not contain the specified item.   |
| <b>CTG</b> | Contains an item which matches a generic string that you provide as a <i>filter-value</i> . If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which match the generic string.                 |
| <b>EXG</b> | Does not contain any item which matches a generic string that you provide as a <i>filter-value</i> . If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which do not match the generic string. |

##### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the TYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. The characters must be

valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC\* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

## **ALL**

Specify ALL to display the results of querying all the parameters. If ALL is specified, any request for a specific parameter is ignored. The result of querying with ALL is to return the results for all of the possible parameters.

This is the default, if you do not specify a generic name and do not request any specific parameters.

If no parameters are specified (and the ALL parameter is not specified or defaulted), the default is that the channel names only are displayed.

## **Requested parameters**

Specify one or more DISPLAY CHANNEL parameters that define the data to be displayed. You can specify the parameters in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, nor is an error raised. The following table shows the parameters that are relevant for each type of channel. There is a description of each parameter after the table. Parameters are optional unless the description states that they are required.

## **BACKLOG**

The number of outstanding connection requests that the telemetry channel can support at any one time. When the backlog limit is reached, any further clients trying to connect will be refused connection until the current backlog is processed. The value is in the range 0 - 999999999. The default value is 4096.

## **CHLTYPE**

Channel type.

There is only one valid value for this parameter: MQTT.

## **JAASCFG**

The name of a stanza in the JAAS configuration file.

## **LOCLADDR**

The local communications address for the channel.

## **MCAUSER**

The message channel agent user identifier.

## **PORT**

The port number on which the telemetry (MQXR) service accepts client connections.

## **PROTOCOL**

The communication protocol supported by the channel.

### SSLCAUTH

Defines whether IBM MQ requires a certificate from the SSL client.

### SSLCIPH

When SSLCIPH is used with a telemetry channel, it means “SSL Cipher Suite”.

### SSLKEYP

The store for digital certificates and their associated private keys. If you do not specify a key file, SSL is not used.

### SSLKEYR

The name of the Secure Sockets Layer (SSL) key repository. For full details, see the SSLKEYR parameter of the ALTER QMGR command.

### TRPTYPE

The transmission protocol to be used. For a Telemetry channel, this is always TCP (that is, the TCP/IP protocol).

### USECLTID

Indicates whether you want to use the MQTT client ID for the connection as the IBM MQ user ID for that connection.

For more details of these parameters, see “DEFINE CHANNEL (MQTT)” on page 610.

### DISPLAY CHINIT:

Use the MQSC command DISPLAY CHINIT to display information about the channel initiator. The command server must be running.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY CHINIT” on page 754
- “Parameter descriptions for DISPLAY CHINIT” on page 754

**Synonym:** DIS CHI or DIS DQM

## DISPLAY CHINIT

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

### Usage notes for DISPLAY CHINIT

1. The response to this command is a series of messages showing the current status of the channel initiator. This includes the following:
  - Whether the channel initiator is running or not
  - Which listeners are started, and information about them.
  - How many dispatchers are started, and how many were requested
  - How many adapter subtasks are started, and how many were requested
  - How many SSL subtasks are started, and how many were requested
  - The TCP system name
  - How many channel connections are current, and whether they are active, stopped, or retrying
  - The maximum number of current connections

### Parameter descriptions for DISPLAY CHINIT

#### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

- ' ' The command is executed on the queue manager on which it was entered. This is the default value.

#### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

## DISPLAY CHLAUTH:

Use the MQSC command DISPLAY CHLAUTH to display the attributes of a channel authentication record.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

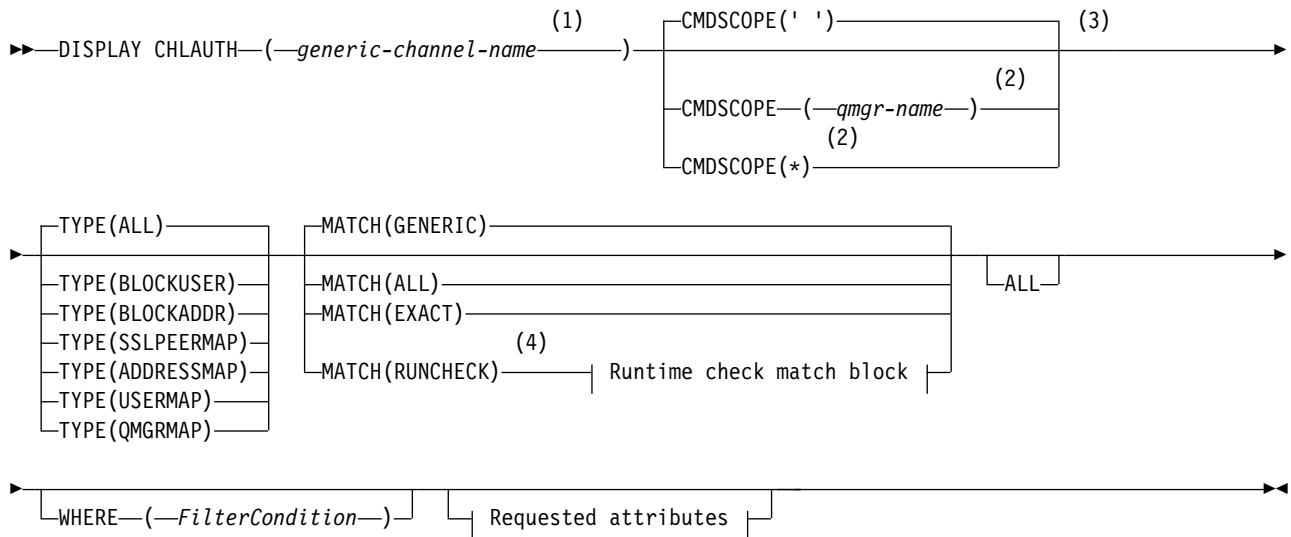

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- Parameters

**Synonym:** DIS CHLAUTH

## DISPLAY CHLAUTH

### Runtime check match block:

### Requested attributes:

**Notes:**

- 1 Must be \* with TYPE(BLOCKADDR) and cannot be generic with MATCH(RUNCHECK)
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Valid only on z/OS.
- 4 Must be combined with TYPE(ALL)

**Parameters**

***generic-channel-name***

The name of the channel or set of channels to display. You can use the asterisk (\*) as a wildcard to specify a set of channels. When an asterisk is used on z/OS, single quotes must be used around the whole value. When **MATCH** is RUNCHECK this parameter must not be generic.

**ADDRESS**

The IP address to be matched.

This parameter is valid only when **MATCH** is RUNCHECK, must not be generic and must not be a hostname.

**ALL**

Specify this parameter to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

**CLNTUSER**

The client asserted user ID to be mapped to a new user ID, allowed through unchanged, or blocked.

This can be the user ID flowed from the client indicating the user ID the client side process is running under, or the user ID presented by the client on an MQCONN call using MQCSP.

This parameter is valid only with TYPE(USERMAP) and when **Match** is MQMATCH\_RUNCHECK.

The maximum length of the string is MQ\_CLIENT\_USER\_ID\_LENGTH.

**z/OS CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is run when the queue manager is a member of a queue-sharing group.

- ' ' The command is run on the queue manager on which it was entered. This is the default value.

### *qmgr-name*

The command is run on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is run on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect is the same as entering the command on every queue manager in the queue-sharing group.

### **MATCH**

Indicates the type of matching to be applied.

### **RUNCHECK**

Returns the record that is matched by a specific inbound channel at run time if it connects to this queue manager. The specific inbound channel is described by providing values that are not generic:

- Channel name.
- **ADDRESS** attribute containing an IP address, that is then reverse looked up as part of running the command to discover the hostname, if the queue manager is configured with **REVDNS(ENABLED)**.
- **SSLCERTI** attribute, only if the inbound channel uses SSL or TLS.
- **SSLPEER** attribute, only if the inbound channel uses SSL or TLS.
- **QMNAME** or **CLNTUSER** attribute, depending on whether the inbound channel is a client or queue manager channel.

If the record discovered has **WARN** set to **YES**, a second record might also be displayed to show the actual record the channel will use at run time. This parameter must be combined with **TYPE(ALL)**.

### **EXACT**

Return only those records which exactly match the channel profile name supplied. If there are no asterisks in the channel profile name, this option returns the same output as **MATCH(GENERIC)**.

### **GENERIC**

Any asterisks in the channel profile name are treated as wild cards. If there are no asterisks in the channel profile name, this returns the same output as **MATCH(EXACT)**. For example, a profile of **ABC\*** could result in records for **ABC**, **ABC\***, and **ABCD** being returned.

- ALL** Return all possible records that match the channel profile name supplied. If the channel name is generic in this case, all records that match the channel name are returned even if more specific matches exist. For example, a profile of **SYSTEM.\*.SVRCONN** could result in records for **SYSTEM.\***, **SYSTEM.DEF.\***, **SYSTEM.DEF.SVRCONN**, and **SYSTEM.ADMIN.SVRCONN** being returned.

### **QMNAME**

The name of the remote partner queue manager to be matched

This parameter is valid only when **MATCH** is **RUNCHECK** and must not be generic.

### **SSLCERTI**

The Certificate issuer Distinguished Name of the certificate to be matched.

The **SSLCERTI** field, if not blank, is matched in addition to the **SSLPEER** value.

This parameter is valid only when **MATCH** is **RUNCHECK** and must not be generic.

### **SSLPEER**

The Subject Distinguished Name of the certificate to be matched.

The **SSLPEER** value is specified in the standard form used to specify a Distinguished Name.

This parameter is valid only when **MATCH** is RUNCHECK and must not be generic.

#### TYPE

The type of Channel Authentication Record for which to display details. Possible values are:

- ALL
- BLOCKUSER
- BLOCKADDR
- SSLPEERMAP
- ADDRESSMAP
- USERMAP
- QMGRMAP

#### WHERE

Specify a filter condition to display only those channel authentication records that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

##### ***filter-keyword***

Any parameter that can be used to display attributes for this DISPLAY command.

##### ***operator***

This is used to determine whether a channel authentication record satisfies the filter value on the given filter keyword. The operators are as follows:

- |            |   |
|------------|---|
| <b>LT</b>  | Less than   |
| <b>GT</b>  | Greater than  |
| <b>EQ</b>  | Equal to  |
| <b>NE</b>  | Not equal to  |
| <b>LE</b>  | Less than or equal to   |
| <b>GE</b>  | Greater than or equal to  |
| <b>LK</b>  | Matches a generic string that you provide as a <i>filter-value</i>  |
| <b>NL</b>  | Does not match a generic string that you provide as a <i>filter-value</i>   |
| <b>CT</b>  | Contains a specified item. If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which contain the specified item.  |
| <b>EX</b>  | Does not contain a specified item. If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which do not contain the specified item.   |
| <b>CTG</b> | Contains an item which matches a generic string that you provide as a <i>filter-value</i> . If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which match the generic string.                 |
| <b>EXG</b> | Does not contain any item which matches a generic string that you provide as a <i>filter-value</i> . If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which do not match the generic string. |

##### ***filter-value***

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, the value can be either explicit or generic:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value ALL on the MATCH parameter), you can only use EQ or NE.

- A generic value. This is a character string with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

You can only use operators LK or NL for generic values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC\* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

**Note:**  On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

### Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

#### TYPE

The type of channel authentication record

#### SSLPEER

The Distinguished Name of the certificate.

#### ADDRESS

The IP address

#### CHCKCLNT

Whether a user ID and password are to be supplied by connections which match this rule.

#### CLNTUSER

The client asserted user ID

#### QMNAME

The name of the remote partner queue manager

#### MCAUSER

The user identifier to be used when the inbound connection matches the SSL DN, IP address, client asserted user ID or remote queue manager name supplied.

#### ADDRLIST

A list of IP address patterns which are banned from connecting into this queue manager on any channel.

#### USERLIST

A list of user IDs which are banned from use of this channel or set of channels.

#### ALTDATE

The date on which the channel authentication record was last altered, in the format *yyyy-mm-dd*.

#### ALTTIME

The time on which the channel authentication record was last altered, in the form *hh.mm.ss*.

#### DESCR

Descriptive information about the channel authentication record.

## SSLCERTI

The Certificate issuer Distinguished Name of the certificate to be matched.

## CUSTOM

Reserved for future use.

### Related information:

Channel authentication records

*Generic IP addresses:*

In the various commands that create and display channel authentication records, you can specify certain parameters as either a single IP address or a pattern to match a set of IP addresses.

When you create a channel authentication record, using the MQSC command SET CHLAUTH or the PCF command Set Channel Authentication Record, you can specify a generic IP address in various contexts. You can also specify a generic IP address in the filter condition when you display a channel authentication record using the commands DISPLAY CHLAUTH or Inquire Channel Authentication Records .

You can specify the address in any of the following ways:

- a single IPv4 address, such as 192.0.2.0
- a pattern based on an IPv4 address, including an asterisk (\*) as a wildcard. The wildcard represents one or more parts of the address, depending on context. For example, the following are all valid values:
  - 192.0.2.\*
  - 192.0.\*
  - 192.0.\*.2
  - 192.\*.2
  - \*
- a pattern based on an IPv4 address, including a hyphen (-) to indicate a range, for example 192.0.2.1-8
- a pattern based on an IPv4 address, including both an asterisk and a hyphen, for example 192.0.\*.1-8
- a single IPv6 address, such as 2001:DB8:0:0:0:0:0:0
- a pattern based on an IPv6 address including an asterisk (\*) as a wildcard. The wildcard represents one or more parts of the address, depending on context. For example, the following are all valid values:
  - 2001:DB8:0:0:0:0:0:\*
  - 2001:DB8:0:0:0:\*
  - 2001:DB8:0:0:0:\*:0:1
  - 2001:\*.1
  - \*
- a pattern based on an IPv6 address, including a hyphen (-) to indicate a range, for example 2001:DB8:0:0:0:0:0:0-8
- a pattern based on an IPv6 address, including both an asterisk and a hyphen, for example 2001:DB8:0:0:0:\*:0:0-8

If your system supports both IPv4 and IPv6, you can use either address format. IBM MQ recognizes IPv4 mapped addresses in IPv6.

Certain patterns are invalid:

- A pattern cannot have fewer than the required number of parts, unless the pattern ends with a single trailing asterisk. For example 192.0.2 is invalid, but 192.0.2.\* is valid.

- A trailing asterisk must be separated from the rest of the address by the appropriate part separator (a dot (.) for IPv4, a colon (:)) for IPv6). For example, 192.0\* is not valid because the asterisk is not in a part of its own.
- A pattern may contain additional asterisks provided that no asterisk is adjacent to the trailing asterisk. For example, 192.\*.2.\* is valid, but 192.0.\*.\* is not valid.
- An IPv6 address pattern cannot contain a double colon and a trailing asterisk, because the resulting address would be ambiguous. For example, 2001::\* could expand to 2001:0000:\*, 2001:0000:0000:\* and so on

**Short status:**

(2)

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Also displayed by selection of the MONITOR parameter.
- 4 Ignored if specified on z/OS.

▶ z/OS

**Usage notes for DISPLAY CHSTATUS**

On z/OS:

1. The command fails if the channel initiator has not been started.
2. The command server must be running.
3. If you want to see the overall status of the channel (that is, the status of the queue sharing group) use the command **DISPLAY CHSTATUS SHORT**, which obtains the status information of the channel from Db2.
4. If any numeric parameter exceeds 999,999,999, it is displayed as 999999999.
5. The status information that is returned for various combinations of CHLDISP, CMDSCOPE, and status type are summarized in Table 102, Table 103, and Table 104 on page 765. ▶ z/OS

Table 102. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS CURRENT

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Common and current-only status for current private channels on the local queue manager	Common and current-only status for current private channels on the named queue manager	Common and current-only status for current private channels on all queue managers
SHARED	Common and current-only status for current shared channels on the local queue manager	Common and current-only status for current shared channels on the named queue manager	Common and current-only status for current shared channels on all queue managers
ALL	Common and current-only status for current private and shared channels on the local queue manager	Common and current-only status for current private and shared channels on the named queue manager	Common and current-only status for current private and shared channels on all active queue managers

▶ z/OS

Table 103. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SHORT

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	STATUS and short status for current private channels on the local queue manager	STATUS and short status for current private channels on the named queue manager	STATUS and short status for current private channels on all active queue managers

Table 103. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SHORT (continued)

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
SHARED	STATUS and short status for current shared channels on all active queue managers in the queue-sharing group	Not permitted	Not permitted
ALL	STATUS and short status for current private channels on the local queue manager and current shared channels in the queue-sharing group ( 5a )	STATUS and short status for current private channels on the named queue manager	STATUS and short status for current private, and shared, channels on all active queue managers in the queue-sharing group ( 5a )

**Note:**

- a. In this case you get two separate sets of responses to the command on the queue manager where it was entered; one for PRIVATE and one for SHARED.

► z/OS

Table 104. CHLDISP and CMDSCOPE for DISPLAY CHSTATUS SAVED

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Common status for saved private channels on the local queue manager	Common status for saved private channels on the named queue manager	Common status for saved private channels on all active queue managers
SHARED	Common status for saved shared channels on all active queue managers in the queue-sharing group	Not permitted	Not permitted
ALL	Common status for saved private channels on the local queue manager and saved shared channels in the queue-sharing group	Common status for saved private channels on the named queue manager	Common status for saved private, and shared, channels on all active queue managers in the queue-sharing group

**Parameter descriptions for DISPLAY CHSTATUS**

You must specify the name of the channel for which you want to display status information. This can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

You can also specify whether you want the current status data (of current channels only), or the saved status data of all channels.

Status for all channels that meet the selection criteria is displayed, whether the channels were defined manually or automatically.

The classes of data available for channel status are **saved** and **current** ► z/OS , and (on z/OS only) **short**.

The status fields available for saved data are a subset of the fields available for current data and are called **common** status fields. Note that although the common data *fields* are the same, the data *values* might be different for saved and current status. The rest of the fields available for current data are called **current-only** status fields.

- **Saved** data consists of the common status fields noted in the syntax diagram.
  - For a sending channel data is updated before requesting confirmation that a batch of messages has been received and when confirmation has been received
  - For a receiving channel data is reset just before confirming that a batch of messages has been received
  - For a server connection channel no data is saved.
  - Therefore, a channel that has never been current cannot have any saved status.

**Note:** Status is not saved until a persistent message is transmitted across a channel, or a nonpersistent message is transmitted with a NPMSPEED of NORMAL. Because status is saved at the end of each batch, a channel does not have any saved status until at least one batch has been transmitted.

- **Current** data consists of the common status fields and current-only status fields as noted in the syntax diagram. The data fields are continually updated as messages are sent/received.
-  **Short** data consists of the STATUS current data item and the short status field as noted in the syntax diagram.

This method of operation has the following consequences:

- An inactive channel might not have any saved status - if it has never been current or has not yet reached a point where saved status is reset.
- The “common” data fields might have different values for saved and current status.
- A current channel always has current status and might have saved status.

Channels can either be current or inactive:

### Current channels

These are channels that have been started, or on which a client has connected, and that have not finished or disconnected normally. They might not yet have reached the point of transferring messages, or data, or even of establishing contact with the partner. Current channels have **current** status and might also have **saved** status.

The term **Active** is used to describe the set of current channels that are not stopped.

### Inactive channels

These are channels that either:

- Have not been started
- On which a client has not connected
- Have finished
- Have disconnected normally

(Note that if a channel is stopped, it is not yet considered to have finished normally - and is, therefore, still current.) Inactive channels have either **saved** status or no status at all.

There can be more than one instance of the same named receiver, requester, cluster-receiver, or server-connection channel current at the same time (the requester is acting as a receiver). This occurs if several senders, at different queue managers, each initiate a session with this receiver, using the same channel name. For channels of other types, there can only be one instance current at any time.

For all channel types, however, there can be more than one set of saved status information available for a channel name. At most one of these sets relates to a current instance of the channel, the rest relate to

previously current instances. Multiple instances arise if different transmission queue names or connection names have been used with the same channel. This can happen in the following cases:

- At a sender or server:
  - If the same channel has been connected to by different requesters (servers only)
  - If the transmission queue name has been changed in the definition
  - If the connection name has been changed in the definition
- At a receiver or requester:
  - If the same channel has been connected to by different senders or servers
  - If the connection name has been changed in the definition (for requester channels initiating connection)

The number of sets that are displayed for a channel can be limited by using the XMITQ, CONNAME, and CURRENT parameters on the command.

( *generic-channel-name* )

The name of the channel definition for which status information is to be displayed. A trailing asterisk (\*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all channel definitions. A value is required for all channel types.

## WHERE

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

The parameter to be used to display attributes for this DISPLAY command.

However, you cannot use the following parameters as filter keywords on distributed platforms COMPRATE, COMPTIME, CURRENT, EXITTIME, JOBNAME, NETTIME, SAVED, SHORT, XBATCSZ, or XQTIME as filter keywords.

 Additionally, on z/OS, you cannot use the following parameters as filter keywords: CHLDISP, CMDSCOPE, MCASTAT, or MONITOR as filter keywords.

You cannot use CONNAME or XMITQ as filter keywords if you also use them to select channel status.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

*operator*

This is used to determine whether a channel satisfies the filter value on the filter keyword.

The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

- CT** Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item.
- EX** Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item.

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the CHLTYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.  
You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

**ALL** Specify this to display all the status information for each relevant instance.

If SAVED is specified, this causes only common status information to be displayed, not current-only status information.

If this parameter is specified, any parameters requesting specific status information that are also specified have no effect; all the information is displayed.

**z/OS CHLDISP**

This parameter applies to z/OS only and specifies the disposition of the channels for which information is to be displayed, as used in the START and STOP CHANNEL commands, and **not** that set by QSGDISP for the channel definition. Values are:

**ALL** This is the default value and displays requested status information for private channels.

If there is a shared queue manager environment and the command is being executed on the queue manager where it was issued, or if CURRENT is specified, this option also displays the requested status information for shared channels.

**PRIVATE**

Display requested status information for private channels.

**SHARED**

Display requested status information for shared channels. This is allowed only if there is a shared queue manager environment, and either:

- CMDSCOPE is blank or the local queue manager
- CURRENT is specified

CHLDISP displays the following values:

**PRIVATE**

The status is for a private channel.

**SHARED**

The status is for a shared channel.

**FIXSHARED**

The status is for a shared channel, tied to a specific queue manager.

**CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

**Note:** See Table 1, Table 2, and Table 3 for the permitted combinations of CHLDISP and CMDSCOPE.

**CONNNAME( *connection-name* )**

The connection name for which status information is to be displayed, for the specified channel or channels.

This parameter can be used to limit the number of sets of status information that is displayed. If it is not specified, the display is not limited in this way.

The value returned for CONNNAME might not be the same as in the channel definition, and might differ between the current channel status and the saved channel status. (Using CONNNAME for limiting the number of sets of status is therefore not recommended.)

For example, when using TCP, if CONNNAME in the channel definition:

- Is blank or is in "host name" format, the channel status value has the resolved IP address.
- Includes the port number, the current channel status value includes the port number z/OS (except on z/OS ), but the saved channel status value does not.

For SAVED z/OS or SHORT status, this value could also be the queue manager name, or queue-sharing group name, of the remote system.

**CURRENT**

This is the default, and indicates that current status information as held by the channel initiator for current channels only is to be displayed.

Both common and current-only status information can be requested for current channels.

Short status information is not displayed if this parameter is specified.

**SAVED**

Specify this to display saved status information for both current and inactive channels.

Only common status information can be displayed. Short and current-only status information is not displayed for current channels if this parameter is specified.

**SHORT**

This indicates that short status information and the STATUS item for current channels only is to be displayed.

Other common status and current-only status information is not displayed for current channels if this parameter is specified.

## MONITOR

Specify this to return the set of online monitoring parameters. These are COMPRATE, COMPTIME, EXITTIME, MONCHL, NETTIME, XBATCSZ, XQMSGSA, and XQTIME. If you specify this parameter, any of the monitoring parameters that you request specifically have no effect; all monitoring parameters are still displayed.

## XMITQ( *q-name* )

The name of the transmission queue for which status information is to be displayed, for the specified channel or channels.

This parameter can be used to limit the number of sets of status information that is displayed. If it is not specified, the display is not limited in this way.

The following information is always returned, for each set of status information:

- The channel name
- The transmission queue name (for sender and server channels)
- The connection name
- The remote queue-manager, or queue-sharing group, name (only for current status, and for all channel types except server-connection channels )
- The remote partner application name (for server-connection channels)
- The type of status information returned (CURRENT, or SAVED , or on z/OS only, SHORT)
- STATUS  (except SAVED on z/OS )
-  On z/OS, CHLDISP
- STOPREQ (only for current status)
- SUBSTATE

If no parameters requesting specific status information are specified (and the ALL parameter is not specified), no further information is returned.

If status information is requested that is not relevant for the particular channel type, this is not an error.

## Summary attributes

When SUMMARY or TOTAL are added to the MQSC command DISPLAY CHSTATUS, the number of conversations is displayed as the CONVS attribute. The following attributes display a summary for either each channel when SUMMARY is specified, or for all the channels when TOTAL is specified.

**ALL** Specify this to display all the status information for each relevant instance. This attribute is the default value if no attributes are requested.

If SAVED is specified, this causes only common status information to be displayed, not current-only status information.

If this parameter is specified, any parameters requesting specific status information that are also specified have no effect; all the information is displayed.

## CURCNV

The number of current conversations.

## Common status

The following information applies to all sets of channel status, whether or not the set is current. Some of this information does not apply to server-connection channels.

## CHLTYPE

The channel type. This is one of the following:

**SDR** A sender channel

**SVR** A server channel

**RCVR** A receiver channel

**RQSTR**  
A requester channel

**CLUSSDR**  
A cluster-sender channel

**CLUSRCVR**  
A cluster-receiver channel

**SVRCONN**  
A server-connection channel

**V8.0.0.4 AMQP**  
An AMQP channel

### **CURLUWID**

The logical unit of work identifier associated with the current batch, for a sending or a receiving channel.

For a sending channel, when the channel is in doubt it is the LUWID of the in-doubt batch.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

It is updated with the LUWID of the next batch when this is known.

This parameter does not apply to server-connection channels.

### **CURMSG**

For a sending channel, this is the number of messages that have been sent in the current batch. It is incremented as each message is sent, and when the channel becomes in doubt it is the number of messages that are in doubt.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

For a receiving channel, it is the number of messages that have been received in the current batch. It is incremented as each message is received.

The value is reset to zero, for both sending and receiving channels, when the batch is committed.

This parameter does not apply to server-connection channels.

### **CURSEQNO**

For a sending channel, this is the message sequence number of the last message sent. It is updated as each message is sent, and when the channel becomes in doubt it is the message sequence number of the last message in the in-doubt batch.

For a saved channel instance, this parameter has meaningful information only if the channel instance is in doubt. However, the parameter value is still returned when requested, even if the channel instance is not in doubt.

For a receiving channel, it is the message sequence number of the last message that was received. It is updated as each message is received.

This parameter does not apply to server-connection channels.

### **INDOUBT**

Whether the channel is currently in doubt.

This is only YES while the sending Message Channel Agent is waiting for an acknowledgment that a batch of messages that it has sent has been successfully received. It is NO at all other times, including the period during which messages are being sent, but before an acknowledgment has been requested.

For a receiving channel, the value is always NO.

This parameter does not apply to server-connection channels.

#### **LSTLUWID**

The logical unit of work identifier associated with the last committed batch of messages transferred.

This parameter does not apply to server-connection channels.

#### **LSTSEQNO**

Message sequence number of the last message in the last committed batch. This number is not incremented by nonpersistent messages using channels with a NPMSPEED of FAST.

This parameter does not apply to server-connection channels.

#### **STATUS**

Current status of the channel. This is one of the following:

##### **BINDING**

Channel is performing channel negotiation and is not yet ready to transfer messages.

##### **INITIALIZING**

The channel initiator is attempting to start a channel.

 On z/OS, this is displayed as INITIALIZI.

##### **PAUSED**

The channel is waiting for the message-retry interval to complete before retrying an MQPUT operation.

##### **REQUESTING**

A local requester channel is requesting services from a remote MCA.

##### **RETRYING**

A previous attempt to establish a connection has failed. The MCA will reattempt connection after the specified time interval.

##### **RUNNING**

The channel is either transferring messages at this moment, or is waiting for messages to arrive on the transmission queue so that they can be transferred.

##### **STARTING**

A request has been made to start the channel but the channel has not yet begun processing. A channel is in this state if it is waiting to become active.

##### **STOPPED**

This state can be caused by one of the following:

- Channel manually stopped

A user has entered a stop channel command against this channel.

- Retry limit reached

The MCA has reached the limit of retry attempts at establishing a connection. No further attempt will be made to establish a connection automatically.

A channel in this state can be restarted only by issuing the START CHANNEL command, or starting the MCA program in an operating-system dependent manner.

##### **STOPPING**

Channel is stopping or a close request has been received.

## SWITCHING

The channel is switching transmission queues.

► **z/OS** On z/OS, STATUS is not displayed if saved data is requested.

On distributed platforms, the value of the STATUS field returned in the saved data is the status of the channel at the time the saved status was written. Normally, the saved status value is RUNNING. To see the current status of the channel, the user can use the DISPLAY CHSTATUS CURRENT command.

**Note:** For an inactive channel, CURMSG, CURSEQNO, and CURLUWID have meaningful information only if the channel is INDOUBT. However they are still displayed and returned if requested.

### Current-only status

The following information applies only to current channel instances. The information applies to all channel types, except where stated.

#### ► **V8.0.0.4** AMQPKA

The keep alive time for an AMQP channel in seconds. If the AMQP client has not sent any frames within the keep alive interval, then the connection is closed with a amqp:resource-limit-exceeded AMQP error condition.

This parameter is valid only for channels with a channel type ( CHLTYPE ) of AMQP

### BATCHES

Number of completed batches during this session (since the channel was started).

### BATCHSZ

The batch size being used for this session.

This parameter does not apply to server-connection channels, and no values are returned; if specified on the command, this is ignored.

### BUFSRCVD

Number of transmission buffers received. This includes transmissions to receive control information only.

### BUFSSENT

Number of transmission buffers sent. This includes transmissions to send control information only.

### BYTSRCVD

Number of bytes received during this session (since the channel was started). This includes control information received by the message channel agent.

### BYTSSENT

Number of bytes sent during this session (since the channel was started). This includes control information sent by the message channel agent.

### CHSTADA

Date when this channel was started (in the form yyyy-mm-dd).

### CHSTATI

Time when this channel was started (in the form hh.mm.ss).

### COMPHDR

The technique used to compress the header data sent by the channel. Two values are displayed:

- The default header data compression value negotiated for this channel.
- The header data compression value used for the last message sent. The header data compression value can be altered in a sending channels message exit. If no message has been sent, the second value is blank.

## COMPMSG

The technique used to compress the message data sent by the channel. Two values are displayed:

- The default message data compression value negotiated for this channel.
- The message data compression value used for the last message sent. The message data compression value can be altered in a sending channels message exit. If no message has been sent, the second value is blank.

## COMPRATE

The compression rate achieved displayed to the nearest percentage. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING. If monitoring data is not being collected, or if no messages have been sent by the channel, the values are shown as blank.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 781.

## COMPTIME

The amount of time for each message, displayed in microseconds, spent during compression or decompression. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

**Note:**  On z/OS, COMPTIME is the amount of time for each message, provided that the message does not have to be processed in segments.

This segmenting of the message on z/OS occurs when the message is:

- 32 KB or larger, or
- 16 KB or larger, and the channel has SSL encryption.

If the message is split into segments, COMPTIME is the time spent compressing each segment. This means that a message that is split into 8 segments actually spends (COMPTIME \* 8) microseconds during compression or decompression.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 781.

## CURSHCNV

The CURSHCNV value is blank for all channel types other than server-connection channels. For each instance of a server-connection channel, the CURSHCNV output gives a count of the number of conversations currently running over that channel instance.

A value of zero indicates that the channel is running as it did in versions of IBM MQ earlier than Version 7.0, regarding:

- Administrator stop-quietce
- Heartbeating
- Read ahead
- Sharing conversations
- Client Asynchronous consumption

## EXITTIME

Amount of time, displayed in microseconds, spent processing user exits per message. Two values are displayed:

- The first value based on recent activity over a short period.

- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values may indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See “Setting monitor values” on page 781.

## HBINT

The heartbeat interval being used for this session.

## JOBNAME

A name that identifies the MQ process that is currently providing and hosting the channel.

- On IBM i, Windows, UNIX and Linux systems, this name is the concatenation of the process identifier and the thread identifier of the MCA program, displayed in hexadecimal.

▶ z/OS This information is not available on z/OS. The parameter is ignored if specified.

▶ z/OS You cannot use JOBNAME as a filter keyword on z/OS.

## ▶ z/OS KAJINT

The keepalive interval being used for this session. This is valid only on z/OS.

## LOCLADDR

Local communications address for the channel. The value returned depends on the TRPTYPE of the channel (currently only TCP/IP is supported).

## LONGRTS

Number of long retry wait start attempts left. This applies only to sender or server channels.

## LSTMSGDA

Date when the last message was sent or MQI call was handled, see LSTMSGTI.

## LSTMSGTI

Time when the last message was sent or MQI call was handled.

For a sender or server, this is the time the last message (the last part of it if it was split) was sent. For a requester or receiver, it is the time the last message was put to its target queue. For a server-connection channel, it is the time when the last MQI call completed.

In the case of a server-connection channel instance on which conversations are being shared, this is the time when the last MQI call completed on any of the conversations running on the channel instance.

## ▶ z/OS MAXMSGL

The maximum message length being used for this session (valid only on z/OS).

## MAXSHCNV

The MAXSHCNV value is blank for all channel types other than server-connection channels. For each instance of a server-connection channel, the MAXSHCNV output gives the negotiated maximum of the number of conversations that can run over that channel instance.

A value of zero indicates that the channel is running as it did in versions of IBM MQ earlier than Version 7.0, regarding:

- Administrator stop-quietce
- Heartbeating
- Read ahead
- Sharing conversations

- Client asynchronous consumption

#### ▶ z/OS **MCASTAT**

Whether the Message Channel Agent is currently running. This is either "running" or "not running".

Note that it is possible for a channel to be in stopped state, but for the program still to be running.

This information is not available on z/OS. The parameter is ignored if specified.

You cannot use MCASTAT as a filter keyword on z/OS.

#### **MCAUSER**

The user ID used by the MCA. This can be the user ID set in the channel definition, the default user ID for message channels, a user ID transferred from a client if this is a server-connection channel, or a user ID specified by a security exit.

This parameter applies only to server-connection, receiver, requester, and cluster-receiver channels.

On server connection channels that share conversations, the MCAUSER field contains a user ID if all the conversations have the same MCA user ID value. If the MCA user ID in use varies across these conversations, the MCAUSER field contains a value of \*.

The maximum length on distributed platforms is 64characters.

▶ z/OS The maximum length on z/OS is 12 characters.

#### **MONCHL**

Current level of monitoring data collection for the channel.

This parameter is also displayed when you specify the MONITOR parameter.

#### **MSGS**

Number of messages sent or received (or, for server-connection channels, the number of MQI calls handled) during this session (since the channel was started).

In the case of a server-connection channel instance on which conversations are being shared, this is the total number of MQI calls handled on all of the conversations running on the channel instance.

#### **NETTIME**

Amount of time, displayed in microseconds, to send a request to the remote end of the channel and receive a response. This time only measures the network time for such an operation. Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values may indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter applies only to sender, server, and cluster-sender channels.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See "Setting monitor values" on page 781.

#### **NPMSPEED**

The nonpersistent message handling technique being used for this session.

**V 8.0.0.4** PORT

The port number used to connect an AMQP channel. The default port for AMQP 1.0 connections is 5672.

**RAPPLTAG**

The remote partner application name. This is the name of the client application at the remote end of the channel. This parameter applies only to server-connection channels.

**RPRODUCT**

The remote partner product identifier. This is the product identifier of the IBM MQ code running at the remote end of the channel. The possible values are shown in Table 105.

Table 105. Product Identifier values

Product Identifier	Description
MQMM	Queue manager on a distributed platform
<b>z/OS</b> MQMV	Queue manager on z/OS
MQCC	IBM MQ C client
MQNC	IBM MQ client for HP Integrity NonStop Server
MQNM	IBM MQ .NET fully managed client
MQJB	IBM MQ Classes for JAVA
MQJM	IBM MQ Classes for JMS (normal mode)
MQJN	IBM MQ Classes for JMS (migration mode)
MQJU	Common Java interface to the MQI
MQXC	XMS client C/C++ (normal mode)
MQXD	XMS client C/C++ (migration mode)
MQXN	XMS client .NET (normal mode)
MQXM	XMS client .NET (migration mode)
MQXU	IBM MQ .NET XMS client (unmanaged/XA)
MQNU	IBM MQ .NET unmanaged client

**RQMNAME**

The queue manager name, or queue-sharing group name, of the remote system. This parameter does not apply to server-connection channels.

**RVERSION**

The remote partner version. This is the version of the IBM MQ code running at the remote end of the channel.

The remote version is displayed as **VVRRMMFF**, where

**VV** Version

**RR** Release

**MM** Maintenance level

**FF** Fix level

**V 8.0.0.2** SECPROT

Security protocol currently in use.

This parameter does not apply to client-connection channels.

The possible values are:

**NONE**

No security protocol

**SSLV3** SSL version 3.0

**TLSV1**

TLS version 1.0

**TLSV12**

TLS version 1.2

▶ **z/OS** SECPROT is not available on z/OS.

**SHORTRTS**

Number of short retry wait start attempts left. This applies only to sender or server channels.

**SSLCERTI**

The full Distinguished Name of the issuer of the remote certificate. The issuer is the Certificate Authority that issued the certificate.

The maximum length is 256 characters. This limit might mean that exceptionally long Distinguished Names are truncated.

▶ **z/OS** **SSLCERTU**

The local user ID associated with the remote certificate. This is valid on z/OS only.

**SSLKEYDA**

Date on which the previous successful SSL secret key reset was issued.

**SSLKEYTI**

Time at which the previous successful SSL secret key reset was issued.

**SSLPEER**

Distinguished Name of the peer queue manager or client at the other end of the channel.

The maximum length is 256 characters. This limit might mean that exceptionally long Distinguished Names are truncated.

**SSLRKEYS**

Number of successful SSL key resets. The count of SSL secret key resets is reset when the channel instance ends.

**STOPREQ**

Whether a user stop request is outstanding. This is either YES or NO.

**SUBSTATE**

Action being performed by the channel when this command is issued. The following substates are listed in precedence order, starting with the substate of the highest precedence:

**ENDBATCH**

Channel is performing end-of-batch processing.

**SEND**

A request has been made to the underlying communication subsystem to send some data.

**RECEIVE**

A request has been made to the underlying communication subsystem to receive some data.

▶ **z/OS** **SERIALIZE**

Channel is serializing its access to the queue manager. Valid on z/OS only.

**RESYNCH**

Channel is resynchronizing with the partner.

**HEARTBEAT**

Channel is heartbeating with the partner.

**SCYEXIT**

Channel is running the security exit.

**RCVEXIT**

Channel is running one of the receive exits.

**SENDEXIT**

Channel is running one of the send exits.

**MSGEXIT**

Channel is running one of the message exits.

**MREXIT**

Channel is running the message retry exit.

**CHADEXIT**

Channel is running through the channel auto-definition exit.

**NETCONNECT**

A request has been made to the underlying communication subsystem to connect a partner machine.

**SSLHANDSHK**

Channel is processing an SSL handshake.

**NAMESERVER**

A request has been made to the name server.

**MQPUT**

A request has been made to the queue manager to put a message on the destination queue.

**MQGET**

A request has been made to the queue manager to get a message from the transmission queue (if this is a message channel ) or from an application queue (if this is an MQI channel).

**MQICALL**

A MQ API call, other than MQPUT and MQGET, is being executed.

**COMPRESS**

Channel is compressing or extracting data.

Not all substates are valid for all channel types or channel states. There are occasions when no substate is valid, at which times a blank value is returned.

For channels running on multiple threads, this parameter displays the substate of the highest precedence.

**► V8.0.0.4 TPROOT**

The topic root for an AMQP channel. The default value for TPROOT is SYSTEM.BASE.TOPIC. With this value, the topic string an AMQP client uses to publish or subscribe has no prefix, and the client can exchange messages with other MQ pub/sub applications. To have AMQP clients publish and subscribe under a topic prefix, first create an MQ topic object with a topic string set to the prefix you want, then set TPROOT to the name of the MQ topic object you created.

This parameter is valid only for channels with a channel type ( CHLTYPE ) of AMQP

**XBATCHSZ**

Size of the batches transmitted over the channel. Two values are displayed:

- The first value based on recent activity over a short period.

- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter does not apply to server-connection channels.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See “Setting monitor values” on page 781.

#### ▶ V8.0.0.4 USECLTID

Specifies that the client ID should be used for authorization checks for an AMQP channel, instead of the MCAUSER attribute value.

#### XQMSGSA

Number of messages queued on the transmission queue available to the channel for MQGETs.

This parameter has a maximum displayable value of 999. If the number of messages available exceeds 999, a value of 999 is displayed.

▶ z/OS On z/OS, if the transmission queue is not indexed by *CorrelId*, this value is shown as blank.

This parameter applies to cluster-sender channels only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See “Setting monitor values” on page 781.

#### XQTIME

The time, in microseconds, that messages remained on the transmission queue before being retrieved. The time is measured from when the message is put onto the transmission queue until it is retrieved to be sent on the channel and, therefore, includes any interval caused by a delay in the putting application.

Two values are displayed:

- The first value based on recent activity over a short period.
- The second value based on activity over a longer period.

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. They are reset every time the channel is started and are displayed only when the STATUS of the channel is RUNNING.

This parameter applies only to sender, server, and cluster-sender channels.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONCHL is set for this channel. See “Setting monitor values” on page 781.

#### ▶ z/OS

#### Short status

The following information applies only to current channel instances.

#### QMNAME

The name of the queue manager that owns the channel instance.

## Setting monitor values

For auto-defined cluster sender channels, these are controlled with the queue manager MONACLS parameter. See “ALTER QMGR” on page 435 for more information. You cannot display or alter auto-defined cluster sender channels. However you can get their status, or issue DISPLAY CLUSQMGR, as described here: Working with auto-defined cluster-sender channels.

For other channels, including manually-defined cluster sender channels, these are controlled with the channel MONCHL parameter. See “ALTER CHANNEL” on page 366 for more information.

## DISPLAY CHSTATUS (AMQP): V 8.0.0.4

Use the MQSC command DISPLAY CHSTATUS (AMQP) to display the status of one or more AMQP channels.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
	✓	✓	

- Syntax diagram
- “Parameter descriptions for DISPLAY CHSTATUS” on page 782
- “Summary attributes” on page 783

**Synonym:** DIS CHS

## DISPLAY CHSTATUS (AMQP)

```

▶▶—DISPLAY CHSTATUS—(—generic-channel-name—)—CHLTYPE—(—AMQP—)——————▶
▶
┌—CLIENTID—(—generic-clientId—)—DetailAttributes—┐ ┌—WHERE—(—FilterCondition—)—┐
└──────────────────────────────────────────────────┘ └──────────────────────────────────┘
  
```

### SummaryAttributes:

```

┌—ALL—┐
├—CONNECTIONS—┤
└—STATUS—┘
  
```

### DetailAttributes:

**Note:**

- The default behavior is for **RUNMQSC** to return a summary of the connections to the channel. If **CLIENTID** is specified then **RUNMQSC** returns details of each client connected to the channel.

**Parameter descriptions for DISPLAY CHSTATUS**

You must specify the name of the channel for which you want to display status information. This parameter can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

( *generic-channel-name* )

The name of the channel definition for which status information is to be displayed. A trailing asterisk (\*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all channel definitions. A value is required for all channel types.

**WHERE**

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

The parameter to be used to display attributes for this DISPLAY command.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

*operator*

This is used to determine whether a channel satisfies the filter value on the filter keyword.

The operators are:

- LT**    Less than
- GT**    Greater than
- EQ**    Equal to
- NE**    Not equal to
- LE**    Less than or equal to
- GE**    Greater than or equal to
- LK**    Matches a generic string that you provide as a *filter-value*

- NL Does not match a generic string that you provide as a *filter-value*
- CT Contains a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which contain the specified item.
- EX Does not contain a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which do not contain the specified item.

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute that is being tested.  
You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the CHLTYPE parameter), you can use EQ or NE only.
- A generic value. This value is a character string with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.  
You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

**ALL**

Specify this parameter to display all the status information for each relevant instance.

If this parameter is specified, any parameters that request specific status information which are also specified have no effect; all the information is displayed.

**Summary attributes**

When no CLIENTID parameter is added to the MQSC command DISPLAY CHSTATUS (AMQP), a summary of AMQP channel information is displayed. The number of connections is displayed as the CONNECTIONS attribute. The following attributes display a summary for each channel.

**ALL**

Specify this parameter to display all the status information for each relevant instance. This attribute is the default value if no attributes are requested.

This parameter is valid for AMQP channels.

If this parameter is specified, any specified parameters that are requesting specific status information have no effect; and all the information is displayed.

**CONNECTIONS**

The number of current connections to this channel.

**STATUS**

The status of this channel.

**Client details mode**

**STATUS**

The status of the client.

**CONNAME**

The name of the remote connection (IP address)

#### **AMQPKA**

The client's keep alive interval.

#### **MCAUSER**

The user ID that the client is using to access IBM MQ resources.

#### **CLNTUSER**

The user ID that the client provided when it connected.

#### **MSGSENT**

Number of messages sent by the client since it connected last.

#### **MSGRCVD**

Number of messages received by the client since it connected last.

#### **LSTMSGDA**

Date last message was received or sent.

#### **LSTMSGTI**

Time last message was received or sent.

#### **CHSTADA**

Date channel started.

#### **CHSTATI**

Time channel was started.

#### **PROTOCOL**

The communication protocol used by the client. The value is AMQP.

#### **Examples**

The following command retrieves a status summary for the AMQP channel named MYAMQP:

```
dis chstatus(MYAMQP) chltype(AMQP) all
```

The command outputs the following status:

```
AMQ8417: Display Channel Status details.
CHANNEL(MYAMQP)                CHLTYPE(AMQP)
CONNECTIONS(1)                  STATUS(RUNNING)
```

The following command retrieves a full status for the AMQP channel named MYAMQP:

```
dis chstatus(*) chltype(AMQP) clientid(*) all
```

The command outputs the following status:

```
AMQ8417: Display Channel Status details.
CHANNEL(MYAMQP)                CHLTYPE(AMQP)
CLIENTID(recv_cc2022b)        STATUS(RUNNING)
CONNAME(192.168.60.1)         AMQPKA(0)
MCAUSER(matt)                 CLNTUSER( )
MSGSENT(0)                    MSGRCVD(0)
LSTMSGDA( )                   LSTMSGTI( )
CHSTADA(2015-09-18)           CHSTATI(06.23.30)
PROTOCOL(AMQP)
```

## DISPLAY CHSTATUS (MQTT):

Use the MQSC command DISPLAY CHSTATUS (MQTT) to display the status of one or more IBM MQ Telemetry channels.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	AIX and Linux	Windows	z/OS
	✓	✓	

**Note:** For the telemetry server, AIX is the only supported UNIX platform.

- Syntax diagram
- “Parameter descriptions for DISPLAY CHSTATUS” on page 786
- “Summary attributes” on page 787

Synonym: DIS CHS

## DISPLAY CHSTATUS ( MQTT )

### SummaryAttributes:

## DetailAttributes:

ALL
STATUS
CLNTUSER
KAIN
MCAUSER
MSGSN
MSGRCVD
INDOUBTIN
INDOUBTOUT
PENDING
PROTOCOL
LMSGDATE
LMSGTIME
CHLSDATE
CHLSTIME

### Note:

- The default behavior is for **RUNMQSC** to return a summary of the connections to the channel. If **CLIENTID** is specified then **RUNMQSC** returns details of each client connected to the channel.
- Either **CLIENTID**, **SUMMARY**, or neither may be specified, but not both at the same time.
- The **DISPLAY CHSTATUS** command for IBM MQ Telemetry has the potential to return a far larger number of responses than if the command was run for an IBM MQ channel. For this reason, the IBM MQ Telemetry server does not return more responses than fit on the reply-to queue. The number of responses is limited to the value of MAXDEPTH parameter of the SYSTEM.MQSC.REPLY.QUEUE queue. When RUNMQSC processes an IBM MQ Telemetry command that is truncated by the IBM MQ Telemetry server, the AMQ8492 message is displayed specifying how many responses are returned based on the size of MAXDEPTH.

### Parameter descriptions for DISPLAY CHSTATUS

You must specify the name of the channel for which you want to display status information. This parameter can be a specific channel name or a generic channel name. By using a generic channel name, you can display either the status information for all channels, or status information for one or more channels that match the specified name.

( *generic-channel-name* )

The name of the channel definition for which status information is to be displayed. A trailing asterisk (\*) matches all channel definitions with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all channel definitions. A value is required for all channel types.

### WHERE

Specify a filter condition to display status information for those channels that satisfy the selection criterion of the filter condition.

The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

The parameter to be used to display attributes for this DISPLAY command.

Status information for channels of a type for which the filter keyword is not valid is not displayed.

### *operator*

This is used to determine whether a channel satisfies the filter value on the filter keyword. The operators are:

- LT** Less than
- GT** Greater than
- EQ** Equal to
- NE** Not equal to
- LE** Less than or equal to
- GE** Greater than or equal to
- LK** Matches a generic string that you provide as a *filter-value*
- NL** Does not match a generic string that you provide as a *filter-value*
- CT** Contains a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which contain the specified item.
- EX** Does not contain a specified item. If the *filter-keyword* is a list, you can use this operator to display objects the attributes of which do not contain the specified item.

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute that is being tested.  
You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value SDR on the CHLTYPE parameter), you can use EQ or NE only.
- A generic value. This value is a character string with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.  
You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

### **ALL**

Specify this parameter to display all the status information for each relevant instance.

If this parameter is specified, any parameters that request specific status information which are also specified have no effect; all the information is displayed.

### **Summary attributes**

When SUMMARY is added to the MQSC command DISPLAY CHSTATUS (MQTT), the number of connections is displayed as the CONNECTIONS attribute. The following attributes display a summary for each channel.

### **ALL**

Specify this parameter to display all the status information for each relevant instance. This attribute is the default value if no attributes are requested.

This parameter is valid for MQTT channels.

If this parameter is specified, any specified parameters that are requesting specific status information have no effect; and all the information is displayed.

## **CONNECTIONS**

The number of current connections to this channel.

## **STATUS**

The status of this channel.

## **Client details mode**

## **STATUS**

The status of the client.

## **CLNTUSER**

The user ID that the client provided when it connected.

## **CONNNAME**

The name of the remote connection (IP address)

## **KAINT**

The client's keep alive interval.

## **MCAUSER**

The user ID that the client is using to access IBM MQ resources. This is the client user ID selected by the process described in MQTT client identity and authorization.

## **MSGSENT**

Number of messages sent by the client since it connected last.

## **MSGRCVD**

Number of messages received by the client since it connected last.

## **INDOUBTIN**

Number of in doubt, inbound messages to the client.

## **INDOUBTOUT**

Number of in doubt, outbound messages to the client.

## **PENDING**

Number of outbound pending messages.

## **PROTOCOL**

The communication protocol used by the client. This is either MQTTV3 or HTTP.

## **LMSGDATE**

Date last message was received or sent.

## **LMSGTIME**

Time last message was received or sent.

## **CHLSDATE**

Date channel started.

## **CHLSTIME**

Time channel was started.

## DISPLAY CLUSQMGR:

Use the MQSC command **DISPLAY CLUSQMGR** to display information about cluster channels for queue managers in a cluster.

### Using MQSC commands

For information on how you use MQSC commands, see *Performing local administration tasks using MQSC commands*.

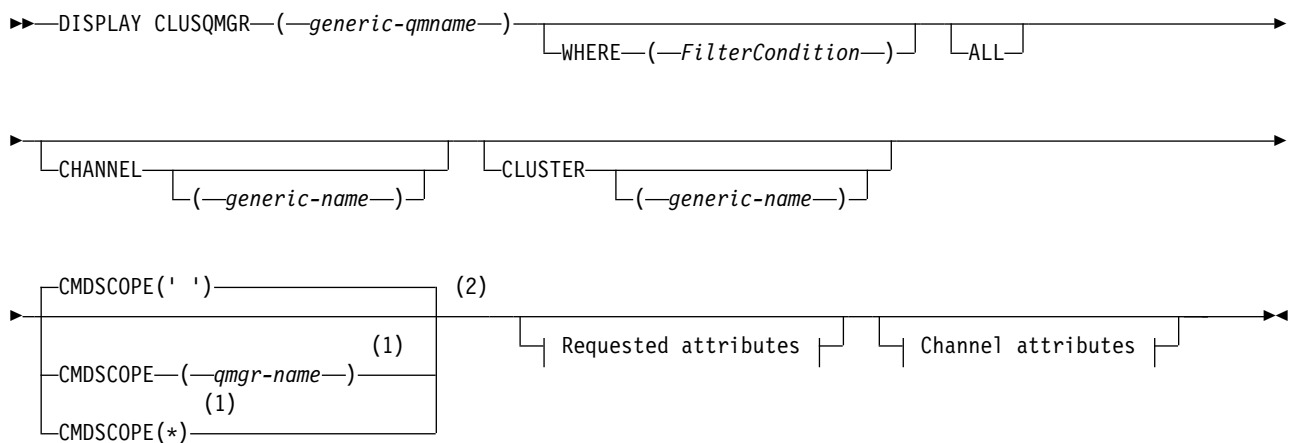

IBM i	UNIX and Linux	Windows	z/OS

## Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.

## Usage notes

Unlike the **DISPLAY CHANNEL** command, this command includes information about cluster channels that are auto-defined, and the status of cluster channels.

## Note:

1. On UNIX systems, the command is valid only on AIX, HP-UX, Linux, and Solaris.
2. On z/OS, the command fails if the channel initiator is not started.

## Parameter descriptions for DISPLAY CLUSQMGR

( *generic-qmgr-name* )

The name of the cluster queue manager for which information is to be displayed.

A trailing asterisk "\*" matches all cluster queue managers with the specified stem followed by zero or more characters. An asterisk "\*" on its own specifies all cluster queue managers.

## WHERE

Specify a filter condition to display only those cluster channels that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this **DISPLAY** command.

However, you cannot use the **CMDSCOPE** or **MCANAME** parameters as filter keywords.

You cannot use **CHANNEL** or **CLUSTER** as filter keywords if you use them to select cluster queue managers.

*operator*

The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

**CT** Contains a specified item. If the *filter-keyword* is a list, you can use **CT** to display objects the attributes of which contain the specified item.

**EX** Does not contain a specified item. If the *filter-keyword* is a list, you can use **EX** to display objects the attributes of which do not contain the specified item.

**CTG** Contains an item which matches a generic string that you provide as a *filter-value*. If the *filter-keyword* is a list, you can use **CTG** to display objects the attributes of which match the generic string.

**EXG** Does not contain any item which matches a generic string that you provide as a

*filter-value*. If the *filter-keyword* is a list, you can use **EXG** to display objects the attributes of which do not match the generic string.

#### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, *filter-value* can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators **LT** , **GT**, **EQ**, **NE**, **LE**, , or **GE** only. If the attribute value is a value from a possible set of values, you can use only **EQ** or **NE** . For example, the value **STARTING** on the **STATUS** parameter.
- A generic value. *filter-value* is a character string. An example is **ABC\***. If the operator is **LK** , all items where the attribute value begins with the string, **ABC** in the example, are listed. If the operator is **NL** , all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.  
You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use **CT** or **EX** as the operator. For example, if the value **DEF** is specified with the operator **CT** , all items where one of the attribute values is **DEF** are listed. If it is generic, use **CTG** or **EXG** as the operator. If **ABC\*** is specified with the operator **CTG** , all items where one of the attribute values begins with **ABC** are listed.

**ALL** Specify **ALL** to display all the parameters. If this parameter is specified, any parameters that are also requested specifically have no effect; all parameters are still displayed.

**ALL** is the default if you do not specify a generic name and do not request any specific parameters.

▶ **z/OS** On z/OS **ALL** is also the default if you specify a filter condition using the **WHERE** parameter, but on other platforms, only requested attributes are displayed.

#### **CHANNEL** ( *generic-name* )

This is optional, and limits the information displayed to cluster channels with the specified channel name. The value can be a generic name.

#### **CLUSTER** ( *generic-name* )

This is optional, and limits the information displayed to cluster queue managers with the specified cluster name. The value can be a generic name.

#### ▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

" The command is executed on the queue manager on which it was entered. " is the default value.

#### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered. You can enter a different queue manager name, if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of \* is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

## Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Some parameters are relevant only for cluster channels of a particular type or types. Attributes that are not relevant for a particular type of channel cause no output, and do not cause an error.

### CLUSDATE

The date on which the definition became available to the local queue manager, in the form yyyy-mm-dd.

### CLUSTIME

The time at which the definition became available to the local queue manager, in the form hh.mm.ss.

### DEFTYPE

How the cluster channel was defined:

#### CLUSSDR

As a cluster-sender channel from an explicit definition.

#### CLUSSDRA

As a cluster-sender channel by auto-definition alone.

#### CLUSSDRB

As a cluster-sender channel by auto-definition and an explicit definition.

#### CLUSRCVR

As a cluster-receiver channel from an explicit definition.

### QMID

The internally generated unique name of the cluster queue manager.

### QMTYPE

The function of the cluster queue manager in the cluster:

#### REPOS

Provides a full repository service.

#### NORMAL

Does not provide a full repository service.

### STATUS

The status of the channel for this cluster queue manager is one of the following values:

#### STARTING

The channel was started and is waiting to become active.

#### BINDING

The channel is performing channel negotiation and is not yet ready to transfer messages.

#### INACTIVE

The channel is not active.

#### INITIALIZING

The channel initiator is attempting to start a channel.

 On z/OS, **INITIALIZING** is displayed as INITIALIZI.

#### RUNNING

The channel is either transferring messages at this moment, or is waiting for messages to arrive on the transmission queue so that they can be transferred.

**STOPPING**

The channel is stopping, or received a close request.

**RETRYING**

A previous attempt to establish a connection failed. The MCA attempts to connect again after the specified time interval.

**PAUSED**

The channel is waiting for the message-retry interval to complete before trying an MQPUT operation again.

**STOPPED**

This state can be caused by one of the following events:

- Channel manually stopped.  
A user entered a stop channel command for this channel.
- The number of attempts to establish a connection reached the maximum number of attempts allowed for the channel.  
No further attempt is made to establish a connection automatically.

A channel in this state can be restarted only by issuing the **START CHANNEL** command, or starting the MCA program in an operating-system dependent manner.

**REQUESTING**

A local requester channel is requesting services from a remote MCA.

**SUSPEND**

Specifies whether this cluster queue manager is suspended from the cluster or not (as a result of the **SUSPEND QMGR** command). The value of **SUSPEND** is either YES or NO.

**VERSION**

The version of the IBM MQ installation that the cluster queue manager is associated with.

The version has the format VVRRMMFF:

- VV: Version
- RR: Release
- MM: Maintenance level
- FF: Fix level

**XMITQ**

The cluster transmission queue.

**Channel parameters****ALTDATE**

The date on which the definition or information was last altered, in the form yyyy-mm-dd

**ALTTIME**

The time at which the definition or information was last altered, in the form hh.mm.ss

**BATCHHB**

The batch heartbeat value being used.

**BATCHINT**

Minimum batch duration.

**BATCHLIM**

Batch data limit.

The limit of the amount of data that can be sent through a channel.

**BATCHSZ**

Batch size.

**CLWLPRTY**  
The priority of the channel for the purposes of cluster workload distribution.

**CLWLRANK**  
The rank of the channel for the purposes of cluster workload distribution.

**CLWLWGHT**  
The weighting of the channel for the purposes of cluster workload distribution.

**COMPHDR**  
The list of header data compression techniques supported by the channel.

**COMPMSG**  
The list of message data compression techniques supported by the channel.

**CONNNAME**  
Connection name.

**CONVERT**  
Specifies whether the sender converts application message data.

**DESCR**  
Description.

**DISCINT**  
Disconnection interval.

**HBINT**  
Heartbeat interval.

**KAINT**  
KeepAlive timing for the channel.

**LOCLADDR**  
Local communications address for the channel.

**LONGRTY**  
Limit of number of attempts to connect using the long duration timer.

**LONGTMR**  
Long duration timer.

**MAXMSGL**  
Maximum message length for channel.

**MCANAME**  
Message channel agent name.  
You cannot use MCANAME as a filter keyword.

**MCATYPE**  
Specifies whether the message channel agent runs as a separate process or a separate thread.

**MCAUSER**  
Message channel agent user identifier.

**MODENAME**  
LU 6.2 mode name.

**MRDATA**  
Channel message-retry exit user data.

**MREXIT**  
Channel message-retry exit name.

**MRRTY**  
Channel message-retry count.

**MRTMR**  
Channel message-retry time.

**MSGDATA**  
Channel message exit user data.

**MSGEXIT**  
Channel message exit names.

**NETPRTY**  
The priority for the network connection.

**NPMSPEED**  
Nonpersistent message speed.

**PASSWORD**  
Password for initiating LU 6.2 session (if nonblank, **PASSWORD** is displayed as asterisks).

**PROPCTL**  
Message property control.

**PUTAUT**  
Put authority.

**RCVDATA**  
Channel receive exit user data.

**RCVEXIT**  
Channel receive exit names.

**SCYDATA**  
Channel security exit user data.

**SCYEXIT**  
Channel security exit name.

**SENDDATA**  
Channel send exit user data.

**SENDEXIT**  
Channel send exit names.

**SEQWRAP**  
Sequence number wrap value.

**SHORTRTY**  
Limit of number of attempts to connect using the short duration timer.

**SHORTTMR**  
Short duration timer.

**SSLCAUTH**  
Specifies whether SSL client authentication is required.

**SSLCIPH**  
Cipher specification for the SSL connection.

**SSLPEER**  
Filter for the Distinguished Name from the certificate of the peer queue manager or client at the other end of the channel.

**TRPTYPE**  
Transport type.

**TPNAME**  
LU 6.2 transaction program name.

## USEDLQ

Determines whether the dead-letter queue is used when messages cannot be delivered by channels.

## USERID

User identifier for initiating LU 6.2 session.

For more information about channel parameters, see “DEFINE CHANNEL” on page 550

## DISPLAY CMDSERV:

Use the MQSC command DISPLAY CMDSERV to display the status of the command server.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			12CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY CMDSERV”

**Synonym:** DIS CS

## DISPLAY CMDSERV

▶▶—DISPLAY CMDSERV—▶▶

### Usage notes for DISPLAY CMDSERV

1. The command server takes messages from the system command input queue, and commands using CMDSCOPE, and processes them. DISPLAY CMDSERV displays the status of the command server.
2. The response to this command is a message showing the current status of the command server, which is one of the following:

#### ENABLED

Available to process commands

#### DISABLED

Not available to process commands

#### STARTING

START CMDSERV in progress

#### STOPPING

STOP CMDSERV in progress

#### STOPPED

STOP CMDSERV completed

#### RUNNING

Available to process commands, currently processing a message

#### WAITING

Available to process commands, currently waiting for a message

## DISPLAY COMMINFO:

Use the MQSC command DISPLAY COMMINFO to display the attributes of a communication information object.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions for DISPLAY COMMINFO”
- “Requested parameters” on page 799

Synonym: DIS COMMINFO

## DISPLAY COMMINFO

### Requested attrs:

### Parameter descriptions for DISPLAY COMMINFO

You must specify the name of the communication information object you want to display. This can be a specific communication information object name or a generic communication information object name. By using a generic communication information object name, you can display either:

- All communication information object definitions
- One or more communication information objects that match the specified name

(*generic-comminfo-name*)

The name of the communication information object definition to be displayed (see Rules for naming IBM MQ objects ). A trailing asterisk (\*) matches all communication information objects with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all communication information objects. The names must all be defined to the local queue manager.

## WHERE

Specify a filter condition to display only those communication information object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command.

*operator*

This is used to determine whether a communication information object definition satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value DISABLED on the COMMEV parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

**ALL** Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

**TYPE** Indicates the type of namelist to be displayed.

### MULTICAST

Displays multicast communication information objects. This is the default.

### Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names and TYPE parameters are displayed.

**ALTDATE**

The date on which the definition was last altered, in the form yyyy-mm-dd

**ALTTIME**

The time at which the definition was last altered, in the form hh.mm.ss

**BRIDGE**

Multicast bridging

**CCSID**

The coded character set identifier that messages are transmitted on.

**COMMEV**

Whether event messages are generated for Multicast.

**DESCR( *string* )**

Description

**ENCODING**

The encoding that the messages are transmitted in.

**GRPADDR**

The group IP address or DNS name.

**MCHBINT**

Multicast heartbeat interval.

**MCPROP**

Multicast property control

**MONINT**

Monitoring frequency.

**MSGHIST**

The amount of message history in kilobytes that is kept by the system to handle retransmissions in the case of NACKs (negative acknowledgments).

**NSUBHIST**

How much history a new subscriber joining a publication stream receives.

**PORT** The port number to transmit on.

**DISPLAY CONN:**

Use the MQSC command DISPLAY CONN to display connection information about the applications connected to the queue manager. This is a useful command because it enables you to identify applications with long-running units of work.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX	Windows	z/OS
✓	✓	✓	2CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

USERID

**Handle attributes:**

ASTATE
DEST
DESTQMGR
HSTATE
OBJNAME
OBJTYPE
OPENOPTS
(1)
QSGDISP
READA
SUBID
SUBNAME
TOPICSTR

**Notes:**

- 1 Valid only on z/OS.

- 2 Valid only when the queue manager is a member of a queue-sharing group.
- 3 Valid only when the connection is associated with a channel.
- 4 Not valid on z/OS.
- 5 IMS only.
- 6 CICS for z/OS only.

#### Usage notes for DISPLAY CONN

1.  This command is issued internally by IBM MQ on z/OS when taking a checkpoint, and when the queue manager is starting and stopping, so that a list of units of work that are in doubt at the time is written to the z/OS console log.
2. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed.
  -  On z/OS, these non-printable characters will be displayed as blanks.
  - On distributed platforms using runmqsc, these non-printable characters will be displayed as dots.
3. The state of asynchronous consumers, ASTATE, reflects that of the server-connection proxy on behalf of the client application; it does not reflect the client application state.

#### Parameter descriptions for DISPLAY CONN

You must specify a connection for which you want to display information. This can be a specific connection identifier or a generic connection identifier. A single asterisk (\*) can be used as a generic connection identifier to display information for all connections.

( *generic-connid* )

The identifier of the connection definition for which information is to be displayed. A single asterisk (\*) specifies that information for all connection identifiers is to be displayed.

When an application connects to IBM MQ, it is given a unique 24-byte connection identifier (ConnectionId). The value for CONN is formed by converting the last eight bytes of the ConnectionId to its 16 -character hexadecimal equivalent.

#### WHERE

Specify a filter condition to display only those connections that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, EXTCONN, QSGDISP, TYPE, and EXTURID parameters as filter keywords.

*operator*

This is used to determine whether a connection satisfies the filter value on the given filter keyword. The operators are:

- |           |   |
|-----------|---|
| <b>LT</b> | Less than   |
| <b>GT</b> | Greater than  |
| <b>EQ</b> | Equal to  |
| <b>NE</b> | Not equal to  |
| <b>LE</b> | Less than or equal to   |
| <b>GE</b> | Greater than or equal to  |
| <b>LK</b> | Matches a generic string that you provide as a <i>filter-value</i>        |
| <b>NL</b> | Does not match a generic string that you provide as a <i>filter-value</i> |

- CT** Contains a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which contain the specified item. You cannot use the CONNOPTS value MQCNO\_STANDARD\_BINDING with this operator.
- EX** Does not contain a specified item. If the *filter-keyword* is a list, you can use this to display objects the attributes of which do not contain the specified item. You cannot use the CONNOPTS value MQCNO\_STANDARD\_BINDING with this operator.

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NONE on the UOWSTATE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string in the APPLTAG parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.  
You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.
- An item in a list of values. Use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed.

**ALL** Specify this to display all the connection information of the requested type for each specified connection. This is the default if you do not specify a generic identifier, and do not request any specific parameters.

**z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which it was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

**EXTCONN**

The value for EXTCONN is based on the first sixteen bytes of the ConnectionId converted to its 32 -character hexadecimal equivalent.

Connections are identified by a 24-byte connection identifier. The connection identifier comprises a prefix, which identifies the queue manager, and a suffix which identifies the connection to that queue manager. By default, the prefix is for the queue manager currently being administered, but you can specify a prefix explicitly by using the EXTCONN parameter. Use the CONN parameter to specify the suffix.

When connection identifiers are obtained from other sources, specify the fully qualified connection identifier (both EXTCONN and CONN) to avoid possible problems related to non-unique CONN values.

Do not specify both a generic value for CONN and a non-generic value for EXTCONN.

You cannot use EXTCONN as a filter keyword.

**TYPE** Specifies the type of information to be displayed. Values are:

**CONN**

Connection information for the specified connection.

▶ **z/OS** On z/OS, this includes threads which may be logically or actually disassociated from a connection, together with those that are in-doubt and for which external intervention is needed to resolve them. These latter threads are those that DIS THREAD TYPE(INDOUBT) would show.

**HANDLE**

Information relating to any objects opened by the specified connection.

\* Display all available information relating to the connection.

**ALL** Display all available information relating to the connection.

▶ **z/OS** On z/OS, if you specify **TYPE(ALL|\*)** and **WHERE(yyyyy)** you only get CONN or HANDLE information returned, based on the **WHERE** specification. That is, if the **yyyyy** is a condition relating to handle attributes then only handle attributes for the connection are returned.

**URDISP**

Specifies the unit of recovery disposition of connections to be displayed. Values are:

**ALL** Display all connections. This is the default option.

**GROUP**

Display only those connections with a GROUP unit of recovery disposition.

**QMGR**

Display only those connections with a QMGR unit of recovery disposition.

**Connection attributes**

If TYPE is set to CONN, the following information is always returned for each connection that satisfies the selection criteria, except where indicated:

- Connection identifier (CONN parameter)
- Type of information returned (TYPE parameter)

The following parameters can be specified for TYPE(CONN) to request additional information for each connection. If a parameter is specified that is not relevant for the connection, operating environment, or type of information requested, that parameter is ignored.

**APPLDESC**

A string containing a description of the application connected to the queue manager, where it is known. If the application is not recognized by the queue manager the description returned is blank.

**APPLTAG**

A string containing the tag of the application connected to the queue manager. It is one of the following:

- ▶ **z/OS** z/OS batch job name

-  TSO USERID
- CICS APPLID
-  IMS region name
- Channel initiator job name
-  IBM i job name
- UNIX process

**Notes:**

-  On HP-UX, if the process name exceeds 14 characters, only the first 14 characters are shown.
  -   On Linux and Solaris, if the process name exceeds 15 characters, only the first 15 characters are shown.
  -  On AIX, if the process name exceeds 28 characters, only the first 28 characters are shown.
  - Windows process
- Note:** This consists of the full program path and executable file name. If it is more than 28 characters long, only the last 28 characters are shown.
- Internal queue manager process name

**APPLTYPE**

A string indicating the type of the application that is connected to the queue manager. It is one of the following:

**BATCH**

Application using a batch connection

**RRSBATCH**

RRS-coordinated application using a batch connection

**CICS** CICS transaction

**IMS** IMS transaction

**CHINIT**

Channel initiator

**OS400** An IBM i application

**SYSTEM**

Queue manager

**SYSTEMEXT**

Application performing an extension of function that is provided by the queue manager

**UNIX** A UNIX application

**USER** A user application

**WINDOWSNT**

A Windows application

 **ASID**

A 4-character address-space identifier of the application identified by APPLTAG. It distinguishes duplicate values of APPLTAG.

This parameter is returned only on z/OS when the APPLTYPE parameter does not have the value SYSTEM.

This parameter is valid only on z/OS.

#### **ASTATE**

The state of asynchronous consumption on this connection handle.

Possible values are:

#### **SUSPENDED**

An MQCTL call with the Operation parameter set to MQOP\_SUSPEND has been issued against the connection handle so that asynchronous message consumption is temporarily suspended on this connection.

#### **STARTED**

An MQCTL call with the Operation parameter set to MQOP\_START has been issued against the connection handle so that asynchronous message consumption can proceed on this connection.

#### **STARTWAIT**

An MQCTL call with the Operation parameter set to MQOP\_START\_WAIT has been issued against the connection handle so that asynchronous message consumption can proceed on this connection.

#### **STOPPED**

An MQCTL call with the Operation parameter set to MQOP\_STOP has been issued against the connection handle so that asynchronous message consumption cannot currently proceed on this connection.

#### **NONE**

No MQCTL call has been issued against the connection handle. Asynchronous message consumption cannot currently proceed on this connection.

#### **CHANNEL**

The name of the channel that owns the connection. If there is no channel associated with the connection, this parameter is blank.

#### **V 8.0.0.2 CLIENTID**

The client ID of the client that is using the connection. If there is no client ID associated with the connection, this parameter is blank.

#### **CONNNAME**

The connection name associated with the channel that owns the connection. If there is no channel associated with the connection, this parameter is blank.

#### **CONNOPTS**

The connect options currently in force for this application connection. Possible values are:

- MQCNO\_HANDLE\_SHARE\_BLOCK
- MQCNO\_HANDLE\_SHARE\_NO\_BLOCK
- MQCNO\_HANDLE\_SHARE\_NONE
- MQCNO\_SHARED\_BINDING
- MQCNO\_STANDARD\_BINDING
- MQCNO\_ISOLATED\_BINDING
- MQCNO\_FASTPATH\_BINDING
- MQCNO\_SERIALIZE\_CONN\_TAG\_Q\_MGR
- MQCNO\_SERIALIZE\_CONN\_TAG\_QSG
- MQCNO\_RESTRICT\_CONN\_TAG\_Q\_MGR
- MQCNO\_RESTRICT\_CONN\_TAG\_QSG
- MQCNO\_ACCOUNTING\_Q\_ENABLED
- MQCNO\_ACCOUNTING\_Q\_DISABLED

- MQCNO\_ACCOUNTING\_MQI\_ENABLED
- MQCNO\_ACCOUNTING\_MQI\_DISABLED

You cannot use the value MQCNO\_STANDARD\_BINDING as a filter value with the CT and EX operators on the WHERE parameter.

## EXTURID

The external unit of recovery identifier associated with this connection. Its format is determined by the value of URTYPE.

You cannot use EXTURID as a filter keyword.

### z/OS NID

Origin identifier, set only if the value of UOWSTATE is UNRESOLVED. This is a unique token identifying the unit of work within the queue manager. It is of the form origin-node.origin-urid where

- origin-node identifies the originator of the thread, except in the case where APPLTYPE is set to RRSBATCH, when it is omitted.
- origin-urid is the hexadecimal number assigned to the unit of recovery by the originating system for the specific thread to be resolved.

This parameter is valid only on z/OS.

**PID** Number specifying the process identifier of the application that is connected to the queue manager.

z/OS This parameter is not valid on z/OS.

### z/OS PSBNAME

The 8-character name of the program specification block (PSB) associated with the running IMS transaction. You can use the PSBNAME and PSTID to purge the transaction using IMS commands. It is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value IMS.

### z/OS PSTID

The 4-character IMS program specification table (PST) region identifier for the connected IMS region. It is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value IMS.

## QMURID

The queue manager unit of recovery identifier.

z/OS On z/OS, this is an 8-byte log RBA, displayed as 16 hexadecimal characters.

On platforms other than z/OS, this is an 8-byte transaction identifier, displayed as m.n where m and n are the decimal representation of the first and last 4 bytes of the transaction identifier.

z/OS You can use QMURID as a filter keyword. On z/OS, you must specify the filter value as a hexadecimal string.

On platforms other than z/OS, you must specify the filter value as a pair of decimal numbers separated by a period (.). You can only use the EQ, NE, GT, LT, GE, or LE filter operators.

z/OS However, on z/OS, if log shunting has taken place, as indicated by message CSQR026I, instead of the RBA you have to use the URID from the message.

### z/OS TASKNO

A 7-digit CICS task number. This number can be used in the CICS command "CEMT SET TASK(taskno) PURGE" to end the CICS task. This parameter is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value CICS.

**TID** Number specifying the thread identifier within the application process that has opened the specified queue.

▶ **z/OS** This parameter is not valid on z/OS.

▶ **z/OS** **TRANSID**

A 4-character CICS transaction identifier. This parameter is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value CICS.

**UOWLOG**

The file name of the extent to which the transaction associated with this connection first wrote.

▶ **z/OS** This parameter is valid only on platforms other than z/OS.

**UOWLOGDA**

The date that the transaction associated with the current connection first wrote to the log.

**UOWLOGTI**

The time that the transaction associated with the current connection first wrote to the log.

**UOWSTATE**

The state of the unit of work. It is one of the following:

**NONE**

There is no unit of work.

**ACTIVE**

The unit of work is active.

**PREPARED**

The unit of work is in the process of being committed.

▶ **z/OS** **UNRESOLVED**

The unit of work is in the second phase of a two-phase commit operation. IBM MQ holds resources on its behalf and external intervention is required to resolve it. This might be as simple as starting the recovery coordinator (such as CICS, IMS, or RRS) or it might involve a more complex operation such as using the RESOLVE INDOUBT command. The UNRESOLVED value can occur only on z/OS.

**UOWSTDA**

The date that the transaction associated with the current connection was started.

**UOWSTTI**

The time that the transaction associated with the current connection was started.

**URTYPE**

The type of unit of recovery as seen by the queue manager. It is one of the following:

- ▶ **z/OS** CICS (valid only on z/OS )
- XA
- ▶ **z/OS** RRS (valid only on z/OS )
- ▶ **z/OS** IMS (valid only on z/OS )
- QMGR

URTYPE identifies the EXTURID type and not the type of the transaction coordinator. When URTYPE is QMGR, the associated identifier is in QMURID (and not EXTURID).

**USERID**

The user identifier associated with the connection.

This parameter is not returned when APPLTYPE has the value SYSTEM.

## Handle attributes

If TYPE is set to HANDLE, the following information is always returned for each connection that satisfies the selection criteria, except where indicated:

- Connection identifier (CONN parameter)
- Read ahead status (DEFREADA parameter)
- Type of information returned (TYPE parameter)
- Handle status (HSTATE)
- Object name (OBJNAME parameter)
- Object type (OBJTYPE parameter)

The following parameters can be specified for TYPE(HANDLE) to request additional information for each queue. If a parameter is specified that is not relevant for the connection, operating environment, or type of status information requested, that parameter is ignored.

### ASTATE

The state of the asynchronous consumer on this object handle.

Possible values are:

#### ACTIVE

An MQCB call has set up a function to call back to process messages asynchronously and the connection handle has been started so that asynchronous message consumption can proceed.

#### INACTIVE

An MQCB call has set up a function to call back to process messages asynchronously but the connection handle has not yet been started, or has been stopped or suspended, so that asynchronous message consumption cannot currently proceed.

#### SUSPENDED

The asynchronous consumption callback has been suspended so that asynchronous message consumption cannot currently proceed on this object handle. This can be either because an MQCB call with Operation MQOP\_SUSPEND has been issued against this object handle by the application, or because it has been suspended by the system. If it has been suspended by the system, as part of the process of suspending asynchronous message consumption the callback function will be called with the reason code that describes the problem resulting in suspension. This will be reported in the Reason field in the MQCBC structure that is passed to the callback function.

For asynchronous message consumption to proceed, the application must issue an MQCB call with the Operation parameter set to MQOP\_RESUME.

#### SUSPTEMP

The asynchronous consumption callback has been temporarily suspended by the system so that asynchronous message consumption cannot currently proceed on this object handle. As part of the process of suspending asynchronous message consumption, the callback function will be called with the reason code that describes the problem resulting in suspension. This will be reported in the Reason field in the MQCBC structure passed to the callback function.

The callback function will be called again when asynchronous message consumption is resumed by the system, when the temporary condition has been resolved.

#### NONE

An MQCB call has not been issued against this handle, so no asynchronous message consumption is configured on this handle.

**DEST** The destination queue for messages that are published to this subscription. This parameter is only relevant for handles of subscriptions to topics. It is not returned for other handles.

#### **DESTQMGR**

The destination queue manager for messages that are published to this subscription. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. If **DEST** is a queue that is hosted on the local queue manager, this parameter will contain the local queue manager name. If **DEST** is a queue that is hosted on a remote queue manager, this parameter will contain the name of the remote queue manager.

#### **HSTATE**

The state of the handle.

Possible values are:

##### **ACTIVE**

An API call from this connection is currently in progress for this object. If the object is a queue, this condition can arise when an **MQGET WAIT** call is in progress.

If there is an **MQGET SIGNAL** outstanding, then this does not mean, by itself, that the handle is active.

##### **INACTIVE**

No API call from this connection is currently in progress for this object. If the object is a queue, this condition can arise when no **MQGET WAIT** call is in progress.

#### **OBJNAME**

The name of an object that the connection has open.

#### **OBJTYPE**

The type of the object that the connection has open. If this handle is that of a subscription to a topic, then the **SUBID** parameter identifies the subscription. You can then use the **DISPLAY SUB** command to find all the details about the subscription.

It is one of the following:

- **QUEUE**
- **PROCESS**
- **QMGR**
-  **STGCLASS** (valid only on z/OS )
- **NAMELIST**
- **CHANNEL**
- **AUTHINFO**
- **TOPIC**

#### **OPENOPTS**

The open options currently in force for the connection for the object. This parameter is not returned for a subscription. Use the value in the **SUBID** parameter and the **DISPLAY SUB** command to find the details about the subscription.

Possible values are:

##### **MQOO\_INPUT\_AS\_Q\_DEF**

Open queue to get messages using queue-defined default.

##### **MQOO\_INPUT\_SHARED**

Open queue to get messages with shared access.

##### **MQOO\_INPUT\_EXCLUSIVE**

Open queue to get messages with exclusive access.

##### **MQOO\_BROWSE**

Open queue to browse messages.

**MQOO\_OUTPUT**

Open queue or topic to put messages.

**MQOO\_INQUIRE**

Open queue to inquire attributes.

**MQOO\_SET**

Open queue to set attributes.

**MQOO\_BIND\_ON\_OPEN**

Bind handle to destination when queue is found.

**MQOO\_BIND\_NOT\_FIXED**

Do not bind to a specific destination.

**MQOO\_SAVE\_ALL\_CONTEXT**

Save context when message retrieved.

**MQOO\_PASS\_IDENTITY\_CONTEXT**

Allow identity context to be passed.

**MQOO\_PASS\_ALL\_CONTEXT**

Allow all context to be passed.

**MQOO\_SET\_IDENTITY\_CONTEXT**

Allow identity context to be set.

**MQOO\_SET\_ALL\_CONTEXT**

Allow all context to be set.

**MQOO\_ALTERNATE\_USER\_AUTHORITY**

Validate with specified user identifier.

**MQOO\_FAIL\_IF QUIESCING**

Fail if queue manager is quiescing.

**QSGDISP**

Indicates the disposition of the object. It is valid on z/OS only. The value is one of the following:

**QMGR**

The object was defined with QSGDISP(QMGR).

**COPY**

The object was defined with QSGDISP(COPY).

**SHARED**

The object was defined with QSGDISP(SHARED).

You cannot use QSGDISP as a filter keyword.

**READA**

The read ahead connection status.

Possible values are:

**NO** Read ahead of non-persistent messages is not enabled for this object.

**YES** Read ahead of non-persistent message is enabled for this object and is being used efficiently.

**BACKLOG**

Read ahead of non-persistent messages is enabled for this object. Read ahead is not being used efficiently because the client has been sent a large number of messages which are not being consumed.

## INHIBITED

Read ahead was requested by the application but has been inhibited because of incompatible options specified on the first MQGET call.

## SUBID

The internal, all-time unique identifier of the subscription. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles.

Not all subscriptions show up in DISPLAY CONN; only those that have current handles open to the subscription show up. You can use the DISPLAY SUB command to see all subscriptions.

## SUBNAME

The application's unique subscription name that is associated with the handle. This parameter is relevant only for handles of subscriptions to topics. It is not returned for other handles. Not all subscriptions will have a subscription name.

## TOPICSTR

The resolved topic string. This parameter is relevant for handles with OBJTYPE(TOPIC). For any other object type, this parameter is not returned.

## Full attributes

If TYPE is set to \*, or ALL, both Connection attributes and Handle attributes are returned for each connection that satisfies the selection criteria.

## DISPLAY ENTAUTH:

Use the MQSC command DISPLAY ENTAUTH to display the authorizations an entity has to a specified object.

## Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

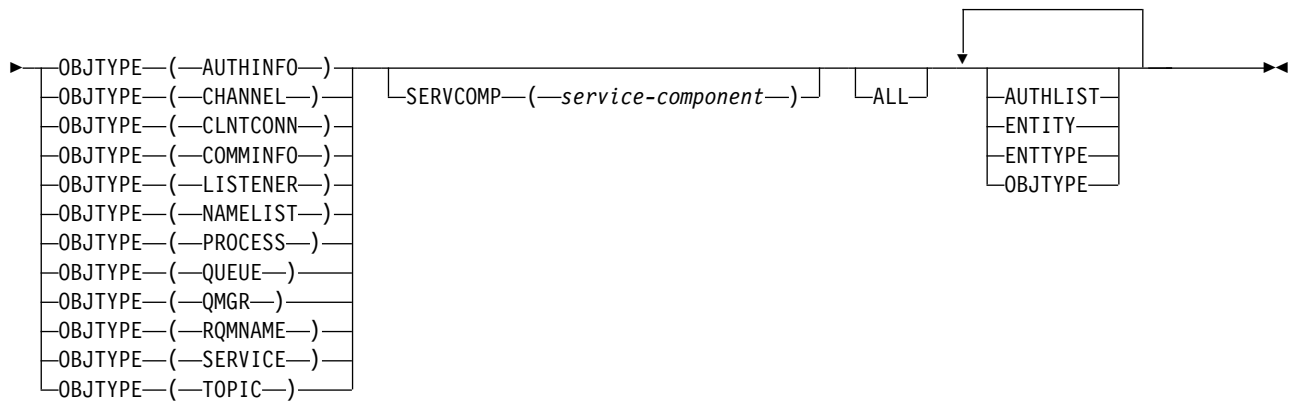

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions” on page 814
- “Requested parameters” on page 815

**Synonym:** DIS ENTAUTH

## DISPLAY ENTAUTH

►►—DISPLAY ENTAUTH—┬──PRINCIPAL—(—*principal-name*—)  
└──GROUP—(—*group-name*—)──┬──OBJNAME—(—*object-name*—)──►

## Parameter descriptions

### PRINCIPAL(*principal-name*)

A principal name. This is the name of a user for whom to retrieve authorizations to the specified object. On IBM MQ for Windows, the name of the principal can optionally include a domain name, specified in this format: `user@domain`.

You must specify either PRINCIPAL or GROUP.

### GROUP(*group-name*)

A group name. This is the name of the user group on which to make the inquiry. You can specify one name only and it must be the name of an existing user group.

For IBM MQ for Windows only, the group name can optionally include a domain name, specified in the following formats:

```
GroupName@domain
domain\GroupName
```

You must specify either PRINCIPAL or GROUP.

### OBJNAME(*object-name*)

The name of the object or generic profile for which to display the authorizations.

This parameter is required unless the OBJTYPE parameter is QMGR. This parameter can be omitted if the OBJTYPE parameter is QMGR.

### OBJTYPE

The type of object referred to by the profile. Specify one of the following values:

#### AUTHINFO

Authentication information record

#### CHANNEL

Channel

#### CLNTCONN

Client connection channel

#### COMMINFO

Communication information object

#### LISTENER

Listener

#### NAMELIST

Namelist

#### PROCESS

Process

**QUEUE**

Queue

**QMGR**

Queue manager

**RQMNAME**

Remote queue manager

**SERVICE**

Service

**TOPIC**

Topic

**SERVCOMP** (*service-component*)

The name of the authorization service for which information is to be displayed.

If you specify this parameter, it specifies the name of the authorization service to which the authorizations apply. If you omit this parameter, the inquiry is made to the registered authorization services in turn in accordance with the rules for chaining authorization services.

**ALL**

Specify this value to display all of the authorization information available for the entity and the specified profile.

**Requested parameters**

You can request the following information about the authorizations:

**AUTHLIST**

Specify this parameter to display the list of authorizations.

**ENTITY**

Specify this parameter to display the entity name.

**ENTTYPE**

Specify this parameter to display the entity type.

**OBJTYPE**

Specify this parameter to display the object type.

**DISPLAY GROUP:** 

Use the MQSC command DISPLAY GROUP to display information about the queue-sharing group to which the queue manager is connected. This command is valid only when the queue manager is a member of a queue-sharing group.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY GROUP” on page 816

- “Parameter descriptions for DISPLAY GROUP”

**Synonym:** DIS GROUP

## DISPLAY GROUP

### Usage notes for DISPLAY GROUP

1. The response to the DISPLAY GROUP command is a series of messages containing information about the queue-sharing group to which the queue manager is connected.

The following information is returned:

- The name of the queue-sharing group
- Whether all the queue managers that belong to the group are active or inactive
- The names of all the queue managers that belong to the group.
- If you specify OBSMSGS (YES), whether queue managers in the group contain obsolete messages in Db2

### Parameter descriptions for DISPLAY GROUP

#### OBSMSGS

Specifies whether the command additionally looks for obsolete messages in Db2. This is optional. Possible values are:

**NO** Obsolete messages in Db2 are not looked for. This is the default value.

**YES** Obsolete messages in Db2 are looked for and messages containing information about any found are returned.

### DISPLAY LISTENER:

Use the MQSC command DISPLAY LISTENER to display information about a listener.

### Using MQSC commands

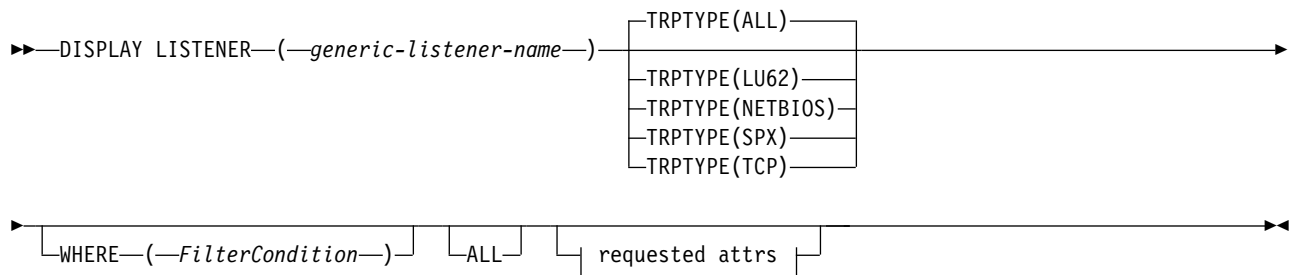

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Usage notes” on page 817
- “Keyword and parameter descriptions for DISPLAY LISTENER” on page 817
- “Requested parameters” on page 819

**Synonym:** DIS LSTR

## DISPLAY LISTENER

### Requested attrs:

### Notes:

- 1 Valid only on Windows.

### Usage notes

The values displayed describe the current definition of the listener. If the listener has been altered since it was started, the currently running instance of the listener object may not have the same values as the current definition.

### Keyword and parameter descriptions for DISPLAY LISTENER

You must specify a listener for which you want to display information. You can specify a listener by using either a specific listener name or a generic listener name. By using a generic listener name, you can display either:

- Information about all listener definitions, by using a single asterisk (\*), or
- Information about one or more listeners that match the specified name.

( *generic-listener-name* )

The name of the listener definition for which information is to be displayed. A single asterisk (\*) specifies that information for all listener identifiers is to be displayed. A character string with an asterisk at the end matches all listeners with the string followed by zero or more characters.

## TRPTYPE

Transmission protocol. If you specify this parameter, it must follow directly after the *generic-listener-name* parameter. If you do not specify this parameter, a default of ALL is assumed. Values are:

**ALL** This is the default value and displays information for all listeners.

**LU62** Displays information for all listeners defined with a value of LU62 in their TRPTYPE parameter.

## NETBIOS

Displays information for all listeners defined with a value of NETBIOS in their TRPTYPE parameter.

**SPX** Displays information for all listeners defined with a value of SPX in their TRPTYPE parameter.

**TCP** Displays information for all listeners defined with a value of TCP in their TRPTYPE parameter.

## WHERE

Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Any parameter that can be used to display attributes for this DISPLAY command.

*operator*

This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.
- A generic value. This is a character string. with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**ALL** Specify this to display all the listener information for each specified listener. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic identifier, and do not request any specific parameters.

On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

### **Requested parameters**

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

#### **ADAPTER**

The adapter number on which NetBIOS listens.

#### **ALTDATE**

The date on which the definition was last altered, in the form yyyy-mm-dd.

#### **ALTTIME**

The time at which the definition was last altered, in the form hh.mm.ss.

#### **BACKLOG**

The number of concurrent connection requests that the listener supports.

#### **COMMANDS**

The number of commands that the listener can use.

#### **CONTROL**

How the listener is to be started and stopped:

##### **MANUAL**

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the START LISTENER and STOP LISTENER commands.

##### **QMGR**

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

##### **STARTONLY**

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

#### **DESCR**

Descriptive comment.

#### **IPADDR**

The listener's IP address.

#### **LOCLNAME**

The NetBIOS local name that the listener uses.

#### **NTBNAMES**

The number of names that the listener can use.

**PORT** The port number for TCP/IP.

#### **SESSIONS**

The number of sessions that the listener can use.

#### **SOCKET**

SPX socket.

## TPNAME

The LU6.2 transaction program name.

For more information on these parameters, see “DEFINE LISTENER” on page 618.

## DISPLAY LOG:

Use the MQSC command DISPLAY LOG to display log system parameters and information.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			12CR

 For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY LOG”
- “Parameter descriptions for DISPLAY LOG” on page 821

**Synonym:** DIS LOG

## DISPLAY LOG

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.

### Usage notes for DISPLAY LOG

1. DISPLAY LOG returns a report that shows the initial log parameters, and the current values as changed by the SET LOG command:
  - Whether log compression is active (COMPLOG).
  - Length of time that an allowed archive read tape unit remains unused before it is deallocated (DEALLCT).
  - Size of input buffer storage for active and archive log data sets (INBUFF).
  - Size of output buffer storage for active and archive log data sets (OUTBUFF).
  - Maximum number of dedicated tape units that can be set to read archive log tape volumes (MAXRTU).
  - Maximum number of archive log volumes that can be recorded (MAXARCH).
  - Maximum number of concurrent log offload tasks (MAXCNOFF)
  - Whether archiving is on or off (OFFLOAD).
  - Whether single or dual active logging is being used (TWOACTV).
  - Whether single or dual archive logging is being used (TWOARCH).

- Whether single or dual BSDS is being used (TWOBSDS).
- Number of output buffers to be filled before they are written to the active log data sets (WRTHRSH).

It also returns a report about the status of the logs.

2. This command is issued internally by IBM MQ at the end of queue manager startup.

### Parameter descriptions for DISPLAY LOG

#### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

### DISPLAY LSSTATUS:

Use the MQSC command DISPLAY LSSTATUS to display status information for one or more listeners.

#### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Keyword and parameter descriptions for DISPLAY LSSTATUS” on page 822
- “Requested parameters” on page 823

**Synonym:** DIS LSSTATUS

## DISPLAY LSSTATUS

### Requested attrs:

### Notes:

- 1 Valid only on Windows.

### Keyword and parameter descriptions for DISPLAY LSSTATUS

You must specify a listener for which you want to display status information. You can specify a listener by using either a specific listener name or a generic listener name. By using a generic listener name, you can display either:

- Status information for all listener definitions, by using a single asterisk (\*), or
- Status information for one or more listeners that match the specified name.

( *generic-listener-name* )

The name of the listener definition for which status information is to be displayed. A single asterisk (\*) specifies that information for all connection identifiers is to be displayed. A character string with an asterisk at the end matches all listeners with the string followed by zero or more characters.

## WHERE

Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Any parameter that can be used to display attributes for this DISPLAY command.

### *operator*

This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.
- A generic value. This is a character string with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**ALL** Display all the status information for each specified listener. This is the default if you do not specify a generic name, and do not request any specific parameters.

## Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

### **ADAPTER**

The adapter number on which NetBIOS listens.

### **BACKLOG**

The number of concurrent connection requests that the listener supports.

### **CONTROL**

How the listener is to be started and stopped:

#### **MANUAL**

The listener is not to be started automatically or stopped automatically. It is to be controlled by use of the START LISTENER and STOP LISTENER commands.

#### **QMGR**

The listener being defined is to be started and stopped at the same time as the queue manager is started and stopped.

**STARTONLY**

The listener is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

**DESCR**

Descriptive comment.

**IPADDR**

The listener's IP address.

**LOCLNAME**

The NetBIOS local name that the listener uses.

**NTBNAMES**

The number of names that the listener can use.

**PID**

The operating system process identifier associated with the listener.

**PORT**

The port number for TCP/IP.

**SESSIONS**

The number of sessions that the listener can use.

**SOCKET**

SPX socket.

**STARTDA**

The date on which the listener was started.

**STARTTI**

The time at which the listener was started.

**STATUS**

The current status of the listener. It can be one of:

**RUNNING**

The listener is running.

**STARTING**

The listener is in the process of initializing.

**STOPPING**

The listener is stopping.

**TPNAME**

The LU6.2 transaction program name.

**TRPTYPE**

Transport type.

For more information on these parameters, see "DEFINE LISTENER" on page 618.

## DISPLAY MAXSMGS: z/OS

Use the MQSC command DISPLAY MAXSMGS to see the maximum number of messages that a task can get or put within a single unit of recovery.

### Using MQSC commands

For information on how you use MQSC commands, see *Performing local administration tasks using MQSC commands*.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see *Using commands on z/OS*.

- Syntax diagram
- “Usage notes”
- “Parameter descriptions for DISPLAY MAXSMGS”

**Synonym:** DIS MAXSM

### DISPLAY MAXSMGS

#### Notes:

- 1 Valid only on full function IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.

#### Usage notes

This command is valid only on z/OS and is retained for compatibility with earlier releases, although it can no longer be issued from the CSQINP1 initialization data set. You should use the MAXUMSGS parameter of the DISPLAY QMGR command instead.

#### Parameter descriptions for DISPLAY MAXSMGS

##### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

##### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

## DISPLAY NAMELIST:

Use the MQSC command DISPLAY NAMELIST to display the names in a namelist.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

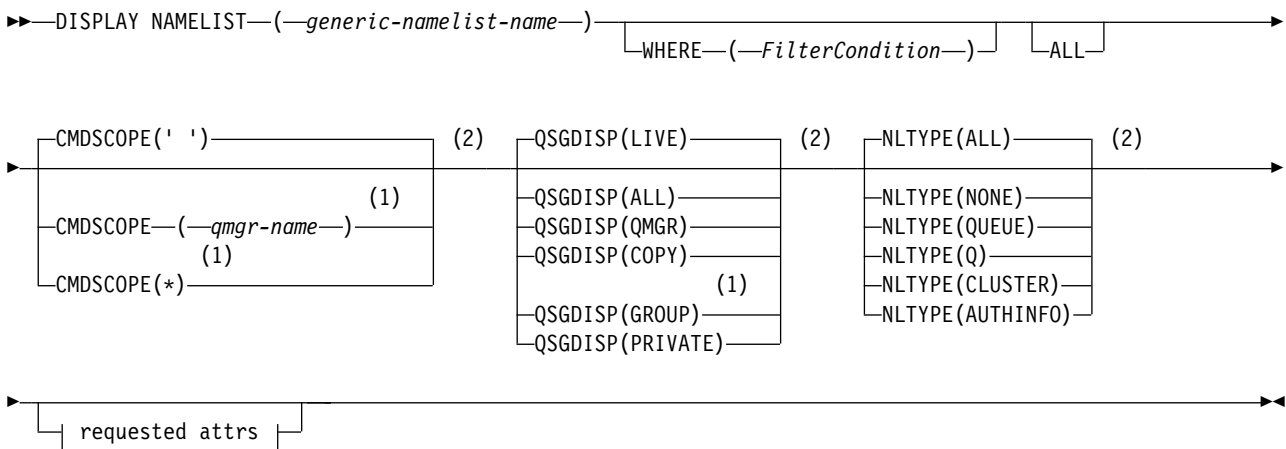

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY NAMELIST” on page 827
- “Requested parameters” on page 829

**Synonym:** DIS NL

## DISPLAY NAMELIST

### Requested attrs:

## Notes:

- 1 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

## Parameter descriptions for DISPLAY NAMELIST

You must specify the name of the namelist definition you want to display. This can be a specific namelist name or a generic namelist name. By using a generic namelist name, you can display either:

- All namelist definitions
- One or more namelists that match the specified name

( *generic-namelist-name* )

The name of the namelist definition to be displayed (see Rules for naming IBM MQ objects ). A trailing asterisk (\*) matches all namelists with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all namelists.

## WHERE

Specify a filter condition to display only those namelists that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords. You cannot use NLTYPE as a filter keyword if you also use it to select namelists.

*operator*

This is used to determine whether a namelist satisfies the filter value on the given filter keyword. The operators are:

- |     |   |
|-----|---|
| LT  | Less than   |
| GT  | Greater than  |
| EQ  | Equal to  |
| NE  | Not equal to  |
| LE  | Less than or equal to   |
| GE  | Greater than or equal to  |
| LK  | Matches a generic string that you provide as a <i>filter-value</i>  |
| NL  | Does not match a generic string that you provide as a <i>filter-value</i>   |
| CT  | Contains a specified item. If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which contain the specified item.  |
| EX  | Does not contain a specified item. If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which do not contain the specified item.   |
| CTG | Contains an item which matches a generic string that you provide as a <i>filter-value</i> . If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which match the generic string.                 |
| EXG | Does not contain any item which matches a generic string that you provide as a <i>filter-value</i> . If the <i>filter-keyword</i> is a list, you can use this to display objects the attributes of which do not match the generic string. |

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NONE on the NLTYPE parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The value can be explicit or, if it is a character value, it can be explicit or generic. If it is explicit, use CT or EX as the operator. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If it is generic, use CTG or EXG as the operator. If ABC\* is specified with the operator CTG, all items where one of the attribute values begins with ABC are listed.

**ALL** Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all the parameters are displayed.

This is the default if you do not specify a generic name, and do not request any specific parameters.

▶ **z/OS** On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

#### ▶ **z/OS** **CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

#### ▶ **z/OS** **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**ALL** Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use  
DISPLAY NAMELIST(name) CMDSCOPE(\*) QSGDISP(ALL)

to list ALL objects matching  
name

in the queue-sharing group without duplicating those in the shared repository.

**COPY** Display information only for objects defined with QSGDISP(COPY).

**GROUP**

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

**PRIVATE**

Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

**QMGR**

Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

**QMGR**

The object was defined with QSGDISP(QMGR).

**GROUP**

The object was defined with QSGDISP(GROUP).

**COPY** The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

▶ **z/OS** **NLTYPE**

Indicates the type of namelist to be displayed.

This parameter is valid only on z/OS.

**ALL**

Displays namelists of all types. This is the default.

**NONE**

Displays namelists of type NONE.

**QUEUE or Q**

Displays namelists that hold lists of queue names.

**CLUSTER**

Displays namelists that are associated with clustering.

**AUTHINFO**

Displays namelists that contain lists of authentication information object names.

**Requested parameters**

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names, and, on z/OS, their NLTYPEs and QSGDISP are displayed.

**ALTDATE**

The date on which the definition was last altered, in the form yyyy-mm-dd

**ALTTIME**

The time at which the definition was last altered, in the form hh.mm.ss

**DESCR**

Description

**NAMCOUNT**

Number of names in the list

**NAMES**

List of names

See “DEFINE NAMELIST” on page 624 for more information about the individual parameters.

**DISPLAY POLICY:**

Use the MQSC command DISPLAY POLICY to display a security policy.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Parameter descriptions for DISPLAY POLICY”

**DISPLAY POLICY**

►►—DISPLAY POLICY—(—*generic-policy-name*—)—————►◄

**Parameter descriptions for DISPLAY POLICY**

(*generic-policy-name*)

Specifies the policy name, or names, to be displayed.

You can specify wildcard characters so that you can display multiple policy names.

The name of the policy, or policies (or part of the policy name or names) to display are the same as the name of the queue, or queues, that the policies control.

## DISPLAY PROCESS:

Use the MQSC command DISPLAY PROCESS to display the attributes of one or more IBM MQ processes.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

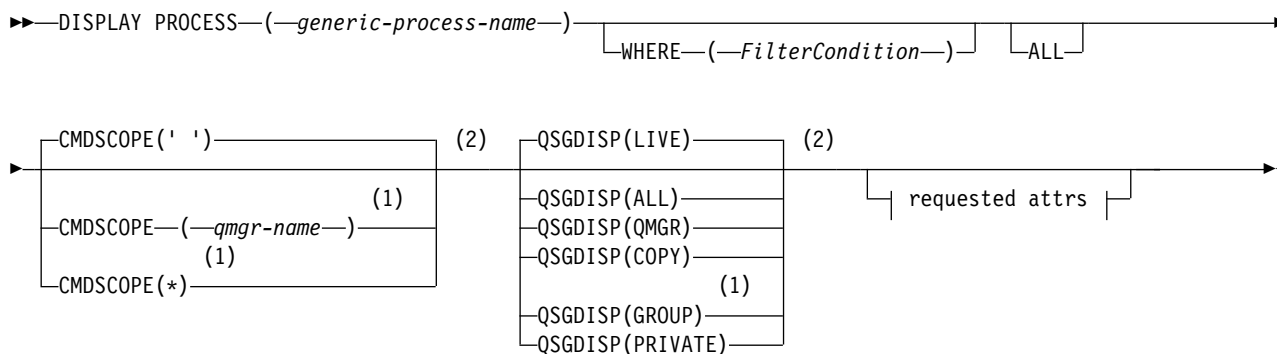

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY PROCESS” on page 832
- “Requested parameters” on page 834

**Synonym:** DIS PRO

## DISPLAY PROCESS

### Requested attrs:

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

## Parameter descriptions for DISPLAY PROCESS

You must specify the name of the process you want to display. This can be a specific process name or a generic process name. By using a generic process name, you can display either:

- All process definitions
- One or more processes that match the specified name

*(generic-process-name)*

The name of the process definition to be displayed (see Rules for naming IBM MQ objects ). A trailing asterisk (\*) matches all processes with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all processes. The names must all be defined to the local queue manager.

### WHERE

Specify a filter condition to display only those process definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command.

 However, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords.

*operator*

This is used to determine whether a process definition satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value DEF on the APPLTYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

**ALL** Specify this to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

On AIX, HP-UX, Linux, IBM i, Solaris, and Windows  , and z/OS, this is the default if you do not specify a generic name and do not request any specific parameters.

▶ **z/OS** On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

▶ **z/OS** **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**ALL** Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(LIVE) is specified or defaulted, or if QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

**COPY** Display information only for objects defined with QSGDISP(COPY).

**GROUP**

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

**PRIVATE**

Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). Note that QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

**QMGR**

Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

**QMGR**

The object was defined with QSGDISP(QMGR).

**GROUP**

The object was defined with QSGDISP(GROUP).

**COPY** The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

## Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is that the object names and, on z/OS only, QSGDISP are displayed.

### ALTDATE

The date on which the definition was last altered, in the form yyyy-mm-dd

### ALTTIME

The time at which the definition was last altered, in the form hh.mm.ss

### APPLICID

Application identifier

### APPLTYPE

Application type. In addition to the values listed for this parameter in "Parameter descriptions for DEFINE PROCESS" on page 629, the value SYSTEM can be displayed. This indicates that the application type is a queue manager.

### DESCR

Description

### ENVRDATA

Environment data

### USERDATA

User data

See "DEFINE PROCESS" on page 628 for more information about individual parameters.

## DISPLAY PUBSUB:

Use the MQSC command DISPLAY PUBSUB to display publish/subscribe status information for a queue manager.

## Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

▶ **z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DISPLAY PUBSUB" on page 835
- "Returned parameters" on page 836

**Synonym:** None

## DISPLAY PUBSUB

### Attrs:

### Notes:

- 1 Valid only on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.

### Parameter descriptions for DISPLAY PUBSUB

**TYPE** The type of publish/subscribe connections.

**ALL** Display the publish/subscribe status for this queue manager and for parent and child hierarchical connections.

#### CHILD

Display the publish/subscribe status for child connections.

#### LOCAL

Display the publish/subscribe status for this queue manager.

#### PARENT

Display the publish/subscribe status for the parent connection.

### z/OS CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

#### qmgr-name

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

## Returned parameters

A group of parameters is returned, containing the attributes TYPE, QMNAME, STATUS, SUBCOUNT, and TPCOUNT. This group is returned for the current queue manager if you set TYPE to LOCAL or ALL, for the parent queue manager if you set TYPE to PARENT or ALL, and for each child queue manager if you set TYPE to CHILD or ALL.

### TYPE

#### CHILD

A child connection.

#### LOCAL

Information for this queue manager.

#### PARENT

The parent connection.

### QMNAME

The name of the current queue manager or the remote queue manager connected as a parent or a child.

### STATUS

The status of the publish/subscribe engine or the hierarchical connection. The publish/subscribe engine is initializing and is not yet operational. If the queue manager is a member of a cluster (has at least one CLUSRCVR defined), it remains in this state until the cluster cache is available.

 On IBM MQ for z/OS, this requires that the Channel Initiator is running.

When TYPE is CHILD, the following values can be returned:

#### ACTIVE

The connection with the child queue manager is active.

#### ERROR

This queue manager is unable to initialize a connection with the child queue manager because of a configuration error. A message is produced in the queue manager logs to indicate the specific error. If you receive error message AMQ5821 or on z/OS systems CSQT821E, possible causes include:

- Transmit queue is full.
- Transmit queue put is disabled.

If you receive error message AMQ5814 or on z/OS systems CSQT814E, take the following actions:

- Check that the child queue manager is correctly specified.
- Ensure that broker is able to resolve the queue manager name of the child broker.

To resolve the queue manager name, at least one of the following resources must be configured:

- A transmission queue with the same name as the child queue manager name.
- A queue manager alias definition with the same name as the child queue manager name.
- A cluster with the child queue manager a member of the same cluster as this queue manager.
- A cluster queue manager alias definition with the same name as the child queue manager name.
- A default transmission queue.

After you have set up the configuration correctly, modify the child queue manager name to blank. Then set with the child queue manager name.

## STARTING

Another queue manager is attempting to request that this queue manager become its parent.

If the child status remains in STARTING without progressing to ACTIVE, take the following actions:

- Check that the sender channel to child queue manager is running
- Check that the receiver channel from child queue manager is running

## STOPPING

The queue manager is disconnecting.

If the child status remains in STOPPING, take the following actions:

- Check that the sender channel to child queue manager is running
- Check that the receiver channel from child queue manager is running

When TYPE is LOCAL, the following values can be returned:

## ACTIVE

The publish/subscribe engine and the queued publish/subscribe interface are running. It is therefore possible to publish or subscribe using the application programming interface and the queues that are monitored by the queued publish/subscribe interface.

## COMPAT

The publish/subscribe engine is running. It is therefore possible to publish or subscribe by using the application programming interface. The queued publish/subscribe interface is not running. Therefore, any message that is put to the queues that are monitored by the queued publish/subscribe interface are not acted upon by IBM MQ.

## ERROR

The publish/subscribe engine has failed. Check your error logs to determine the reason for the failure.

## INACTIVE

The publish/subscribe engine and the queued publish/subscribe interface are not running. It is therefore not possible to publish or subscribe using the application programming interface. Any publish/subscribe messages that are put to the queues that are monitored by the queued publish/subscribe interface are not acted upon by IBM MQ.

If inactive and you want to start the publish/subscribe engine use the command **ALTER QMGR PSMODE(ENABLED)**.

## STARTING

The publish/subscribe engine is initializing and is not yet operational. If the queue manager is a member of a cluster, that is, it has at least one CLUSRCVR defined, it remains in this state until the cluster cache is available.

▶ **z/OS** On IBM MQ for z/OS, this requires that the Channel Initiator is running.

## STOPPING

The publish/subscribe engine is stopping.

When TYPE is PARENT, the following values can be returned:

## ACTIVE

The connection with the parent queue manager is active.

## ERROR

This queue manager is unable to initialize a connection with the parent queue manager because of a configuration error. A message is produced in the queue manager logs to indicate the specific error. If you receive error message AMQ5821, ▶ **z/OS** or on z/OS systems CSQT821E, possible causes include:

- Transmit queue is full.
- Transmit queue put is disabled.

If you receive error message AMQ5814, or on z/OS systems CSQT814E, take the following actions:

- Check that the parent queue manager is correctly specified.
- Ensure that broker is able to resolve the queue manager name of the parent broker.

To resolve the queue manager name, at least one of the following resources must be configured:

- A transmission queue with the same name as the parent queue manager name.
- A queue manager alias definition with the same name as the parent queue manager name.
- A cluster with the parent queue manager a member of the same cluster as this queue manager.
- A cluster queue manager alias definition with the same name as the parent queue manager name.
- A default transmission queue.

After you have set up the configuration correctly, modify the parent queue manager name to blank. Then set with the parent queue manager name.

#### **REFUSED**

The connection has been refused by the parent queue manager. This might be caused by the following:

- The parent queue manager already has a child queue manager with the same name as this queue manager.
- The parent queue manager has used the command `RESET QMGR TYPE(PUBSUB) CHILD` to remove this queue manager as one of its children.

#### **STARTING**

The queue manager is attempting to request that another queue manager become its parent.

If the parent status remains in `STARTING` without progressing to `ACTIVE`, take the following actions:

- Check that the sender channel to parent queue manager is running
- Check that the receiver channel from parent queue manager is running

#### **STOPPING**

The queue manager is disconnecting from its parent.

If the parent status remains in `STOPPING`, take the following actions:

- Check that the sender channel to parent queue manager is running
- Check that the receiver channel from parent queue manager is running

#### **SUBCOUNT**

When `TYPE` is `LOCAL`, the total number of subscriptions against the local tree is returned. When `TYPE` is `CHILD` or `PARENT`, queue manager relations are not inquired and the value `NONE` is returned.

#### **TPCOUNT**

When `TYPE` is `LOCAL`, the total number of topic nodes in the local tree is returned. When `TYPE` is `CHILD` or `PARENT`, queue manager relations are not inquired and the value `NONE` is returned.

## DISPLAY QMGR:

Use the MQSC command DISPLAY QMGR to display the queue manager parameters for this queue manager.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

### Parameter descriptions for DISPLAY QMGR

**ALL** Specify this parameter to display all the parameters. If this parameter is specified, any parameters that are requested specifically are ineffective; all parameters are still displayed.

On AIX, HP-UX, Linux, IBM i, Solaris, and Windows, this parameter is the default if you do not request any specific parameters.

#### z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is run when the queue manager is a member of a queue-sharing group.

' ' The command is run on the queue manager on which it was entered. This command is the default value.

*qmgr-name*

The command is run on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is run on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of running this command is the same as entering the command on every queue manager in the queue-sharing group.

## SYSTEM

Specify this parameter to display the set of queue manager system attributes that are available in the Queue manager system attrs list. See "Requested parameters" for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

## EVENT

Specify this parameter to display the set of event control attributes that are available in the Event control attrs list. See "Requested parameters" for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

## CHINIT

Specify this parameter to display the set of attributes relating to distributed queuing that are available in the Distributed queuing attrs list. You can also specify DQM to display the same set of attributes. See "Requested parameters" for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

## CLUSTER

Specify this parameter to display the set of attributes relating to clustering that are available in the Cluster attrs list. See "Requested parameters" for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

## PUBSUB

Specify this parameter to display the set of attributes relating to publish/subscribe that are available in the Queue manager pub/sub attrs list. See "Requested parameters" for information about these parameters.

If you specify this parameter, any request you make to display individual parameters within this set is ineffective.

## Requested parameters

**Note:** If no parameters are specified (and the ALL parameter is not specified or defaulted), the queue manager name is returned.

You can request the following information for the queue manager:

## ACCTCONO

Whether the settings of the ACCTQMQUI and ACCTQ queue manager parameters can be overridden. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**ACCTINT**

The interval at which intermediate accounting records are written. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**ACCTMQI**

Whether accounting information is to be collected for MQI data. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**ACCTQ**

Whether accounting data collection is to be enabled for queues.

**z/OS ACTCHL**

The maximum number of channels that can be active at any time.

This parameter is valid only on z/OS.

**ACTIVREC**

Whether activity reports are to be generated if requested in the message.

**ACTVCONO**

Whether the settings of the ACTVTRC queue manager parameter can be overridden. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**ACTVTRC**

Whether IBM MQ MQI application activity tracing information is to be collected. See Setting ACTVTRC to control collection of activity trace information. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**z/OS ADOPTCHK**

Which elements are checked to determine whether an MCA is adopted when a new inbound channel is detected with the same name as an already active MCA.

This parameter is valid only on z/OS.

**z/OS ADOPTMCA**

Whether an orphaned MCA instance is to be restarted when a new inbound channel request matching the ADOPTCHK parameters is detected.

This parameter is valid only on z/OS.

**ALTDATE**

The date on which the definition was last altered, in the form yyyy-mm-dd.

**ALTIME**

The time at which the definition was last altered, in the form hh.mm.ss.

**AUTHOREV**

Whether authorization events are generated.

**z/OS BRIDGEEV**

On z/OS only, whether IMS bridge events are generated.

**CCSID**

Coded character set identifier. This parameter applies to all character string fields defined by the application programming interface (API), including the names of objects, and the creation date and time of each queue. It does not apply to application data carried as the text of messages.

**CERTLABL**

Specifies the certificate label that this queue manager used.

**z/OS CERTQSG**

Specifies the queue sharing group (QSG) certificate label.

This parameter is valid only on z/OS.

## CERTVPOL

Specifies which SSL/TLS certificate validation policy is used to validate digital certificates received from remote partner systems. This attribute can be used to control how strictly the certificate chain validation conforms to industry security standards. For more information about certificate validation policies, see Certificate validation policies in IBM MQ.

This parameter is valid on only UNIX, Linux, and Windows.

## z/OS CFCONLOS

Specifies the action to be taken when the queue manager loses connectivity to the administration structure, or any CF structure with CFCONLOS set to ASQMGR.

This parameter is valid only on z/OS.

## CHAD

Whether auto-definition of receiver and server-connection channels is enabled.

z/OS This parameter is not valid on z/OS.

## CHADEV

Whether auto-definition events are enabled.

z/OS This parameter is not valid on z/OS.

## CHADEXIT

The name of the channel auto-definition exit.

## CHIADAPS

The number of adapter subtasks to use to process IBM MQ calls.

z/OS This parameter is valid only on z/OS.

## z/OS CHDISPS

The number of dispatchers to use for the channel initiator.

This parameter is valid only on z/OS.

## CHISERVP

This field is reserved for IBM use only.

## CHLAUTH

Whether channel authentication records are checked.

## CHLEV

Whether channel events are generated.

## CLWLEXIT

The name of the cluster workload exit.

## CLWLDATA

The data passed to the cluster workload exit.

## CLWLLEN

The maximum number of bytes of message data that is passed to the cluster workload exit.

This parameter is not valid on Linux.

## CLWLMRUC

The maximum number of outbound cluster channels.

## CLWLUSEQ

The behavior of MQPUTs for queues where CLWLUSEQ has a value of QMGR.

## CMDEV

Whether command events are generated.

**CMDLEVEL**

Command level. This indicates the level of system control commands supported by the queue manager.

**COMMANDQ**

The name of the system-command input queue. Suitably authorized applications can put commands on this queue.

**CONFIGEV**

Whether configuration events are generated.

**CONNAUTH**

The name of an authentication information object that is used to provide the location of user ID and password authentication.

**CPILEVEL**

Reserved, this value has no significance.

**CRDATE**

The date on which the queue manager was created (in the form yyyy-mm-dd).

**CRTIME**

The time at which the queue manager was created (in the form hh.mm.ss).

**CUSTOM**

This attribute is reserved for the configuration of new features before separate attributes have been introduced. It can contain the values of zero or more attributes as pairs of attribute name and value in the form NAME(VALUE).

**DEADQ**

The name of the queue to which messages are sent if they cannot be routed to their correct destination (the dead-letter queue or undelivered-message queue). The default is blanks.

For example, messages are put on this queue when:

- A message arrives at a queue manager, destined for a queue that is not yet defined on that queue manager
- A message arrives at a queue manager, but the queue for which it is destined cannot receive it because, possibly:
  - The queue is full
  - The queue is inhibited for puts
  - The sending node does not have authority to put the message on the queue
- An exception message must be generated, but the queue named is not known to that queue manager

**Note:** Messages that have passed their expiry time are not transferred to this queue when they are discarded.

If the dead-letter queue is not defined, or full, or unusable for some other reason, a message that would have been transferred to it by a message channel agent is retained instead on the transmission queue.

If a dead-letter queue or undelivered-message queue is not specified, all blanks are returned for this parameter.

**DEFCLXQ**

The DFTCLXQ attribute controls which transmission queue is selected by default by cluster-sender channels to get messages from, to send the messages to cluster-receiver channels.

**SCTQ**

All cluster-sender channels send messages from `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. The `correlID` of messages placed on the transmission queue identifies which cluster-sender channel the message is destined for.

`SCTQ` is set when a queue manager is defined. This behavior is implicit in versions of IBM WebSphere MQ, earlier than Version 7.5. In earlier versions, the queue manager attribute `DEFCLXQ` was not present.

## CHANNEL

Each cluster-sender channel sends messages from a different transmission queue. Each transmission queue is created as a permanent dynamic queue from the model queue `SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE`.

If the queue manager attribute, `DEFCLXQ`, is set to `CHANNEL`, the default configuration is changed to cluster-sender channels being associated with individual cluster transmission queues. The transmission queues are permanent-dynamic queues created from the model queue `SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE`. Each transmission queue is associated with one cluster-sender channel. As one cluster-sender channel services a cluster transmission queue, the transmission queue contains messages for only one queue manager in one cluster. You can configure clusters so that each queue manager in a cluster contains only one cluster queue. In this case, the message traffic from a queue manager to each cluster queue is transferred separately from messages to other queues.

## DEFXMITQ

Default transmission queue name. This parameter is the transmission queue on which messages, destined for a remote queue manager, are put if there is no other suitable transmission queue defined.

## DESCR

Description.

## DISTL

Whether distribution lists are supported by the queue manager.

▶ **z/OS** This parameter is not valid on z/OS.

## ▶ **z/OS** DNSGROUP

This parameter is no longer used. Refer to WLM/DNS no longer supported. This parameter is valid only on z/OS

## ▶ **z/OS** DNSWLM

This parameter is no longer used. Refer to WLM/DNS no longer supported. This parameter is valid only on z/OS.

## ▶ **z/OS** EXPRYINT

On z/OS only, the approximate interval between scans for expired messages.

## ▶ **z/OS** GROUPUR

On z/OS only, whether XA client applications are allowed to connect to this queue manager with a `GROUP` unit of recovery disposition.

## ▶ **z/OS** IGQ

On z/OS only, whether intra-group queuing is to be used.

## ▶ **z/OS** IGQAUT

On z/OS only, displays the type of authority checking used by the intra-group queuing agent.

## ▶ **z/OS** IGQUSER

On z/OS only, displays the user ID used by the intra-group queuing agent.

**INHIBTEV**

Whether inhibit events are generated.

**IPADDRV**

Whether to use an IPv4 or IPv6 IP address for a channel connection in ambiguous cases.

**LOCALEV**

Whether local error events are generated.

**LOGGEREV**

Whether recovery log events are generated. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**LSTRTMR**

The time interval, in seconds, between attempts by IBM MQ to restart the listener after an APPC or TCP/IP failure.

This parameter is valid only on z/OS.

**z/OS LUGROUP**

The generic LU name to be used by the LU 6.2 listener that handles inbound transmissions for the queue-sharing group.

This parameter is valid only on z/OS.

**z/OS LUNAME**

The name of the LU to use for outbound LU 6.2 transmissions.

This parameter is valid only on z/OS.

**z/OS LU62ARM**

The suffix of the APPCPM member of SYS1.PARMLIB. This suffix nominates the LUADD for this channel initiator. When automatic restart manager (ARM) restarts the channel initiator, the z/OS command SET APPC= xx is issued.

This parameter is valid only on z/OS.

**z/OS LU62CHL**

The maximum number of channels that can be current, or clients that can be connected, that use the LU 6.2 transmission protocol. If the value of LU62CHL is zero, the LU 6.2 transmission protocol is not used.

This parameter is valid only on z/OS.

**MARKINT**

The mark browse interval in milliseconds.

**z/OS MAXCHL**

The maximum number of channels that can be current (including server-connection channels with connected clients).

This parameter is valid only on z/OS.

**MAXHANDS**

The maximum number of open handles that any one connection can have at any one time.

**MAXMSGL**

The maximum message length that can be handled by the queue manager. Individual queues or channels might have a smaller maximum than the value of this parameter.

**MAXPROPL ( integer )**

The maximum length of property data in bytes that can be associated with a message.

This parameter is valid only on IBM i, z/OS, UNIX, Linux, and Windows systems.

## MAXPRTY

The maximum priority. This value is 9.

## MAXUMSGS

Maximum number of uncommitted messages within one sync point. The default value is 10000.

MAXUMSGS has no effect on IBM MQ Telemetry. IBM MQ Telemetry tries to batch requests to subscribe, unsubscribe, send, and receive messages from multiple clients into batches of work within a transaction.

## MONACLS

Whether online monitoring data is to be collected for auto-defined cluster-sender channels, and, if so, the rate of data collection.

## MONCHL

Whether online monitoring data is to be collected for channels, and, if so, the rate of data collection.

## MONQ

Whether online monitoring data is to be collected for queues, and, if so, the rate of data collection.

## ▶ z/OS OPORTMAX

The maximum value in the range of port numbers to be used when binding outgoing channels.

This parameter is valid only on z/OS.

## ▶ z/OS OPORTMIN

The minimum value in the range of port numbers to be used when binding outgoing channels.

This parameter is valid only on z/OS.

## PARENT

The name of the queue manager to which this queue manager is connected hierarchically as its child.

## PERFMEV

Whether performance-related events are generated.

## PLATFORM

The architecture of the platform on which the queue manager is running. The value of this parameter is ▶ z/OS MVS (for z/OS platforms), NSK, OS2, OS400, ▶ V8.0.0.2 APPLIANCE, UNIX, or WINDOWSNT.

## PSCLUS

Controls whether this queue manager participates in publish subscribe activity across any clusters in which it is a member. No clustered topic objects can exist in any cluster when modifying from ENABLED to DISABLED.

## PSMODE

Controls whether the publish/subscribe engine and the queued publish/subscribe interface are running, and therefore controls whether applications can publish or subscribe by using the application programming interface and the queues that are monitored by the queued publish/subscribe interface.

## PSNPMSG

If the queued publish/subscribe interface cannot process a non-persistent input message it might attempt to write the input message to the dead-letter queue (depending on the report options of the input message). If the attempt to write the input message to the dead-letter queue fails, and the MQRO\_DISCARD\_MSG report option was specified on the input message or PSNPMSG=DISCARD, the broker discards the input message. If PSNPMSG=KEEP is specified, the interface only discards the input message if the MQRO\_DISCARD\_MSG report option was set in the input message.

**PSNPRES**

If the queued publish/subscribe interface attempts to generate a response message in response to a non-persistent input message, and the response message cannot be delivered to the reply-to queue, this attribute indicates whether the interface tries to write the undeliverable message to the dead-letter queue or whether to discard the message.

**PSRTYCNT**

When the queued publish/subscribe interface fails to process a command message under sync point (for example a publish message that cannot be delivered to a subscriber because the subscriber queue is full and it is not possible to put the publication on the dead letter queue), the unit of work is backed out and the command tries this number of times again before the broker attempts to process the command message according to its report options instead.

**PSSYNCPT**

If this attribute is set to IFPER, when the queued publish/subscribe interface reads a publish or delete publication messages from a stream queue during normal operation then it specifies MQGMO\_SYNCPOINT\_IF\_PERSISTENT. This value makes the queued pubsub daemon receive non-persistent messages outside sync point. If the daemon receives a publication outside sync point, the daemon forwards that publication to subscribers known to it outside sync point.

**QMID**

The internally generated unique name of the queue manager.

**QMNAME**

The name of the local queue manager. See Rules for naming IBM MQ objects.

**z/OS QSGNAME**

The name of the queue-sharing group to which the queue manager belongs, or blank if the queue manager is not a member of a queue-sharing group. You can use queue-sharing groups only on IBM MQ for z/OS.

**z/OS RCVTIME**

The approximate length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state. The value of this parameter is the numeric value qualified by RCVTTYPE.

This parameter is valid only on z/OS.

**z/OS RCVTMIN**

The minimum length of time that a TCP/IP channel waits to receive data, including heartbeats, from its partner before returning to an inactive state.

This parameter is valid only on z/OS.

**z/OS RCVTTYPE**

The qualifier to apply to the value in RCVTIME.

This parameter is valid only on z/OS.

**REMOTEEV**

Whether remote error events are generated.

**REPOS**

The name of a cluster for which this queue manager is to provide a repository manager service.

**REPOSNL**

The name of a list of clusters for which this queue manager is to provide a repository manager service.

**REVDNS**

Whether reverse lookup of the host name from a Domain Name Server (DNS) is done for the IP address from which a channel has connected.

## ROUTEREC

Whether trace-route information is to be recorded if requested in the message.

## SCHINIT

Whether the channel initiator is to be started automatically when the queue manager starts.

▶ **z/OS** This parameter is not valid on z/OS.

## SCMDSERV

Whether the command server is to be started automatically when the queue manager starts.

▶ **z/OS** This parameter is not valid on z/OS.

## ▶ **z/OS** SCYCASE

Whether the security profiles are uppercase or mixed case.

This parameter is valid only on z/OS.

If this parameter has been altered but the REFRESH SECURITY command has not yet been issued, the queue manager might not be using the case of profiles you expect. Use DISPLAY SECURITY to verify which case of profiles is actually in use.

## SPLCAP

Indicates if IBM MQ Advanced Message Security ( IBM MQ AMS) capabilities are available to the queue manager. If the IBM MQ AMS component is installed for the version of IBM MQ that the queue manager is running under, the attribute has a value ENABLED (MQCAP\_SUPPORTED). If the IBM MQ AMS component is not installed, the value is DISABLED (MQCAP\_NOT\_SUPPORTED).

## ▶ **z/OS** SQQMNAME

When a queue manager makes an MQOPEN call for a shared queue and the queue manager that is specified in the *ObjectQmgrName* parameter of the MQOPEN call is in the same queue-sharing group as the processing queue manager, the SQQMNAME attribute specifies whether the *ObjectQmgrName* is used or whether the processing queue manager opens the shared queue directly.

This parameter is valid only on z/OS.

## SSLCRLNL

Indicates the namelist of AUTHINFO objects being used for the queue manager for certificate revocation checking.

Only authentication information objects with types of LDAPCRL or OCSP are allowed in the namelist referred to by SSLCRLNL. Any other type results in an error message when the list is processed and is subsequently ignored.

## SSLCRYP

Indicates the name of the parameter string being used to configure the cryptographic hardware present on the system. The PKCS #11 password appears as xxxxxx. This is valid only on UNIX, Linux, and Windows systems.

## SSLEV

Whether SSL events are generated.

## SSLFIPS

Whether only FIPS-certified algorithms are to be used if cryptography is executed in IBM MQ rather than in the cryptographic hardware itself.

## SSLKEYR

Indicates the name of the Secure Sockets Layer key repository.

## SSLRKEYC

Indicates the number of bytes to be sent and received within an SSL conversation before the secret key is renegotiated.

▶ z/OS **SSLTASKS**

On z/OS only, indicates the number of server subtasks to use for processing SSL calls.

**STATACLS**

Whether statistics data is to be collected for auto-defined cluster-sender channels, and, if so, the rate of data collection.

**STATCHL**

It determines whether statistics data is to be collected for channels, and, if so, the rate of data collection.

**STATINT**

The interval at which statistics monitoring data is written to the monitoring queue. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**STATMQI**

Whether statistics monitoring data is to be collected for the queue manager. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**STATQ**

Whether statistics data is to be collected for queues. This parameter is valid only on IBM i, UNIX, Linux, and Windows systems.

**STRSTPEV**

Whether start and stop events are generated.

**SUITEB**

Whether Suite B compliant cryptography is used. For more information about Suite B configuration and its effect on SSL and TLS channels, see NSA Suite B Cryptography in IBM MQ

**SYNCPT**

Whether sync point support is available with the queue manager.

▶ z/OS **TCPCHL**

The maximum number of channels that can be current, or clients that can be connected, that use the TCP/IP transmission protocol. If zero, the TCP/IP transmission protocol is not used.

This parameter is valid only on z/OS.

▶ z/OS **TCPKEEP**

Whether the KEEPALIVE facility is to be used to check that the other end of the connection is still available. If it is unavailable, the channel is closed.

This parameter is valid only on z/OS.

▶ z/OS **TCPNAME**

The name of the preferred TCP/IP stack to be used in a CINET multiple stack environment. In INET single stack environments the channel initiator uses the only available TCP/IP stack.

This parameter is valid only on z/OS.

▶ z/OS **TCPSTACK**

Whether the channel initiator uses only the TCP/IP stack specified in TCPNAME, or can optionally bind to any of the TCP/IP stacks defined in a CINET multiple stack environment.

This parameter is valid only on z/OS.

▶ z/OS **TRAXSTR**

Whether channel initiator trace starts automatically.

This parameter is valid only on z/OS.

**z/OS TRAXTBL**

The size, in megabytes, of the trace data space of the channel initiator.

This parameter is valid only on z/OS.

**TREELIFE**

The lifetime of non-administrative topics.

**TRIGINT**

The trigger interval.

**VERSION**

The version of the IBM MQ installation that the queue manager is associated with. The version has the format VRRMMFF:

VV: Version

RR: Release

MM: Maintenance level

FF: Fix level

**XRCAP**

Whether IBM MQ Telemetry capability is supported by the queue manager.

For more details of these parameters, see "ALTER QMGR" on page 435.

**DISPLAY QMSTATUS:**

Use the MQSC command DISPLAY QMSTATUS to display status information associated with this queue manager.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- "Parameter descriptions for DISPLAY QMSTATUS" on page 853
- "Requested parameters" on page 853

**Synonym:** DIS QMSTATUS

**DISPLAY QMSTATUS**

**Requested attrs:**

### Parameter descriptions for DISPLAY QMSTATUS

**ALL** Specify this parameter to display all the parameters. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This parameter is the default if you do not request any specific parameters.

### Requested parameters

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

#### CHINIT

The status of the channel initiator reading SYSTEM.CHANNEL.INITQ. It is one of the following:

##### STOPPED

The channel initiator is not running.

##### STARTING

The channel initiator is in the process of initializing and is not yet operational.

##### RUNNING

The channel initiator is fully initialized and is running.

##### STOPPING

The channel initiator is stopping.

#### CMDSERV

The status of the command server. It is one of the following:

##### STOPPED

The command server is not running.

##### STARTING

The command server is in the process of initializing and is not yet operational.

##### RUNNING

The command server is fully initialized and is running.

##### STOPPING

The command server is stopping.

#### CONNS

The current number of connections to the queue manager.

**CURRLOG**

The name of the log extent being written to at the time that the DISPLAY QMSTATUS command is processed. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

**INSTDESC**

Description of the installation associated with the queue manager. This parameter is not valid on IBM i.

**INSTNAME**

Name of the installation associated with the queue manager. This parameter is not valid on IBM i.

**INSTPATH**

Path of the installation associated with the queue manager. This parameter is not valid on IBM i.

**LDAPCONN**

The status of the connection to the LDAP server. It is one of the following:

**CONNECTED**

The queue manager currently has a connection to the LDAP server.

**ERROR**

The queue manager attempted to make a connection to the LDAP server and failed.

**INACTIVE**

The queue manager is not configured to use an LDAP server or has not yet made a connection to the LDAP server.

**MEDIALOG**

The name of the oldest log extent required by the queue manager to perform media recovery. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

**QMNAME**

The name of the queue manager. This parameter is always returned.

**RECLOG**

The name of the oldest log extent required by the queue manager to perform restart recovery. If the queue manager is using circular logging, and this parameter is explicitly requested, a blank string is displayed.

**STANDBY**

Whether a standby instance is permitted. It is one of the following:

**NOPERMIT**

Standby instances are not permitted.

**PERMIT**

Standby instances are permitted.

**STATUS**

The status of the queue manager. It is one of the following:

**STARTING**

The queue manager is in the process of initializing.

**RUNNING**

The queue manager is fully initialized and is running.

**QUIESCING**

The queue manager is quiescing.

**STARTDA**

The date on which the queue manager was started (in the form yyyy-mm-dd).

## STARTTI

The time at which the queue manager was started (in the form hh.mm.ss).

## DISPLAY QSTATUS:

Use the MQSC command DISPLAY QSTATUS to display the status of one or more queues.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

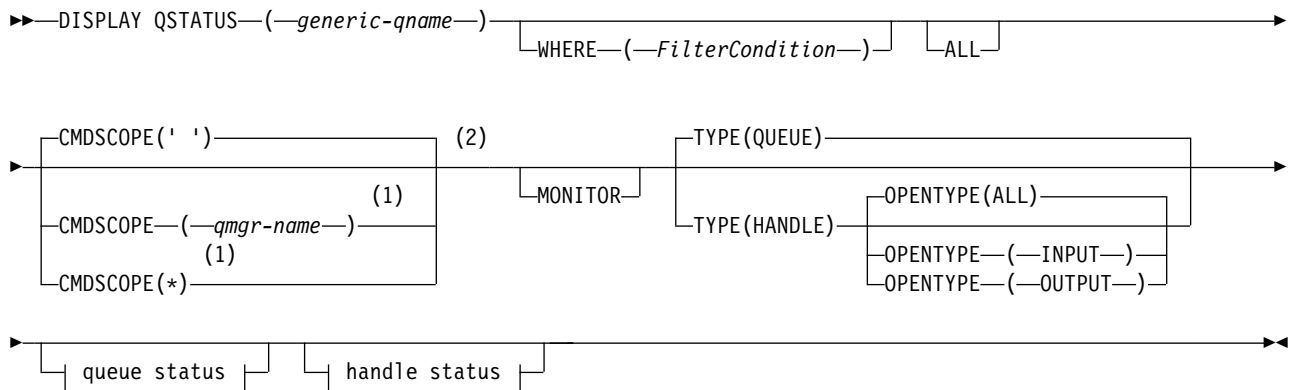

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- “Usage notes for DISPLAY QSTATUS” on page 857
- “Parameter descriptions for DISPLAY QSTATUS” on page 858
- “Queue status” on page 860
- “Handle status” on page 862

**Synonym:** DIS QS

## DISPLAY QSTATUS

### Queue status:

**Handle status:**

APPLDESC
APPLTAG
APPLTYPE
(2)
ASID
ASTATE
BROWSE
(5)
CHANNEL
(5)
CONNAME
HSTATE
INPUT
INQUIRE
OUTPUT
(4)
PID
(6)
PSBNAME
(6)
PSTID
QMURID
(2)
QSGDISP
SET
(7)
TASKNO
(4)
TID
(7)
TRANSID
URID
URTYPE
USERID

**Notes:**

- 1 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid on z/OS only.
- 3 Also displayed by selection of the MONITOR parameter.
- 4 Not valid on z/OS.
- 5 Channel initiator only
- 6 IMS only
- 7 CICS only

**Usage notes for DISPLAY QSTATUS**

The state of asynchronous consumers, *ASTATE*, reflects that of the server-connection proxy on behalf of the client application; it does not reflect the client application state.

## Parameter descriptions for DISPLAY QSTATUS

You must specify the name of the queue for which you want to display status information. This name can either be a specific queue name or a generic queue name. By using a generic queue name you can display either:

- Status information for all queues, or
- Status information for one or more queues that match the specified name and other selection criteria

You must also specify whether you want status information about:

- Queues
- Handles that are accessing the queues

**Note:** You cannot use the DISPLAY QSTATUS command to display the status of an alias queue or remote queue. If you specify the name of one of these types of queue, no data is returned. You can, however, specify the name of the local queue or transmission queue to which the alias queue or remote queue resolves.

( *generic-qname* )

The name of the queue for which status information is to be displayed. A trailing asterisk (\*) matches all queues with the specified stem followed by zero or more characters. An asterisk (\*) on its own matches all queues.

### WHERE

Specify a filter condition to display status information for queues that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, MONITOR, OPENTYPE, QSGDISP, QTIME, TYPE, or URID parameters as filter keywords.

*operator*

The operator is used to determine whether a queue satisfies the filter value on the given filter keyword. The operators are:

**LT**    Less than

**GT**    Greater than

**EQ**    Equal to

**NE**    Not equal to

**LE**    Less than or equal to

**GE**    Greater than or equal to

**LK**    Matches a generic string that you provide as a *filter-value*

**NL**    Does not match a generic string that you provide as a *filter-value*

**CT**    Contains a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes contain the specified item.

**EX**    Does not contain a specified item. If the *filter-keyword* is a list, you can use this filter to display objects whose attributes do not contain the specified item.

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value NO on the UNCOM parameter), you can only use EQ or NE.

- A generic value. This value is a character string (such as the character string in the APPLTAG parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- An item in a list of values. The operator must be CT or EX. If it is a character value, it can be explicit or generic. For example, if the value DEF is specified with the operator CT, all items where one of the attribute values is DEF are listed. If ABC\* is specified, all items where one of the attribute values begins with ABC are listed.

**ALL** Display all the status information for each specified queue.

This value is the default if you do not specify a generic name, and do not request any specific parameters.

**z/OS** On z/OS, this value is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only the requested attributes are displayed.

#### **z/OS** CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group. It is valid on z/OS only.

' ' The command is executed on the queue manager on which it was entered. This value is the default.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this value is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

#### **MONITOR**

Specify this value to return the set of online monitoring parameters. These are LGETDATE, LGETTIME, LPUTDATE, LPUTTIME, MONQ, MSGAGE, and QTIME. If you specify this parameter, any of the monitoring parameters that you request specifically have no effect; all monitoring parameters are still displayed.

#### **OPENTYPE**

Restricts the queues selected to queues which have handles with the specified type of access:

**ALL** Selects queues that are open with any type of access. This value is the default if the OPENTYPE parameter is not specified.

#### **INPUT**

Selects queues that are open for input only. This option does not select queues that are open for browse.

#### **OUTPUT**

Selects queues that are open only for output.

The OPENTYPE parameter is valid only if TYPE(HANDLE) is also specified.

You cannot use OPENTYPE as a filter keyword.

**TYPE** Specifies the type of status information required:

**QUEUE**

Status information relating to queues is displayed. This value is the default if the TYPE parameter is not specified.

**HANDLE**

Status information relating to the handles that are accessing the queues is displayed.

You cannot use TYPE as a filter keyword.

### Queue status

For queue status, the following information is always returned for each queue that satisfies the selection criteria, except where indicated:

- Queue name
- Type of information returned (TYPE parameter)
- Current queue depth (CURDEPTH parameter)  on platforms other than z/OS
-  On z/OS only, the queue-sharing group disposition (QSGDISP parameter)

The following parameters can be specified for TYPE(QUEUE) to request additional information for each queue. If a parameter is specified that is not relevant for the queue, operating environment, or type of status information requested, that parameter is ignored.

**CURDEPTH**

The current depth of the queue, that is, the number of messages on the queue, including both committed messages and uncommitted messages.

**IPPROCS**

The number of handles that are currently open for input for the queue (either input-shared or input-exclusive). This number does not include handles that are open for browse.

For shared queues, the number returned applies only to the queue manager generating the reply. The number is not the total for all the queue managers in the queue-sharing group.

**LGETDATE**

The date on which the last message was retrieved from the queue since the queue manager started. A message being browsed does not count as a message being retrieved. When no get date is available, perhaps because no message has been retrieved from the queue since the queue manager was started, the value is shown as a blank.

 For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

**LGETTIME**

The time at which the last message was retrieved from the queue since the queue manager started. A message being browsed does not count as a message being retrieved. When no get time is available, perhaps because no message has been retrieved from the queue since the queue manager was started, the value is shown as a blank.

 For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter. A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

#### **LPUTDATE**

The date on which the last message was put to the queue since the queue manager started. When no put date is available, perhaps because no message has been put to the queue since the queue manager was started, the value is shown as a blank.

▶ **z/OS** For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter. A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

#### **LPUTTIME**

The time at which the last message was put to the queue since the queue manager started. When no put time is available, perhaps because no message has been put to the queue since the queue manager was started, the value is shown as a blank.

▶ **z/OS** For queues with QSGDISP(SHARED), the value shown is for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter. A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

**Note:** Moving the system clock backwards should be avoided in case the LPUTTIME is being used to monitor the messages. The LPUTTIME of a queue is only updated when a message that arrives on the queue has a PutTime greater than the existing value of LPUTTIME. Because the PutTime of the message is less than the existing LPUTTIME of the queue in this case, the time is left unchanged.

#### **MEDIALOG**

The log extent or journal receiver needed for media recovery of the queue. On queue managers on which circular logging is in place, MEDIALOG is returned as a null string.

This parameter is valid on AIX, HP-UX, Linux, IBM i, Solaris, and Windows.

#### **MONQ**

Current level of monitoring data collection for the queue.

This parameter is also displayed when you specify the MONITOR parameter.

#### **MSGAGE**

Age, in seconds, of the oldest message on the queue. The maximum displayable value is 999999999; if the age exceeds this value, 999999999 is displayed.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

#### **OPPROCS**

This is the number of handles that are currently open for output for the queue.

For shared queues, the number returned applies only to the queue manager generating the reply. The number is not the total for all the queue managers in the queue-sharing group.

#### ▶ **z/OS** **QSGDISP**

Indicates the disposition of the queue. The value displayed is one of the following:

#### **QMGR**

The object was defined with QSGDISP(QMGR).

**COPY** The object was defined with QSGDISP(COPY).

**SHARED**

The object was defined with QSGDISP(SHARED).

This parameter is valid on z/OS only.

For shared queues, if the CF structure used by the queue is unavailable or has failed, the status information might be unreliable.

You cannot use QSGDISP as a filter keyword.

**QTIME**

Interval, in microseconds, between messages being put on the queue and then being destructively read. The maximum displayable value is 999999999; if the interval exceeds this value, 999999999 is displayed.

The interval is measured from the time that the message is placed on the queue until it is destructively retrieved by an application and, therefore, includes any interval caused by a delay in committing by the putting application.

Two values are displayed and these are recalculated only when messages are processed:

- A value based on the last few messages processed
- A value based on a larger sample of the recently processed messages

These values depend on the configuration and behavior of your system, as well as the levels of activity within it, and serve as an indicator that your system is performing normally. A significant variation in these values might indicate a problem with your system. For queues with QSGDISP(SHARED), the values shown are for measurements collected on this queue manager only.

This parameter is also displayed when you specify the MONITOR parameter.

A value is only displayed for this parameter if MONQ is set to a value other than OFF for this queue.

**UNCOM**

Indicates whether there are any uncommitted changes (puts and gets) pending for the queue. The value displayed is one of the following:

**YES**

On z/OS, there are one or more uncommitted changes pending.

**NO** There are no uncommitted changes pending.

*n* On platforms other than z/OS, an integer value indicating how many uncommitted changes are pending.

For shared queues, the value returned applies only to the queue manager generating the reply. The value does not apply to all the queue managers in the queue-sharing group.

**Handle status**

For handle status, the following information is always returned for each queue that satisfies the selection criteria, except where indicated:

- Queue name
- Type of information returned (TYPE parameter)
- On platforms other than z/OS, user identifier (USERID parameter) - not returned for APPLTYPE(SYSTEM)
- On platforms other than z/OS, process ID (PID parameter)
- On platforms other than z/OS, thread ID (TID parameter)

- On platforms other than z/OS, application tag (APPLTAG parameter)
- Application type (APPLTYPE parameter)
- On platforms other than z/OS, whether the handle provides input access (INPUT parameter)
- On platforms other than z/OS, whether the handle provides output access (OUTPUT parameter)
- On platforms other than z/OS, whether the handle provides browse access (BROWSE parameter)
- On platforms other than z/OS, whether the handle provides inquire access (INQUIRE parameter)
- On platforms other than z/OS, whether the handle provides set access (SET parameter)

The following parameters can be specified for TYPE(HANDLE) to request additional information for each queue. If a parameter that is not relevant is specified for the queue, operating environment, or type of status information requested, that parameter is ignored.

#### APPLDESC

A string containing a description of the application connected to the queue manager, where it is known. If the application is not recognized by the queue manager the description returned is blank.

#### APPLTAG

A string containing the tag of the application connected to the queue manager. It is one of the following:

-  z/OS batch job name
-  TSO USERID
- CICS APPLID
- IMS region name
- Channel initiator job name
- IBM i job name
- UNIX process

**Note:** On HP-UX if the process name exceeds 14 characters, only the first 14 characters are shown. On all other platforms if the process name exceeds 28 characters, only the first 28 characters are shown.

- Windows process

**Note:** The returned value consists of the full program path and executable file name. If it is more than 28 characters long, only the first 28 characters are shown.

- Internal queue manager process name

Application name represents the name of the process or job that has connected to the queue manager. In the instance that this process or job is connected via a channel, the application name represents the remote process or job rather than the local channel process or job name.

#### APPLTYPE

A string indicating the type of the application that is connected to the queue manager. It is one of the following:

##### BATCH

Application using a batch connection

##### RRSBATCH

RRS-coordinated application using a batch connection

**CICS** CICS transaction

**IMS** IMS transaction

**CHINIT**

Channel initiator

**SYSTEM**

Queue manager

**SYSTEMEXT**

Application performing an extension of function that is provided by the queue manager

**USER** A user application

z/OS

**ASID**

A four-character address-space identifier of the application identified by APPLTAG. It distinguishes duplicate values of APPLTAG.

This parameter is returned only when the queue manager owning the queue is running on z/OS, and the APPLTYPE parameter does not have the value SYSTEM.

**ASTATE**

The state of the asynchronous consumer on this queue.

Possible values are:

**ACTIVE**

An MQCB call has set up a function to call back to process messages asynchronously and the connection handle has been started so that asynchronous message consumption can proceed.

**INACTIVE**

An MQCB call has set up a function to call back to process messages asynchronously but the connection handle has not yet been started, or has been stopped or suspended, so that asynchronous message consumption cannot currently proceed.

**SUSPENDED**

The asynchronous consumption call-back has been suspended so that asynchronous message consumption cannot currently proceed on this queue. This can be either because an MQCB call with Operation MQOP\_SUSPEND has been issued against this object handle by the application, or because it has been suspended by the system. If it has been suspended by the system, as part of the process of suspending asynchronous message consumption the call-back function is initiated with the reason code that describes the problem resulting in suspension. This code is reported in the Reason field in the MQCBC structure that is passed to the call-back function.

For asynchronous message consumption to proceed, the application must issue an MQCB call with the Operation parameter set to MQOP\_RESUME.

**SUSPTEMP**

The asynchronous consumption call-back has been temporarily suspended by the system so that asynchronous message consumption cannot currently proceed on this queue. As part of the process of suspending asynchronous message consumption, the call-back function is called with the reason code that describes the problem resulting in suspension. This code is reported in the Reason field in the MQCBC structure passed to the call-back function.

The call-back function is initiated again when asynchronous message consumption is resumed by the system, when the temporary condition has been resolved.

**NONE**

An MQCB call has not been issued against this handle, so no asynchronous message consumption is configured on this handle.

**BROWSE**

Indicates whether the handle is providing browse access to the queue. The value is one of the following:

**YES** The handle is providing browse access.

**NO** The handle is not providing browse access.

**CHANNEL**

The name of the channel that owns the handle. If there is no channel associated with the handle, this parameter is blank.

This parameter is returned only when the handle belongs to the channel initiator.

**CONNNAME**

The connection name associated with the channel that owns the handle. If there is no channel associated with the handle, this parameter is blank.

This parameter is returned only when the handle belongs to the channel initiator.

**HSTATE**

Whether an API call is in progress.

Possible values are:

**ACTIVE**

An API call from a connection is currently in progress for this object. For a queue, this condition can arise when an MQGET WAIT call is in progress.

If there is an MQGET SIGNAL outstanding, then this value does not mean, by itself, that the handle is active.

**INACTIVE**

No API call from a connection is currently in progress for this object. For a queue, this condition can arise when no MQGET WAIT call is in progress.

**INPUT**

Indicates whether the handle is providing input access to the queue. The value is one of the following:

**SHARED**

The handle is providing shared-input access.

**EXCL** The handle is providing exclusive-input access.

**NO** The handle is not providing input access.

**INQUIRE**

Indicates whether the handle currently provides inquire access to the queue. The value is one of the following:

**YES** The handle provides inquire access.

**NO** The handle does not provide inquire access.

**OUTPUT**

Indicates whether the handle is providing output access to the queue. The value is one of the following:

**YES** The handle is providing output access.

**NO** The handle is not providing output access.

**PID** Number specifying the process identifier of the application that has opened the specified queue.

 This parameter is not valid on z/OS.

▶ **z/OS PSBNAME**

The eight characters long name of the program specification block (PSB) associated with the running IMS transaction. You can use the PSBNAME and PSTID to purge the transaction using IMS commands. It is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value IMS.

▶ **z/OS PSTID**

The four character IMS program specification table (PST) region identifier for the connected IMS region. It is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value IMS.

**QMURID**

The queue manager unit of recovery identifier. On z/OS, this value is an 8-byte log RBA, displayed as 16 hexadecimal characters. On platforms other than z/OS, this value is an 8-byte transaction identifier, displayed as m.n where m and n are the decimal representation of the first and last 4 bytes of the transaction identifier.

You can use QMURID as a filter keyword. On z/OS, you must specify the filter value as a hexadecimal string. On platforms other than z/OS, you must specify the filter value as a pair of decimal numbers separated by a period (.). You can only use the EQ, NE, GT, LT, GE, or LE filter operators.

▶ **z/OS QSGDISP**

Indicates the disposition of the queue. It is valid on z/OS only. The value is one of the following:

**QMGR**

The object was defined with QSGDISP(QMGR).

**COPY** The object was defined with QSGDISP(COPY).

**SHARED**

The object was defined with QSGDISP(SHARED).

You cannot use QSGDISP as a filter keyword.

**SET** Indicates whether the handle is providing set access to the queue. The value is one of the following:

**YES** The handle is providing set access.

**NO** The handle is not providing set access.

▶ **z/OS TASKNO**

A seven-digit CICS task number. This number can be used in the CICS command "CEMT SET TASK(taskno) PURGE" to end the CICS task. This parameter is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value CICS.

**TID** Number specifying the thread identifier within the application process that has opened the specified queue.

▶ **z/OS** This parameter is not valid on z/OS.

An asterisk indicates that this queue was opened using a shared connection.

For further information about shared connections see Shared (thread independent) connections with MQCONN.

▶ **z/OS TRANSID**

A four-character CICS transaction identifier. This parameter is valid on z/OS only.

This parameter is returned only when the APPLTYPE parameter has the value CICS.

**URID** The external unit of recovery identifier associated with the connection. It is the recovery identifier known in the external syncpoint coordinator. Its format is determined by the value of URTYPE.

You cannot use URID as a filter keyword.

**URTYPE**

The type of unit of recovery as seen by the queue manager. It is one of the following:

- CICS (valid only on z/OS )
- XA
- RRS (valid only on z/OS )
- IMS (valid only on z/OS )
- QMGR

URTYPE identifies the EXTURID type and not the type of the transaction coordinator. When URTYPE is QMGR, the associated identifier is in QMURID (and not URID).

**USERID**

The user identifier associated with the handle.

This parameter is not returned when APPLTYPE has the value SYSTEM.

**DISPLAY QUEUE:**

Use the MQSC command **DISPLAY QUEUE** to display the attributes of one or more queues of any type.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

XMITQ

**Notes:**

- 1 Valid only on z/OS.
- 2 On z/OS, you cannot issue this from CSQINP2.
- 3 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.

- 4 Valid only on an alias queue.
- 5 Not valid on z/OS.
- 6 Not valid on z/OS or IBM i.

### Usage notes

1. You can use the following commands (or their synonyms) as an alternative way to display these attributes.

- **DISPLAY QALIAS**
- **DISPLAY QCLUSTER**
- **DISPLAY QLOCAL**
- **DISPLAY QMODEL**
- **DISPLAY QREMOTE**

These commands produce the same output as the `DISPLAY QUEUE TYPE(queue-type)` command. If you enter the commands this way, do not use the `TYPE` parameter.

2.  On z/OS, the channel initiator must be running before you can display information about cluster queues (using `TYPE(QCLUSTER)` or the `CLUSINFO` parameter).
3. The command might not show every clustered queue in the cluster when issued on a partial repository, because the partial repository only knows about a queue once it has tried to use it.

### Parameter descriptions for DISPLAY QUEUE

You must specify the name of the queue definition you want to display. This can be a specific queue name or a generic queue name. By using a generic queue name, you can display either:

- All queue definitions
- One or more queues that match the specified name

#### *queue-name*

The local name of the queue definition to be displayed (see Rules for naming IBM MQ objects ). A trailing asterisk `*` matches all queues with the specified stem followed by zero or more characters. An asterisk (`*`) on its own specifies all queues.

### WHERE

Specify a filter condition to display only those queues that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

#### *filter-keyword*

Almost any parameter that can be used to display attributes for this **DISPLAY** command.

However, you cannot use the  `CMDSCOPE`, `QDPHIEV`, `QDPLOEV`, `QDPMAXEV`,

 `QSGDISP`, or `QSVCIIEV` parameters as filter keywords. You cannot use

 `CFSTRUCT`, `CLUSTER`,  `PSID`,  `STGCLASS`, or `CLUSNL` if these are also used to select queues. Queues of a type for which the filter keyword is not a valid attribute are not displayed.

#### *operator*

This is used to determine whether a queue satisfies the filter value on the given filter keyword. The operators are:

- |           |              |
|-----------|--------------|
| <b>LT</b> | Less than    |
| <b>GT</b> | Greater than |
| <b>EQ</b> | Equal to     |
| <b>NE</b> | Not equal to |

- LE** Less than or equal to
- GE** Greater than or equal to
- LK** Matches a generic string that you provide as a *filter-value*
- NL** Does not match a generic string that you provide as a *filter-value*

#### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value QALIAS on the CLUSQT parameter), you can only use EQ or NE. For the parameters HARDENBO, SHARE, and TRIGGER, use either EQ YES or EQ NO.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

- ALL** Specify this to display all the attributes. If this parameter is specified, any attributes that are also requested specifically have no effect; all attributes are still displayed.

On AIX, HP-UX, Linux, IBM i, Solaris, and Windows , and z/OS, this is the default if you do not specify a generic name and do not request any specific attributes.

 On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

#### **CFSTRUCT** (*generic-name*)

This parameter is optional and limits the information displayed to those queues where the value of the coupling facility structure is specified in brackets.

The value can be a generic name. If you do not enter a value for this parameter, **CFSTRUCT** is treated as a requested parameter.

#### **CLUSINFO**

This requests that, in addition to information about attributes of queues defined on this queue manager, information about these and other queues in the cluster that match the selection criteria is displayed. In this case, there might be multiple queues with the same name displayed. The cluster information is obtained from the repository on this queue manager.

This parameter is valid only on AIX, HP-UX, Linux, IBM i, Solaris, and Windows , and z/OS.

 Note that, on z/OS, you cannot issue DISPLAY QUEUE CLUSINFO commands from CSQINP2.

#### **CLUSNL** (*generic-name*)

This is optional, and limits the information displayed if entered with a value in brackets:

- For queues defined on the local queue manager, only those with the specified cluster list. The value can be a generic name. Only queue types for which **CLUSNL** is a valid parameter are restricted in this way; other queue types that meet the other selection criteria are displayed.
- For cluster queues, only those belonging to clusters in the specified cluster list if the value is not a generic name. If the value is a generic name, no restriction is applied to cluster queues.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster list information is returned about all the queues displayed.

This parameter is valid only on AIX, HP-UX, Linux, IBM i, Solaris, Windows, and , and z/OS

**Note:**  If the disposition requested is SHARED, CMDSCOPE must be blank or the local queue manager.

### CLUSTER ( *generic-name* )

This is optional, and limits the information displayed to queues with the specified cluster name if entered with a value in brackets. The value can be a generic name. Only queue types for which **CLUSTER** is a valid parameter are restricted in this way by this parameter; other queue types that meet the other selection criteria are displayed.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster name information is returned about all the queues displayed.

This parameter is valid only on AIX, HP-UX, Linux, IBM i, Solaris, Windows , and z/OS.

### **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

**CMDSCOPE** must be blank, or the local queue manager, if QSGDISP is set to GROUP or SHARED.

" The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use **CMDSCOPE** as a filter keyword.

### **PSID ( *integer* )**

The identifier of the page set where a queue resides. This is optional. Specifying a value limits the information displayed to queues that have an active association to the specified page set. The value consists of two numeric characters, in the range 00 - 99. An asterisk \* on its own specifies all page set identifiers. If you do not enter a value, page set information is returned about all the queues displayed.

The page set identifier is displayed only if there is an active association of the queue to a page set, that is, after the queue has been the target of an MQPUT request. The association of a queue to a page set is not active when:

- The queue is just defined
- The STGCLASS attribute of the queue is altered, and there is no subsequent MQPUT request to the queue
- The queue manager is restarted and there are no messages on the queue

This parameter is valid only on z/OS.

**QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, also display information for objects defined with QSGDISP(SHARED).

**ALL** Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP) or QSGDISP(SHARED).

In a shared queue manager environment:

```
DISPLAY QUEUE(name) CMDSCOPE(*) QSGDISP(ALL)
```

The command lists objects matching name in the queue-sharing group, without duplicating those in the shared repository.

**COPY** Display information only for objects defined with QSGDISP(COPY).

**GROUP**

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

**PRIVATE**

Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**QMGR**

Display information only for objects defined with QSGDISP(QMGR).

**SHARED**

Display information only for objects defined with QSGDISP(SHARED). This is allowed only in a shared queue manager environment.

**Note:** For cluster queues, this is always treated as a requested parameter. The value returned is the disposition of the real queue that the cluster queue represents.

If QSGDISP(LIVE) is specified or defaulted, or if QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

**Note:** In the QSGDISP(LIVE) case, this occurs only where a shared and a non-shared queue have the same name; such a situation should not occur in a well-managed system.

**QSGDISP** displays one of the following values:

**QMGR**

The object was defined with QSGDISP(QMGR).

**GROUP**

The object was defined with QSGDISP(GROUP).

**COPY** The object was defined with QSGDISP(COPY).

**SHARED**

The object was defined with QSGDISP(SHARED).

You cannot use **QSGDISP** as a filter keyword.

**STGCLASS** (*generic-name*)

This is optional, and limits the information displayed to queues with the storage class specified if entered with a value in brackets. The value can be a generic name.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and storage class information is returned about all the queues displayed.

This parameter is valid only on z/OS.

**TARGETTYPE** ( *target-type* )

This is optional and specifies the target type of the alias queue you want to be displayed.

**TYPE** ( *queue-type* )

This is optional, and specifies the type of queues you want to be displayed. If you specify ALL, which is the default value, all queue types are displayed; this includes cluster queues if CLUSINFO is also specified.

As well as ALL, you can specify any of the queue types allowed for a **DEFINE** command: QALIAS, QLOCAL, QMODEL, QREMOTE, or their synonyms, as follows:

**QALIAS**

Alias queues

**QLOCAL**

Local queues

**QMODEL**

Model queues

**QREMOTE**

Remote queues

You can specify a queue type of QCLUSTER to display only cluster queue information. If QCLUSTER is specified, any selection criteria specified by the CFSTRUCT, STGCLASS, or PSID parameters are ignored. Note that you cannot issue **DISPLAY QUEUE TYPE(QCLUSTER)** commands from CSQINP2.

On platforms other than z/OS, **QTYPE** ( *type* ) can be used as a synonym for this parameter.

The queue name and queue type  (and, on z/OS, the queue disposition) are always displayed.

**Requested parameters**

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Most parameters are relevant only for queues of a particular type or types. Parameters that are not relevant for a particular type of queue cause no output, nor is an error raised.

The following table shows the parameters that are relevant for each type of queue. There is a brief description of each parameter after the table, but for more information, see the **DEFINE** command for each queue type.

*Table 106. Parameters that can be returned by the DISPLAY QUEUE command.*

Cross-tabulation of queue parameters and queue types. If the parameter applies to the queue type, the cell contains a check mark.

	Local queue	Model queue	Alias queue	Remote queue	Cluster queue

XMITQ	N/A	N/A	N/A	✓	N/A

**ACCTQ**

Whether accounting (on z/OS, thread-level and queue-level accounting) data collection is to be enabled for the queue.

**ALTDATE**

The date on which the definition or information was last altered, in the form yyyy-mm-dd.

**ALLTIME**

The time at which the definition or information was last altered, in the form hh.mm.ss.

**BOQNAME**

Backout requeue name.

**BOTHRESH**

Backout threshold.

**CLCHNAME**

CLCHNAME is the generic name of the cluster-sender channels that use this queue as a transmission queue. The attribute specifies which cluster-sender channels send messages to a cluster-receiver channel from this cluster transmission queue.

**CLUSDATE**

The date on which the definition became available to the local queue manager, in the form yyyy-mm-dd.

**CLUSNL**

The namelist that defines the cluster that the queue is in.

**CLUSQMGR**

The name of the queue manager that hosts the queue.

**CLUSQT**

Cluster queue type. This can be:

**QALIAS**

The cluster queue represents an alias queue.

**QLOCAL**

The cluster queue represents a local queue.

**QMGR**

The cluster queue represents a queue manager alias.

**QREMOTE**

The cluster queue represents a remote queue.

**CLUSTER**

The name of the cluster that the queue is in.

**CLUSTIME**

The time at which the definition became available to the local queue manager, in the form hh.mm.ss.

**CLWLPRTY**

The priority of the queue for the purposes of cluster workload distribution.

**CLWLRANK**

The rank of the queue for the purposes of cluster workload distribution.

**CLWLUSEQ**

Whether puts are allowed to other queue definitions apart from local ones.

**CRDATE**

The date on which the queue was defined (in the form yyyy-mm-dd).

## CRTIME

The time at which the queue was defined (in the form hh.mm.ss).

## CURDEPTH

Current depth of queue.

On z/OS, CURDEPTH is returned as zero for queues defined with a disposition of GROUP. It is also returned as zero for queues defined with a disposition of SHARED if the CF structure that they use is unavailable or has failed.

Messages put on a queue count toward the current depth as they are put. Messages got from a queue do not count toward the current depth. This is true whether operations are done under syncpoint or not. Commit has no effect on current depth. Therefore:

- Messages put under syncpoint (but not yet committed) are included in the current depth.
- Messages got under syncpoint (but not yet committed) are not included in the current depth.

## CUSTOM

This attribute is reserved for the configuration of new features before separate attributes have been introduced. It can contain the values of zero or more attributes as pairs of attribute name and value in the form NAME(VALUE).

## DEFBIND

Default message binding.

## DEFPRESP

Default put response; defines the behavior that should be used by applications when the put response type in the MQPMO options has been set to MQPMO\_RESPONSE\_AS\_Q\_DEF.

## DEFPRTY

Default priority of the messages put on the queue.

## DEFPSIST

Whether the default persistence of messages put on this queue is set to NO or YES. NO means that messages are lost across a restart of the queue manager.

## DEFREADA

This specifies the default read ahead behavior for non-persistent messages delivered to the client.

## DEFLOPT

Default share option on a queue opened for input.

## DEFTYPE

Queue definition type. This can be:

- PREDEFINED (Predefined)

The queue was created with a DEFINE command, either by an operator or by a suitably authorized application sending a command message to the service queue.

- PERMDYN (Permanent dynamic)

Either the queue was created by an application issuing **MQOPEN** with the name of a model queue specified in the object descriptor (MQOD), or (if this is a model queue) this determines the type of dynamic queue that can be created from it.

On z/OS the queue was created with QSGDISP(QMGR).

- TEMPDPY (Temporary dynamic)

Either the queue was created by an application issuing **MQOPEN** with the name of a model queue specified in the object descriptor (MQOD), or (if this is a model queue) this determines the type of dynamic queue that can be created from it.

On z/OS the queue was created with QSGDISP(QMGR).

- SHAREDYD

A permanent dynamic queue was created when an application issued an **MQOPEN** API call with the name of this model queue specified in the object descriptor (MQOD).

On z/OS, in a queue-sharing group environment, the queue was created with QSGDISP(SHARED).

**DESCR**

Descriptive comment.

**DISTL**

Whether distribution lists are supported by the partner queue manager. (Supported only on AIX, HP-UX, Linux, IBM i, Solaris, and Windows.)

**GET** Whether the queue is enabled for gets.

**HARDENBO**

Whether the back out count is hardened to ensure that the count of the number of times that a message has been backed out is accurate.

**Note:** This parameter affects only IBM MQ for z/OS. It can be set and displayed on other platforms but has no effect.

**INDXTYPE**

Index type (supported only on z/OS ).

**INITQ**

Initiation queue name.

**IPPROCS**

Number of handles indicating that the queue is open for input.

On z/OS, IPPROCS is returned as zero for queues defined with a disposition of GROUP. With a disposition of SHARED, only the handles for the queue manager sending back the information are returned, not the information for the whole group.

**MAXDEPTH**

Maximum depth of queue.

**MAXMSGL**

Maximum message length.

**MONQ**

Online monitoring data collection.

**MSGDLVSQ**

Message delivery sequence.

**NPMCLASS**

Level of reliability assigned to non-persistent messages that are put to the queue.

**OPPROCS**

Number of handles indicating that the queue is open for output.

On z/OS, OPPROCS is returned as zero for queues defined with a disposition of GROUP. With a disposition of SHARED, only the handles for the queue manager sending back the information are returned, not the information for the whole group.

**PROCESS**

Process name.

**PROPCTL**

Property control attribute.

This parameter is applicable to Local, Alias and Model queues.

This parameter is optional.

Specifies how message properties are handled when messages are retrieved from queues using the MQGET call with the MQGMO\_PROPERTIES\_AS\_Q\_DEF option.

Permissible values are:

**ALL** To contain all the properties of the message, except those contained in the message descriptor (or extension), select ALL. The ALL value enables applications that cannot be changed to access all the message properties from MQRFH2 headers.

**COMPAT**

If the message contains a property with a prefix of **mcd.**, **jms.**, **usr.**, or **mqext.**, all message properties are delivered to the application in an MQRFH2 header. Otherwise all properties of the message, except those contained in the message descriptor (or extension), are discarded and are no longer accessible to the application.

This is the default value; it allows applications which expect JMS related properties to be in an MQRFH2 header in the message data to continue to work unmodified.

**FORCE**

Properties are always returned in the message data in an MQRFH2 header regardless of whether the application specifies a message handle.

A valid message handle supplied in the `MsgHandle` field of the MQGMO structure on the MQGET call is ignored. Properties of the message are not accessible via the message handle.

**NONE**

All properties of the message, except those in the message descriptor (or extension), are removed from the message before the message is delivered to the application.

**PUT** Whether the queue is enabled for puts.

**QDEPTHHI**

Queue Depth High event generation threshold.

**QDEPTHLO**

Queue Depth Low event generation threshold.

**QDPHIEV**

Whether Queue Depth High events are generated.

You cannot use QDPHIEV as a filter keyword.

**QDPLOEV**

Whether Queue Depth Low events are generated.

You cannot use QDPLOEV as a filter keyword.

**QDPMAXEV**

Whether Queue Full events are generated.

You cannot use QDPMAXEV as a filter keyword.

**QMID**

The internally generated unique name of the queue manager that hosts the queue.

**QSVCIEV**

Whether service interval events are generated.

You cannot use QSVCIEV as a filter keyword.

**QSVCIINT**

Service interval event generation threshold.

**QTYPE**

Queue type.

On AIX, HP-UX, Linux, IBM i, Solaris, Windows, and z/OS, the queue type is always displayed.

On AIX, HP-UX, Linux, IBM i, Solaris, and Windows, TYPE( *type* ) can be used as a synonym for this parameter.

**RETINTVL**

Retention interval.

**RNAME**

Name of the local queue, as known by the remote queue manager.

**RQMNAME**

Remote queue manager name.

**SCOPE**

Scope of queue definition (not supported on z/OS ).

**SHARE**

Whether the queue can be shared.

**STATQ**

Whether statistics data information is to be collected.

**STGCLASS**

Storage class.

**TARGET**

This parameter requests that the base object name of an aliased queue is displayed.

**TARGETTYPE**

This parameter requests that the target (base) type of an aliased queue is displayed.

**TPIPE** The TPIPE names used for communication with OTMA via the IBM MQ - IMS bridge if the bridge is active. This parameter is supported only on z/OS.

 For more information about TPIPEs, see Controlling the IMS bridge.

**TRIGDATA**

Trigger data.

**TRIGDPH**

Trigger depth.

**TRIGGER**

Whether triggers are active.

**TRIGMPRI**

Threshold message priority for triggers.

**TRIGTYPE**

Trigger type.

**USAGE**

Whether the queue is a transmission queue.

**XMITQ**

Transmission queue name.

For more details of these parameters, see “DEFINE queues” on page 635.

## DISPLAY SBSTATUS:

Use the MQSC command DISPLAY SBSTATUS to display the status of a subscription.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

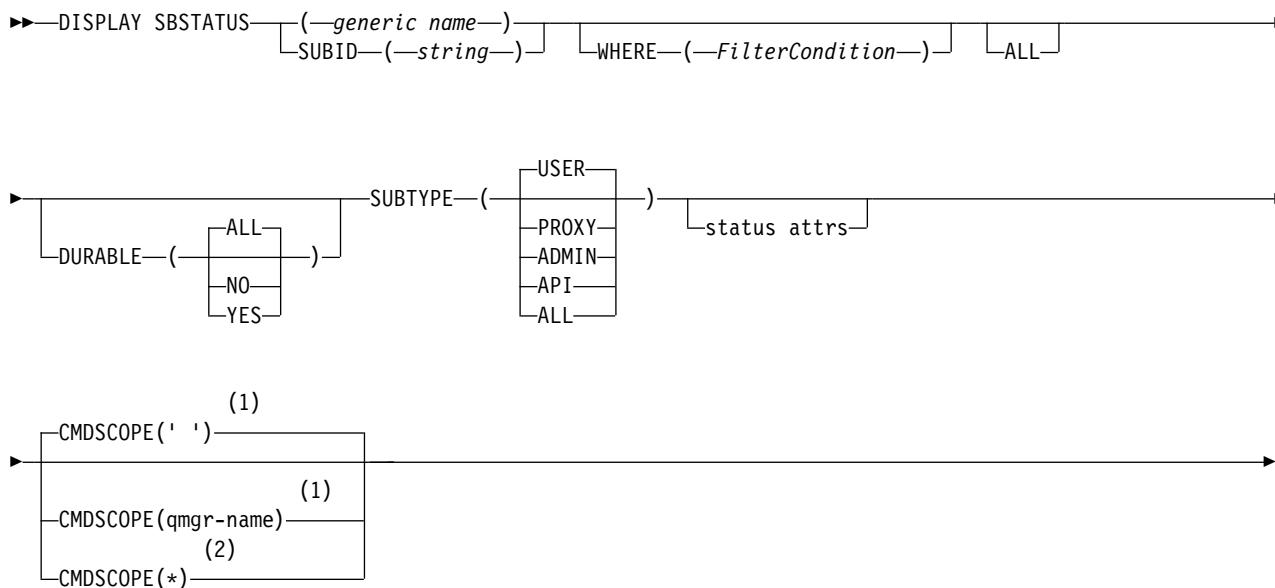

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY SBSTATUS” on page 884
- “Requested parameters” on page 886

**Synonym:** DIS SBSTATUS

## DISPLAY SBSTATUS

### Status attributes:

**Notes:**

- 1 Valid only on z/OS.
- 2 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 3 Not valid on z/OS.

**Parameter descriptions for DISPLAY SBSTATUS**

You must specify the name of the subscription definition for which you want to display status information. This can be a specific subscription name or a generic subscription name. By using a generic subscription name, you can display either:

- All subscription definitions
- One or more subscriptions that match the specified name

*(generic-name)*

The local name of the subscription definition to be displayed. A trailing asterisk (\*) matches all subscriptions with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all subscriptions.

**WHERE**

Specify a filter condition to display only those subscriptions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command.

▶ **z/OS** However, you cannot use the CMDSCOPE parameter as a filter keyword.

Subscriptions of a type for which the filter keyword is not a valid attribute are not displayed.

*operator*

This is used to determine whether a subscription satisfies the filter value on the given filter keyword. The operators are:

- LT** Less than
- GT** Greater than
- EQ** Equal to
- NE** Not equal to
- LE** Less than or equal to
- GE** Greater than or equal to

- LK** Matches a generic string that you provide as a *filter-value*
- NL** Does not match a generic string that you provide as a *filter-value*

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value USER on the SUBTYPE parameter), you can only use EQ or NE.
- A generic value. This is a character string (such as the character string you supply for the SUBUSER parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.  
You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**ALL** Display all the status information for each specified subscription definition. This is the default if you do not specify a generic name, and do not request any specific parameters.

▶ **z/OS** On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only, requested attributes are displayed.

▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is processed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is processed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is processed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

**DURABLE**

Specify this attribute to restrict the type of subscriptions which are displayed.

**ALL** Display all subscriptions.

**NO** Only information about nondurable subscriptions is displayed.

**YES** Only information about durable subscriptions is displayed.

**SUBTYPE**

Specify this attribute to restrict the type of subscriptions which are displayed.

**USER** Displays only **API** and **ADMIN** subscriptions.

**PROXY**

Only system created subscriptions relating to inter-queue-manager subscriptions are selected.

**ADMIN**

Only subscriptions that have been created by an administration interface or modified by an administration interface are selected.

**API** Only subscriptions created by applications using an IBM MQ API call are selected.

**ALL** All subscription types are displayed (no restriction).

**Requested parameters**

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

**ACTCONN**

Returns the *ConnId* of the *HConn* that currently has this subscription open.

**DURABLE**

A durable subscription is not deleted when the creating application closes its subscription handle.

**NO** The subscription is removed when the application that created it is closed or disconnected from the queue manager.

**YES** The subscription persists even when the creating application is no longer running or has been disconnected. The subscription is reinstated when the queue manager restarts.

**LMSGDATE**

The date on which a message was last published to the destination specified by this subscription.

**LMSGTIME**

The time on which a message was last published to the destination specified by this subscription.

**MCASTREL**

Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues the user can switch on event message generation, using the **COMMEV** parameter of the **COMMINFO** objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

**NUMMSGS**

The number of messages put to the destination specified by this subscription since it was created, or since the queue manager was restarted, whichever is more recent. This number might not reflect the total number of messages that are, or have been, available to the consuming application. This is because it might also include publications that were partially processed but then undone by the queue manager due to a publication failure, or publications that were made within syncpoint that were rolled-back by the publishing application.

**RESMDATE**

The date of the most recent **MQSUB** API call that connected to the subscription.

**RESMTIME**

The time of the most recent **MQSUB** API call that connected to the subscription.

**SUBID**( *string* )  
The internal, unique key identifying a subscription.

**SUBUSER**( *string* )  
The owing user id of the subscription.

**SUBTYPE**  
Indicates how the subscription was created.

**PROXY**  
An internally created subscription used for routing publications through a queue manager.

**ADMIN**  
Created using the **DEF SUB** MQSC or PCF command. This **SUBTYPE** also indicates that a subscription has been modified using an administrative command.

**API** Created using an **MQSUB** API call.

**TOPICSTR**  
Returns the fully resolved topic string of the subscription.

For more details of these parameters, see “DEFINE SUB” on page 674.

**DISPLAY SECURITY:** z/OS

Use the MQSC command **DISPLAY SECURITY** to display the current settings for the security parameters.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY SECURITY” on page 888

**Note:** From IBM WebSphere MQ Version 7.0 onwards, this command is no longer allowed to be issued from CSQINP1 or CSQINP2 on z/OS.

**Synonym:** DIS SEC

**DISPLAY SECURITY**

## Requested attrs:

## Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.

## Parameter descriptions for DISPLAY SECURITY

### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

- ' ' The command is executed on the queue manager on which it was entered. This is the default value.

#### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

**ALL** Display the **TIMEOUT**, **INTERVAL**, and **SWITCHES** parameters. This is the default if no requested parameters are specified.

The command also outputs an additional message, either CSQH037I or CSQH038I, stating whether security is currently using upper or mixed case security classes.

The command also outputs messages CSQH040I through CSQH042I showing the connection authentication settings currently in use.

### **INTERVAL**

Time interval between checks.

### **SWITCHES**

Display the current setting of the switch profiles.

If the subsystem security switch is off, no other switch profile settings are displayed.

### **TIMEOUT**

Timeout value.

See "ALTER SECURITY" on page 499 for details of the **TIMEOUT** and **INTERVAL** parameters.

**Related information:**

Displaying security status

**DISPLAY SERVICE:**

Use the MQSC command DISPLAY SERVICE to display information about a service.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Keyword and parameter descriptions for DISPLAY SERVICE”
- “Requested parameters” on page 890

**Synonym:**

**DISPLAY SERVICE**

**Requested attrs:**

ALTDAT
ALTTIME
CONTROL
DESCR
SERVTYPE
STARTARG
STARTCMD
STDERR
STDOUT
STOPARG
STOPCMD

**Keyword and parameter descriptions for DISPLAY SERVICE**

You must specify a service for which you want to display information. You can specify a service by using either a specific service name or a generic service name. By using a generic service name, you can display either:

- Information about all service definitions, by using a single asterisk (\*), or
- Information about one or more service that match the specified name.

( generic-service-name )

The name of the service definition for which information is to be displayed. A single asterisk (\*)

specifies that information for all service identifiers is to be displayed. A character string with an asterisk at the end matches all services with the string followed by zero or more characters.

## WHERE

Specify a filter condition to display information for those listeners that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Any parameter that can be used to display attributes for this DISPLAY command.

### *operator*

This is used to determine whether a listener satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value MANUAL on the CONTROL parameter), you can only use EQ or NE. .
- A generic value. This is a character string. with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**ALL** Specify this to display all the service information for each specified service. If this parameter is specified, any parameters that are requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic identifier, and do not request any specific parameters.

On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

## Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

## ALTDATE

The date on which the definition was last altered, in the form yyyy-mm-dd.

**ALTTIME**

The time at which the definition was last altered, in the form hh.mm.ss.

**CONTROL**

How the service is to be started and stopped:

**MANUAL**

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the `START SERVICE` and `STOP SERVICE` commands.

**QMGR**

The service is to be started and stopped at the same time as the queue manager is started and stopped.

**STARTONLY**

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

**DESCR**

Descriptive comment.

**SERVTYPE**

Specifies the mode in which the service is to run:

**COMMAND**

A command service object. Multiple instances of a command service object can be executed concurrently. You cannot monitor the status of command service objects.

**SERVER**

A server service object. Only one instance of a server service object can be executed at a time. The status of server service objects can be monitored using the `DISPLAY SVSTATUS` command.

**STARTARG**

Specifies the arguments to be passed to the user program at queue manager startup.

**STARTCMD**

Specifies the name of the program which is to run.

**STDERR**

Specifies the path to the file to which the standard error (stderr) of the service program is to be redirected.

**STDOUT**

Specifies the path to the file to which the standard output (stdout) of the service program is to be redirected.

**STOPARG**

Specifies the arguments to be passed to the stop program when instructed to stop the service.

**STOPCMD**

Specifies the name of the executable program to run when the service is requested to stop.

For more details of these parameters, see "DEFINE SERVICE" on page 667.

## DISPLAY SMDS: z/OS

Use the MQSC command DISPLAY SMDS to display the parameters of existing IBM MQ shared message data sets associated with a specified application structure.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- "Parameter descriptions for DISPLAY SMDS"
- "Usage notes for DISPLAY SMDSCONN" on page 896

**Synonym:**

### DISPLAY SMDS

### Requested attrs:

### Notes:

- z/OS For more information about this parameter, see Planning your coupling facility and offload storage environment.

### Parameter descriptions for DISPLAY SMDS

The parameter descriptions for the DISPLAY SMDS command.

#### SMDS( *qmgr-name* | \* )

Specifies the queue manager for which the shared message data set properties are to be displayed, or an asterisk to display the properties for all shared message data sets associated with the specified CFSTRUCT.

#### CFSTRUCT( *structure-name* )

Specify the coupling facility application structure for which the properties of one or more shared message data sets are to be displayed.

## WHERE

Specify a filter condition to display only the SMDS information that satisfies the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Any parameter that can be used to display attributes for this DISPLAY command.

### *operator*

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the RECOVER parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

You can only use operators LK or NL for generic values on the DISPLAY SMDS command.

**ALL** Specify this keyword to display all attributes. If this keyword is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default behavior if you do not specify a generic name and do not request any specific attributes.

## Requested parameters for DISPLAY SMDS

The following information is returned for each selected data set:

### SMDS

The queue manager name which owns the shared message data set for which properties are being displayed.

### CFSTRUCT

The coupling facility application structure name.

## DSBUFS

Displays the override value for the number of buffers to be used by the owning queue manager for accessing shared message data sets for this structure, or DEFAULT if the group value from the CFSTRUCT definition is being used.

## DSEXPAND

Displays the override value (YES or NO) for the data set expansion option, or DEFAULT if the group value from the CFSTRUCT definition is being used.

## DISPLAY SMDSCONN: z/OS

Use the MQSC command DISPLAY SMDSCONN to display status and availability information about the connection between the queue manager and the shared message data sets for the specified CFSTRUCT.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY SMDSCONN”

Synonym:

## DISPLAY SMDSCONN

### Parameter descriptions for DISPLAY SMDSCONN

The parameter descriptions for the DISPLAY SMDS command.

#### SMDSCONN( *qmgr-name* | \* )

Specify the queue manager which owns the SMDS for which the connection information is to be displayed, or an asterisk to display the connection information for all shared message data sets associated with the specified CFSTRUCT.

#### CFSTRUCT( *structure-name* )

Specify the structure name for which the shared message data set connection information is required.

## WHERE

Specify a filter condition to display only the SMDS connection information that satisfies the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Any parameter that can be used to display attributes for this DISPLAY command.

### *operator*

This is used to determine whether a CF application structure satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use any of the operators except LK and NL. However, if the value is one from a possible set of values returnable on a parameter (for example, the value YES on the RECOVER parameter), you can only use EQ or NE.

- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. The characters must be valid for the attribute you are testing. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

You can only use operators LK or NL for generic values on the DISPLAY SMDSCONN command.

## CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

**''** The command is executed on the queue manager on which it was entered.

This is the default value.

### **qmgr-name**

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group. You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

## Usage notes for DISPLAY SMDSCONN

This command is only supported when the CFSTRUCT definition is currently using the option OFFLOAD(SMDS).

This information indicates whether the queue manager is currently able to allocate and open the data set.

The following results are returned for each selected connection:

### **SMDSCONN**

The name of the queue manager which owns the shared message data set for this connection.

### **CFSTRUCT**

The name of the coupling facility application structure.

### **OPENMODE**

The mode in which the data set is currently open by this queue manager. This is one of the following:

#### **NONE**

The data set is not currently open.

#### **READONLY**

The data set is owned by another queue manager and is open for read-only access.

#### **UPDATE**

The data set is owned by this queue manager and is open for update access.

#### **RECOVERY**

The data set is open for recovery processing.

### **STATUS**

The connection status as seen by this queue manager. This is one of the following:

#### **CLOSED**

This data set is not currently open.

#### **OPENING**

This queue manager is currently in the process of opening and validating this data set (including space map restart processing when necessary).

**OPEN** This queue manager has successfully opened this data set and it is available for normal use.

#### **CLOSING**

This queue manager is currently in the process of closing this data set, including quiescing normal I/O activity and storing the saved space map if necessary.

#### **NOTENABLED**

The SMDS definition is not in the ACCESS(ENABLED) state so the data set is not currently available for normal use. This status is only set when the SMDSCONN status does not already indicate some other form of failure.

#### **ALLOCFAIL**

This queue manager was unable to locate or allocate this data set.

#### **OPENFAIL**

This queue manager was able to allocate the data set but was unable to open it, so it has now been deallocated.

#### **STGFAIL**

The data set could not be used because the queue manager was unable to allocate associated storage areas for control blocks, or for space map or header record processing.

**DATAFAIL**

The data set was successfully opened but the data was found to be invalid or inconsistent, or a permanent I/O error occurred, so it has now been closed and deallocated.

This may result in the shared message data set itself being marked as STATUS(FAILED).

**AVAIL**

The availability of this data set connection as seen by this queue manager. This is one of the following:

**NORMAL**

The connection can be used and no error has been detected.

**ERROR**

The connection is unavailable because of an error.

The queue manager may try to enable access again automatically if the error may no longer be present, for example when recovery completes or the status is manually set to RECOVERED. Otherwise, it can be enabled again using the START SMDSCONN command in order to retry the action which originally failed.

**STOPPED**

The connection cannot be used because it has been explicitly stopped using the STOP SMDSCONN command. It can only be made available again by using a START SMDSCONN command to enable it.

**EXPANDST**

The data set automatic expansion status. This is one of the following:

**NORMAL**

No problem has been noted which would affect automatic expansion.

**FAILED**

A recent expansion attempt failed, causing the DSEXPAND option to be set to NO for this specific data set. This status is cleared when ALTER SMDS is used to set the DSEXPAND option back to YES or DEFAULT

**MAXIMUM**

The maximum number of extents has been reached, so future expansion is not possible (except by taking the data set out of service and copying it to larger extents).

Note, that the command works only if the structure is currently connected, that is, some shared queues allocated to that structure have been opened.

**Related reference:**

“START SMDSCONN” on page 1017

Use the MQSC command START SMDSCONN to enable a previously stopped connection from this queue manager to the specified shared message data sets, allowing them to be allocated and opened again.

“STOP SMDSCONN” on page 1037

Use the MQSC command STOP SMDSCONN to terminate the connection from this queue manager to one or more specified shared message data sets (causing them to be closed and deallocated) and to mark the connection as STOPPED.

**DISPLAY STGCLASS:** z/OS

Use the MQSC command DISPLAY STGCLASS to display information about storage classes.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

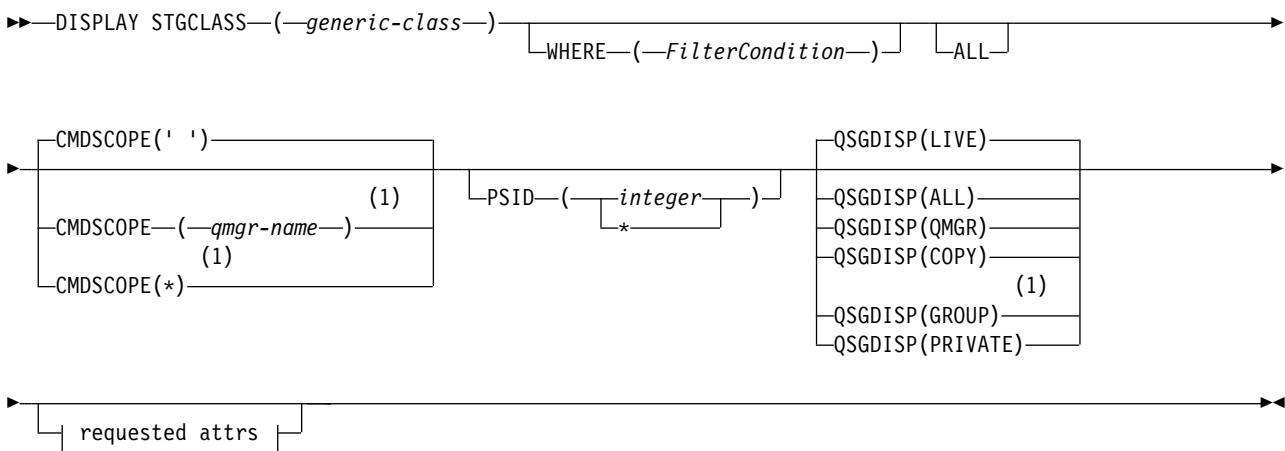

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Parameter descriptions for DISPLAY STGCLASS” on page 899
- “Requested parameters” on page 901

**Synonym:** DIS STC

**DISPLAY STGCLASS**

**Requested attrs:**

**Notes:**

- 1 Valid only on IBM MQ for z/OS when the queue manager is a member of a queue-sharing group.

**Parameter descriptions for DISPLAY STGCLASS**

You use DISPLAY STGCLASS to show the page set identifiers that are associated with each storage class.

*(generic-class)*

Name of the storage class. This is required.

This is 1 through 8 characters. The first character is in the range A through Z; subsequent characters are A through Z or 0 through 9.

A trailing asterisk (\*) matches all storage classes with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all storage classes.

**WHERE**

Specify a filter condition to display only those storage classes that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE or QSGDISP parameters as filter keywords. You cannot use PSID as a filter keyword if you also use it to select storage classes.

*operator*

This is used to determine whether a connection satisfies the filter value on the given filter keyword. The operators are:

- LT** Less than
- GT** Greater than
- EQ** Equal to
- NE** Not equal to
- LE** Less than or equal to
- GE** Greater than or equal to
- LK** Matches a generic string that you provide as a *filter-value*
- NL** Does not match a generic string that you provide as a *filter-value*

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can only use EQ or NE.
- A generic value. This is a character string (such as the character string in the DESCR parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items

where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string ABC are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**ALL** Specify this to display all the parameters. If this parameter is specified, any parameters that are also requested specifically have no effect; all parameters are still displayed.

This is the default if you do not specify a generic name, and do not request any specific parameters.

On z/OS this is also the default if you specify a filter condition using the WHERE parameter, but on other platforms only requested attributes are displayed.

## **CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

If QSGDISP is set to GROUP, CMDSCOPE must be blank or the local queue manager.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

## **PSID( *integer* )**

The page set identifier that a storage class maps to. This is optional.

The string consists of two numeric characters, in the range 00 through 99. An asterisk (\*) on its own specifies all page set identifiers. See "DEFINE PSID" on page 633.

## **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** This is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**ALL** Displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use

```
DISPLAY STGCLASS(generic-class) CMDSCOPE(*) QSGDISP(ALL)
```

to list ALL objects matching

*name*

in the queue-sharing group without duplicating those in the shared repository.

**COPY**

Display information only for objects defined with QSGDISP(COPY).

**GROUP**

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

**PRIVATE**

Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**QMGR**

Display information only for objects defined with QSGDISP(QMGR).

QSGDISP displays one of the following values:

**QMGR**

The object was defined with QSGDISP(QMGR).

**GROUP**

The object was defined with QSGDISP(GROUP).

**COPY**

The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

**Requested parameters**

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

The default, if no parameters are specified (and the ALL parameter is not specified) is the storage class names, their page set identifiers and queue sharing group dispositions are displayed.

**ALTDATE**

The date on which the definition was last altered, in the form yyyy-mm-dd.

**ALTTIME**

The time at which the definition was last altered, in the form hh.mm.ss.

**DESCR**

Descriptive comment.

**PASSTKTA**

The application name used to authenticate IMS bridge passtickets. A blank value indicates that the default batch job profile name is to be used.

**XCFGNAME**

The name of the XCF group that IBM MQ is a member of.

**XCFMNAME**

The XCF member name of the IMS system within the XCF group specified in XCFGNAME.

For more details of these parameters, see "DEFINE STGCLASS" on page 670.

## DISPLAY SUB:

Use the MQSC command DISPLAY SUB to display the attributes associated with a subscription.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

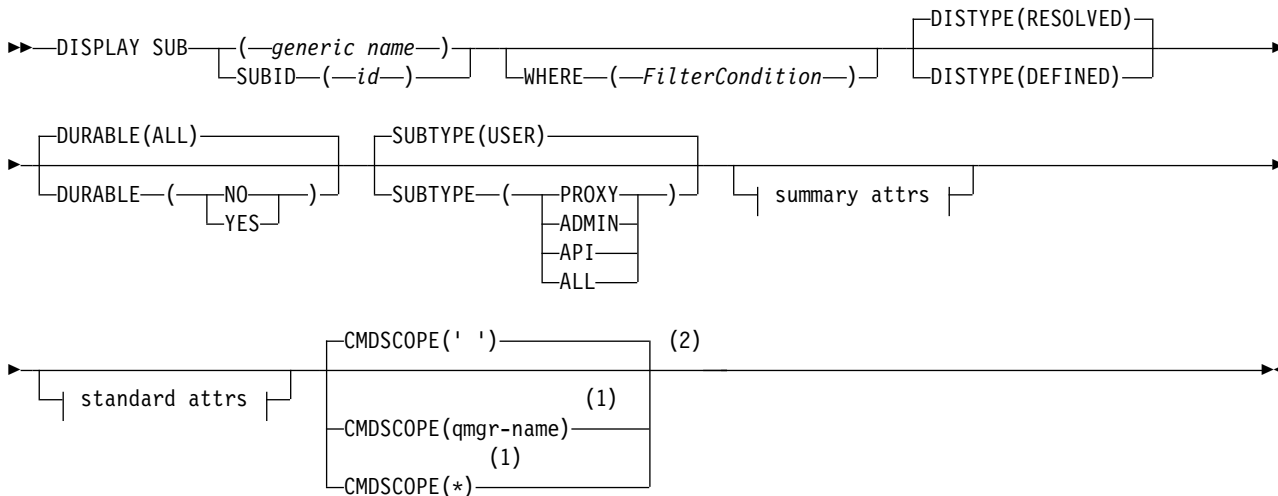

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY SUB” on page 903
- “Parameter descriptions for DISPLAY SUB” on page 903

**Synonym:** DIS SUB

## DISPLAY SUB

### summary attributes:

## standard attributes:

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Usage notes for DISPLAY SUB

1. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed. On z/OS, these non-printable characters will be displayed as blanks. On distributed platforms using runmqsc, these non-printable characters will be displayed as dots.

### Parameter descriptions for DISPLAY SUB

You must specify either the name or the identifier of subscription you want to display. This can be a specific subscription name, or SUBID, or a generic subscription name. By using a generic subscription name, you can display either:

- All subscription definitions
- One or more subscriptions that match the specified name

The following are valid forms:

```
DIS SUB(xyz)
DIS SUB SUBID(123)
DIS SUB(xyz*)
```

(*generic-name*)

The local name of the subscription definition to be displayed. A trailing asterisk (\*) matches all subscriptions with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all subscriptions.

### WHERE

Specify a filter condition to display only those subscriptions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE parameter as a filter keyword. Subscriptions of a type for which the filter keyword is not a valid attribute are not displayed.

### *operator*

This is used to determine whether a subscription satisfies the filter value on the given filter keyword. The operators are:

<b>LT</b>	Less than
<b>GT</b>	Greater than
<b>EQ</b>	Equal to
<b>NE</b>	Not equal to
<b>LE</b>	Less than or equal to
<b>GE</b>	Greater than or equal to
<b>LK</b>	Matches a generic string that you provide as a <i>filter-value</i>
<b>NL</b>	Does not match a generic string that you provide as a <i>filter-value</i>

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value QALIAS on the CLUSQT parameter), you can only use EQ or NE. For the parameters HARDENBO, SHARE, and TRIGGER, use either EQ YES or EQ NO.
- A generic value. This is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**Note:**  On z/OS there is a 256 character limit for the filter-value of the MQSC WHERE clause. This limit is not in place for other platforms.

## **SUMMARY**

Specify this to display the set of summary attributes that you want displayed.

**ALL** Specify this to display all the attributes.

If this parameter is specified, any attributes that are also requested specifically have no effect; all attributes are still displayed.

On AIX, HP-UX, Linux, IBM i, Solaris, Windows, and z/OS, this is the default if you do not specify a generic name and do not request any specific attributes.

## **ALTDATE( *string* )**

The date of the most recent **MQSUB** or **ALTER SUB** command that modified the properties of the subscription.

## **ALTTIME( *string* )**

The time of the most recent **MQSUB** or **ALTER SUB** command that modified the properties of the subscription.

**CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is processed when the queue manager is a member of a queue-sharing group.

' ' The command is processed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is processed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is processed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of setting this value is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

**CRDATE( *string* )**

The date of the first **MQSUB** or **DEF SUB** command that created this subscription.

**CRTIME( *string* )**

The time of the first **MQSUB** or **DEF SUB** command that created this subscription.

**DEST( *string* )**

The destination for messages published to this subscription; this parameter is the name of a queue.

**DESTCLAS**

System managed destination.

**PROVIDED**

The destination is a queue.

**MANAGED**

The destination is managed.

**DESTCORL( *string* )**

The *CorrelId* used for messages published to this subscription.

A blank value (default) results in a system generated correlation identifier being used.

If set to '00' (48 zeros) the **CorrelId** set by the publishing application will be maintained in the copy of the message delivered to the subscription, unless messages are propagated across a publish/subscribe hierarchy.

**DESTQMGR( *string* )**

The destination queue manager for messages published to this subscription.

**DISTYPE**

Controls the output returned in the **TOPICSTR** and **TOPICOBJ** attributes.

**RESOLVED**

Returns the resolved (full) topic string in the **TOPICSTR** attribute. The value of the **TOPICOBJ** attribute is also returned. This is the default value.

**DEFINED**

Returns the values of the **TOPICOBJ** and **TOPICSTR** attributes provided when the subscription was created. The **TOPICSTR** attribute will contain the application part of the topic string only. You can use the values returned with **TOPICOBJ** and **TOPICSTR** to fully recreate the subscription by using **DISTYPE(DEFINED)**.

**DURABLE**

A durable subscription is not deleted when the creating application closes its subscription handle.

**ALL** Display all subscriptions.

**NO** The subscription is removed when the application that created it, is closed or disconnected from the queue manager.

**YES** The subscription persists even when the creating application is no longer running or has been disconnected. The subscription is reinstated when the queue manager restarts.

**EXPIRY**

The time to expiry of the subscription object from the creation date and time.

( *integer* )

The time to expiry, in tenths of a second, from the creation date and time.

**UNLIMITED**

There is no expiry time. This is the default option supplied with the product.

**PSPROP**

The manner in which publish subscribe related message properties are added to messages sent to this subscription.

**NONE**

Do not add publish subscribe properties to the message.

**COMPAT**

Publish subscribe properties are added within an MQRFH version 1 header unless the message was published in PCF format.

**MSGPROP**

Publish subscribe properties are added as message properties.

**RFH2** Publish subscribe properties are added within an MQRFH version 2 header.

**PUBACCT**( *string* )

Accounting token passed by the subscriber, for propagation into messages published to this subscription in the *AccountingToken* field of the MQMD.

**PUBAPPID**( *string* )

Identity data passed by the subscriber, for propagation into messages published to this subscription in the *AppIdentityData* field of the MQMD.

**PUBPRTY**

The priority of the message sent to this subscription.

**AS PUB**

Priority of the message sent to this subscription is taken from the priority supplied in the published message.

**ASQDEF**

Priority of the message sent to this subscription is taken from the default priority of the queue defined as a destination.

(*integer*)

An integer providing an explicit priority for messages published to this subscription.

**REQONLY**

Indicates whether the subscriber polls for updates using the MQSUBRQ API call, or whether all publications are delivered to this subscription.

**NO** All publications on the topic are delivered to this subscription.

**YES** Publications are only delivered to this subscription in response to an MQSUBRQ API call.

This parameter is equivalent to the subscribe option MQSO\_PUBLICATIONS\_ON\_REQUEST.

**SELECTOR**( *string* )

A selector that is applied to messages published to the topic.

**SELTYPE**

The type of selector string that has been specified.

**NONE**

No selector has been specified.

**STANDARD**

The selector references only the properties of the message, not its content, using the standard IBM MQ selector syntax. Selectors of this type are to be handled internally by the queue manager.

**EXTENDED**

The selector uses extended selector syntax, typically referencing the content of the message. Selectors of this type cannot be handled internally by the queue manager; extended selectors can be handled only by another program such as IBM Integration Bus.

**SUB**( *string* )

The application's unique identifier for a subscription.

**SUBID**( *string* )

The internal, unique key identifying a subscription.

**SUBLEVEL**( *integer* )

The level within the subscription hierarchy at which this subscription is made. The range is zero through 9.

**SUBSCOPE**

Determines whether this subscription is forwarded to other queue managers, so that the subscriber receives messages published at those other queue managers.

**ALL** The subscription is forwarded to all queue managers directly connected through a publish/subscribe collective or hierarchy.

**QMGR**

The subscription forwards messages published on the topic only within this queue manager.

**Note:** Individual subscribers can only *restrict* **SUBSCOPE**. If the parameter is set to ALL at topic level, then an individual subscriber can restrict it to QMGR for this subscription. However, if the parameter is set to QMGR at topic level, then setting an individual subscriber to ALL has no effect.

**SUBTYPE**

Indicates how the subscription was created.

**USER** Displays only **API** and **ADMIN** subscriptions.

**PROXY**

An internally created subscription used for routing publications through a queue manager.

 Subscriptions of type PROXY are not modified to ADMIN when alterations are attempted.

**ADMIN**

Created using **DEF SUB** MQSC or PCF command. This **SUBTYPE** also indicates that a subscription has been modified using an administrative command.

**API** Created using an **MQSUB** API request.

**ALL** All.

**SUBUSER( *string* )**

Specifies the user ID that is used for security checks that are performed to ensure that publications can be put to the destination queue associated with the subscription. This ID is either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription. The length of this parameter must not exceed 12 characters.

**TOPICOBJ( *string* )**

The name of a topic object used by this subscription.

**TOPICSTR( *string* )**

Returns a topic string, that can contain wildcard characters to match a set of topic strings, for the subscription. The topic string will either be the application provided portion only, or fully qualified, depending on the value of **DISTYPE**.

**USERDATA( *string* )**

Specifies the user data associated with the subscription. The string is a variable length value that can be retrieved by the application on an MQSUB API call and passed in a message sent to this subscription as a message property.

**V 8.0.0.7** From IBM MQ Version 8.0.0, Fix Pack 7, an IBM MQ classes for JMS application can retrieve the subscription user data from the message by using the constant `JMS_IBM_SUBSCRIPTION_USER_DATA` in the `JmsConstants` interface with the method `javax.jms.Message.getStringProperty(java.lang.String)`. For more information, see Retrieval of user subscription data.

**VARUSER**

Specifies whether a user other than the subscription creator can connect to and take over ownership of the subscription.

**ANY** Any user can connect to and takeover ownership of the subscription.

**FIXED**

Takeover by another **USERID** is not permitted.

**WSHEMA**

The schema to be used when interpreting any wildcard characters in the topic string.

**CHAR**

Wildcard characters represent portions of strings.

**TOPIC**

Wildcard characters represent portions of the topic hierarchy.

## DISPLAY SVSTATUS:

Use the MQSC command DISPLAY SVSTATUS to display status information for one or more services. Only services with a **SERVTYPE** of SERVER are displayed.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Keyword and parameter descriptions for DISPLAY SVSTATUS”
- “Requested parameters” on page 910

Synonym:

## DISPLAY SVSTATUS

### Requested attributes:

### Keyword and parameter descriptions for DISPLAY SVSTATUS

You must specify a service for which you want to display status information. You can specify a service by using either a specific service name or a generic service name. By using a generic service name, you can display either:

- Status information for all service definitions, by using a single asterisk (\*), or
- Status information for one or more services that match the specified name.

( *generic-service-name* )

The name of the service definition for which status information is to be displayed. A single asterisk (\*) specifies that information for all connection identifiers is to be displayed. A character string with an asterisk at the end matches all services with the string followed by zero or more characters.

## WHERE

Specify a filter condition to display status information for those services that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Any parameter that can be used to display attributes for this DISPLAY command.

*operator*

This is used to determine whether a service satisfies the filter value on the given filter keyword. The operators are:

LT	Less than
GT	Greater than
EQ	Equal to
NE	Not equal to
LE	Less than or equal to
GE	Greater than or equal to

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter (for example, the value MANUAL on the CONTROL parameter), you can only use EQ or NE.
- A generic value. This is a character string with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**ALL** Display all the status information for each specified service. This is the default if you do not specify a generic name, and do not request any specific parameters.

## Requested parameters

Specify one or more attributes that define the data to be displayed. The attributes can be specified in any order. Do not specify the same attribute more than once.

## CONTROL

How the service is to be started and stopped:

### MANUAL

The service is not to be started automatically or stopped automatically. It is to be controlled by use of the START SERVICE and STOP SERVICE commands.

### QMGR

The service is to be started and stopped at the same time as the queue manager is started and stopped.

**STARTONLY**

The service is to be started at the same time as the queue manager is started, but is not requested to stop when the queue manager is stopped.

**DESCR**

Descriptive comment.

**PID** The operating system process identifier associated with the service.

**SERVTYPE**

The mode in which the service runs. A service can have a **SERVTYPE** of SERVER or COMMAND, but only services with **SERVTYPE(SERVER)** are displayed by this command.

**STARTARG**

The arguments passed to the user program at startup.

**STARTCMD**

The name of the program being run.

**STARTDA**

The date on which the service was started.

**STARTTI**

The time at which the service was started.

**STATUS**

The status of the process:

**RUNNING**

The service is running.

**STARTING**

The service is in the process of initializing.

**STOPPING**

The service is stopping.

**STDERR**

Destination of the standard error (stderr) of the service program.

**STDOUT**

Destination of the standard output (stdout) of the service program.

**STOPARG**

The arguments to be passed to the stop program when instructed to stop the service.

**STOPCMD**

The name of the executable program to run when the service is requested to stop.

For more details of these parameters, see "DEFINE SERVICE" on page 667.

## DISPLAY SYSTEM: z/OS

Use the MQSC command DISPLAY SYSTEM to display general system parameters and information.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			12CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY SYSTEM”
- “Parameter descriptions for DISPLAY SYSTEM” on page 913

**Synonym:** DIS SYSTEM

## DISPLAY SYSTEM

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.

### Usage notes for DISPLAY SYSTEM

1. DISPLAY SYSTEM returns a report that shows the initial values of the system parameters and the current values as changed by the SET SYSTEM command:
  - Default user ID for command security checks (CMDUSER).
  - Time in seconds for which queue manager exits can execute during each invocation (EXITLIM).
  - How many started server tasks to use to run queue manager exits (EXITTCB).
  - Number of log records written by IBM MQ between the start of one checkpoint and the next (LOGLOAD).
  - The Measured Usage Pricing property for this queue manager (MULCCAPT). This property is only displayed if the MULCCAPT property is set to REFINED.
  - The Operation Mode for this system (OPMODE). This is an integer list of two elements; the first indicates whether the queue manager is operating in compatibility mode or new function mode, and the second shows the current compatibility level.
  - The OTMA connection parameters (OTMACON).
  - Whether queue manager restart waits until all indexes are built, or completes before all indexes are built (QINDEXBLD).
  - Coded character set identifier for the queue manager (QMCCSID).
  - The queue-sharing group parameters (QSGDATA).
  - The RESLEVEL auditing parameter (RESAUDIT).

- The message routing code assigned to messages not solicited from a specific console (ROUTCDE).
  - Whether SMF accounting data is collected when IBM MQ is started (SMFACCT).
  - Whether SMF statistics are collected when IBM MQ is started (SMFSTAT).
  - Default time, in minutes, between each gathering of statistics (STATIME).
  - Whether tracing is started automatically (TRACSTR).
  - Size of trace table, in 4 KB blocks, to be used by the global trace facility (TRACTBL).
  - Time between scanning the queue index for WLM-managed queues (WLMTIME).
  - WLMTIMU indicates whether WLMTIME is given in seconds or minutes.
  - Whether batch jobs can currently be swapped out during some MQ API calls or not (CONNSWAP).
  - A list of messages excluded from being written to any log (EXCLMSG).
  - It might also return a report about system status.
2. This command is issued internally by IBM MQ at the end of queue manager startup.
  3. Message CSQY101I includes the system parameter value for OPMODE that is being used in CSQ6SYSP.  For more details, see Using CSQ6SYSP.

In contrast, the OPMODE returned by the DISPLAY SYSTEM command has a second parameter containing the current compatibility level. When the queue manager is operating in compatibility mode, the compatibility level indicates which version the queue manager has been migrated from and therefore can fall back to if necessary providing the appropriate backward migration PTFs have been installed at that release.

When the compatibility level matches the current queue manager level then functions introduced at the current release are enabled when NEWFUNC mode is used, and disabled when COMPAT mode is used.

This parameter is valid only on z/OS.

## Parameter descriptions for DISPLAY SYSTEM

### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect is the same as entering the command on every queue manager in the queue-sharing group.

## DISPLAY TCLUSTER:

Use the MQSC command DISPLAY TCLUSTER to display the attributes of the IBM MQ cluster topic object.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

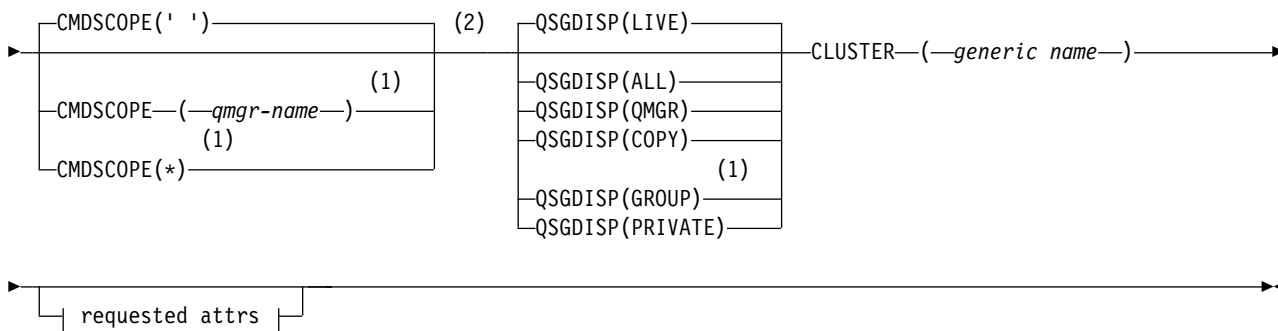

The DISPLAY TCLUSTER command produces the same output as the DISPLAY TOPIC TYPE(CLUSTER) command.

See “DISPLAY TOPIC” on page 920 for further information.

**Synonym:** DIS TOPIC

## DISPLAY TCLUSTER

►► DISPLAY TCLUSTER—(*—generic-cluster-name—*)—  
 └─ WHERE—(*—FilterCondition—*)—┘ └─ ALL—┘

## Requested attrs:

## Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

## Parameter descriptions for DISPLAY TCLUSTER

You must specify the name of the cluster topic definition you want to display. This name can be a specific cluster topic name or a generic cluster topic name. By using a generic topic name, you can display either:

*(generic-cluster-name)*

The name of the administrative cluster definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (\*) matches all administrative topic objects with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all administrative topic objects.

### WHERE

Specify a filter condition to display only those administrative topic object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command.

 However, you cannot use the CMDSCOPE, or QSGDISP parameters as filter keywords.

*operator*

This part is used to determine whether a topic object satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**Note:**  On z/OS there is a 256 character limit for the filter-value of the MQSC WHERE clause. This limit is not in place for other platforms.

**ALL** Specify this parameter to display all the attributes. If this parameter is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default if you do not specify a generic name, and do not request any specific attributes.

#### z/OS **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This value is the default value.

#### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this process is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

#### z/OS **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** LIVE is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**ALL** Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use  
DISPLAY TOPIC(name) CMDSCOPE(\*) QSGDISP(ALL)

to list ALL objects matching name in the queue-sharing group without duplicating those objects in the shared repository.

**COPY** Display information only for objects defined with QSGDISP(COPY).

#### **GROUP**

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

#### **PRIVATE**

Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

#### **QMGR**

Display information only for objects defined with QSGDISP(QMGR).

#### **QSGDISP**

QSGDISP displays one of the following values:

#### **QMGR**

The object was defined with QSGDISP(QMGR).

**GROUP**

The object was defined with QSGDISP(GROUP).

**COPY** The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

**CLUSTER**

Displays topics with the specified cluster name. The value can be a generic name.

**Requested attributes****CLROUTE**

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

**CLSTATE**

The current state of this topic in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

**ACTIVE**

The cluster topic is correctly configured and being adhered to by this queue manager.

**PENDING**

Only seen by a hosting queue manager, this state is reported when the topic has been created but the full repository has not yet propagated it to the cluster. This might be because the host queue manager is not connected to a full repository, or because the full repository has deemed the topic to be invalid.

**INVALID**

This clustered topic definition conflicts with an earlier definition in the cluster and is therefore not currently active.

**ERROR**

An error has occurred with respect to this topic object.

This parameter is typically used to aid diagnosis when multiple definitions of the same clustered topic are defined on different queue managers, and the definitions are not identical. See Routing for publish/subscribe clusters: Notes on behavior.

**CLUSDATE**

The date on which the information became available to the local queue manager, in the form yyyy-mm-dd.

**CLUSQMGR**

The name of the queue manager that hosts the topic.

**CLUSTIME**

The time at which the information became available to the local queue manager, in the form hh.mm.ss.

**QMID**

The internally generated unique name of the queue manager that hosts the topic.

**Usage notes for DISPLAY TCLUSTER**

1. On z/OS, the channel initiator must be running before you can display information about cluster topics.
2. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed. On z/OS, these non-printable characters are displayed as blanks. On distributed platforms using the **runmqsc** command, these non-printable characters are displayed as dots.

**Related reference:**

“DISPLAY TPSTATUS” on page 928

Use the MQSC command DISPLAY TPSTATUS to display the status of one or more topics in a topic tree.

“DISPLAY TOPIC” on page 920

Use the MQSC command DISPLAY TOPIC to display the attributes of one or more IBM MQ topic objects of any type.

**DISPLAY THREAD:** z/OS

Use the MQSC command DISPLAY THREAD to display information about active and in-doubt threads.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

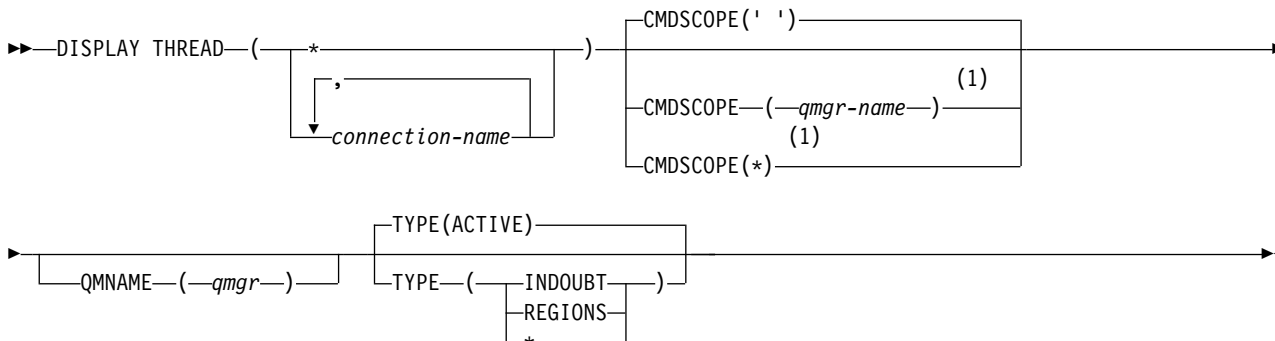

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes”
- “Parameter descriptions for DISPLAY THREAD” on page 919

**Synonym:** DIS THD

**DISPLAY THREAD**

**Notes:**

- 1 Valid only when the queue manager is a member of a queue-sharing group.

**Usage notes**

Threads shown as in doubt on one invocation of this command will probably be resolved for subsequent invocations.

This command is retained for compatibility with earlier release of IBM MQ. It has been superseded by the DISPLAY CONN command which is preferable to use.

## Parameter descriptions for DISPLAY THREAD

(*connection-name*)

List of one or more *connection-name* s (of 1 through 8 characters each).

- For batch connections, this name is the batch job name
- For CICS connections, this name is the CICS applid
- For IMS connections, this name is the IMS job name
- For TSO connections, this name is the TSO user ID
- For RRS connections, this is RRSBATCH for all RRSBATCH-type connections, or the batch job name

Threads are selected from the address spaces associated with these connections only.

(\*) Displays threads associated with all connections to IBM MQ.

## CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

**TYPE** The type of thread to display. This parameter is optional.

### ACTIVE

Display only active threads.

An active thread is one for which a unit of recovery has started but not completed. Resources are held in IBM MQ on its behalf.

This is the default if TYPE is omitted.

### INDOUBT

Display only in-doubt threads.

An in-doubt thread is one that is in the second phase of the two-phase commit operation. Resources are held in IBM MQ on its behalf. External intervention is needed to resolve the status of in-doubt threads. You might only have to start the recovery coordinator (CICS, IMS, or RRS), or you might need to do more. They might have been in doubt at the last restart, or they might have become in doubt since the last restart.

### REGIONS

Display a summary of active threads for each active connection.

**Note:** Threads used internally by IBM MQ are excluded.

\* Display both active and in-doubt threads, but not regions.

If, during command processing, an active thread becomes in doubt, it might appear twice: once as active and once as in doubt.

### Notes:

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.

### Usage notes for DISPLAY TOPIC

1. **z/OS** On z/OS, the channel initiator must be running before you can display information about cluster topics, using TYPE(CLUSTER) or the CLUSINFO parameter.
2. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed.  
**z/OS** On z/OS, these non-printable characters are displayed as blanks. On distributed platforms using the runmqsc command, these non-printable characters are displayed as dots
3. You can use the following command (or synonym) as an alternative way to display these attributes.

- **DISPLAY TCLUSTER**

This command produces the same output as the DISPLAY TOPIC TYPE(CLUSTER) command. If you enter the command in this way, do not use the TYPE parameter.

## Parameter descriptions for DISPLAY TOPIC

You must specify the name of the topic definition you want to display. This name can be a specific topic name or a generic topic name. By using a generic topic name, you can display either:

- All topic definitions
- One or more topic definitions that match the specified name

*(generic-topic-name)*

The name of the administrative topic definition to be displayed (see Rules for naming IBM MQ objects). A trailing asterisk (\*) matches all administrative topic objects with the specified stem followed by zero or more characters. An asterisk (\*) on its own specifies all administrative topic objects.

## WHERE

Specify a filter condition to display only those administrative topic object definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

*filter-keyword*

Almost any parameter that can be used to display attributes for this DISPLAY command. However, you cannot use the CMDSCOPE, or QSGDISP parameters as filter keywords.

*operator*

This part is used to determine whether a topic object satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *filter-value*

**NL** Does not match a generic string that you provide as a *filter-value*

*filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value, that is a valid value for the attribute being tested.  
You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.
- A generic value. This value is a character string (such as the character string you supply for the DESCR parameter) with an asterisk at the end, for example ABC\*. If the operator is LK, all items where the attribute value begins with the string (ABC in the example) are listed. If the operator is NL, all items where the attribute value does not begin with the string are listed. Only a single trailing wildcard character (asterisk) is permitted.

You cannot use a generic filter-value for parameters with numeric values or with one of a set of values.

**Note:**  On z/OS there is a 256 character limit for the filter-value of the MQSC **WHERE** clause. This limit is not in place for other platforms.

**ALL** Specify this parameter to display all the attributes. If this parameter is specified, any attributes that are requested specifically have no effect; all attributes are still displayed.

This is the default if you do not specify a generic name, and do not request any specific attributes.

▶ **z/OS** **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE must be blank, or the local queue manager, if QSGDISP is set to GROUP.

' ' The command is executed on the queue manager on which it was entered. This value is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this process is the same as entering the command on every queue manager in the queue-sharing group.

You cannot use CMDSCOPE as a filter keyword.

▶ **z/OS** **QSGDISP**

Specifies the disposition of the objects for which information is to be displayed. Values are:

**LIVE** LIVE is the default value and displays information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

**ALL** Display information for objects defined with QSGDISP(QMGR) or QSGDISP(COPY).

If there is a shared queue manager environment, and the command is being executed on the queue manager where it was issued, this option also displays information for objects defined with QSGDISP(GROUP).

If QSGDISP(ALL) is specified in a shared queue manager environment, the command might give duplicated names (with different dispositions).

In a shared queue manager environment, use  
DISPLAY TOPIC(name) CMDSCOPE(\*) QSGDISP(ALL)

to list ALL objects matching name in the queue-sharing group without duplicating those objects in the shared repository.

**COPY** Display information only for objects defined with QSGDISP(COPY).

**GROUP**

Display information only for objects defined with QSGDISP(GROUP). This is allowed only if there is a shared queue manager environment.

**PRIVATE**

Display information only for objects defined with QSGDISP(QMGR) or QSGDISP(COPY). QSGDISP(PRIVATE) displays the same information as QSGDISP(LIVE).

**QMGR**

Display information only for objects defined with QSGDISP(QMGR).

**QSGDISP**

QSGDISP displays one of the following values:

**QMGR**

The object was defined with QSGDISP(QMGR).

**GROUP**

The object was defined with QSGDISP(GROUP).

**COPY** The object was defined with QSGDISP(COPY).

You cannot use QSGDISP as a filter keyword.

**CLUSINFO**

Requests that, in addition to information about attributes of topics defined on this queue manager, information about these and other topics in the cluster, that match the selection criteria, is displayed. In this case, there might be multiple topics with the same topic string displayed. The cluster information is obtained from the repository on this queue manager.

▶ **z/OS** On z/OS, the channel initiator must be running before you can use the CLUSINFO parameter to display information about cluster topics.

**CLUSTER**

Limits the information displayed to topics with the specified cluster name if entered with a value in brackets. The value can be a generic name.

If you do not enter a value to qualify this parameter, it is treated as a requested parameter, and cluster name information is returned about all the topics displayed.

▶ **z/OS** On z/OS, the channel initiator must be running before you can use the CLUSINFO parameter to display information about cluster topics.

**TYPE** Specifies the type of topics that you want to be displayed. Values are:

**ALL** Display all topic types, including cluster topics if you also specify CLUSINFO.

**LOCAL**

Display locally defined topics.

**CLUSTER**

Display topics that are defined in publish/subscribe clusters. Cluster attributes include:

**CLUSDATE**

The date on which the definition became available to the local queue manager, in the form yyyy-mm-dd.

**CLUSQMGR**

The name of the queue manager hosting the topic.

**CLUSTIME**

The time at which the definition became available to the local queue manager, in the form hh.mm.ss.

**QMID**

The internally generated, unique name of the queue manager hosting the topic.

**Requested parameters**

Specify one or more parameters that define the data to be displayed. The parameters can be specified in any order, but do not specify the same parameter more than once.

Most of the parameters are relevant for both types of topics, but parameters that are not relevant for a particular type of topic cause no output, nor is an error raised.

The following table shows the parameters that are relevant for each type of topic. There is a brief description of each parameter after the table, but for more information, see "DEFINE TOPIC" on page 679.

Table 107. Parameters that can be returned by the DISPLAY TOPIC command

Table 107. Parameters that can be returned by the DISPLAY TOPIC command (continued)

	Local topic	Cluster topic
SUB	✓	✓
SUBSCOPE	✓	✓
TOPICSTR	✓	✓
TYPE	✓	✓
USEDLQ	✓	
WILDCARD	✓	✓

**ALTDATE**

The date on which the definition or information was last altered, in the form yyyy-mm-dd.

**ALTTIME**

The time at which the definition or information was last altered, in the form hh.mm.ss.

**CLROUTE**

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter.

**CLSTATE**

The current state of this topic in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

**ACTIVE**

The cluster topic is correctly configured and being adhered to by this queue manager.

**PENDING**

Only seen by a hosting queue manager, this state is reported when the topic has been created but the full repository has not yet propagated it to the cluster. This might be because the host queue manager is not connected to a full repository, or because the full repository has deemed the topic to be invalid.

**INVALID**

This clustered topic definition conflicts with an earlier definition in the cluster and is therefore not currently active.

**ERROR**

An error has occurred with respect to this topic object.

This parameter is typically used to aid diagnosis when multiple definitions of the same clustered topic are defined on different queue managers, and the definitions are not identical. See Routing for publish/subscribe clusters: Notes on behavior.

**CLUSDATE**

The date on which the information became available to the local queue manager, in the form yyyy-mm-dd.

**CLUSQMGR**

The name of the queue manager that hosts the topic.

**CLUSTER**

The name of the cluster that the topic is in.

**CLUSTIME**

The time at which the information became available to the local queue manager, in the form hh.mm.ss.

**COMMINFO**

The communication information object name.

**CUSTOM**

This attribute is reserved for the configuration of new features before separate attributes have been introduced. It can contain the values of zero or more attributes as pairs of attribute name and value in the form NAME(VALUE).

**DEFPRTY**

Default priority of the messages published to this topic.

**DEFPSIST**

Default persistence of messages published to this topic.

**DEFPRESP**

Default put response for this topic. This attribute defines the behavior that must be used by applications when the put response type in the MQPMO options has been set to MQPMO\_RESPONSE\_AS\_TOPIC\_DEF.

**DESCR**

Description of this administrative topic object.

**DURSUB**

Determines whether the topic permits durable subscriptions to be made.

**MCAST**

Specifies whether the topic is enabled for multicast.

**MDURMDL**

The name of the model queue for durable managed subscriptions.

**MNDURMDL**

The name of the model queue for non-durable managed subscriptions.

**NPMSGDLV**

The delivery mechanism for non-persistent messages.

**PMSGDLV**

The delivery mechanism for persistent messages.

**PROXYSUB**

Determines whether a proxy subscription is forced for this subscription, even if no local subscriptions exist.

**PUB** Determines whether the topic is enabled for publication.

**PUBSCOPE**

Determines whether this queue manager propagates publications to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

**QMID**

The internally generated unique name of the queue manager that hosts the topic.

**SUB** Determines whether the topic is enabled for subscription.

**SUBSCOPE**

Determines whether this queue manager propagates subscriptions to queue managers as part of a hierarchy or as part of a publish/subscribe cluster.

**TOPICSTR**

The topic string.

**TYPE** Specifies whether this object is a local topic or cluster topic.

**USEDLQ**

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue.

**WILDCARD**

The behavior of wildcard subscriptions with respect to this topic.

For more details of these parameters, except the **CLSTATE** parameter, see “DEFINE TOPIC” on page 679.

**Related reference:**

“DISPLAY TPSTATUS”

Use the MQSC command DISPLAY TPSTATUS to display the status of one or more topics in a topic tree.

**DISPLAY TPSTATUS:**

Use the MQSC command DISPLAY TPSTATUS to display the status of one or more topics in a topic tree.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

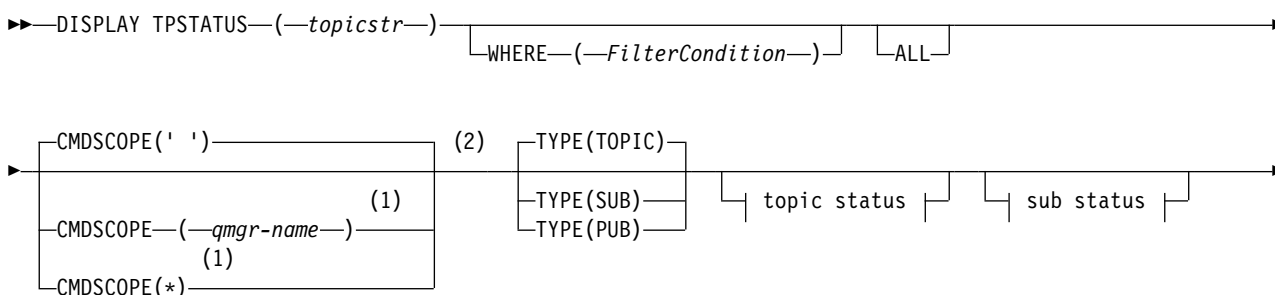

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	2CR

**z/OS** For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for DISPLAY TPSTATUS” on page 930
- “Parameter descriptions for DISPLAY TPSTATUS” on page 930
- “Topic status parameters” on page 932
- “Sub status parameters” on page 933
- “Pub status parameters” on page 934

**Synonym:** DIS TPS

**DISPLAY TPSTATUS**

**Topic status:**

**Sub status:**

**Pub status:**

**Notes:**

- 1 Valid only on z/OS when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.
- 3 Not valid on z/OS.

**Usage notes for DISPLAY TPSTATUS**

1. The TOPICSTR parameter might contain characters that cannot be translated into printable characters when the command output is displayed. On distributed platforms using the **runmqsc** command, these non-printable characters are displayed as dots.
  - ▶ **z/OS** On z/OS, these non-printable characters are displayed as blanks.
2. The topic-string input parameter on this command must match the topic you want to act on. Keep the character strings in your topic strings as characters that can be used from the location issuing the command. If you issue commands using MQSC, you have fewer characters available to you than if you are using an application that submits PCF messages, such as the IBM MQ Explorer.

**Parameter descriptions for DISPLAY TPSTATUS**

The DISPLAY TPSTATUS command requires a topic string value to determine which topic nodes the command returns.

*(topicstr)*

The value of the topic string for which you want to display status information. You cannot specify the name of an IBM MQ topic object.

The topic string can have one of the following values:

- A specific topic string value. For example, DIS TPS('Sports/Football') returns just the 'Sports/Football' node.
- A topic string containing a "+" wildcard character. For example, DIS TPS('Sports/Football/+') returns all direct child nodes of the 'Sports/Football' node.
- A topic string containing a "#" wildcard character. For example, DIS TPS('Sports/Football/#') returns the 'Sports/Football' node and all its descendant nodes.
- A topic string containing more than one wildcard. For example, DIS TPS('Sports/+/Teams/#') returns any direct child node of 'Sports' that also has a 'teams' child, with all descendants of the latter nodes.

The **DISPLAY TPSTATUS** command does not support the '\*' wildcard. For more information about using wildcards, see the related topic.

- To return a list of all root-level topics, use DIS TPS('+')
- To return a list of all topics in the topic tree, use DIS TPS('#'), but note that this command might return a large amount of data.
- To filter the list of topics returned, use the **WHERE** parameter. For example, DIS TPS('Sports/Football/+') WHERE(TOPICSTR LK 'Sports/Football/L\*') returns all direct child nodes of the 'Sports/Football' node, that begin with the letter "L".

## WHERE

Specifies a filter condition to display only those administrative topic definitions that satisfy the selection criterion of the filter condition. The filter condition is in three parts: *filter-keyword*, *operator*, and *filter-value*:

### *filter-keyword*

Except for the CMDSCOPE parameter, any parameter that you can use with this DISPLAY command.

### *operator*

Determines whether a topic string satisfies the filter value on the given filter keyword. The operators are:

**LT** Less than

**GT** Greater than

**EQ** Equal to

**NE** Not equal to

**LE** Less than or equal to

**GE** Greater than or equal to

**LK** Matches a generic string that you provide as a *topicstr*

**NL** Does not match a generic string that you provide as a *topicstr*

### *filter-value*

The value that the attribute value must be tested against using the operator. Depending on the filter-keyword, this value can be:

- An explicit value that is a valid value for the attribute being tested.

You can use operators LT, GT, EQ, NE, LE, or GE only. However, if the attribute value is one from a possible set of values on a parameter, you can use only EQ or NE.

- A generic value. This value is a character string with an asterisk at the end, for example ABC\*. If the operator is LK, the command lists all topic nodes that begin with the string (ABC in the example). If the operator is NL, the command lists all topic nodes that do not begin with the string.

You cannot use a generic *filter-value* for parameters with numeric values or with one of a set of values.

**ALL** Use this parameter to display all attributes.

If this parameter is specified, any attributes that you request specifically have no effect; the command displays all attributes.

This parameter is the default parameter if you do not specify a generic name, and do not request any specific attributes.

z/OS

## **CMDSCOPE**

This parameter applies to z/OS only and specifies how the command runs when the queue manager is a member of a queue-sharing group.

' ' The command runs on the queue manager on which it was entered. This value is the default value.

### *qmgr-name*

The command runs on the named queue manager, if the queue manager is active within the queue-sharing group.

You can specify a queue manager name other than the queue manager on which you enter the command, but only if you are using a queue-sharing group environment and the command server is enabled.

- \* The command runs on the local queue manager and on every active queue manager in the queue-sharing group. The effect of this option is equivalent to entering the command on every queue manager in the queue-sharing group.

## TYPE

### TOPIC

The command displays status information relating to each topic node, which is the default if you do not provide a **TYPE** parameter.

**PUB** The command displays status information relating to applications that have topic nodes open for publish.

**SUB** The command displays status information relating to applications that subscribe to the topic node or nodes. The subscribers that the command returns are not necessarily the subscribers that would receive a message published to this topic node. The value of `SelectionString` or `SubLevel` determines which subscribers receive such messages.

## Topic status parameters

Topic status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

Topic objects can be defined with attributes that have a value of *ASPARENT*. Topic status shows the resolved values that result in finding the setting of the closest parent administrative topic object in the topic tree, and so will never display a value of *ASPARENT*.

### ADMIN

If the topic node is an admin-node, the command displays the associated topic object name containing the node configuration. If the field is not an admin-node the command displays a blank.

### CLROUTE

The routing behavior to use for topics in the cluster defined by the **CLUSTER** parameter. The values can be as follows:

#### *DIRECT*

A publication on this topic string, originating from this queue manager, is sent direct to any queue manager in the cluster with a matching subscription.

#### *TOPICHOST*

A publication on this topic string, originating from this queue manager, is sent to one of the queue managers in the cluster that hosts a definition of the corresponding clustered topic object, and from there to any queue manager in the cluster with a matching subscription.

#### *NONE*

This topic node is not clustered.

### CLUSTER

The name of the cluster to which this topic belongs.

' ' This topic does not belong to a cluster. Publications and subscriptions for this topic are not propagated to publish/subscribe cluster-connected queue managers.

### COMMINFO

Displays the resolved value of the name of the communication information object to be used for this topic node.

### DEFPRESP

Displays the resolved default put response of messages published to the topic. The value can be *SYNC* or *ASYNC*.

**DEFPRTY**

Displays the resolved default priority of messages published to the topic.

**DEFPSIST**

Displays the resolved default persistence for this topic string. The value can be *YES* or *NO*.

**DURSUB**

Displays the resolved value that shows whether applications can make durable subscriptions. The value can be *YES* or *NO*.

**MCAST**

Displays the resolved value that shows whether the topic could be transmittable via multicast or not. The value can be *ENABLED*, *DISABLED*, or *ONLY*.

**MDURMDL**

Displays the resolved value of the name of the model queue to be used for durable subscriptions.

**MNDURMDL**

Displays the resolved value of the name of the model queue used for non-durable subscriptions.

**NPMSGDLV**

Displays the resolved value for the delivery mechanism for non-persistent messages published to this topic. The value can be *ALL*, *ALLDUR*, or *ALLAVAIL*.

**PMSGDLV**

Displays the resolved value for the delivery mechanism for persistent messages published to this topic. The value can be *ALL*, *ALLDUR*, or *ALLAVAIL*.

**PUB** Displays the resolved value that shows whether publications are allowed for this topic. The values can be *ENABLED* or *DISABLED*.

**PUBCOUNT**

Displays the number of handles that are open for publish on this topic node.

**PUBSCOPE**

Determines whether this queue manager propagates publications, for this topic node, to other queue managers as part of a hierarchy or a cluster, or whether it restricts them to only subscriptions defined on the local queue manager. The value can be *QMGR* or *ALL*.

**RETAINED**

Displays whether there is a retained publication associated with this topic. The value can be *YES* or *NO*.

**SUB** Displays the resolved value that shows whether subscriptions are allowed for this topic. The values can be *ENABLED* or *DISABLED*.

**SUBCOUNT**

Displays the number of subscribers to this topic node, including durable subscribers that are not currently connected.

**SUBSCOPE**

Determines whether this queue manager propagates subscriptions, for this topic node, to other queue managers as part of a cluster or hierarchy, or whether it restricts the subscriptions to only the local queue manager. The value can be *QMGR* or *ALL*.

**USEDLQ**

Determines whether the dead-letter queue is used when publication messages cannot be delivered to their correct subscriber queue. The value can be *YES* or *NO*.

**Sub status parameters**

Sub status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

**ACTCONN**

Detects local publications, returning the currently active ConnectionId (CONNID) that opened this subscription.

**DURABLE**

Indicates whether a durable subscription is not deleted when the creating application closes its subscription handle, and persists over queue manager restart. The value can be *YES* or *NO*.

**LMSGDATE**

The date on which an MQPUT call last sent a message to this subscription. The MQPUT call updates the date field only when the call successfully puts a message to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

**LMSGTIME**

The time at which an MQPUT call last sent a message to this subscription. The MQPUT call updates the time field only when the call successfully puts a message to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

**MCASTREL**

Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues the user can switch on event message generation, use the **COMMEV** parameter of the COMMINFO objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

**NUMMSGS**

Number of messages put to the destination specified by this subscription. An MQSUBRQ call causes an update to this value.

**RESMDATE**

Date of the most recent MQSUB call that connected to this subscription.

**RESMTIME**

Time of the most recent MQSUB call that connected to this subscription.

**SUBID**

An all time unique identifier for this subscription, assigned by the queue manager. The format of **SUBID** matches that of a CorrelId. For durable subscriptions, the command returns the **SUBID** even if the subscriber is not currently connected to the queue manager.

**SUBTYPE**

The type of subscription, indicating how it was created. The value can be *ADMIN*, *API*, or *PROXY*.

**SUBUSER**

The user ID that owns this subscription, which can be either the user ID associated with the creator of the subscription or, if subscription takeover is permitted, the user ID that last took over the subscription.

**Pub status parameters**

Pub status parameters define the data that the command displays. You can specify these parameters in any order but must not specify the same parameter more than once.

**ACTCONN**

The currently active ConnectionId (CONNID) associated with the handle that has this topic node open for publish.

**LPUBDATE**

The date on which this publisher last sent a message.

**LPUBTIME**

The time at which this publisher last sent a message.

**MCASTREL**

Indicator of the reliability of the multicast messages.

The values are expressed as a percentage. A value of 100 indicates that all messages are being delivered without problems. A value less than 100 indicates that some of the messages are experiencing network issues. To determine the nature of these issues the user can switch on event message generation, using the **COMMEV** parameter of the **COMMINFO** objects, and examine the generated event messages.

The following two values are returned:

- The first value is based on recent activity over a short period.
- The second value is based on activity over a longer period.

If no measurement is available the values are shown as blanks.

**NUMPUBS**

Number of publishes by this publisher. This value records the actual number of publishes, not the total number of messages published to all subscribers.

**DISPLAY TRACE:** 

Use the MQSC command **DISPLAY TRACE** to display a list of active traces.

**Using MQSC commands**

For information on how you use MQSC commands, see *Performing local administration tasks using MQSC commands*.

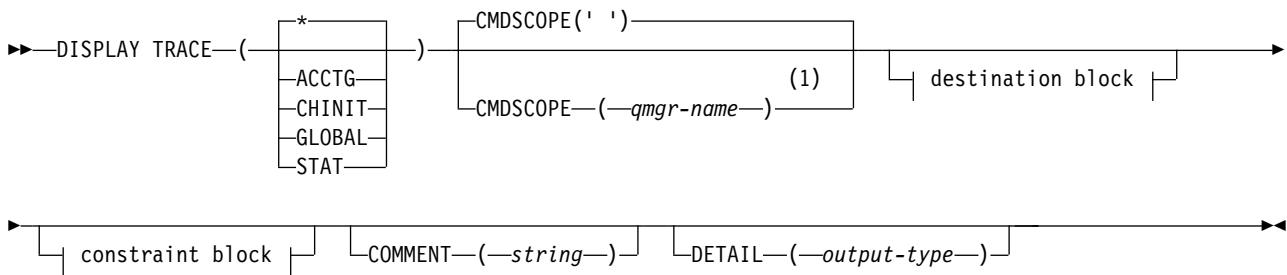

IBM i	UNIX and Linux	Windows	z/OS
			12CR

 For an explanation of the symbols in the z/OS column, see *Using commands on z/OS*.

- Syntax diagram
- “Parameter descriptions for **DISPLAY TRACE**” on page 936
- “Destination block” on page 937
- “Constraint block” on page 937

**Synonym:** DIS TRACE

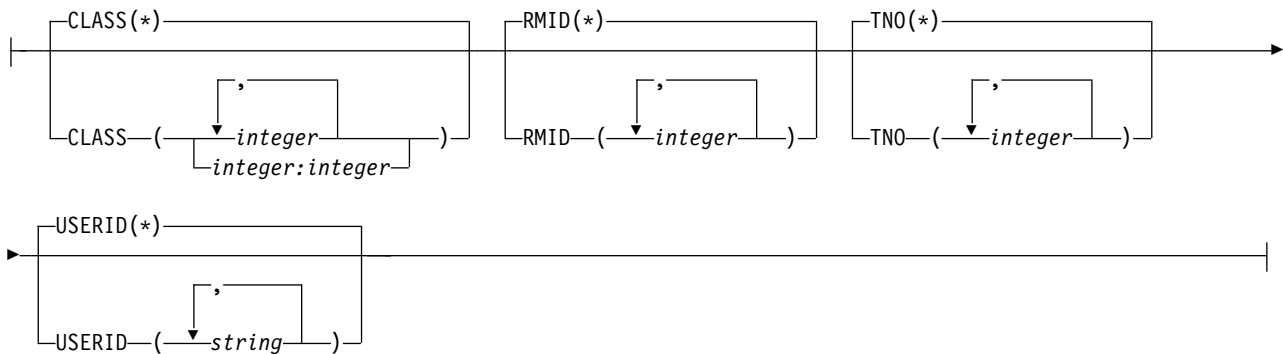

## DISPLAY TRACE

### Destination block:

### Constraint block:

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.

### Parameter descriptions for DISPLAY TRACE

All parameters are optional. Each option that is used limits the effect of the command to active traces that were started using the same option, either explicitly or by default, with exactly the same parameter values.

- \* Does not limit the list of traces. This is the default. The CLASS option cannot be used with DISPLAY TRACE(\*).

Each remaining parameter in this section limits the list to traces of the corresponding type:

#### ACCTG

Accounting data (the synonym is A)

#### CHINIT

Service data from the channel initiator. The synonym is CHI or DQM.

**GLOBAL**

Service data from the entire queue manager except the channel initiator. The synonym is G.

**STAT** Statistical data (the synonym is S)

**COMMENT( *string* )**

Specifies a comment. This does not appear in the display, but it might be recorded in trace output.

**DETAIL( *output-type* )**

This parameter is ignored; it is retained only for compatibility with earlier releases.

Possible values for *output-type* are \*, 1, or 2.

**CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

CMDSCOPE cannot be used for commands issued from the first initialization input data set CSQINP1.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

***qmgr-name***

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

**Destination block**

**DEST** Limits the list to traces started for particular destinations. More than one value can be specified, but do not use the same value twice. If no value is specified, the list is not limited.

Possible values and their meanings are:

**GTF** The Generalized Trace Facility

**RES** A wraparound table residing in the ECSA (extended common service area)

**SMF** The System Management Facility

**SRV** A serviceability routine designed for IBM for problem diagnosis

**Constraint block****CLASS( *integer* )**

Limits the list to traces started for particular classes. See "START TRACE" on page 1019 for a list of allowed classes.

The default is CLASS(\*), which does not limit the list.

**RMID( *integer* )**

Limits the list to traces started for particular resource managers. See "START TRACE" on page 1019 for a list of allowed resource manager identifiers. Do not use this option with the STAT or CHINIT trace type.

The default is RMID(\*), which does not limit the list.

**TNO( *integer* )**

Limits the list to particular traces, identified by their trace number (0 to 32). Up to 8 trace numbers can be used. If more than one number is used, only one value for USERID can be used. The default is TNO(\*), which does not limit the list.

0 is the trace that the channel initiator can start automatically. Traces 1 to 32 are those for queue manager or the channel initiator that can be started automatically by the queue manager, or manually, using the START TRACE command.

**USERID**( *string* )

Limits the list to traces started for particular user IDs. Up to 8 user IDs can be used. If more than one user ID is used, only one value can be used for TNO. Do not use this option with STAT. The default is USERID(\*), which does not limit the list.

**DISPLAY USAGE:** z/OS

Use the MQSC command DISPLAY USAGE to display information about the current state of a page set, to display information about the log data sets, or to display information about the shared message data sets.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

**Attention:** From IBM MQ Version 8.0, the output of the DISPLAY USAGE command includes message CSQI065I +MP11 Buffer pool attributes, instead of message CSQP001I +MG11 Buffer pool 0 has 25000 buffers.

- Syntax diagram
- "Parameter descriptions for DISPLAY USAGE"

**Synonym:** DIS USAGE

**DISPLAY USAGE**

**Notes:**

- 1 Valid only when the queue manager is a member of a queue-sharing group.

**Parameter descriptions for DISPLAY USAGE**

**CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

- ' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

- \* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

**PSID( *integer* )**

The page-set identifier. This is optional.

This is a number, in the range 00 through 99. An asterisk (\*) on its own specifies all page set identifiers.

The command fails if PSID has been specified together with TYPE(DATASET), or TYPE(SMDS).

If the command is running at the same time as an ALTER BUFFPOOL command the buffer pool attributes might not be entirely consistent. For example, the value of the location parameter might be BELOW, but the number of available buffers value might be more than can fit below the bar. If this occurs, run the display command again when the ALTER BUFFPOOL command has completed.

**TYPE** Defines the type of information to be displayed. Values are:

**PAGESET**

Display page set and buffer pool information. This is the default.

**DATASET**

Display data set information for log data sets. This returns messages containing 44-character data set names for the following:

- The log data set containing the BEGIN\_UR record for the oldest incomplete unit of work for this queue manager, or if there are no incomplete units of work, the log data set containing the current highest written RBA.
- The log data set containing the oldest restart\_RBA of any pageset owned by this queue manager.
- The log data set with a timestamp range that includes the timestamp of the last successful backup of any application structure known within the queue-sharing group.

**SMDS**

Display data set space usage information and buffer pool information for shared message data sets owned by this queue manager. Space usage information is only available when the data set is open. Buffer pool information is only available when the queue manager is connected to the structure. For more information about the displayed information, see the descriptions of messages CSQE280I and CSQE285I.

**ALL**

Display page set, data set, and SMDS information.

**Note:** This command is issued internally by IBM MQ:

- During queue manager shutdown so that the restart RBA is recorded on the z/OS console log.
- At queue manager startup so that page set information can be recorded.
- When DEFINE PSID is used to dynamically define the first page set in the queue manager that uses the buffer pool specified on the DEFINE PSID command.

## MOVE QLOCAL: z/OS

Use the MQSC command MOVE QLOCAL to move all the messages from one local queue to another.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
			2CR

z/OS For an explanation of the symbols in the z/OS column, see Using commands on z/OS.

- Syntax diagram
- “Usage notes for MOVE QLOCAL”
- “Parameter descriptions for MOVE QLOCAL” on page 941

**Synonym:** MOVE QL

### MOVE QLOCAL

#### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.

#### Usage notes for MOVE QLOCAL

1. A typical use of the MOVE QLOCAL command is to move messages from a private queue to a shared queue when you are setting up a queue-sharing group environment.
2. The MOVE QLOCAL command *moves* messages; it does not copy them.
3. The MOVE QLOCAL command moves messages in a similar way to an application performing successive MQGET and MQPUT calls. However, the MOVE QLOCAL command does not physically delete logically-expired messages and, therefore, no expiration reports are generated.
4. The priority, context, and persistence of each message are not changed.
5. The command performs no data conversion and calls no exits.
6. Confirm-on-delivery (COD) report messages are not generated but confirm-on-arrival (COA) report messages are. This means that more than one COA report message can be generated for a message.
7. The MOVE QLOCAL command transfers the messages in batches. At COMMIT time, if the trigger conditions are met, trigger messages are produced. This might be at the end of the move operation.

**Note:** Before the transfer of messages begins, this command verifies that the number of messages on the source queue, when added to the number of messages on the target queue, does not exceed MAXDEPTH on the target queue.

If the MAXDEPTH of the target queue were to be exceeded, no messages are moved.

8. The MOVE QLOCAL command can change the sequence in which messages can be retrieved. The sequence remains unchanged only if:
  - You specify **TYPE(MOVE)** and
  - The MSGDLVSQ parameter of the source and target queues is the same.
9. Messages are moved within one or more syncpoints. The number of messages in each syncpoint is determined by the queue manager.
10. If anything prevents the moving of one or more messages, the command stops processing. This can mean that some messages have already been moved, while others remain on the source queue. Some of the reasons that prevent a message being moved are:
  - The target queue is full.
  - The message is too long for the target queue.
  - The message is persistent, but the target queue cannot store persistent messages.
  - The page set is full.

### Parameter descriptions for MOVE QLOCAL

You must specify the names of two local queues: the one you want to move messages from (the source queue) and the one you want to move the messages to (the target queue).

*source* The name of the local queue from which messages are moved. The name must be defined to the local queue manager.

The command fails if the queue contains uncommitted messages.

If an application has this queue open, or has open a queue that eventually resolves to this queue, the command fails. For example, the command fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

An application can open this queue while the command is in progress but the application waits until the command has completed.

### CMDSCOPE

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.

### QSGDISP

Specifies the disposition of the source queue.

#### PRIVATE

The queue is defined with QSGDISP(QMGR) or QSGDISP(COPY). This is the default value.

#### SHARED

The queue is defined with QSGDISP(SHARED). This is valid only in a queue-sharing group environment.

**TYPE** Specifies how the messages are moved.

## MOVE

Move the messages from the source queue to the empty target queue.

The command fails if the target queue already contains one or more messages. The messages are deleted from the source queue. This is the default value.

**ADD** Move the messages from the source queue and add them to any messages already on the target queue.

The messages are deleted from the source queue.

*target* The name of the local queue to which messages are moved. The name must be defined to the local queue manager.

The name of the target queue can be the same as that of the source queue only if the queue exists as both a shared and a private queue. In this case, the command moves messages to the queue that has the opposite disposition (shared or private) from that specified for the source queue on the **QSGDISP** parameter.

If an application has this queue open, or has open a queue that eventually resolves to this queue, the command fails. The command also fails if this queue is a transmission queue, and any queue that is, or resolves to, a remote queue that references this transmission queue, is open.

No application can open this queue while the command is in progress.

If you specify **TYPE(MOVE)**, the command fails if the target queue already contains one or more messages.

The **DEFTYPE**, **HARDENBO**, and **USAGE** parameters of the target queue must be the same as those of the source queue.

## PING CHANNEL:

Use the MQSC command **PING CHANNEL** to test a channel by sending data as a special message to the remote queue manager, and checking that the data is returned. The data is generated by the local queue manager.

### Using MQSC commands

For information on how you use MQSC commands, see *Performing local administration tasks using MQSC commands*.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	CR

 For an explanation of the symbols in the z/OS column, see *Using commands on z/OS*.

- Syntax diagram
- “Usage notes” on page 943
- “Parameter descriptions for **PING CHANNEL**” on page 943

**Synonym:** PING CHL

## PING CHANNEL

### Notes:

- 1 Valid only when the queue manager is a member of a queue-sharing group.
- 2 Valid only on z/OS.

### Usage notes

1. **z/OS** On z/OS, the command server and the channel initiator must be running.
2. Where there is both a locally defined channel and an auto-defined cluster-sender channel of the same name, the command applies to the locally defined channel. If there is no locally defined channel but more than one auto-defined cluster-sender channel, the command applies to the channel that was last added to the local queue manager's repository.
3. This command can be used only for sender (SDR), server (SVR), and cluster-sender (CLUSSDR) channels (including those that have been defined automatically). It is not valid if the channel is running; however, it is valid if the channel is stopped or in retry mode.

### Parameter descriptions for PING CHANNEL

*(channel-name)*

The name of the channel to be tested. This is required.

#### **z/OS** CMDSCOPE

This parameter applies to z/OS only and specifies how the command is executed when the queue manager is a member of a queue-sharing group.

If CHLDISP is set to SHARED, CMDSCOPE must be blank or the local queue manager.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

*qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name only if you are using a queue-sharing group environment and if the command server is enabled.

\* The command is executed on the local queue manager and is also passed to every active queue manager in the queue-sharing group. The effect of this is the same as entering the command on every queue manager in the queue-sharing group.

**Note:** The '\*' option is not permitted if CHLDISP is FIXSHARED.

**CHLDISP**

This parameter applies to z/OS only and can take the values of:

- DEFAULT
- PRIVATE
- SHARED
- FIXSHARED

If this parameter is omitted, then the DEFAULT value applies. This is the value of the default channel disposition attribute, DEFCDISP, of the channel object.

In conjunction with the various values of the CMDSCOPE parameter, this parameter controls two types of channel:

**SHARED**

A receiving channel is shared if it was started in response to an inbound transmission directed to the queue-sharing group.

A sending channel is shared if its transmission queue has a disposition of SHARED.

**PRIVATE**

A receiving channel is private if it was started in response to an inbound transmission directed to the queue manager.

A sending channel is private if its transmission queue has a disposition other than SHARED.

**Note:** This disposition is **not** related to the disposition set by the disposition of the queue-sharing group of the channel definition.

The combination of the CHLDISP and CMDSCOPE parameters also controls from which queue manager the channel is operated. The possible options are:

- On the local queue manager where the command is issued.
- On another specific named queue manager in the group.
- On the most suitable queue manager in the group, determined automatically by the queue manager itself.

The various combinations of CHLDISP and CMDSCOPE are summarized in the following table.

Table 108. CHLDISP and CMDSCOPE for PING CHANNEL

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
PRIVATE	Ping private channel on the local queue manager	Ping private channel on the named queue manager	Ping private channel on all active queue managers

Table 108. CHLDISP and CMDSCOPE for PING CHANNEL (continued)

CHLDISP	CMDSCOPE( ) or CMDSCOPE (local-qmgr)	CMDSCOPE (qmgr-name)	CMDSCOPE(*)
SHARED	<p>Ping a shared channel on the most suitable queue manager in the group</p> <p>This might automatically generate a command using CMDSCOPE and send it to the appropriate queue manager. If there is no definition for the channel on the queue manager to which the command is sent, or if the definition is unsuitable for the command, the command fails.</p> <p>The definition of a channel on the queue manager where the command is entered might be used to determine the target queue manager where the command is actually run. Therefore, it is important that channel definitions are consistent. Inconsistent channel definitions might result in unexpected command behavior.</p>	Not permitted	Not permitted
FIXSHARED	Ping a shared channel on the local queue manager	Ping a shared channel on the named queue manager	Not permitted

**DATALEN( integer )**

The length of the data, in the range 16 through 32 768. This is optional.

**PING QMGR:**

Use the MQSC command PING QMGR to test whether the queue manager is responsive to commands.

**Using MQSC commands**

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	UNIX and Linux	Windows	z/OS
✓	✓	✓	

- Syntax diagram
- “Usage notes”

Synonym: PING QMGR

**PING QMGR**

▶▶—PING QMGR—◀◀

**Usage notes**

If commands are issued to the queue manager by sending messages to the command server queue, this command causes a special message to be sent to it, consisting of a command header only, and checking

that a positive reply is returned.

## PURGE CHANNEL:

**V8.0.0.4** Use the MQSC command PURGE CHANNEL to stop and purge a telemetry or AMQP channel. Purging a telemetry or AMQP channel disconnects all the MQTT or AMQP clients connected to it, cleans up the state of the MQTT or AMQP clients, and stops the telemetry or AMQP channel. Cleaning the state of a client deletes all the pending publications and removes all the subscriptions from the client.

### Using MQSC commands

For information on how you use MQSC commands, see Performing local administration tasks using MQSC commands.

IBM i	AIX and Linux	Windows	z/OS
	✓	✓	

- Syntax diagram
- “Parameter descriptions for PURGE CHANNEL”

**Synonym:** None

## PURGE CHANNEL

►► PURGE CHANNEL—(—*channel-name*—)—CHLTYPE—(—

MQTT
AMQP

—)—CLIENTID—(—*clientid*—)—►►

### Parameter descriptions for PURGE CHANNEL

(*channel name*)

**V8.0.0.4** The name of the telemetry or AMQP channel to be stopped and purged. This parameter is required.

**CHLTYPE** (*MQTT*)

Channel type. This parameter is required. **V8.0.0.4** It must follow immediately after the (*channel-name*) parameter **z/OS** on all platforms except z/OS, and the value must currently be either MQTT or AMQP.

**CLIENTID** (*string*)

Client identifier. **V8.0.0.4** The client identifier is a 23 byte string that identifies an IBM MQ Telemetry Transport or AMQP client. When the PURGE CHANNEL command specifies a CLIENTID, only the connection for the specified client identifier is purged. If the CLIENTID is not specified, all the connections on the channel are purged.

## RECOVER CFSTRUCT: z/OS

Use the MQSC command RECOVER CFSTRUCT to initiate recovery of CF application structures and associated shared message data sets. This command is valid only when the queue manager is a member of a queue-sharing group.

### Using MQSC commands

For information on how you use MQSC commands, see *Performing local administration tasks using MQSC commands*.

IBM i	UNIX and Linux	Windows	z/OS
			CR

z/OS For an explanation of the symbols in the z/OS column, see *Using commands on z/OS*.

- Syntax diagram

**Synonym:** REC CFSTRUCT

### RECOVER CFSTRUCT

### Usage notes for RECOVER CFSTRUCT

- The command fails if neither the specified application structure nor its associated shared message data sets are flagged as being in a FAILED state.
- If a data set is marked as FAILED but the corresponding structure is not, then the **RECOVER CFSTRUCT** command changes the structure state to FAILED, deleting the contents to perform recovery. This action deletes all nonpersistent messages stored in the structure and makes the structure unavailable until recovery is complete.
- For a structure with associated shared message data sets, the **RECOVER CFSTRUCT** command recovers the structure plus the offloaded message data for any data sets which are either already marked as FAILED or found to be empty or invalid when opened by recovery processing. Any data sets which are marked as ACTIVE and have valid headers are assumed not to require recovery.
- When recovery processing completes normally, all associated shared message data sets for the recovered structures (including data sets which did not need recovery) are marked as RECOVERED, indicating that the space map needs to be rebuilt.
- Following recovery, space map rebuild processing is performed for each affected data set, to map the space occupied by the recovered message data (ignoring any existing messages which were nonpersistent or backed out). When the space map has been rebuilt for each data set, it is marked as ACTIVE again.
- The command fails if any one of the specified structure names is not defined in the CFRM policy data set.
- The recovery process is both I/O and processor intensive, and can only run on a single z/OS image. It should therefore be run on the most powerful or least busy system in the queue-sharing group.

- The most likely failure is the loss of a complete CF and hence the simultaneous loss of all the application structures therein. If backup date and times are similar for each failed application structure, it is more efficient to recover them in a single **RECOVER CFSTRUCT** command.
- This command fails if any of the specified CF structures is defined with either a CFLEVEL of less than 3, or with RECOVER set to NO.
- To use TYPE(NORMAL), you must have taken a backup of the CF structures, using the **BACKUP CFSTRUCT** command.
- If backups of the requested CF structures have not been taken recently, using TYPE(NORMAL) may take a considerable amount of time.
- If a backup of the CF structure, or a required archive log, is not available, you can recover to an empty CF structure using TYPE(PURGE).
- The command **RECOVER CFSTRUCT(CSQSYSAPPL) TYPE(PURGE)** is prohibited. This is to prevent the accidental loss of queue manager internal objects.

### Keyword and parameter descriptions for RECOVER CFSTRUCT

#### **CFSTRUCT**( *structure-names ...* )

Specify list of names of up to 256 structure names for which the coupling facility application structures are to be recovered, along with any associated shared message data sets which also need recovery. If resources for more than one structure need to be recovered, it is more efficient to recover them at the same time.

#### **CMDSCOPE**

This parameter specifies how the command is executed when the queue manager is a member of a queue-sharing group.

' ' The command is executed on the queue manager on which it was entered. This is the default value.

#### *qmgr-name*

The command is executed on the queue manager you specify, providing the queue manager is active within the queue-sharing group.

You can specify a queue manager name, other than the queue manager on which the command was entered, only if you are using a queue-sharing group environment and if the command server is enabled.
