Planning an IBM MQ architecture

When planning your IBM® MQ environment, consider the support that IBM MQ provides for single and multiple queue manager architectures, and for point-to-point and publish/subscribe messaging styles. Also plan your resource requirements, and your use of logging and backup facilities.

Before you plan your IBM MQ architecture, familiarize yourself with the basic IBM MQ concepts. See IBM MQ Technical overview.

IBM MQ architectures range from simple architectures using a single queue manager, to more complex networks of interconnected queue managers. Multiple queue managers are connected together using distributed queuing techniques. For more information about planning single queue manager and multiple queue manager architectures, see the following topics:

- "Architectures based on a single queue manager" on page 5
- "Architectures based on multiple queue managers" on page 6
  - "Planning your distributed queues and clusters" on page 7
  - "Planning your distributed publish/subscribe network" on page 61

z/OS On IBM MQ for z/OS® you can use shared queues and queue-sharing groups to enable you to implement workload balancing, and your IBM MQ applications to be scalable and highly available. For information about shared queues and queue-sharing groups, see Shared queues and queue-sharing groups.

IBM MQ provides two different release models:

- The Long Term Support (LTS) release is most suitable for systems requiring a long term deployment and maximum stability
- The Continuous Delivery (CD) release is intended for systems which need to rapidly exploit the latest functional enhancements for IBM MQ.

Both release types are installed in the same way, but there are considerations relating to support and migration which you need to understand. See "IBM MQ release types" for further information.

For information about planning for multiple installations, storage and performance requirements, and use of clients, see the other subtopics.

IBM MQ release types

V 9.0.0

From IBM MQ Version 9.0 there are two types of release; a Long Term Support (LTS) release and Continuous Delivery (CD) release. The aim of the two release types is to meet the requirement for delivery of new and enhanced IBM MQ functions as rapidly as possible in the next CD release, while at the same time maintaining a stable long term support release for systems that need a long term deployment of IBM MQ, and for customers who prefer this traditional option.

The release model

The two release types are distinguishable by the modification number in the version.release.modification (`v.r.m`) release identifier.

IBM MQ Version 9.0.0 has a zero modification number and is designated as LTSR.

CD Continuous Delivery releases have a non-zero modification number, for example, 9.0.1, 9.0.2, and so on.

CD releases are made available on a regular basis, and contain *functional enhancements* as well as the latest set of defect fixes and security updates.

Each CD release replaces the prior ones for that version of IBM MQ, so it is possible for you to skip CD releases, if a specific CD release does not contain any function that is relevant for your enterprise. However, fixes will only be provided on the latest two CD releases.

LTS LTS releases are updated by fix packs or PTFs, which provide defect fixes and security updates in a predictable fashion. This process matches the way service has been provided on prior versions of IBM MQ. Fix packs are numbered according to a `v.r.m.f` scheme so, for example, the first fix pack for the IBM MQ Version 9.0.0 LTS release will be numbered 9.0.0.1.

For more information, see IBM MQ FAQ for Long Term Support and Continuous Delivery releases.

The next sections describe the specific detail of the process for obtaining, installing, and using IBM MQ code in the new release model for IBM MQ for z/OS and IBM MQ for Multiplatforms.

z/OS
Considerations for IBM MQ for z/OS

Ordering

When ordering IBM MQ for z/OS Version 9.0, two separate features are offered on ShopZ. The features correspond to the LTS release and the CD release.

Both features are applicable to the same product ID (PID). It is the product ID that is licensed, so where one feature is licensed, there is entitlement to use the alternative feature if required.

When ordering the following IBM MQ for z/OS products, select the feature corresponding with either the LTS release or CD release:
- IBM MQ for z/OS Version 9.0
- Managed File Transfer for z/OS Version 9.0

If you are selecting products for inclusion in a ServerPac, it is not possible to choose both the LTS release and CD release in the same ServerPac order, because the products cannot be installed by SMP/E in the same target zone.

Advanced Message Security for z/OS (AMS) Version 9.0 provides both the LTS release and CD release options.

The release options are selected by choosing the equivalent release for the base product, IBM MQ for z/OS Version 9.0, and enabling with the product 5655-AM9.

Attention: You cannot choose CD release enhancements for AMS functions on an LTS release IBM MQ base.

If your enterprise uses IBM MQ for z/OS Value Unit Edition (VUE) Version 9.0, the same product 5655-VU9 enables VUE licensing in either the LTS release or CD release of IBM MQ for z/OS Version 9.0.

Installation

The LTS and CD releases are provided in separate sets of FMIDs. Note that these FMIDs cannot be installed in the same SMP/E target zone.

Where you require both the LTS and CD releases, you should:
- Install the LTS release and CD release in separate target zones
- Maintain separate target and distribution libraries for the two releases

As the releases use different FMIDs, it is not possible to update a CD release with maintenance for an LTS release or the other way round. Similarly, there is no way to switch a version of the product code from LTS release to CD release or the other way round.

However it is possible to switch a queue manager between the release models, for further information see Migration

Maintenance

The LTS release is serviced by the application of PTFs which provide defect fixes. Note that the PTFs resolve specific issues, and are not cumulative.

IBM provides groups of fixes in RSU levels for an LTS release.

The CD release is serviced by the application of PTFs which deliver both defect fixes and functional enhancements.

Each set of PTFs is cumulative and increases the modification level of the CD release. That is, a set of PTFs will update the product and change the reported `v.r.m` from V9.0.1 to V9.0.2. The subsequent set of PTFs supersedes the first set, and updates the installed product to V9.0.3.

Migration between LTS release and CD release

There are constraints and limitations, but generally a single queue manager can be migrated from using LTS release code to CD release code or from using CD release code to LTS release code provided that the target release is higher than that in use prior to the migration.

IBM MQ for z/OS has traditionally provided a fallback capability (backward migration) so that after a period of running following a migration, it is possible to fallback to the prior release without loss of data provided that new release operation is restricted to compatible operations through the OPMODE(COMPAT) control.

This capability is retained for LTS releases, but is not possible when the source or target of a migration is a CD release. The following are valid migration scenarios and illustrate this principle:

Source release	Destination release	Notes
V8.0.0	V9.0.0 LTSR	backward migration supported while V9.0.0 in OPMODE(COMPAT)
V8.0.0	V9.0.1 CDR	No backward migration, target release is CD
V9.0.0 LTSR	V9.0.2 CDR	No backward migration, target release is CD

Once a queue manager starts running a CD release of code, the queue manager sets the OPMODE to NEWFUNC at the new release level. The queue manager command level will also be updated to indicate the new release level.

Multi

Considerations for IBM MQ for Multiplatforms

Ordering

Within Passport Advantage there are two separate eAssemblies for IBM MQ Version 9.0. One contains installation images for IBM MQ Version 9.0.0 Long Term Support release, and the other contains installation images for IBM MQ Version 9.0.x Continuous Delivery release.

Download installation images from the eAssembly according to your choice of release.

Alternatively, for the LTS release only, a media pack is available, containing product installation DVDs.

All IBM MQ versions, and for IBM MQ Version 9.0 both the LTS releases and CD releases, belong to the same Product Id.

Entitlement to use IBM MQ extends across the entire product (PID) subject to the constraints of licensed components and pricing metrics. This means that you can freely choose between LTS release and CD release installation images for IBM MQ Version 9.0.

Installation

Once an installation image has been downloaded from Passport Advantage, you should only select for installation the components for which you have purchased entitlement. See IBM MQ license information for further information about which installable components are included for each chargeable component.

It is possible to install IBM MQ Version 9.0 LTS release and IBM MQ Version 9.0 CD release on the same operating system image.

If you do this, the components appear as separate installations, as supported by IBM MQ multi-version support. Each version has distinct sets of queue managers associated with that version.

Each new CD release is provided as an installation image. The new CD release can be installed along side an existing release, or, an earlier CD release can be updated in place by the installer to the new release.

Maintenance

The LTS release is serviced by the application of fix packs, which provide defect fixes. The fix packs are made available periodically and are cumulative.

The only maintenance provided for a CD release will be in the form of an iFix delivered to resolve a specific customer issue, if required, on the two latest CD releases, which could be on a subsequent version.

Migration between LTS release and CD release

There are constraints and limitations but, generally, a single queue manager can be migrated from using LTS release code to CD release code, or from using CD release code to LTS release code, provided that the target release is higher than that in use prior to the migration.

Two approaches are possible:
- Install the new release of code in place so that an existing installation of IBM MQ is updated. Any queue managers associated with the installation use the new release of code when started.
- Install the new release of code as a new installation, then move individual queue manager instances to the new installation using the setmqm command.

Once a queue manager starts running a CD release of code, the queue manager command level is updated to indicate the new release level. This means any new functions provided in the release are enabled, and it will no longer be possible to restart the queue manager using a code release with a lower `v.r.m`.

Architectures based on a single queue manager

The simplest IBM MQ architectures involve the configuration and use of a single queue manager.

Before you plan your IBM MQ architecture, familiarize yourself with the basic IBM MQ concepts. See IBM MQ Technical overview.

A number of possible architectures using a single queue manager are described in the following sections:
- “Single queue manager with local applications accessing a service”
- “Single queue manager with remote applications accessing a service as clients”
- “Single queue manager with a publish/subscribe configuration”

Single queue manager with local applications accessing a service

The first architecture based on a single queue manager is where the applications accessing a service are running on the same system as the applications providing the service. An IBM MQ queue manager provides asynchronous intercommunication between the applications requesting the service and the applications providing the service. This means that communication between the applications can continue even if one of the applications is offline for an extended period of time.

Single queue manager with remote applications accessing a service as clients

The second architecture based on a single queue manager has the applications running remotely from the applications providing the service. The remote applications are running on different systems to the services. The applications connect as clients to the single queue manager. This means that access to a service can be provided to multiple systems through a single queue manager.

A limitation of this architecture is that a network connection must be available for an application to operate. The interaction between the application and the queue manager over the network connection is synchronous.

Single queue manager with a publish/subscribe configuration

An alternative architecture using a single queue manager is to use a publish/subscribe configuration. In publish/subscribe messaging, you can decouple the provider of information from the consumers of that information. This differs from the point to point messaging styles in the previously described architectures, where the applications must know information about the target application, for example the queue name to put messages on. Using IBM MQ publish/subscribe the sending application publishes a message with a specified topic based on the subject of the information. IBM MQ handles the distribution of the message to applications that have registered an interest in that subject through a subscription. The receiving applications also do not need to know anything about the source of the messages to receive them. For more information, see Publish/subscribe messaging and Example of a single queue manager publish/subscribe configuration.

Introduction to IBM MQ

Creating and managing queue managers on Multiplatforms

Architectures based on multiple queue managers

You can use distributed message queuing techniques to create an IBM MQ architecture involving the configuration and use of multiple queue managers.

Before you plan your IBM MQ architecture, familiarize yourself with the basic IBM MQ concepts. See IBM MQ Technical overview.

An IBM MQ architecture can be changed, without alteration to applications that provide services, by adding additional queue managers.

Applications can be hosted on the same machine as a queue manager, and then gain asynchronous communication with a service hosted on another queue manager on another system. Alternatively, applications accessing a service can connect as clients to a queue manager that then provides asynchronous access to the service on another queue manager.

Routes that connect different queue managers and their queues are defined using distributed queuing techniques. The queue managers within the architecture are connected using channels. Channels are used to move messages automatically from one queue manager to another in one direction depending on the configuration of the queue managers.

For a high level overview of planning an IBM MQ network, see "Designing distributed queue manager networks" on page 8.

For information about how to plan channels for your IBM MQ architecture, see IBM MQ distributed queuing techniques.

Distributed queue management enables you to create and monitor the communication between queue managers. For more information about distributed queue management, see Introduction to distributed queue management.

Creating and managing queue managers on Multiplatforms

Planning your distributed queues and clusters

You can manually connect queues hosted on distributed queue managers, or you can create a queue manager cluster and let the product connect the queue managers for you. To choose a suitable topology for your distributed messaging network, you need to consider your requirements for manual control, network size, frequency of change, availability and scalability.

Before you begin

This task assumes that you understand what distributed messaging networks are, and how they work. For a technical overview, see Distributed queuing and clusters.

About this task

To create a distributed messaging network, you can manually configure channels to connect queues hosted on different queue managers, or you can create a queue manager cluster. Clustering enables queue managers to communicate with each other without the need to set up extra channel definitions or remote queue definitions, simplifying their configuration and management.

To choose a suitable topology for your distributed publish/subscribe network, you need to consider the following broad questions:

- How much manual control do you need over the connections in your network?
- How big will your network be?
- How dynamic will it be?
- What are your availability and scalability requirements?

Procedure

- Consider how much manual control you need over the connections in your network.

  If you only need a few connections, or if individual connections need to be very precisely defined, you should probably create the network manually.

  If you need multiple queue managers that are logically related, and that need to share data and applications, you should consider grouping them together in a queue manager cluster.
- Estimate how big your network needs to be.
  1. Estimate how many queue managers you need. Bear in mind that queues can be hosted on more than one queue manager.
  2. If you are considering using a cluster, add two extra queue managers to act as full repositories.

  For larger networks, manual configuration and maintenance of connections can be very time consuming, and you should consider using a cluster.
- Consider how dynamic the network activity will be.

  Plan for busy queues to be hosted on performant queue managers.

  If you expect queues to be frequently created and deleted, consider using a cluster.
- Consider your availability and scalability requirements.

1. Decide whether you need to guarantee high availability of queue managers. If so, estimate how many queue managers this requirement applies to.
2. Consider whether some of your queue managers are less capable than others.
3. Consider whether the communication links to some of your queue managers are more fragile than to others.
4. Consider hosting queues on multiple queue managers.

Manually configured networks and clusters can both be configured to be highly available and scalable. If you use a cluster, you need to define two extra queue managers as full repositories. Having two full repositories ensures that the cluster continues to operate if one of the full repositories becomes unavailable. Make sure that the full repository queue managers are robust, performant, and have good network connectivity. Do not plan to use the full repository queue managers for any other work.

- Based on these calculations, use the links provided to help you decide whether to manually configure connections between queue managers, or to use a cluster.

What to do next

You are now ready to configure your distributed messaging network.

Configuring distributed queuing

Configuring a queue manager cluster

Designing distributed queue manager networks

IBM MQ sends and receives data between applications, and over networks using Queue Managers and Channels. Network planning involves defining requirements to create a framework for connecting these systems over a network.

Channels can be created between your system and any other system with which you need to have communications. Multi-hop channels can be created to connect to systems where you have no direct connections. The message channel connections described in the scenarios are shown as a network diagram in Figure 1 on page 9.

Channel and transmission queue names

Transmission queues can be given any name. But to avoid confusion, you can give them the same names as the destination queue manager names, or queue manager alias names, as appropriate. This associates the transmission queue with the route they use, giving a clear overview of parallel routes created through intermediate (multi-hopped) queue managers.

It is not so clear-cut for channel names. The channel names in Figure 1 on page 9 for QM2, for example, must be different for incoming and outgoing channels. All channel names can still contain their transmission queue names, but they must be qualified to make them unique.

For example, at QM2, there is a QM3 channel coming from QM1, and a QM3 channel going to QM3. To make the names unique, the first one might be named QM3_from_QM1, and the second might be named QM3_from_QM2. In this way, the channel names show the transmission queue name in the first part of the name. The direction and adjacent queue manager name are shown in the second part of the name.

A table of suggested channel names for Figure 1 on page 9 is given in Table 1 on page 9.

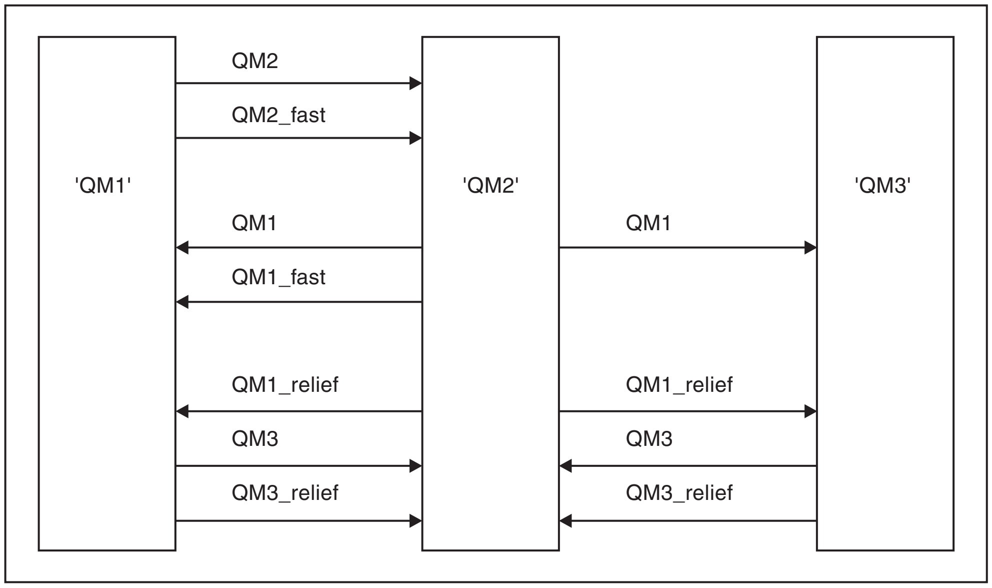

Figure 1. Network diagram showing all channels

Table 1. Example of channel names

Route name	Queue managers hosting channel	Transmission queue name	Suggested channel name
QM1	QM1 & QM2	QM1 (at QM2)	QM1.from.QM2
QM1	QM2 & QM3	QM1 (at QM3)	QM1.from.QM3
QM1_fast	QM1 & QM2	QM1_fast (at QM2)	QM1_fast.from.QM2
QM1_relief	QM1 & QM2	QM1_relief (at QM2)	QM1_relief.from.QM2
QM1_relief	QM2 & QM3	QM1_relief (at QM3)	QM1_relief.from.QM3
QM2	QM1 & QM2	QM2 (at QM1)	QM2.from.QM1
QM2_fast	QM1 & QM2	QM2_fast (at QM1)	QM2_fast.from.QM1
QM3	QM1 & QM2	QM3 (at QM1)	QM3.from.QM1
QM3	QM2 & QM3	QM3 (at QM2)	QM3.from.QM2
QM3_relief	QM1 & QM2	QM3_relief (at QM1)	QM3_relief.from.QM1
QM3_relief	QM2 & QM3	QM3_relief (at QM2)	QM3_relief.from.QM2

Note:

1. z/OS On IBM MQ for z/OS, queue manager names are limited to four characters.
2. Name all the channels in your network uniquely. As shown in Table 1, including the source and target queue manager names in the channel name is a good way to do so.

Network planner

Creating a network assumes that there is another, higher level function of *network planner* whose plans are implemented by the other members of the team.

For widely used applications, it is more economical to think in terms of local access sites for the concentration of message traffic, using wide-band links between the local access sites, as shown in Figure 2 on page 10.

In this example there are two main systems and a number of satellite systems. Tthe actual configuration would depend on business considerations. There are two concentrator queue managers located at convenient centers. Each QM-concentrator has message channels to the local queue managers:

- QM-concentrator 1 has message channels to each of the three local queue managers, QM1, QM2, and QM3. The applications using these queue managers can communicate with each other through the QM-concentrators.
- QM-concentrator 2 has message channels to each of the three local queue managers, QM4, QM5, and QM6. The applications using these queue managers can communicate with each other through the QM-concentrators.
- The QM-concentrators have message channels between themselves thus allowing any application at a queue manager to exchange messages with any other application at another queue manager.

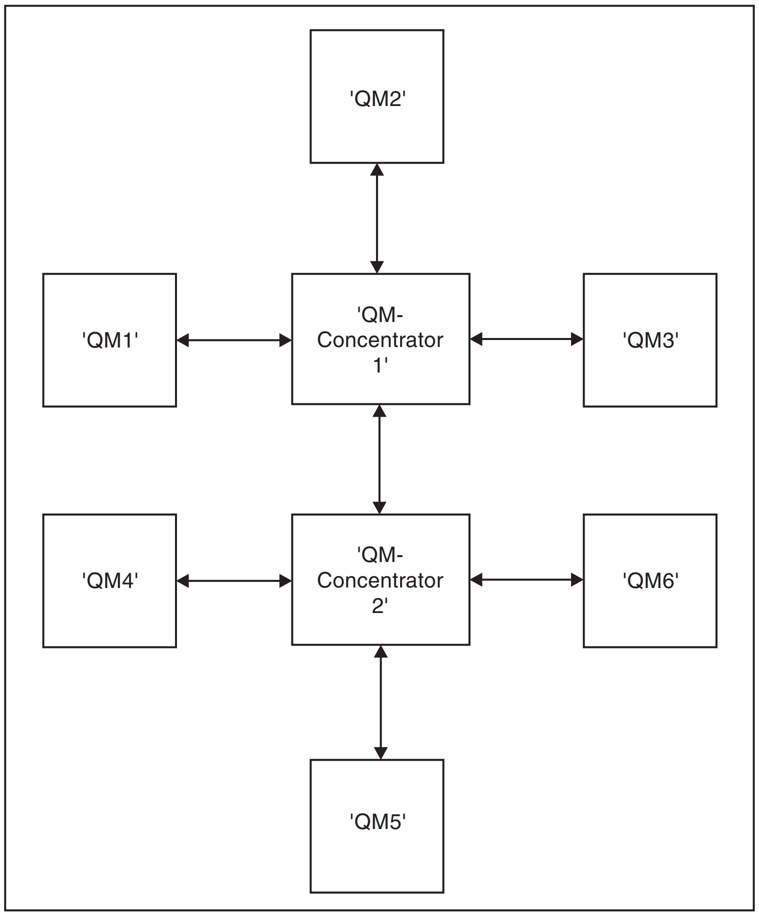

Figure 2. Network diagram showing QM-concentrators

Designing clusters

Clusters provide a mechanism for interconnecting queue managers in a way that simplifies both the initial configuration and the ongoing management. Clusters must be carefully designed, to ensure that they function correctly, and that they achieve the required levels of availability and responsiveness.

Before you begin

For an introduction to clustering concepts, see the following topics:
- Distributed queuing and clusters
- "Comparison of clustering and distributed queuing" on page 17
- Components of a cluster

When you are designing your queue manager cluster you have to make some decisions. You must first decide which queue managers in the cluster are to hold the full repositories of cluster information. Any queue manager you create can work in a cluster. You can choose any number of queue managers for this purpose but the ideal number is two. For information about selecting queue managers to hold the full repositories, see"How to choose cluster queue managers to hold full repositories" on page 19.

See the following topics for more information about designing your cluster:
- "Example clusters" on page 27
- "Organizing a cluster" on page 21
- "Cluster naming conventions" on page 22
- "Queue-sharing groups and clusters" on page 23
- "Overlapping clusters" on page 23

What to do next

See the following topics for more information about configuring and working with clusters:
- Establishing communication in a cluster
- Configuring a queue manager cluster
- Routing messages to and from clusters
- Using clusters for workload management

For more information to help you configure your cluster, see"Clustering tips" on page 24.

Planning how you use multiple cluster transmission queues:

You can explicitly define transmission queues, or have the system generate the transmission queues for you. If you define the transmission queues yourself, you have more control over the queue definitions. z/OS On z/OS, you also have more control over the page set where the messages are held.

Defining the transmission queues

There are two methods of defining transmission queues:
- Automatically, using the queue manager attribute DEFCLXQ, as follows:
  ```
  ALTER QMGR DEFCLXQ(SCTQ | CHANNEL)
  ```
  DEFCLXQ(SCTQ) indicates that the default transmission queue for all cluster-sender channels is SYSTEM.CLUSTER.TRANSMIT.QUEUE. This is the default value.

  DEFCLXQ(CHANNEL) indicates that by default each cluster-sender channel uses a separate transmission queue named SYSTEM.CLUSTER.TRANSMIT.*channel name*. Each transmission queue is automatically defined by the queue manager. See "Automatically-defined cluster transmission queues" on page 13 for more information.

- Manually, by defining a transmission queue with a value specified for the CLCHNAME attribute. The CLCHNAME attribute indicates which cluster-sender channels should use the transmission queue. See “Planning for manually-defined cluster transmission queues” on page 15for more information.

What security do I need?

To initiate a switch, either automatically or manually, you need authority to start a channel.

To define the queue used as a transmission queue, you need standard IBM MQ authority to define the queue.

When is a suitable time to implement the change?

When changing the transmission queue used by cluster-sender channels, you need to allocate a time in which to make the update, considering the following points:

- The time required for a channel to switch transmission queue depends on the total number of messages on the old transmission queue, how many messages need to be moved, and the size of the messages.
- Applications can continue to put messages to the transmission queue while the change is happening. This might lead to an increase in the transition time.
- You can change the CLCHNAME parameter of any transmission queue or DEFCLXQ at any time, preferably when the workload is low.

  Note that nothing happens immediately.
- Changes occur only when a channel starts or restarts. When a channel starts it checks the current configuration and switches to a new transmission queue if required.
- There are several changes that might alter the association of a cluster-sender channel with a transmission queue:
  - Altering the value of a transmission queue's CLCHNAME attribute, making CLCHNAME less specific or blank.
  - Altering the value of a transmission queue's CLCHNAME attribute, making CLCHNAME more specific.
  - Deleting a queue with CLCHNAME specified.
  - Altering the queue manager attribute DEFCLXQ.

How long will the switch take?

During the transition period, any messages for the channel are moved from one transmission queue to another. The time required for a channel to switch transmission queue depends on the total number of messages on the old transmission queue, and how many messages need to be moved.

For queues containing a few thousand messages, it should take under a second to move the messages. The actual time depends on the number and size of the messages. Your queue manager should be able to move messages at many megabytes each second.

Applications can continue to put messages to the transmission queue while the change is happening. This might lead to an increase in the transition time.

Each affected cluster-sender channel must be restarted for the change to take effect. Therefore, it is best to change the transmission queue configuration when the queue manager is not busy, and few messages are stored on the cluster transmission queues.

The **`runswchl`** command, z/OS or the SWITCH CHANNEL(*) STATUS command in CSQUTIL on z/OS, can be used to query the status of cluster-sender channels and what pending changes are outstanding to their transmission queue configuration.

How to implement the change

See Implementing the system using multiple cluster transmission queues for details on how you make the change to multiple cluster transmission queues, either automatically or manually.

Undoing the change

See Undoing a change for details on how you back out changes if you encounter problems.

Automatically-defined cluster transmission queues:

You can have the system generate the transmission queues for you.

About this task

If a channel does not have a manually defined cluster transmission queue that is associated with it, and you specify DEFCLXQ(CHANNEL), when the channel starts the queue manager automatically defines a permanent-dynamic queue for the cluster sender channel. This channel has the name `SYSTEM.CLUSTER.TRANSMIT.ChannelName`, and uses the model queue `SYSTEM.CLUSTER.TRANSMIT.MODEL`.

z/OS To set up the cluster transmission queues manually, see "Planning for manually-defined cluster transmission queues" on page 15.

Important: z/OS

If the queue manager is migrated to IBM MQ Version 8.0, the queue manager does not have the SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE.

Define this queue first, so that the command ALTER QGMR DEFCLXQ(CHANNEL) takes effect.

The following JCL is an example of the code you can use to define the model queue:

```
//CLUSMODL JOB MSGCLASS=H,NOTIFY=&SYSUID
/*JOBPARM SYSAFF=(MVCC)
//MQCMD EXEC PGM=CSQUTIL,REGION=4096K,PARM='CDLK'
//STEPLIB DD DISP=SHR,DSN=SCEN.MQ.V000.COM.BASE.SCSQAUTH
// DD DISP=SHR,DSN=SCEN.MQ.V000.COM.BASE.SCSQANLE
//SYSPRINT DD SYSOUT=*
//SYSIN DD *

Procedure

1. Use the *DEFCLXQ* queue manager attribute. For more information on this attribute, see ALTER QMGR.

   There are two options:

   SCTQ This option is the default, and means that you use the single SYSTEM.CLUSTER.TRANSMIT.QUEUE.

   CHANNEL
   Means that you use multiple cluster transmission queues.
2. To switch to the new association:
   - Stop and restart the channel.
   - The channel uses the new transmission queue definition.
   - Messages are transferred by a transitional switch process from the old queue to the new transmission queue.

   Note that any application messages are put to the old definition.

   When the number of messages on the old queue reaches zero, new messages are placed directly on the new transmission queue.
3. To monitor when the switching process finishes:
   a. A switch of transmission queue that is initiated by a channel runs in the background and your administrator can monitor the queue manager job log to determine when it has completed.
   b. Monitor messages on the job log to show the progress of the switch.
   c. To make sure that only the channels that you wanted are using this transmission queue, issue the command DIS CLUSQMGR(*) where, for example, the transmission queue property that defines the transmission queue is `APPQMGR.CLUSTER1.XMITQ`.
   d. z/OS Use the SWITCH CHANNEL (*) STATUS command under CSQUTIL. This option tells you what pending changes are outstanding, and how many messages need to be moved between transmission queues.

Results

You have set up your cluster transmission queue, or queues.

Related tasks:

"Planning for manually-defined cluster transmission queues"
If you define the transmission queues yourself you have more control over the definitions, and the page set on which the messages are held.

Related information:

ALTER QMGR

DISPLAY CLUSQMGR

Planning for manually-defined cluster transmission queues:

If you define the transmission queues yourself you have more control over the definitions, and the page set on which the messages are held.

About this task

Your administrator manually defines a transmission queue and uses a new queue attribute CLCHNAME to define which cluster sender channel, or channels, will use this queue as their transmission queue.

Note that CLCHNAME can include a wildcard character at the beginning, or end, to allow a single queue to be used for multiple channels.

To set up cluster transmission queues automatically, see "Automatically-defined cluster transmission queues" on page 13.

Procedure

1. For example, enter the following:
   ```
   DEFINE QLOCAL(APPQMGR.CLUSTER1.XMITQ)
   CLCHNAME(CLUSTER1.TO.APPQMGR)
   USAGE(XMITQ) STGCLASS(STG1)
   INDXTYPE( CORRELID ) SHARE

   DEFINE STGCLASS(STG1) PSID(3)
   DEFINE PSID(3) BUFFERPOOL(4)
   ```

   Tip: You need to plan which page set (and buffer pool) you use for your transmission queues. You can have different page sets for different queues, and provide isolation between them, so one page set filling up, does not impact transmission queues in other page sets.

   See Working with cluster transmission queues and cluster-sender channels for information on how each channel selects the appropriate queue.

   When the channel starts it switches its association to the new transmission queue. In order to make sure no message is lost, the queue manager automatically transfers messages from the old cluster transmission queue to the new transmission queue in order.
2. Use the CSQUTIL SWITCH function to change to the new association. See Switch the transmission queue associated with cluster-sender channels (SWITCH) for further information.
   a. STOP the channel, or channels, whose transmission queue is to be changed, so that they are in STOPPED status. For example:
      ```
      STOP CHANNEL(CLUSTER1.TO.APPQMGR)
      ```
   b. Change the `CLCHNAME(XXXX)` attribute on the transmission queue.
   c. Use the SWITCH function to switch the messages or monitor what is happening. Use the command
      ```
      SWITCH CHANNEL(*) MOVEMSGS(YES)
      ```

      to move the messages without starting the channel.

d. Start the channel, or channels, and check whether the channel is using the correct queues. For example:

```
DIS CHS(CLUSTER1.TO.APPQMGR)
DIS CHS(*) where(XMITQ eq APPQMGR.CLUSTER1.XMITQ)
```

Tip:

- The following process uses the CSQUTIL SWITCH function; for more information, see Switch the transmission queue associated with cluster-sender channels (SWITCH).

  You do not have to use this function but using this function gives more options:

  – Using SWITCH CHANNEL (*) STATUS provides an easy way to identify the switching status of cluster-sender channels. It allows your administrator to see what channels are currently switching, and those channels having a switch pending that take effect when those channels next start.

    Without this capability your administrator needs to use multiple DISPLAY commands, and then process the resulting output to ascertain this information. Your administrator can also confirm that a configuration change has the required result.

  – If CSQUTIL is used to initiate the switch, CSQUTIL continues to monitor the progress of this operation, and only ends when the switch has completed.

    This can make it much easier to perform these operations in batch. Also, if CSQUTIL is run to switch multiple channels, CSQUTIL performs these actions sequentially; this can have less impact for your enterprise than multiple switches running in parallel.

Results

You have set up your cluster transmission queue, or queues.

Access control and multiple cluster transmission queues:

Choose between three modes of checking when an application puts messages to remote cluster queues. The modes are checking remotely against the cluster queue, checking locally against `SYSTEM.CLUSTER.TRANSMIT.QUEUE`, or checking against local profiles for the cluster queue, or cluster queue manager.

IBM MQ gives you the choice of checking locally, or locally and remotely, that a user has permission to put a message to a remote queue. A typical IBM MQ application uses local checking only, and relies on the remote queue manager trusting the access checks made on the local queue manager. If remote checking is not used, the message is put to the target queue with the authority of the remote message channel process. To use remote checking you must set the put authority of the receiving channel to context security.

The local checks are made against the queue that the application opens. In distributed queuing, the application usually opens a remote queue definition, and access checks are made against the remote queue definition. If the message is put with a full routing header, the checks are made against the transmission queue. If an application opens a cluster queue that is not on the local queue manager, there is no local object to check. The access control checks are made against the cluster transmission queue, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. Even with multiple cluster transmission queues, from Version 7.5, local access control checks for remote cluster queues are made against `SYSTEM.CLUSTER.TRANSMIT.QUEUE`.

The choice of local or remote checking is a choice between two extremes. Checking remotely is fine-grained. Every user must have an access control profile on every queue manager in the cluster to put to any cluster queue. Checking locally is coarse-grained. Every user needs only one access control profile for the cluster transmission queue on the queue manager they are connected to. With that profile, they can put a message to any cluster queue on any queue manager in any cluster.

Since Version 7.1, administrators have another way to set up access control for cluster queues. You can create a security profile for a cluster queue on any queue manager in the cluster using the **setmqaut** command. The profile takes affect if you open a remote cluster queue locally, specifying only the queue name. You can also set up a profile for a remote queue manager. If you do so, the queue manager can check the profile of a user that opens a cluster queue by providing a fully qualified name.

The new profiles work only if you change the queue manager stanza, **ClusterQueueAccessControl** to RQMName. The default is Xmitq. You must create profiles for all the cluster queues existing applications use cluster queues. If you change the stanza to RQMName without creating profiles the applications are likely to fail.

Tip: The changes made to cluster queue accessing checking in Version 7.1 do not apply to remote queuing. Access checks are still made against local definitions. The changes mean that you can follow the same approach to configure access checking on cluster queues and cluster topics. z/OS The changes also align the access checking approach for cluster queues more closely with z/OS. The commands to set up access checking on z/OS are different, but both check access against a profile rather than against the object itself.

Setting ClusterQueueAccessControl

Comparison of clustering and distributed queuing:

Compare the components that need to be defined to connect queue managers using distributed queuing and clustering.

If you do not use clusters, your queue managers are independent and communicate using distributed queuing. If one queue manager needs to send messages to another, you must define:

- A transmission queue
- A channel to the remote queue manager

Figure 3 shows the components required for distributed queuing.

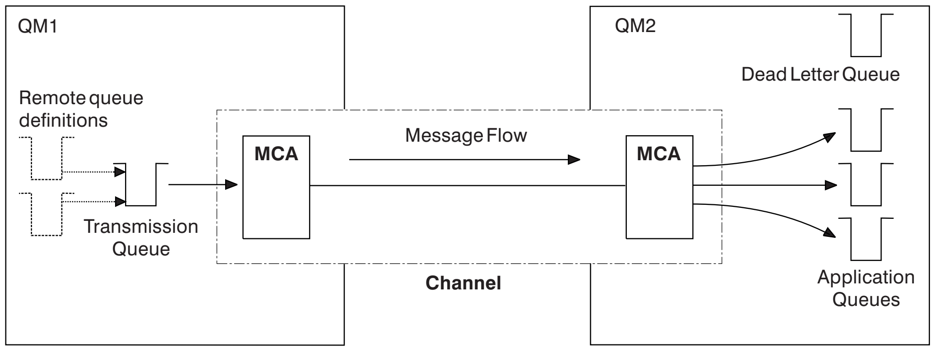

Figure 3. Distributed queuing

If you group queue managers in a cluster, queues on any queue manager are available to any other queue manager in the cluster. Any queue manager can send a message to any other queue manager in the same cluster without explicit definitions. You do not provide channel definitions, remote-queue definitions, or transmission queues for each destination. Every queue manager in a cluster has a single transmission queue from which it can transmit messages to any other queue manager in the cluster. Each queue manager in a cluster needs to define only:

- One cluster-receiver channel on which to receive messages

- One cluster-sender channel with which it introduces itself and learns about the cluster

Definitions to set up a cluster versus distributed queuing

Look at Figure 4, which shows four queue managers each with two queues. Consider how many definitions are needed to connect these queue managers using distributed queuing. Compare how many definitions are needed to set up the same network as a cluster.

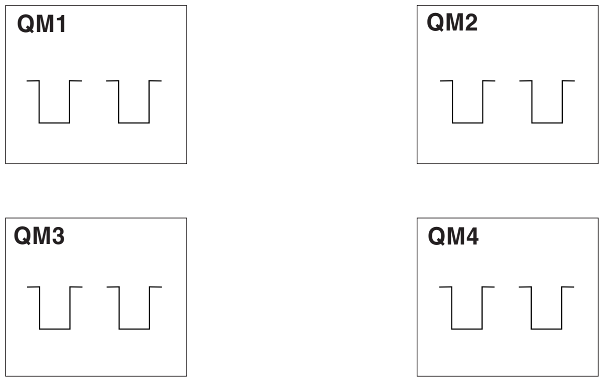

Figure 4. A network of four queue managers

Definitions to set up a network using distributed queuing

To set up the network shown in Figure 3 on page 17 using distributed queuing, you might have the following definitions:

Table 2. Definitions for distributed queuing

Description	Number per queue manager	Total number
A sender-channel definition for a channel on which to send messages to every other queue manager	3	12
A receiver-channel definition for a channel on which to receive messages from every other queue manager	3	12
A transmission-queue definition for a transmission queue to every other queue manager	3	12
A local-queue definition for each local queue	2	8
A remote-queue definition for each remote queue to which this queue manager wants to put messages	6	24

You might reduce this number of definitions by using generic receiver-channel definitions. The maximum number of definitions could be as many as 17 on each queue manager, which is a total of 68 for this network.

Definitions to set up a network using clusters

To set up the network shown in Figure 3 on page 17 using clusters you need the following definitions:

Table 3. Definitions for clustering

Description	Number per queue manager	Total number
A cluster-sender channel definition for a channel on which to send messages to a repository queue manager	1	4
A cluster-receiver channel definition for a channel on which to receive messages from other queue managers in the cluster	1	4
A local-queue definition for each local queue	2	8

To set up this cluster of queue managers (with two full repositories), you need four definitions on each queue manager, a total of sixteen definitions altogether. You also need to alter the queue manager definitions for two of the queue managers, to make them full repository queue managers for the cluster.

Only one CLUSSDR and one CLUSRCVR channel definition is required. When the cluster is defined, you can add or remove queue managers (other than the repository queue managers) without any disruption to the other queue managers.

Using a cluster reduces the number of definitions required to set up a network containing many queue managers.

With fewer definitions to make there is less risk of error:
- Object names always match, for example the channel name in a sender-receiver pair.
- The transmission queue name specified in a channel definition always matches the correct transmission queue definition or the transmission queue name specified in a remote queue definition.
- A QREMOTE definition always points to the correct queue at the remote queue manager.

Once a cluster is set up, you can move cluster queues from one queue manager to another within the cluster without having to do any system management work on any other queue manager. There is no chance of forgetting to delete or modify channel, remote-queue, or transmission-queue definitions. You can add new queue managers to a cluster without any disruption to the existing network.

How to choose cluster queue managers to hold full repositories:

In each cluster you must choose at least one, and preferably two queue managers to hold full repositories. Two full repositories are sufficient for all but the most exceptional circumstances. If possible, choose queue managers that are hosted on robust and permanently-connected platforms, that do not have coinciding outages, and that are in a central position geographically. Also consider dedicating systems as full repository hosts, and not using these systems for any other tasks.

Full repositories are queue managers that maintain a complete picture of the state of the cluster. To share this information, each full repository is connected by CLUSSDR channels (and their corresponding CLUSRCVR definitions) to every other full repository in the cluster. You must manually define these channels.

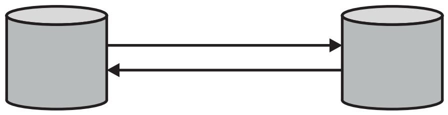

Figure 5. Two connected full repositories.

Every other queue manager in the cluster maintains a picture of what it currently knows about the state of the cluster in a *partial repository*. These queue managers publish information about themselves, and request information about other queue managers, using any two available full repositories. If a chosen full repository is not available, another is used. When the chosen full repository becomes available again, it collects the latest new and changed information from the others so that they keep in step. If all the full repositories go out of service, the other queue managers use the information they have in their partial repositories. However, they are limited to using the information that they have; new information and requests for updates cannot be processed. When the full repositories reconnect to the network, messages are exchanged to bring all repositories (both full and partial) up to date.

When planning the allocation of full repositories, include the following considerations:

- The queue managers chosen to hold full repositories need to be reliable and managed. Choose queue managers that are hosted on a robust and permanently-connected platform.
- Consider the planned outages for the systems hosting your full repositories, and ensure that they do not have coinciding outages.
- Consider network performance: Choose queue managers that are in a central position geographically, or that share the same system as other queue managers in the cluster.
- Consider whether a queue manager is a member of more than one cluster. It can be administratively convenient to use the same queue manager to host the full repositories for several clusters, provided this benefit is balanced against how busy you expect the queue manager to be.
- Consider dedicating some systems to contain only full repositories, and not using these systems for any other tasks. This ensures that these systems only require maintenance for queue manager configuration, and are not removed from service for the maintenance of other business applications. It also ensures that the task of maintaining the repository does not compete with applications for system resources. This can be particularly beneficial in large clusters (say, clusters of more than a thousand queue managers), where full repositories have a much higher workload in maintaining the cluster state.

Having more than two full repositories is possible, but rarely recommended. Although object definitions (that is, queues, topics and channels) flow to all available full repositories, requests only flow from a partial repository to a maximum of two full repositories. This means that, when more than two full repositories are defined, and any two full repositories become unavailable, some partial repositories might not receive updates they would expect. See WMQ Clusters: Why only two Full Repositories?

One situation in which you might find it useful to define more than two full repositories is when migrating existing full repositories to new hardware or new queue managers. In this case, you should introduce the replacement full repositories, and confirm that they have become fully populated, before you remove the previous full repositories. Whenever you add a full repository, remember that you must directly connect it to every other full repository with `CLUSSDR` channels.

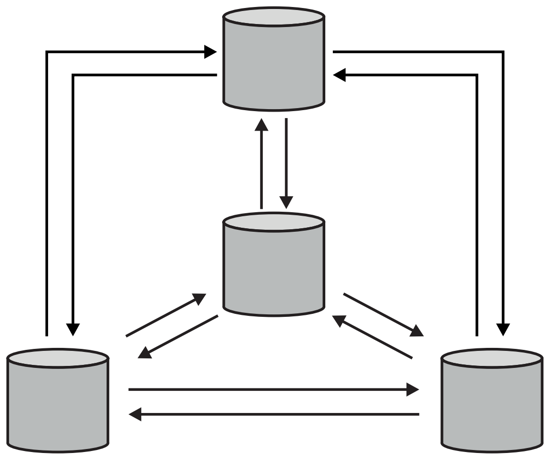

Figure 6. More than two connected full repositories

Related information:

WMQ Clusters: Why only two Full Repositories?

How big can a WMQ Cluster be?

Organizing a cluster:

Select which queue managers to link to which full repository. Consider the performance effect, the queue manager version, and whether multiple CLUSSDR channels are desirable.

Having selected the queue managers to hold full repositories, you need to decide which queue managers to link to which full repository. The CLUSSDR channel definition links a queue manager to a full repository from which it finds out about the other full repositories in the cluster. From then on, the queue manager sends messages to any two full repositories. It always tries to use the one to which it has a CLUSSDR channel definition first. You can choose to link a queue manager to either full repository. In choosing, consider the topology of your configuration, and the physical or geographical location of the queue managers.

z/OS Queue managers on IBM MQ z/OS Version 6.0 or later support PCF commands. The IBM MQ Explorer can use them to query information about the cluster (in just the same way as with distributed queue managers).

z/OS z/OS queue managers up to IBM MQ v5.3.1 do not support PCF commands. The IBM MQ Explorer cannot use them to query information about the cluster. For this reason, the IBM MQ Explorer does not allow you to select IBM MQ v5.3.1 z/OS queue managers at the source of the information about a cluster.

Because all cluster information is sent to two full repositories, there might be situations in which you want to make a second CLUSSDR channel definition. You might define a second CLUSSDR channel in a cluster that has many full repositories spread over a wide area. You can then control which two full repositories your information is sent to.

Cluster naming conventions:

Consider naming queue managers in the same cluster using a naming convention that identifies the cluster to which the queue manager belongs. Use a similar naming convention for channel names and extend it to describe the channel characteristics. z/OS Do not use a generic connection in defining cluster-receiver channels on z/OS.

This information contains the old guidance on naming conventions, and the current guidance. As the IBM MQ technology improves, and as customers use technology in new or different ways, new recommendations and information must be provided for these scenarios.

Cluster naming conventions: Old best practices

When setting up a new cluster, consider a naming convention for the queue managers. Every queue manager must have a different name. If you give queue managers in a cluster a set of similar names, it might help you to remember which queue managers are grouped where.

When defining channels, remember that all cluster-sender channels have the same name as their corresponding cluster-receiver channel. Channel names are limited to a maximum of 20 characters.

Every cluster-receiver channel must also have a unique name. One possibility is to use the queue manager name preceded by the cluster name. For example, if the cluster name is `CLUSTER1` and the queue managers are `QM1`, `QM2`, then cluster-receiver channels are `CLUSTER1.QM1`, `CLUSTER1.QM2`.

You might extend this convention if channels have different priorities or use different protocols; for example, `CLUSTER1.QM1.S1`, `CLUSTER1.QM1.N3`, and `CLUSTER1.QM1.T4`. In this example, `S1` might be the first SNA channel, `N3` might be the NetBIOS channel with a network priority of three.

A final qualifier might describe the class of service the channel provides.

z/OS In IBM MQ for z/OS, you can define VTAM generic resources or *Dynamic Domain Name Server* (DDNS) generic names. You can define connection names using generic names. However, when you create a cluster-receiver definition, do not use a generic connection name.

The problem with using generic connection names for cluster-receiver definitions is as follows. If you define a `CLUSRCVR` with a generic `CONNAME` there is no guarantee that your `CLUSSDR` channels point to the queue managers you intend. Your initial `CLUSSDR` might end up pointing to any queue manager in the queue-sharing group, not necessarily one that hosts a full repository. If a channel starts trying a connection again, it might reconnect to a different queue manager with the same generic name disrupting the flow of messages.

Cluster naming conventions: Current best practices

A good naming convention can help to reduce confusion over ownership and scope of clusters. A clear naming convention throughout the cluster topology causes a lot less confusion if clusters get merged at a later time. This situation is also improved if everyone involved is clear about who owns which queue managers and which clusters. Probably the most important point for cluster naming conventions is to put the queue manager name in the channel name, see the following example:

```
CLUSNAME.QMGRNAME
```

This convention might not be obvious to experienced IBM MQ users that are unfamiliar with clusters. This oversight is because the `XXX.TO.YYY` format is such a common method. For example, `CLUSTER.TO.XX` or `CLUSTER.X` are commonly used formats that are not recommended for clustering, as they can quickly reach the 20 character limit. The commonly used `CLUSTER.TO.XX` format becomes confusing if another channel is added later (for example when joining another cluster).

Other objects also benefit from sensible rules, such as: `LOB.PROJECT.QNAME` or `LOB.CLUSTER.ALIAS.NAME`.

Queue-sharing groups and clusters:

Shared queues can be cluster queues and queue managers in a queue-sharing group can also be cluster queue managers.

z/OS On IBM MQ for z/OS you can group queue managers into queue-sharing groups. A queue manager in a queue-sharing group can define a local queue that is to be shared by up to 32 queue managers.

Shared queues can also be cluster queues. Furthermore, the queue managers in a queue-sharing group can also be in one or more clusters.

z/OS In IBM MQ for z/OS, you can define VTAM generic resources or *Dynamic Domain Name Server* (DDNS) generic names. You can define connection names using generic names. However, when you create a cluster-receiver definition, do not use a generic connection name.

z/OS The problem with using generic connection names for cluster-receiver definitions is as follows. If you define a `CLUSRCVR` with a generic `CONNAME` there is no guarantee that your `CLUSSDR` channels point to the queue managers you intend. Your initial `CLUSSDR` might end up pointing to any queue manager in the queue-sharing group, not necessarily one that hosts a full repository. If a channel starts trying a connection again, it might reconnect to a different queue manager with the same generic name disrupting the flow of messages.

Overlapping clusters:

Overlapping clusters provide additional administrative capabilities. Use namelists to reduce the number of commands needed to administer overlapping clusters.

You can create clusters that overlap. There are a number of reasons you might define overlapping clusters; for example:
- To allow different organizations to have their own administration.
- To allow independent applications to be administered separately.
- To create classes of service.

In Figure 7 on page 24, the queue manager `STF2` is a member of both the clusters. When a queue manager is a member of more than one cluster, you can take advantage of namelists to reduce the number of definitions you need. Namelists contain a list of names, for example, cluster names. You can create a namelist naming the clusters. Specify the namelist on the `ALTER QMGR` command for `STF2` to make it a full repository queue manager for both clusters.

If you have more than one cluster in your network, you must give them different names. If two clusters with the same name are ever merged, it is not possible to separate them again. It is also a good idea to give the clusters and channels different names. They are more easily distinguished when you look at the output from the `DISPLAY` commands. Queue manager names must be unique within a cluster for it to work correctly.

Defining classes of service

Imagine a university that has a queue manager for each member of staff and each student. Messages between members of staff are to travel on channels with a high priority and high bandwidth. Messages between students are to travel on cheaper, slower channels. You can set up this network using traditional distributed queuing techniques. IBM MQ selects which channels to use by looking at the destination queue name and queue manager name.

To clearly differentiate between the staff and students, you could group their queue managers into two clusters as shown in Figure 7. IBM MQ moves messages to the meetings queue in the staff cluster only over channels that are defined in that cluster. Messages for the gossip queue in the students cluster go over channels defined in that cluster and receive the appropriate class of service.

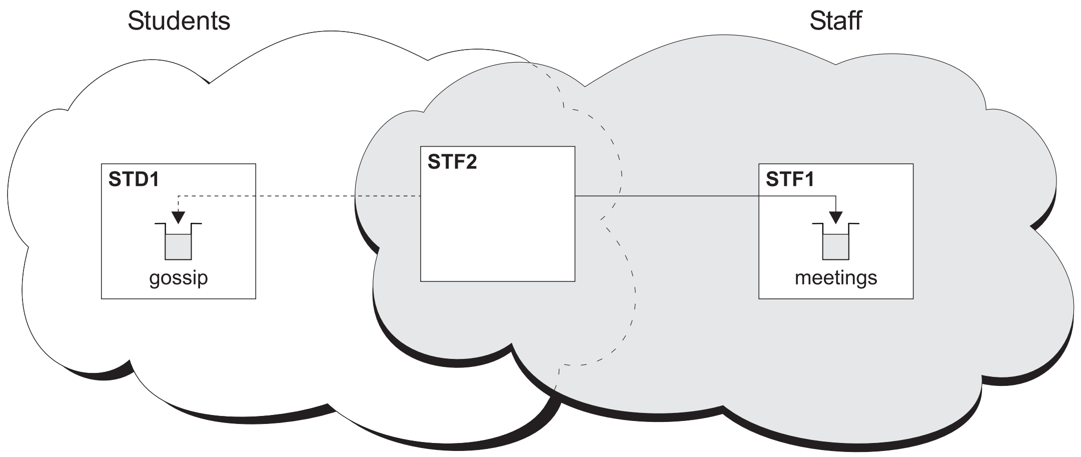

Figure 7. Classes of service

Clustering tips:

You might need to make some changes to your systems or applications before using clustering. There are both similarities and differences from the behavior of distributed queuing.

- z/OS The IBM MQ Explorer cannot directly administer IBM MQ for z/OS queue managers at versions earlier than Version 6.0.
- You must add manual configuration definitions to queue managers outside a cluster for them to access cluster queues.
- If you merge two clusters with the same name, you cannot separate them again. Therefore it is advisable to give all clusters a unique name.
- If a message arrives at a queue manager but there is no queue there to receive it, the message is put on the dead-letter queue. If there is no dead-letter queue, the channel fails and tries again. The use of the dead-letter queue is the same as with distributed queuing.
- The integrity of persistent messages is maintained. Messages are not duplicated or lost as a result of using clusters.
- Using clusters reduces system administration. Clusters make it easy to connect larger networks with many more queue managers than you would be able to contemplate using distributed queuing. There is a risk that you might consume excessive network resources if you attempt to enable communication between every queue manager in a cluster.
- If you use the IBM MQ Explorer, which presents the queue managers in a tree structure, the view for large clusters might be cumbersome.
- z/OS IBM MQ Explorer can administer a cluster with repository queue managers on IBM MQ for z/OS Version 6 or later. You need not nominate an additional repository on a separate system. For earlier versions of IBM MQ on z/OS, the IBM MQ Explorer cannot administer a cluster with repository queue managers. You must nominate an additional repository on a system that the IBM MQ Explorer can administer.

- Multi The purpose of distribution lists is to use a single MQPUT command to send the same message to multiple destinations. Distribution lists are supported on IBM MQ for Multiplatforms. You can use distribution lists with queue manager clusters. In a cluster, all the messages are expanded at MQPUT time. The advantage, in terms of network traffic, is not so great as in a non-clustering environment. The advantage of distribution lists is that the numerous channels and transmission queues do not need to be defined manually.
- If you are going to use clusters to balance your workload examine your applications. See whether they require messages to be processed by a particular queue manager or in a particular sequence. Such applications are said to have message affinities. You might need to modify your applications before you can use them in complex clusters.
- You might choose to use the `MQOO_BIND_ON_OPEN` option on an MQOPEN to force messages to be sent to a specific destination. If the destination queue manager is not available the messages are not delivered until the queue manager becomes available again. Messages are not routed to another queue manager because of the risk of duplication.
- If a queue manager is to host a cluster repository, you need to know its host name or IP address. You have to specify this information in the `CONNAME` parameter when you make the `CLUSSDR` definition on other queue managers joining the cluster. If you use DHCP, the IP address is subject to change because DHCP can allocate a new IP address each time you restart a system. Therefore, you must not specify the IP address in the `CLUSSDR` definitions. Even if all the `CLUSSDR` definitions specify the host name rather than the IP address, the definitions would still not be reliable. DHCP does not necessarily update the DNS directory entry for the host with the new address. If you must nominate queue managers as full repositories on systems that use DHCP, install software that guarantees to keep your DNS directory up to date.
- Do not use generic names, for example VTAM generic resources or Dynamic Domain Name Server (DDNS) generic names as the connection names for your channels. If you do, your channels might connect to a different queue manager than expected.
- You can only get a message from a local cluster queue, but you can put a message to any queue in a cluster. If you open a queue to use the MQGET command, the queue manager opens the local queue.
- You do not need to alter any of your applications if you set up a simple IBM MQ cluster. The application can name the target queue on the MQOPEN call and does not need to know about the location of the queue manager. If you set up a cluster for workload management you must review your applications and modify them as necessary.
- You can view current monitoring and status data for a channel or queue using the `DISPLAY CHSTATUS` and the `DISPLAY QSTATUS` **`runmqsc`** commands. The monitoring information can be used to help gauge the performance and health of the system. Monitoring is controlled by queue manager, queue, and channel attributes. Monitoring of auto-defined cluster-sender channels is possible with the `MONACLS` queue manager attribute.

How long do the queue manager repositories retain information?:

Queue manager repositories retain information for 30 days. An automatic process efficiently refreshes information that is being used.

When a queue manager sends out some information about itself, the full and partial repository queue managers store the information for 30 days. Information is sent out, for example, when a queue manager advertises the creation of a new queue. To prevent this information from expiring, queue managers automatically resend all information about themselves after 27 days. If a partial repository sends a new request for information part way through the 30 day lifetime, the expiry time remains the original 30 days.

When information expires, it is not immediately removed from the repository. Instead it is held for a grace period of 60 days. If no update is received within the grace period, the information is removed. The grace period allows for the fact that a queue manager might have been temporarily out of service at the expiry date. If a queue manager becomes disconnected from a cluster for more than 90 days, it stops being part of the cluster. However, if it reconnects to the network it becomes part of the cluster again. Full repositories do not use information that has expired to satisfy new requests from other queue managers.

Similarly, when a queue manager sends a request for up-to-date information from a full repository, the request lasts for 30 days. After 27 days IBM MQ checks the request. If it has been referenced during the 27 days, it is refreshed automatically. If not, it is left to expire and is refreshed by the queue manager if it is needed again. Expiring requests prevents a buildup of requests for information from dormant queue managers.

Note: For large clusters, it can be disruptive if many queue managers automatically resend all information about themselves at the same time. See Refreshing in a large cluster can affect performance and availability of the cluster.

Related information:
Clustering: Using REFRESH CLUSTER best practices

Example clusters:

The first example shows the smallest possible cluster of two queue managers. The second and third examples show two versions of a three queue manager cluster.

The smallest possible cluster contains only two queue managers. In this case both queue managers contain full repositories. You need only a few definitions to set up the cluster, and yet there is a high degree of autonomy at each queue manager.

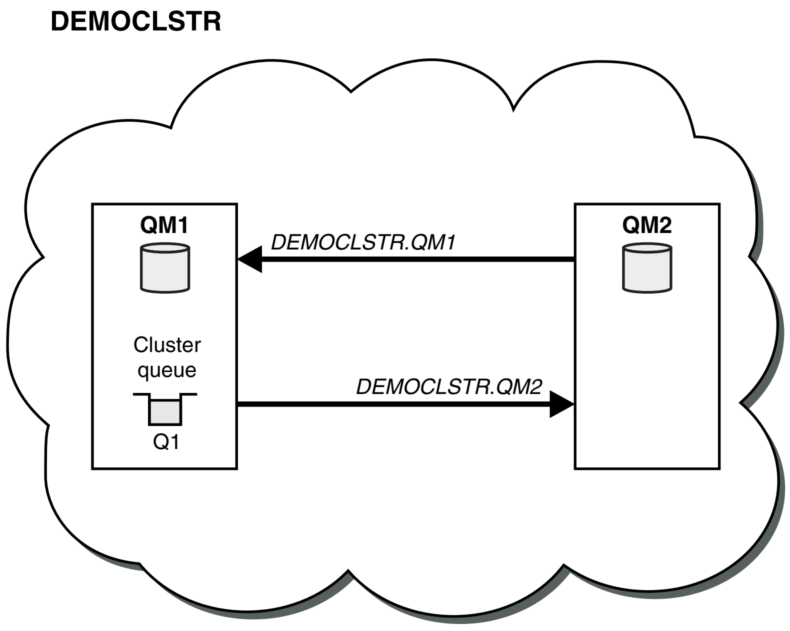

Figure 8. A small cluster of two queue managers

- The queue managers can have long names such as `LONDON` and `NEWYORK`. z/OS On IBM MQ for z/OS, queue manager names are limited to four characters.
- Each queue manager is typically configured on a separate machine. However, you can have multiple queue managers on the same machine.

For instructions on setting up a similar example cluster, see Setting up a new cluster.

Figure 9 on page 28 shows the components of a cluster called `CLSTR1`.
- In this cluster, there are three queue managers, `QM1`, `QM2`, and `QM3`.
- `QM1` and `QM2` host repositories of information about all the queue managers and cluster-related objects in the cluster. They are referred to as *full repository queue managers*. The repositories are represented in the diagram by the shaded cylinders.
- `QM2` and `QM3` host some queues that are accessible to any other queue manager in the cluster. Queues that are accessible to any other queue manager in the cluster are called *cluster queues*. The cluster queues are represented in the diagram by the shaded queues. Cluster queues are accessible from anywhere in the cluster. IBM MQ clustering code ensures that remote queue definitions for cluster queues are created on any queue manager that refers to them.

As with distributed queuing, an application uses the MQPUT call to put a message on a cluster queue at any queue manager in the cluster. An application uses the MQGET call to retrieve messages from a cluster queue only on the queue manager where the queue resides.

- Each queue manager has a manually created definition for the receiving end of a channel called *cluster_name*. *queue_manager_name* on which it can receive messages. On the receiving queue manager, *cluster_name*. *queue_manager_name* is a cluster-receiver channel. A cluster-receiver channel is like a receiver channel used in distributed queuing; it receives messages for the queue manager. In addition, it also receives information about the cluster.
-

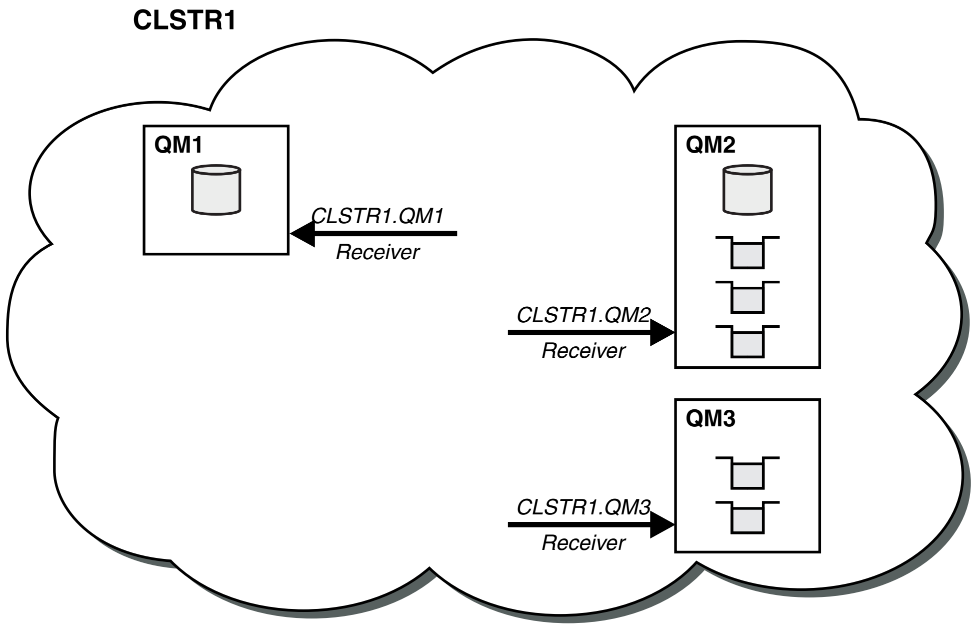

Figure 9. A cluster of queue managers

- In Figure 10 on page 29 each queue manager also has a definition for the sending end of a channel. It connects to the cluster-receiver channel of one of the full repository queue managers. On the sending queue manager, *cluster_name*. *queue_manager_name* is a cluster-sender channel. QM1 and QM3 have cluster-sender channels connecting to CLSTR1.QM2, see dotted line "2".

  QM2 has a cluster-sender channel connecting to CLSTR1.QM1, see dotted line "3". A cluster-sender channel is like a sender-channel used in distributed queuing; it sends messages to the receiving queue manager. In addition, it also sends information about the cluster.

  Once both the cluster-receiver end and the cluster-sender end of a channel are defined, the channel starts automatically.

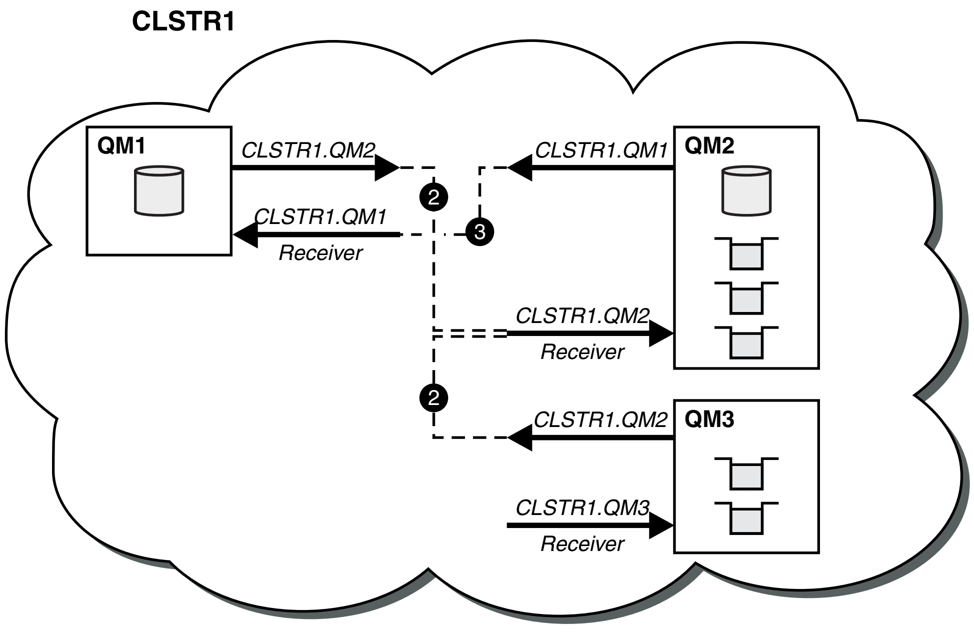

Figure 10. A cluster of queue managers with sender channels

Defining a cluster-sender channel on the local queue manager introduces that queue manager to one of the full repository queue managers. The full repository queue manager updates the information in its full repository accordingly. Then it automatically creates a cluster-sender channel back to the original queue manager, and sends that queue manager information about the cluster. Thus a queue manager learns about a cluster and a cluster learns about a queue manager.

Look again at Figure 9 on page 28. Suppose that an application connected to queue manager `QM3` wants to send some messages to the queues at `QM2`. The first time that `QM3` must access those queues, it discovers them by consulting a full repository. The full repository in this case is `QM2`, which is accessed using the sender channel `CLSTR1.QM2`. With the information from the repository, it can automatically create remote definitions for those queues. If the queues are on `QM1`, this mechanism still works, because `QM2` is a full repository. A full repository has a complete record of all the objects in the cluster. In this latter case, `QM3` would also automatically create a cluster-sender channel corresponding to the cluster-receiver channel on `QM1`, allowing direct communication between the two.

Figure 11 on page 30 shows the same cluster, with the two cluster-sender channels that were created automatically. The cluster-sender channels are represented by the two dashed lines that join with the cluster-receiver channel `CLSTR1.QM3`. It also shows the cluster transmission queue, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`, which `QM1` uses to send its messages. All queue managers in the cluster have a cluster transmission queue, from which they can send messages to any other queue manager in the same cluster.

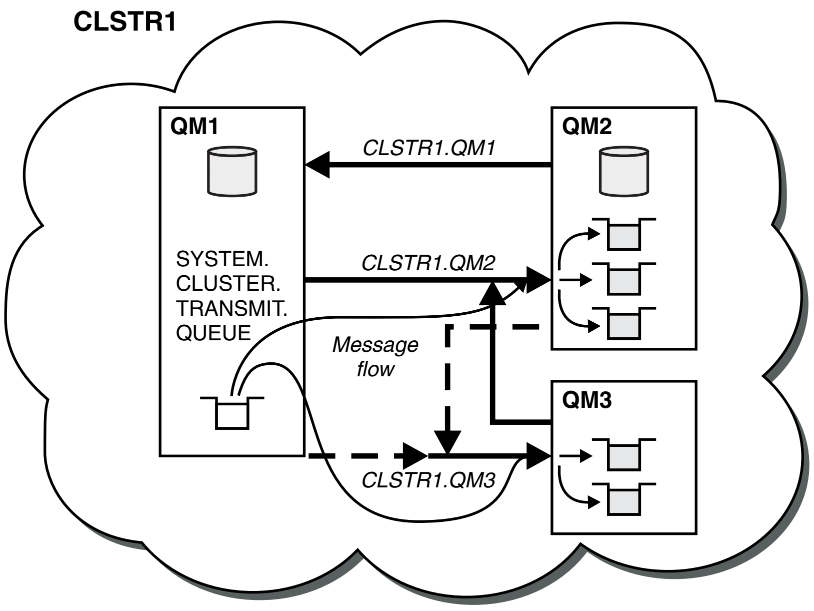

Figure 11. A cluster of queue managers, showing auto-defined channels

Note: Other diagrams show only the receiving ends of channels for which you make manual definitions. The sending ends are omitted because they are mostly defined automatically when needed. The auto-definition of most cluster-sender channels is crucial to the function and efficiency of clusters.

Setting up a new cluster

Clustering: Best practices:

Clusters provide a mechanism for interconnecting queue managers. The best practices described in this section are based on testing and feedback from customers.

A successful cluster setup is dependent on good planning and a thorough understanding of IBM MQ fundamentals, such as good application management and network design. Ensure that you are familiar with the information in the related topics before continuing.

Related tasks:

"Designing clusters" on page 11
Clusters provide a mechanism for interconnecting queue managers in a way that simplifies both the initial configuration and the ongoing management. Clusters must be carefully designed, to ensure that they function correctly, and that they achieve the required levels of availability and responsiveness.

- "Cluster naming conventions" on page 32

Cluster ownership

Familiarize yourself with overlapping clusters before reading the following information. See "Overlapping clusters" on page 23 and Configuring message paths between clusters for the necessary information.

When configuring and managing a system that consists of overlapping clusters, it is best to adhere to the following:
- Although IBM MQ clusters are 'loosely coupled' as previously described, it is useful to consider a cluster as a single unit of administration. This concept is used because the interaction between definitions on individual queue managers is critical to the smooth functioning of the cluster. For example: When using workload balanced cluster queues it is important that a single administrator or team understand the full set of possible destinations for messages, which depends on definitions spread throughout the cluster. More trivially, cluster sender/receiver channel pairs must be compatible throughout.
- Considering this previous concept; where multiple clusters meet (which are to be administered by separate teams / individuals), it is important to have clear policies in place controlling administration of the gateway queue managers.
- It is useful to treat overlapping clusters as a single namespace: Channel names and queue manager names must be unique throughout a single cluster. Administration is much easier when unique throughout the entire topology. It is best to follow a suitable naming convention, possible conventions are described in "Cluster naming conventions" on page 32.
- Sometimes administrative and system management cooperation is essential/unavoidable: For example, cooperation between organizations that own different clusters that need to overlap. A clear understanding of who owns what, and enforceable rules/conventions helps clustering run smoothly when overlapping clusters.

Overlapping clusters: Gateways

In general, a single cluster is easier to administer than multiple clusters. Therefore creating large numbers of small clusters (one for every application for example) is something to be avoided generally.

However, to provide classes of service, you can implement overlapping clusters. For example:
- Concentric clusters where the smaller one is for Publish/Subscribe. See How to size systems: for more information.

- Some queue managers are to be administered by different teams (see "Cluster ownership" on page 31).
- If it makes sense from an organizational or geographical point of view.
- Equivalent clusters to work with name resolution, as when implementing TLS in an existing cluster.

There is no security benefit from overlapping clusters; allowing clusters administered by two different teams to overlap, effectively joins the teams as well as the topology. Any:
- Name advertised in such a cluster is accessible to the other cluster.
- Name advertised in one cluster can be advertised in the other to draw off eligible messages.
- Non-advertised object on a queue manager adjacent to the gateway can be resolved from any clusters of which the gateway is a member.

The namespace is the union of both clusters and must be treated as a single namespace. Therefore, ownership of an overlapping cluster is shared amongst all the administrators of both clusters.

When a system contains multiple clusters, there might be a requirement to route messages from queue managers in one cluster to queues on queue managers in another cluster. In this situation, the multiple clusters must be interconnected in some way: A good pattern to follow is the use of gateway queue managers between clusters. This arrangement avoids building up a difficult-to-manage mesh of point-to-point channels, and provides a good place to manage such issues as security policies. There are two distinct ways of achieving this arrangement:
1. Place one (or more) queue managers in both clusters using a second cluster receiver definition. This arrangement involves fewer administrative definitions but, as previously stated, means that ownership of an overlapping cluster is shared amongst all the administrators of both clusters.
2. Pair a queue manager in cluster one with a queue manager in cluster teo using traditional point-to-point channels.

In either of these cases, various tools can be used to route traffic appropriately. In particular, queue or queue manager aliases can be used to route into the other cluster, and a queue manager alias with blank **RQMNAME** property re-drives workload balancing where it is wanted.

Cluster naming conventions

This information contains the previous guidance on naming conventions, and the current guidance. As the IBM MQ technology improves, and as customers use technology in new or different ways, new recommendations and information must be provided for these scenarios.

Cluster naming conventions: Previous guidance

When setting up a new cluster, consider a naming convention for the queue managers. Every queue manager must have a different name, but it might help you to remember which queue managers are grouped where if you give them a set of similar names.

Every cluster-receiver channel must also have a unique name.

If you have more than one channel to the same queue manager, each with different priorities or using different protocols, you might extend the names to include the different protocols; for example `QM1.S1`, `QM1.N3`, and `QM1.T4`. In this example, `S1` might be the first SNA channel, `N3` might be the NetBIOS channel with a network priority of 3.

The final qualifier might describe the class of service the channel provides. For more information, see Defining classes of service.

Remember that all cluster-sender channels have the same name as their corresponding cluster-receiver channel.

Do not use generic connection names on your cluster-receiver definitions. In IBM MQ for z/OS, you can define VTAM generic resources or *Dynamic Domain Name Server* (DDNS) generic names, but do not do this if you are using clusters. If you define a CLUSRCVR with a generic **CONNAME**, there is no guarantee that your CLUSSDR channels point to the queue managers that you intend. Your initial CLUSSDR might end up pointing to any queue manager in the queue-sharing group, not necessarily one that hosts a full repository. Furthermore, if a channel goes to retry status, it might reconnect to a different queue manager with the same generic name and the flow of your messages is disrupted.

Cluster naming conventions: Current guidance

The previous guidance in the section, "Cluster naming conventions: Previous guidance" on page 32, is still valid. However the following guidance is intended as an update when designing new clusters. This updated suggestion ensures uniqueness of channels across multiple clusters, allowing multiple clusters to be successfully overlapped. Because queue managers and clusters can have names of up to 48 characters, and a channel name is limited to 20 characters, care must be taken when naming objects from the beginning to avoid having to change the naming convention midway through a project.

When setting up a new cluster, consider a naming convention for the queue managers. Every queue manager must have a different name. If you give queue managers in a cluster a set of similar names, it might help you to remember which queue managers are grouped where.

When defining channels, remember that all automatically created cluster-sender channels on any queue manager in the cluster have the same name as their corresponding cluster-receiver channel configured on the receiving queue manager in the cluster, and must therefore be unique and make sense across the cluster to the administrators of that cluster. Channel names are limited to a maximum of 20 characters.

One possibility is to use the queue manager name preceded by the cluster-name. For example, if the cluster-name is CLUSTER1 and the queue managers are QM1, QM2, then cluster-receiver channels are CLUSTER1.QM1, CLUSTER1.QM2.

You might extend this convention if channels have different priorities or use different protocols; for example, `CLUSTER1.QM1.S1`, `CLUSTER1.QM1.N3`, and `CLUSTER1.QM1.T4`. In this example, `S1` might be the first SNA channel, `N3` might be the NetBIOS channel with a network priority of three.

A final qualifier might describe the class of service the channel provides.

z/OS In IBM MQ for z/OS, you can define VTAM generic resources or *Dynamic Domain Name Server* (DDNS) generic names. You can define connection names using generic names. However, when you create a cluster-receiver definition, do not use a generic connection name.

z/OS The problem with using generic connection names for cluster-receiver definitions is as follows. If you define a `CLUSRCVR` with a generic `CONNAME` there is no guarantee that your `CLUSSDR` channels point to the queue managers you intend. Your initial `CLUSSDR` might end up pointing to any queue manager in the queue-sharing group, not necessarily one that hosts a full repository. If a channel starts trying a connection again, it might reconnect to a different queue manager with the same generic name disrupting the flow of messages.

Clustering: Topology design considerations:

This topic provides guidance for planning and administering IBM MQ clusters. This information is a guide based on testing and feedback from customers.

By thinking about where user applications and internal administrative processes are going to be located in advance, many problems can either be avoided, or minimized at a later date. This topic contains information about design decisions that can improve performance, and simplify maintenance tasks as the cluster scales.

- "Performance of the clustering infrastructure"
- "Full repositories" on page 35
- "Should applications use queues on full repositories?" on page 36
- "Managing channel definitions" on page 36
- "Workload balancing over multiple channels" on page 36

Performance of the clustering infrastructure

When an application tries to open a queue on a queue manager in a cluster, the queue manager registers its interest with the full repositories for that queue so that it can learn where the queue exists in the cluster. Any updates to the queue location or configuration are automatically sent by the full repositories to the interested queue manager. This registering of interest is internally known as a subscription (these subscriptions are not the same as IBM MQ subscriptions used for publish/subscribe messaging in IBM MQ)

All information about a cluster goes through every full repository. Full repositories are therefore always being used in a cluster for administrative message traffic. The high usage of system resources when managing these subscriptions, and the transmission of them and the resulting configuration messages, can cause a considerable load on the clustering infrastructure. There are a number of things to consider when ensuring that this load is understood and minimized wherever possible:

- The more individual queue managers using a cluster queue, the more subscriptions are in the system, and thus the bigger the administrative overhead when changes occur and interested subscribers need to be notified, especially on the full repository queue managers. One way to minimize unnecessary traffic and full repository load is by connecting similar applications (that is, those applications that work with the same queues) to a smaller number of queue managers.
- In addition to the number of subscriptions in the system affecting the performance the rate of change in the configuration of clustered objects can affect performance, for example the frequent changing of a clustered queue configuration.
- When a queue manager is a member of multiple clusters (that is, it is part of an overlapping cluster system) any interest made in a queue results in a subscription for each cluster it is a member of, even if the same queue managers are the full repositories for more than one of the clusters. This arrangement increases the load on the system, and is one reason to consider whether multiple overlapping clusters are necessary, rather than a single cluster.
- Application message traffic (that is, the messages being sent by IBM MQ applications to the cluster queues) does not go via the full repositories to reach the destination queue managers. This message traffic is sent directly between the queue manager where the message enters the cluster, and the queue manager where the cluster queue exists. It is not therefore necessary to accommodate high rates of application message traffic with respect to the full repository queue managers, unless the full repository queue managers happen to be either of those two queue managers mentioned. For that reason, it is recommended that full repository queue managers are not used for application message traffic in clusters where the clustering infrastructure load is significant.

Full repositories

A repository is a collection of information about the queue managers that are members of a cluster. A queue manager that hosts a complete set of information about every queue manager in the cluster has a full repository. For more information about full repositories and partial repositories, see Cluster repository.

Full repositories must be held on servers that are reliable and as highly available as possible and single points of failure must be avoided. The cluster design must always have two full repositories. If there is a failure of a full repository, the cluster can still operate.

Details of any updates to cluster resources made by a queue manager in a cluster; for example, clustered queues, are sent from that queue manager to two full repositories at most in that cluster (or to one if there is only one full repository queue manager in the cluster). Those full repositories hold the information and propagate it to any queue managers in the cluster that show an interest in it (that is, they subscribe to it). To ensure that each member of the cluster has an up-to-date view of the cluster resources there, each queue manager must be able to communicate with at least one full repository queue manager at any one time.

If, for any reason a queue manager cannot communicate with any full repositories, it can continue to function in the cluster based on its already cached level of information for a period time, but no new updates or access to previously unused cluster resources are available.

For this reason, you must aim to keep the two full repositories available at all times. However, this arrangement does not mean that extreme measures must be taken because the cluster functions adequately for a short while without a full repository.

There is another reason that a cluster must have two full repository queue managers, other than the availability of cluster information: This reason is to ensure that the cluster information held in the full repository cache exists in two places for recovery purposes. If there is only one full repository, and it loses its information about the cluster, then manual intervention on all queue managers within the cluster is required in order to get the cluster working again. If there are two full repositories however, then because information is always published to and subscribed for from two full repositories, the failed full repository can be recovered with the minimum of effort.

- It is possible to perform maintenance on full repository queue managers in a two full repository cluster design without impacting users of that cluster: The cluster continues to function with only one repository, so where possible bring the repositories down, apply the maintenance, and back up again one at a time. Even if there is an outage on the second full repository, running applications are unaffected for a minimum of three days.
- Unless there is a good reason for using a third repository, such as using a geographically local full repository for geographical reasons, use the two repository design. Having three full repositories means that you never know which are the two that are currently in use, and there might be administrative problems caused by interactions between multiple workload management parameters. It is not recommend to have more than two full repositories.
- If you still need better availability, consider hosting the full repository queue managers as multi-instance queue managers or using platform specific high availability support to improve their availability.
- You must fully interconnect all the full repository queue managers with manually defined cluster sender channels. Particular care must be taken when the cluster does have, for some justifiable reason, more than two full repositories. In this situation it is often possible to miss one or more channels and for it not to be immediately apparent. When full interconnection does not occur, hard to diagnose problems often arise. They are hard to diagnose because some full repositories not holding all repository data and therefore resulting in queue managers in the cluster having different views of the cluster depending on the full repositories that they connect to.

Should applications use queues on full repositories?

A full repository is in most ways exactly like any other queue manager, and it is therefore possible to host application queues on the full repository and connect applications directly to these queue managers. Should applications use queues on full repositories?

The commonly accepted answer is "No?". Although this configuration is possible, many customers prefer to keep these queue managers dedicated to maintaining the full repository cluster cache. Points to consider when deciding on either option are described here, but ultimately the cluster architecture must be appropriate to the particular demands of the environment.

- Upgrades: Usually, in order to use new cluster features in new releases of IBM MQ the full repository queue managers of that cluster must be upgraded first. When an application in the cluster wants to use new features, it might be useful to be able to update the full repositories (and some subset of partial repositories) without testing a number of co-located applications.
- Maintenance: In a similar way if you must apply urgent maintenance to the full repositories, they can be restarted or refreshed with the `REFRESH` command without touching applications.
- Performance: As clusters grow and demands on the full repository cluster cache maintenance become greater, keeping applications separate reduces risk of this affecting application performance through contention for system resources.
- Hardware requirements: Typically, full repositories do not need to be powerful; for example, a simple UNIX server with a good expectation of availability is sufficient. Alternatively, for very large or constantly changing clusters, the performance of the full repository computer must be considered.
- Software requirements: Requirements are usually the main reason for choosing to host application queues on a full repository. In a small cluster, collocation might mean a requirement for fewer queue managers/servers over all.

Managing channel definitions

Even within a single cluster, multiple channel definitions can exist giving multiple routes between two queue managers.

There is sometimes an advantage to having parallel channels within a single cluster, but this design decision must be considered thoroughly; apart from adding complexity, this design might result in channels being under-used which reduces performance. This situation occurs because testing usually involves sending lots of messages at a constant rate, so the parallel channels are fully used. But with real-world conditions of a non-constant stream of messages, the workload balancing algorithm causes performance to drop as the message flow is switched from channel to channel.

When a queue manager is a member of multiple clusters, the option exists to use a single channel definition with a cluster namelist, rather than defining a separate CLUSRCVR channel for each cluster. However, this setup can cause administration difficulties later; consider for example the case where TLS is to be applied to one cluster but not a second. It is therefore preferable to create separate definitions, and the naming convention suggested in “Cluster naming conventions” on page 32 supports this.

Workload balancing over multiple channels

This information is intended as an advanced understanding of the subject. For the basic explanation of this subject (which must be understood before using the information here), see Using clusters for workload management, Workload balancing in clusters, and The cluster workload management algorithm.

The cluster workload management algorithm provides a large set of tools, but they must not all be used with each other without fully understanding how they work and interact. It might not be immediately obvious how important channels are to the workload balancing process: The workload management round-robin algorithm behaves as though multiple cluster channels to a queue manager that owns a clustered queue, are treated as multiple instances of that queue. This process is explained in more detail in the following example:

1. There are two queue managers hosting a queue in a cluster: `QM1` and `QM2`.
2. There are five cluster receiver channels to `QM1`.
3. There is only one cluster receiver channel to `QM2`.
4. When **`MQPUT`** or **`MQOPEN`** on `QM3` chooses an instance, the algorithm is five times more likely to send the message to `QM1` than to `QM2`.
5. The situation in step 4 occurs because the algorithm sees six options to choose from (5+1) and round-robins across all five channels to `QM1` and the single channel to `QM2`.

Another subtle behavior is that even when putting messages to a clustered queue that happens to have one instance configured on the local queue manager, IBM MQ uses the state of the local cluster receiver channel to decide whether messages are to be put to the local instance of the queue or remote instances of the queue. In this scenario:

1. When putting messages the workload management algorithm does not look at individual cluster queues, it looks at the cluster channels which can reach those destinations.
2. To reach local destinations, the local receiver channels are included in this list (although they are not used to send the message).
3. When a local receiver channel is stopped, the workload management algorithm, prefers an alternative instance by default if its CLUSRCVR is not stopped. If there are multiple local CLUSRCVR instances for the destination and at least one is not stopped, the local instance remains eligible.

Clustering: Application isolation using multiple cluster transmission queues:

You can isolate the message flows between queue managers in a cluster. You can place messages being transported by different cluster-sender channels onto different cluster transmission queues. You can use the approach in a single cluster or with overlapping clusters. The topic provides examples and some best practices to guide you in choosing an approach to use.

When you deploy an application, you have a choice over which IBM MQ resources it shares with other applications and which resources it does not share. There are a number of types of resources that can be shared, the main ones being the server itself, the queue manager, channels, and queues. You can choose to configure applications with fewer shared resources; allocating separate queues, channels, queue managers, or even servers to individual applications. If you do so, the overall system configuration becomes bigger and more complex. Using IBM MQ clusters reduces the complexity of managing more servers, queue managers, queues, and channels, but it introduces another shared resource, the cluster transmission queue, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`.

Figure 12 on page 39 is a slice out of a large IBM MQ deployment that illustrates the significance of sharing `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. In the diagram, the application, `Client App`, is connected to the queue manager `QM2` in cluster `CL1`. A message from `Client App` is processed by the application, `Server App`. The message is retrieved by `Server App` from the cluster queue `Q1` on the queue manager `QM3` in `CLUSTER2`. Because the client and server applications are not in the same cluster, the message is transferred by the gateway queue manager `QM1`.

The normal way to configure a cluster gateway is to make the gateway queue manager a member of all the clusters. On the gateway queue manager are defined clustered alias queues for cluster queues in all the clusters. The clustered queue aliases are available in all the clusters. Messages put to the cluster queue aliases are routed via the gateway queue manager to their correct destination. The gateway queue manager puts messages sent to the clustered alias queues onto the common `SYSTEM.CLUSTER.TRANSMIT.QUEUE` on `QM1`.

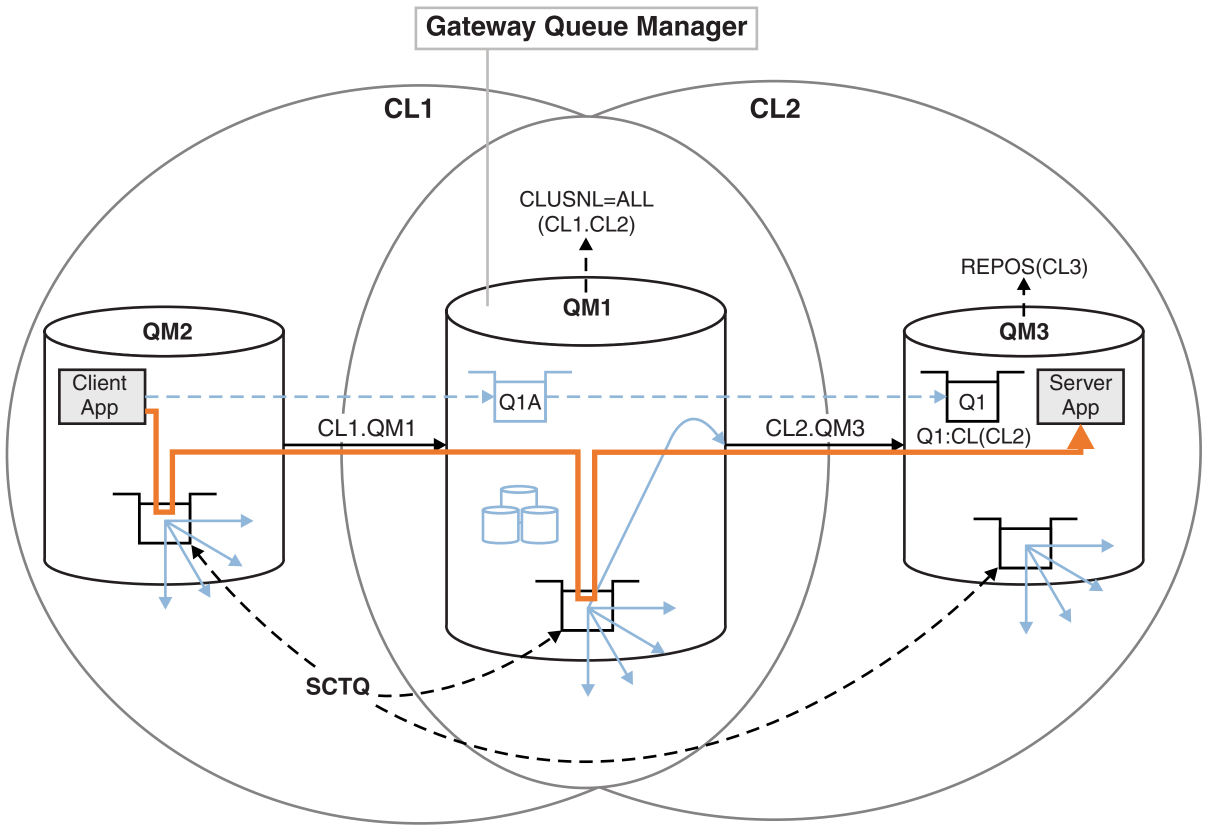
The hub and spoke architecture requires all messages between clusters to pass through the gateway queue manager. The result is that all messages flow through the single cluster transmission queue on `QM1`, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`.

From a performance perspective, a single queue is not a problem. A common transmission queue generally does not represent a performance bottleneck. Message throughput on the gateway is largely determined by the performance of the channels that connect to it. Throughput is not generally affected by the number of queues, or the number of messages on the queues that use the channels.

From some other perspectives, using a single transmission queue for multiple applications has drawbacks:

- You cannot isolate the flow of messages to one destination from the flow of messages to another destination. You cannot separate the storage of messages before they are forwarded, even if the destinations are in different clusters on different queue managers.

  If one cluster destination becomes unavailable, messages for that destination build-up in the single transmission queue, and eventually the messages fill it up. Once the transmission queue is full, it stops messages from being placed onto the transmission queue for any cluster destination.
- It is not easy to monitor the transfer of messages to different cluster destinations. All the messages are on the single transmission queue. Displaying the depth of the transmission queue gives you little indication whether messages are being transferred to all destinations.



Note: The arrows in Figure 12 and following figures are of different types. Solid arrows represent message flows. The labels on solid arrows are message channel names. The gray solid arrows are potential message flows from the SYSTEM.CLUSTER.TRANSMIT.QUEUE onto cluster-sender channels. Black dashed lines connect labels to their targets. Gray dashed arrows are references; for example from an MQOPEN call by Client App to the cluster alias queue definition Q1A.

Figure 12. Client-server application deployed to hub and spoke architecture using IBM MQ clusters

In Figure 12, clients of Server App open the queue Q1A. Messages are put to SYSTEM.CLUSTER.TRANSMIT.QUEUE on QM2, transferred to SYSTEM.CLUSTER.TRANSMIT.QUEUE on QM1, and then transferred to Q1 on QM3, where they are received by the Server App application.

The message from Client App passes through system cluster transmission queues on QM2 and QM1. In Figure 12, the objective is to isolate the message flow on the gateway queue manager from the client application, so that its messages are not stored on SYSTEM.CLUSTER.TRANSMIT.QUEUE. You can isolate flows on any of the other clustered queue managers. You can also isolate flows in the other direction, back to the client. To keep the descriptions of the solutions brief, the descriptions consider only a single flow from the client application.

Solutions to isolating cluster message traffic on a cluster gateway queue manager

One way to solve the problem is to use queue manager aliases, or remote queue definitions, to bridge between clusters. Create a clustered remote queue definition, a transmission queue, and a channel, to separate each message flow on the gateway queue manager; see Adding a remote queue definition to isolate messages sent from a gateway queue manager.

From Version 7.5 onwards, cluster queue managers are not limited to a single cluster transmission queue. You have two choices:

1. Define additional cluster transmission queues manually, and define which cluster-sender channels transfer messages from each transmission queue; see Adding a cluster transmit queue to isolate cluster message traffic sent from a gateway queue manager.
2. Allow the queue manager to create and manage additional cluster transmission queues automatically. It defines a different cluster transmission queue for each cluster-sender channel; see Changing the default to separate cluster transmission queues to isolate message traffic.

You can combine manually defined cluster transmission queues for some cluster-sender channels, with the queue manager managing the rest. The combination of transmission queues is the approach taken in Adding a cluster transmit queue to isolate cluster message traffic sent from a gateway queue manager. In that solution, most messages between clusters use the common `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. One application is critical, and all its message flows are isolated from other flows by using one manually defined cluster transmission queue.

The configuration in Adding a cluster transmit queue to isolate cluster message traffic sent from a gateway queue manager is limited. It does not separate the message traffic going to a cluster queue on the same queue manager in the same cluster as another cluster queue. You can separate the message traffic to individual queues by using the remote queue definitions that are part of distributed queuing. With clusters, using multiple cluster transmission queues, you can separate message traffic that goes to different cluster-sender channels. Multiple cluster queues in the same cluster, on the same queue manager, share a cluster-sender channel. Messages for those queues are stored on the same transmission queue, before being forwarded from the gateway queue manager. In the configuration in Adding a cluster and a cluster transmit queue to isolate cluster message traffic sent from a gateway queue manager, the limitation is side-stepped by adding another cluster and making the queue manager and cluster queue a member of the new cluster. The new queue manager might be the only queue manager in the cluster. You could add more queue managers to the cluster, and use the same cluster to isolate cluster queues on those queue managers as well.

Clustering: Planning how to configure cluster transmission queues:

You are guided through the choices of cluster transmission queues. You can configure one common default queue, separate default queues, or manually defined queues. z/OS To configure a cluster-sender channel to use a transmission queue other than SYSTEM.CLUSTER.TRANSMIT.QUEUE, you need to enable new function, using the mode of operation (OPMODE) system parameter in the CSQ6SYSP parameter.

Before you begin

Review "How to choose what type of cluster transmission queue to use" on page 43.

z/OS See the mode of operation (OPMODE) topic for more information.

About this task

You have some choices to make when you are planning how to configure a queue manager to select a cluster transmission queue.

1. What is the default cluster transmission queue for cluster message transfers?
   a. A common cluster transmission queue, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`.
   b. Separate cluster transmission queues. The queue manager manages the separate cluster transmission queues. It creates them as permanent-dynamic queues from the model queue, `SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE`. It creates one cluster transmission queue for each cluster-sender channel it uses.
2. For the cluster transmission queues that you do decide to create manually, you have a further two choices:
   a. Define a separate transmission queue for each cluster-sender channel that you decide to configure manually. In this case, set the **`CLCHNAME`** queue attribute of the transmission queue to the name of a cluster-sender channel. Select the cluster-sender channel that is to transfer messages from this transmission queue.
   b. Combine message traffic for a group of cluster-sender channels onto the same cluster transmission queue; see Figure 13 on page 42. In this case, set the **`CLCHNAME`** queue attribute of each common transmission queue to a generic cluster-sender channel name. A generic cluster-sender channel name is a filter to group cluster-sender channel names. For example, `SALES.*` groups all cluster-sender channels that have names beginning with `SALES.`. You can place multiple wildcard characters anywhere in the filter-string. The wildcard character is an asterisk, "*". It represents from zero to any number of characters.

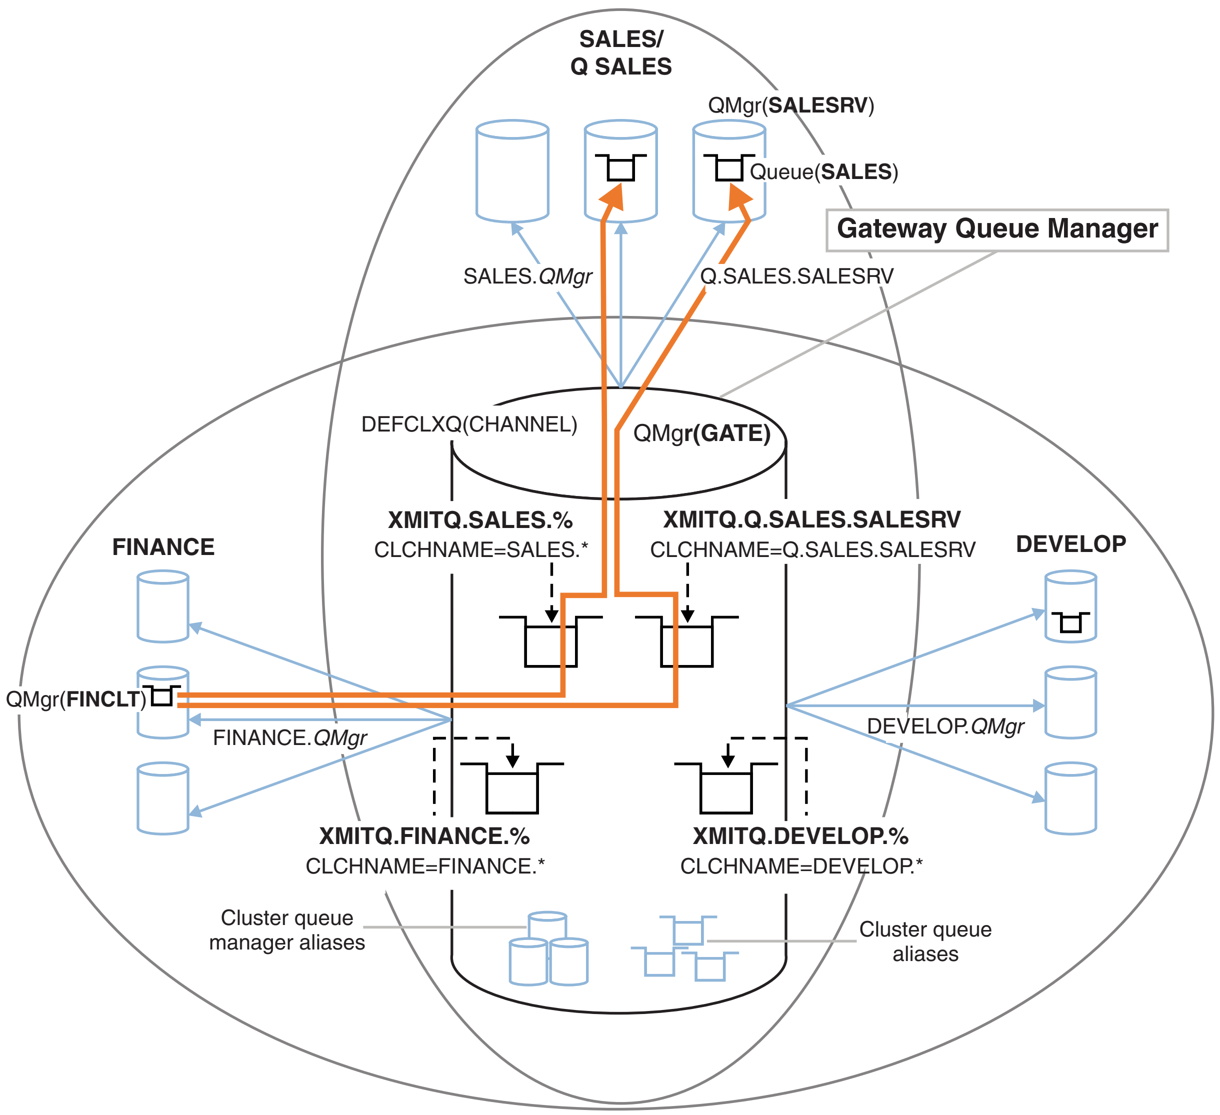

Figure 13. Example of specific transmission queues for different departmental IBM MQ clusters

Procedure

1. Select the type of default cluster transmission queue to use.
   - Choose a single cluster transmission queue, or separate queues for each cluster connection.

   Leave the default setting or run the **MQSC** command:

   ```
   ALTER QMGR DEFCLXQ(CHANNEL)
   ```
2. Isolate any message flows that must not share a cluster transmission queue with other flows.
   - See "Clustering: Example configuration of multiple cluster transmission queues" on page 45. In the example the `SALES` queue, which must be isolated, is a member of the `SALES` cluster, on `SALESRV`. To isolate the `SALES` queue, create a new cluster `Q.SALES`, make the `SALESRV` queue manager a member, and modify the `SALES` queue to belong to `Q.SALES`.
   - Queue managers that send messages to `SALES` must also be members of the new cluster. If you use a clustered queue alias and a gateway queue manager, as in the example, in many cases you can limit the changes to making the gateway queue manager a member of the new cluster.
   - However, separating flows from the gateway to the destination does not separate flows to the gateway from the source queue manager. But it sometimes turns out to be sufficient to separate flows from the gateway and not flows to the gateway. If it is not sufficient, then add the source

queue manager into the new cluster. If you want messages to travel through the gateway, move the cluster alias to the new cluster and continue to send messages to the cluster alias on the gateway, and not directly to the target queue manager.

Follow these steps to isolate message flows:

a. Configure the destinations of the flows so that each target queue is the only queue in a specific cluster, on that queue manager.
b. Create the cluster-sender and cluster-receiver channels for any new clusters you have created following a systematic naming convention.
   - See "Clustering: Special considerations for overlapping clusters" on page 31.
c. Define a cluster transmission queue for each isolated destination on every queue manager that sends messages to the target queue.
   - A naming convention for cluster transmission queues is to use the value of the cluster channel name attribute, `CLCHNAME`, prefixed with `XMITQ.`

3. Create cluster transmission queues to meet governance or monitoring requirements.
   - Typical governance and monitoring requirements result in a transmission queue per cluster or a transmission queue per queue manager. If you follow the naming convention for cluster channels, *`ClusterName. QueueManagerName`*, it is easy to create generic channel names that select a cluster of queue managers, or all the clusters a queue manager is a member of; see "Clustering: Example configuration of multiple cluster transmission queues" on page 45.
   - Extend the naming convention for cluster transmission queues to cater for generic channel names, by replacing the asterisk symbol by a percent sign. For example,

```
DEFINE QLOCAL(XMITQ.SALES.%) USAGE(XMITQ) CLCHNAME(SALES.*)
```

Configuring message paths between clusters

How to choose what type of cluster transmission queue to use:

How to choose between different cluster transmission queue configuration options.

From Version 7.5 onwards, you can choose which cluster transmission queue is associated with a cluster-sender channel.

1. You can have all cluster-sender channels associated with the single default cluster transmit queue, `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. This option is the default, and is the only choice for queue managers that run version Version 7.1, or earlier.

2. You can set all cluster-sender channels to be automatically associated with a separate cluster transmission queue. The queues are created by the queue manager from the model queue SYSTEM.CLUSTER.TRANSMIT.MODEL.QUEUE and named SYSTEM.CLUSTER.TRANSMIT. *ChannelName*. Channels will use their uniquely named cluster transmit queue if the queue manager attribute **DEFCLXQ** is set to CHANNEL.
3. You can set specific cluster-sender channels to be served by a single cluster transmission queue. Select this option by creating a transmission queue and setting its **CLCHNAME** attribute to the name of the cluster-sender channel.
4. You can select groups of cluster-sender channels to be served by a single cluster transmission queue. Select this option by creating a transmission queue and setting its **CLCHNAME** attribute to a generic channel name, such as *ClusterName*.*. If you name cluster channels by following the naming conventions in "Clustering: Special considerations for overlapping clusters" on page 31, this name selects all cluster channels connected to queue managers in the cluster *ClusterName*.

You can combine either of the default cluster transmission queue options for some cluster-sender channels, with any number of specific and generic cluster transmission queue configurations.

Best practices

In most cases, for existing IBM MQ installations, the default configuration is the best choice. A cluster queue manager stores cluster messages on a single cluster transmission queue, SYSTEM.CLUSTER.TRANSMIT.QUEUE. You have the choice of changing the default to storing messages for different queue managers and different clusters on separate transmission queues, or of defining your own transmission queues.

In most cases, for new IBM MQ installations, the default configuration is also the best choice. The process of switching from the default configuration to the alternative default of having one transmission queue for each cluster-sender channel is automatic. Switching back is also automatic. The choice of one or the other is not critical, you can reverse it.

The reason for choosing a different configuration is more to do with governance, and management, than with functionality or performance. With a couple of exceptions, configuring multiple cluster transmission queues does not benefit the behavior of the queue manager. It results in more queues, and requires you to modify monitoring and management procedures you have already set up that refer to the single transmission queue. That is why, on balance, remaining with the default configuration is the best choice, unless you have strong governance or management reasons for a different choice.

The exceptions are both concerned with what happens if the number of messages stored on SYSTEM.CLUSTER.TRANSMIT.QUEUE increases. If you take every step to separate the messages for one destination from the messages for another destination, then channel and delivery problems with one destination ought not to affect the delivery to another destination. However, the number of messages stored on SYSTEM.CLUSTER.TRANSMIT.QUEUE can increase due to not delivering messages fast enough to one destination. The number of messages on SYSTEM.CLUSTER.TRANSMIT.QUEUE for one destination can affect the delivery of messages to other destinations.

To avoid problems that result from filling up a single transmission queue, aim to build sufficient capacity into your configuration. Then, if a destination fails and a message backlog starts to build up, you have time to fix the problem.

If messages are routed through a hub queue manager, such as a cluster gateway, they share a common transmission queue, SYSTEM.CLUSTER.TRANSMIT.QUEUE. If the number of messages stored on SYSTEM.CLUSTER.TRANSMIT.QUEUE on the gateway queue manager reaches its maximum depth, the queue manager starts to reject new messages for the transmission queue until its depth reduces. The congestion affects messages for all destinations that are routed through the gateway. Messages back up the transmission queues of other queue managers that are sending messages to the gateway. The problem manifests itself in messages written to queue manager error logs, falling message throughput, and longer elapsed times between sending a message and the time that a message arrives at its destination.

The effect of congestion on a single transmission queue can become apparent, even before it is full. If you have a mixed message traffic, with some large non-persistent messages and some small messages, the time to deliver small messages increases as the transmission queue fills. The delay is due to writing large non-persistent messages to disk that would not normally get written to disk. If you have time critical message flows, sharing a cluster transmission queue with other mixed messages flows, it could be worth configuring a special message path to isolate it from other message flows; see Adding a cluster and a cluster transmit queue to isolate cluster message traffic sent from a gateway queue manager.

The other reasons for configuring separate cluster transmission queues are to meet governance requirements, or to simplify monitoring messages that are sent to different cluster destinations. For example, you might have to demonstrate that messages for one destination never share a transmission queue with messages for another destination.

Change the queue manager attribute **`DEFCLXQ`** that controls the default cluster transmission queue, to create different cluster transmission queues for every cluster-sender channel. Multiple destinations can share a cluster-sender channel, so you must plan your clusters to meet this objective fully. Apply the method Adding a cluster and a cluster transmit queue to isolate cluster message traffic sent from a gateway queue manager systematically to all your cluster queues. The result you are aiming for is for no cluster destination to share a cluster-sender channel with another cluster destination. As a consequence, no message for a cluster destination shares its cluster transmission queue with a message for another destination.

Creating a separate cluster transmission queue for some specific message flow, makes it easy to monitor the flow of messages to that destination. To use a new cluster transmission queue, define the queue, associate it with a cluster-sender channel, and stop and start the channel. The change does not have to be permanent. You could isolate a message flow for a while, to monitor the transmission queue, and then revert to using the default transmission queue again.

Clustering: Example configuration of multiple cluster transmission queues:

In this task you apply the steps to plan multiple cluster transmission queues to three overlapping clusters. The requirements are to separate messages flows to one cluster queue, from all other message flows, and to store messages for different clusters on different cluster transmission queues.

About this task

The steps in this task show how to apply the procedure in “Clustering: Planning how to configure cluster transmission queues” on page 41 and arrive at the configuration shown in Figure 14 on page 46. It is an example of three overlapping clusters, with a gateway queue manager, that is configured with separate cluster transmission queues. The MQSC commands to define the clusters are described in “Creating the example clusters” on page 48.

For the example, there are two requirements. One is to separate the message flow from the gateway queue manager to the sales application that logs sales. The second is to query how many messages are waiting to be sent to different departmental areas at any point in time. The `SALES`, `FINANCE`, and `DEVELOP` clusters are already defined. Cluster messages are currently forwarded from `SYSTEM.CLUSTER.TRANSMIT.QUEUE`.

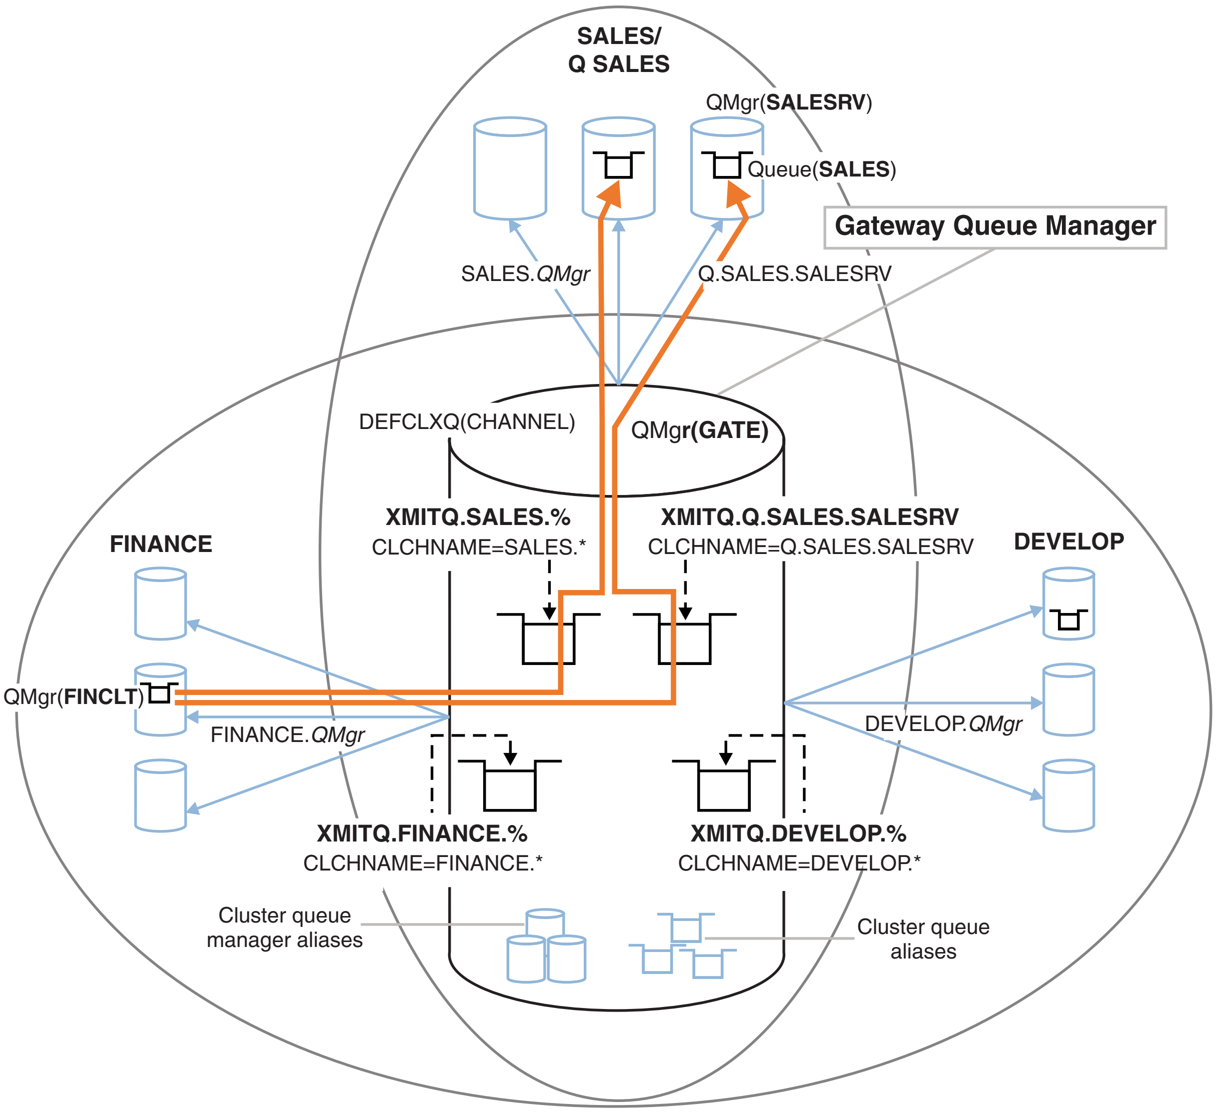

Figure 14. Example of specific transmission queues for different departmental IBM MQ clusters

The steps to modify the clusters are as follows; see Figure 16 on page 50 for the definitions.

Procedure

1. The first configuration step is to " Select the type of default cluster transmission queue to use ".

   The decision is to create separate default cluster transmission queues by running the following **MQSC** command on the GATE queue manager.

   ```
   ALTER QMGR DEFCLXQ(CHANNEL)
   ```

   There is no strong reason for choosing this default, as the intention is to manually define cluster transmission queues. The choice does have a weak diagnostic value. If a manual definition is done wrongly, and a message flows down a default cluster transmission queue, it shows up in the creation of a permanent-dynamic cluster transmission queue.
2. The second configuration step is to " Isolate any message flows that must not share a cluster transmission queue with other flows ". In this case the sales application that receives messages from the queue SALES on SALESRV requires isolation. Only isolation of messages from the gateway queue manager is required. The three sub-steps are:

   a. “ Configure the destinations of the flows so that each target queue is the only queue in a specific cluster, on that queue manager ”.

      The example requires adding the queue manager SALESRV to a new cluster within the sales department. If you have few queues that require isolation, you might decide on creating a specific cluster for the SALES queue. A possible naming convention for the cluster name is to name such clusters, Q. *QueueName*, for example Q.SALES. An alternative approach, which might be more practical if you have a large number of queues to be isolated, is to create clusters of isolated queues where and when needed. The clusters names might be QUEUES. *n*.

      In the example, the new cluster is called Q.SALES. To add the new cluster, see the definitions in Figure 16 on page 50. The summary of definition changes is as follows:

      1) Add Q.SALES to the namelist of clusters on the repository queue managers. The namelist is referred to in the queue manager **REPOSNL** parameter.
      2) Add Q.SALES to the namelist of clusters on the gateway queue manager. The namelist is referred to in all the cluster queue alias and cluster queue manager alias definitions on the gateway queue manager.
      3) Create a namelist on the queue manager SALESRV, for both the clusters it is a member of, and change the cluster membership of the SALES queue:

```
DEFINE NAMELIST(CLUSTERS) NAMES(SALES, Q.SALES) REPLACE
ALTER QLOCAL(SALES) CLUSTER(' ') CLUSNL(SALESRV.CLUSTERS)
```

         The SALES queue is a member of both clusters, just for the transition. Once the new configuration is running, you remove the SALES queue from the SALES cluster; see Figure 17 on page 50.

   b. “ Create the cluster-sender and cluster-receiver channels for any new clusters you have created following a systematic naming convention ”.

      1) Add the cluster-receiver channel Q.SALES. *RepositoryQMgr* to each of the repository queue managers
      2) Add the cluster-sender channel Q.SALES. *OtherRepositoryQMgr* to each of the repository queue managers, to connect to the other repository manager. Start these channels.
      3) Add the cluster receiver channels Q.SALES.SALESRV, and Q.SALES.GATE to either of the repository queue managers that is running.
      4) Add the cluster-sender channels Q.SALES.SALESRV, and Q.SALES.GATE to the SALESRV and GATE queue managers. Connect the cluster-sender channel to the repository queue manager that you created the cluster-receiver channels on.

   c. “ Define a cluster transmission queue for each isolated destination on every queue manager that sends messages to the target queue ”.

      On the gateway queue manager define the cluster transmission queue XMITQ.Q.SALES.SALESRV for the Q.SALES.SALESRV cluster-sender channel:

```
DEFINE QLOCAL(XMITQ.Q.SALES.SALESRV) USAGE(XMITQ) CLCHNAME(Q.SALES.SALESRV) REPLACE
```

3. The third configuration step is to “ Create cluster transmission queues to meet governance or monitoring requirements ”.

   On the gateway queue manager define the cluster transmission queues:

```
DEFINE QLOCAL(XMITQ.SALES)  USAGE(XMITQ) CLCHNAME(SALES.*)  REPLACE
DEFINE QLOCAL(XMITQ.DEVELOP) USAGE(XMITQ) CLCHNAME(DEVELOP.*) REPLACE
DEFINE QLOCAL(XMITQ.FINANCE) USAGE(XMITQ) CLCHNAME(SALES.*)  REPLACE
```

What to do next

Switch to the new configuration on the gateway queue manager.

The switch is triggered by starting the new channels, and restarting the channels that are now associated with different transmission queues. Alternatively, you can stop and start the gateway queue manager.

1. Stop the following channels on the gateway queue manager:
   ```
   SALES. Qmgr
   DEVELOP. Qmgr
   FINANCE. Qmgr
   ```
2. Start the following channels on the gateway queue manager:
   ```
   SALES. Qmgr
   DEVELOP. Qmgr
   FINANCE. Qmgr
   Q.SALES.SAVESRV
   ```

When the switch is complete, remove the `SALES` queue from the `SALES` cluster; see Figure 17 on page 50.

Creating the example clusters:

The definitions and instructions to create the example cluster, and modify it to isolate the `SALES` queue and separate messages on the gateway queue manager.

About this task

The full **`MQSC`** commands to create the `FINANCE`, `SALES`, and `Q.SALES` clusters are provided in Figure 15 on page 49, Figure 16 on page 50, and Figure 17 on page 50. The definitions for the basic clusters are in Figure 15 on page 49. The definitions in Figure 16 on page 50 modify the basic clusters to isolate the `SALES` queue, and to separate cluster messages to `FINANCE` and `SALES`. Finally, to remove the `SALES` queue from the `SALES` cluster; see Figure 17 on page 50. The `DEVELOP` cluster is omitted from the definitions, to keep the definitions shorter.

Procedure

1. Create the `SALES` and `FINANCE` clusters, and the gateway queue manager.
   a. Create the queue managers.

      Run the command: `crtmqm -sax -u SYSTEM.DEAD.LETTER.QUEUE` *`QmgrName`* for each of the queue manager names in Table 4.

Table 4. Queue manager names and port numbers

Description	Queue Manager Name	Port number
Finance repository	`FINR1`	`1414`
Finance repository	`FINR2`	`1415`
Finance client	`FINCLT`	`1418`
Sales repository	`SALER1`	`1416`
Sales repository	`SALER2`	`1417`
Sales server	`SALESRV`	`1419`
Gateway	`GATE`	`1420`

   b. Start all the queue managers

      Run the command: `strmqm` *`QmgrName`* for each of the queue manager names in Table 4.

   c. Create the definitions for each of the queue managers

      Run the command: `runmqsc` *`QmgrName`* < *`filename`* where the files are listed in Figure 15 on page 49, and the file name matches the queue manager name.

Figure 15. Definitions for the basic clusters

2. Test the configuration by running the sample request program.
   a. Start the trigger monitor program on the `SALESRV` queue manager

      On Windows, open a command window and run the command `runmqtrm -m SALESRV`
   b. Run the sample request program, and send a request.

      On Windows, open a command window and run the command `amqsreq A.SALES FINCLT`

      The request message is echoed back, and after 15 seconds the sample program finishes.

3. Create the definitions to isolate the SALES queue in the Q.SALES cluster and separate cluster messages for the SALES and FINANCE cluster on the gateway queue manager.

   Run the command: `runmqsc` *QmgrName* < *filename* where the files are listed in Figure 16, and the file name almost matches the queue manager name.

```

Figure 16. Changes to isolate the sales queue in a new cluster and separate the gateway cluster transmission queues

4. Remove the SALES queue from the SALES cluster.

   Run the **MQSC** command in Figure 17:

```
ALTER QLOCAL(SALES) CLUSTER('Q.SALES') CLUSNL(' ')
```

Figure 17. Remove the sales queue on queue manager SALESRV from the sales cluster

5. Switch the channels to the new transmission queues.

   The requirement is to stop and start all the channels that the GATE queue manager is using. To do this with the least number of commands, stop and start the queue manager

   ```
   endmqm -i GATE
   strmqm GATE
   ```

What to do next

1. Rerun the sample request program to verify the new configuration works; see step 2 on page 49
2. Monitor the messages flowing through all the cluster transmission queues on the GATE queue manager:
   a. Alter the definition of each of the cluster transmission queues to turn queue monitoring on.

      `ALTER QLOCAL(SYSTEM.CLUSTER.TRANSMIT. *name*) STATQ(ON)`

   b. Check queue manager statistics monitoring is OFF, to minimize output, and set the monitoring interval to a lower value to perform multiple tests conveniently.

      ```
      ALTER QMGR STATINT(60) STATCHL(OFF) STATQ(OFF) STATMQI(OFF) STATACLS(OFF)
      ```

   c. Restart the GATE queue manager.

d. Run the sample request program a few times to verify that an equal number of messages are flowing through `SYSTEM.CLUSTER.TRANSMIT.Q.SALES.SALESRV` and `SYSTEM.CLUSTER.TRANSMIT.QUEUE`. Requests flow through `SYSTEM.CLUSTER.TRANSMIT.Q.SALES.SALESRV` and replies through `SYSTEM.CLUSTER.TRANSMIT.QUEUE`.

```
amqsmon -m GATE -t statistics
```

e. The results over a couple of intervals are as follows:

One request and reply message were sent in the first interval and two in the second. You can infer that the request messages were placed on `SYSTEM.CLUSTER.TRANSMIT.Q.SALES.SAVESRV`, and the reply messages on `SYSTEM.CLUSTER.TRANSMIT.QUEUE`.

Clustering: Switching cluster transmission queues:

Plan how the changes to the cluster transmission queues of an existing production queue manager are going to be brought into effect.

Before you begin

If you reduce the number of messages the switching process has to transfer to the new transmission queue, switching completes more quickly. Read How the process to switch cluster-sender channel to a different transmission queue works for the reasons for trying to empty the transmission queue before proceeding any further.

About this task

You have a choice of two ways of making the changes to cluster transmission queues take effect.

1. Let the queue manager make the changes automatically. This is the default. The queue manager switches cluster-sender channels with pending transmission queue changes when a cluster-sender channel next starts.
2. Make the changes manually. You can make the changes to a cluster-sender channel when it is stopped. You can switch it from one cluster transmission queue to another before the cluster-sender channel starts.

What factors do you take into account when deciding which of the two options to choose, and how do you manage the switch?

Procedure

- Option 1: Let the queue manager make the changes automatically; see “Switching active cluster-sender channels to another set of cluster-transmission queues” on page 54.

  Choose this option if you want the queue manager to make the switch for you.

  An alternative way to describe this option is to say the queue manager switches a cluster-sender channel without you forcing the channel to stop. You do have the option of forcing the channel to stop, and then starting the channel, to make the switch happen sooner. The switch starts when the channel starts, and runs while the channel is running, which is different to option 2. In option 2, the switch takes place when the channel is stopped.

If you choose this option by letting the switch happen automatically, the switching process starts when a cluster-sender channel starts. If the channel is not stopped, it starts after it becomes inactive, if there is a message to process. If the channel is stopped, start it with the `START CHANNEL` command.

The switch process completes as soon as there are no messages left for the cluster-sender channel on the transmission queue the channel was serving. As soon as that is the case, newly arrived messages for the cluster-sender channel are stored directly on the new transmission queue. Until then, messages are stored on the old transmission queue, and the switching process transfers messages from the old transmission queue to the new transmission queue. The cluster-sender channel forwards messages from the new cluster transmission queue during the whole switching process.

When the switch process completes depends on the state of the system. If you are making the changes in a maintenance window, assess beforehand whether the switching process will complete in time. Whether it will complete in time depends on whether the number of messages that are awaiting transfer from the old transmission queue reaches zero.

The advantage of the first method is it is automatic. A disadvantage is that if the time to make the configuration changes is limited to a maintenance window, you must be confident that you can control the system to complete the switch process inside the maintenance window. If you cannot be sure, option 2 might be a better choice.

- Option 2: Make the changes manually; see "Switching a stopped cluster-sender channel to another cluster transmission queue" on page 55.

Choose this option if you want to control the entire switching process manually, or if you want to switch a stopped or inactive channel. It is a good choice, if you are switching a few cluster-sender channels, and you want to do the switch during a maintenance window.

An alternative description of this option is to say that you switch the cluster-sender channel, while the cluster-sender channel is stopped.

If you choose this option you have complete control over when the switch takes place.

You can be certain about completing the switching process in a fixed amount of time, within a maintenance window. The time the switch takes depends on how many messages have to be transferred from one transmission queue to the other. If messages keep arriving, it might take a time for the process to transfer all the messages.

You have the option of switching the channel without transferring messages from the old transmission queue. The switch is "instant".

When you restart the cluster-sender channel, it starts processing messages on the transmission queue you newly assigned to it.

The advantage of the second method is you have control over the switching process. The disadvantage is that you must identify the cluster-sender channels to be switched, run the necessary commands, and resolve any in-doubt channels that might be preventing the cluster-sender channel stopping.

Related tasks:

"Switching active cluster-sender channels to another set of cluster-transmission queues"
This task gives you three options for switching active cluster-sender channels. One option is to let the queue manager make the switch automatically, which does not affect running applications. The other options are to stop and start channels manually, or to restart the queue manager.

"Switching a stopped cluster-sender channel to another cluster transmission queue" on page 55

Related information:

How the process to switch cluster-sender channel to a different transmission queue works

Switching active cluster-sender channels to another set of cluster-transmission queues:

This task gives you three options for switching active cluster-sender channels. One option is to let the queue manager make the switch automatically, which does not affect running applications. The other options are to stop and start channels manually, or to restart the queue manager.

Before you begin

Change the cluster transmission queue configuration. You can change the **DEFCLXQ** queue manager attribute, or add or modify the **CLCHNAME** attribute of transmission queues.

If you reduce the number of messages the switching process has to transfer to the new transmission queue, switching completes more quickly. Read How the process to switch cluster-sender channel to a different transmission queue works for the reasons for trying to empty the transmission queue before proceeding any further.

About this task

Use the steps in the task as a basis for working out your own plan for making cluster-transmission queue configuration changes.

Procedure

1. Optional: Record the current channel status

   Make a record of the status of current and saved channels that are serving cluster transmission queues. The following commands display the status associated with system cluster transmission queues. Add your own commands to display the status associated with cluster-transmission queues that you have defined. Use a convention, such as `XMITQ.` *`ChannelName`*, to name cluster transmission queues that you define to make it easy to display the channel status for those transmission queues.

   ```
   DISPLAY CHSTATUS(*) WHERE(XMITQ LK 'SYSTEM.CLUSTER.TRANSMIT.*')
   DISPLAY CHSTATUS(*) SAVED WHERE(XMITQ LK 'SYSTEM.CLUSTER.TRANSMIT.*')
   ```
2. Switch transmission queues.
   - Do nothing. The queue manager switches cluster-sender channels when they restart after being stopped or inactive.

     Choose this option if you have no rules or concerns about altering a queue manager configuration. Running applications are not affected by the changes.
   - Restart the queue manager. All cluster-sender channels are stopped and restarted automatically on demand.

     Choose this option to initiate all the changes immediately. Running applications are interrupted by the queue manager as it shuts down and restarts.
   - Stop individual cluster-sender channels and restart them.

     Choose this option to change a few channels immediately. Running applications experience a short delay in message transfer between your stopping and starting the message channel again. The cluster-sender channel remains running, except during the time you stopped it. During the switch process messages are delivered to the old transmission queue, transferred to the new transmission queue by the switching process, and forwarded from the new transmission queue by the cluster-sender channel.

3. Optional: Monitor the channels as they switch

   Display the channel status and the transmission queue depth during the switch. The following example display the status for system cluster transmission queues.

   ```
   DISPLAY CHSTATUS(*) WHERE(XMITQ LK 'SYSTEM.CLUSTER.TRANSMIT.*')
   DISPLAY CHSTATUS(*) SAVED WHERE(XMITQ LK 'SYSTEM.CLUSTER.TRANSMIT.*')
   DISPLAY QUEUE('SYSTEM.CLUSTER.TRANSMIT.*') CURDEPTH
   ```
4. Optional: Monitor the messages " AMQ7341 `The transmission queue for channel` *`ChannelName`* `switched from queue` *`QueueName`* `to` *`QueueName`* " that are written to the queue manager error log.

Switching a stopped cluster-sender channel to another cluster transmission queue:

Before you begin

You might make some configuration changes, and now want to make them effective without starting the cluster-sender channels that are affected. Alternatively, you make the configuration changes you require as one of the steps in the task.

If you reduce the number of messages the switching process has to transfer to the new transmission queue, switching completes more quickly. Read How the process to switch cluster-sender channel to a different transmission queue works for the reasons for trying to empty the transmission queue before proceeding any further.

About this task

This task switches the transmission queues served by stopped or inactive cluster-sender channels. You might do this task because a cluster-sender channel is stopped, and you want to switch its transmission queue immediately. For example, for some reason a cluster-sender channel is not starting, or has some other configuration problem. To resolve the problem, you decide to create a cluster-sender channel, and associate the transmission queue for the old cluster-sender channel with the new cluster-sender channel you defined.

A more likely scenario is you want to control when reconfiguration of cluster transmission queues is performed. To fully control the reconfiguration, you stop the channels, change the configuration, and then switch the transmission queues.

Procedure

1. Stop the channels that you intend to switch
   a. Stop any running or inactive channels that you intend to switch. Stopping an inactive cluster-sender channel prevents it starting while you are making configuration changes.

      ```
      STOP CHANNEL(ChannelName) MODE(QUIESCSE) STATUS(STOPPED)
      ```
2. Optional: Make the configuration changes.

   For example, see "Clustering: Example configuration of multiple cluster transmission queues" on page 45.
3. Switch the cluster-sender channels to the new cluster transmission queues. Multi On Multiplatforms, issue the following command:

   ```
   runswchl -m QmgrName -c ChannelName
   ```

   z/OS On z/OS, use the SWITCH function of the CSQUTIL command to switch the messages or monitor what is happening. Use the following command.

   ```
   SWITCH CHANNEL(channel_name) MOVEMSGS(YES)
   ```

For more information, see SWITCH function.

The `runswchl`, or CSQUTIL SWITCH, command transfers any messages on the old transmission queue to the new transmission queue. When the number of messages on the old transmission queue for this channel reaches zero, the switch is completed. The command is synchronous. The command writes progress messages to the window during the switching process.

During the transfer phase existing and new messages destined for the cluster-sender channel are transferred in order to the new transmission queue.

Because the cluster-sender channel is stopped, the messages build up on the new transmission queue. Contrast the stopped cluster-sender channel, to step 2 on page 54 in "Switching active cluster-sender channels to another set of cluster-transmission queues" on page 54. In that step, the cluster-sender channel is running, so messages do not necessarily build up on the new transmission queue.

4. Optional: Monitor the channels as they switch

   In a different command window, display the transmission queue depth during the switch. The following example display the status for system cluster transmission queues.

   ```
   DISPLAY QUEUE('SYSTEM.CLUSTER.TRANSMIT.*') CURDEPTH
   ```
5. Optional: Monitor the messages " AMQ7341 `The transmission queue for channel` *`ChannelName`* `switched from queue` *`QueueName`* `to` *`QueueName`* " that are written to the queue manager error log.
6. Restart the cluster-sender channels that you stopped.

   The channels do not start automatically, as you stopped them, placing them into `STOPPED` status.

   ```
   START CHANNEL(ChannelName)
   ```

Clustering: Migration and modification best practices:

This topic provides guidance for planning and administering IBM MQ clusters. This information is a guide based on testing and feedback from customers.

1. "Moving objects in a cluster" (Best practices for moving objects around inside a cluster, without installing any fix packs or new versions of IBM MQ).
2. "Upgrades and maintenance installations" on page 57 (Best practices for keeping a working cluster architecture up and running, while applying maintenance or upgrades and testing the new architecture).

Moving objects in a cluster

Applications and their queues

When you must move a queue instance hosted on one queue manager to be hosted on another, you can work with the workload balancing parameters to ensure a smooth transition.

Create an instance of the queue where it is to be newly hosted, but use cluster workload balancing settings to continue sending messages to the original instance until your application is ready to switch. This is achieved with the following steps:

1. Set the **`CLWLRANK`** property of the existing queue to a high value, for example five.
2. Create the new instance of the queue and set its **`CLWLRANK`** property to zero.
3. Complete any further configuration of the new system, for example deploy and start consuming applications against the new instance of the queue.
4. Set the **`CLWLRANK`** property of the new queue instance to be higher than the original instance, for example nine.

5. Allow the original queue instance to process any queued messages in the system and then delete the queue.

Moving entire queue managers

If the queue manager is staying on the same host, but the IP address is changing, then the process is as follows:

- DNS, when used correctly, can help simplify the process. For information about using DNS by setting the Connection name (CONNAME) channel attribute, see ALTER CHANNEL.
- If moving a full repository, ensure that you have at least one other full repository which is running smoothly (no problems with channel status for example) before making changes.
- Suspend the queue manager using the SUSPEND QMGR command to avoid traffic buildup.
- Modify the IP address of the computer. If your CLUSRCVR channel definition uses an IP address in the CONNAME field, modify this IP address entry. The DNS cache might need to be flushed through to ensure that updates are available everywhere.
- When the queue manager reconnects to the full repositories, channel auto-definitions automatically resolve themselves.
- If the queue manager hosted a full repository and the IP address changes, it is important to ensure that partials are switched over as soon as possible to point any manually defined CLUSSDR channels to the new location. Until this switch is carried out, these queue managers might be able to only contact the remaining (unchanged) full repository, and warning messages might be seen regarding the incorrect channel definition.
- Resume the queue manager using the RESUME QMGR command.

If the queue manager must be moved to a new host, it is possible to copy the queue manager data and restore from a backup. This process is not recommended however, unless there are no other options; it might be better to create a queue manager on a new machine and replicate queues and applications as described in the previous section. This situation gives a smooth rollover/rollback mechanism.

If you are determined to move a complete queue manager using backup, follow these best practices:

- Treat the whole process as a queue manager restore from backup, applying any processes you would usually use for system recovery as appropriate for your operating system environment.
- Use the `REFRESH CLUSTER` command after migration to discard all locally held cluster information (including any auto-defined channels that are in doubt), and force it to be rebuilt.

  Note: For large clusters, using the `REFRESH CLUSTER` command can be disruptive to the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster.

When creating a queue manager and replicating the setup from an existing queue manager in the cluster (as described previously in this topic), never treat the two different queue managers as actually being the same. In particular, do not give a new queue manager the same queue manager name and IP address. Attempting to 'drop in' a replacement queue manager is a frequent cause of problems in IBM MQ clusters. The cache expects to receive updates including the `QMID` attribute, and state can be corrupted.

If two different queue managers are accidentally created with the same name, it is recommended to use the RESET CLUSTER `QMID` command to eject the incorrect entry from the cluster.

Upgrades and maintenance installations

Avoid the so-called big bang scenario (for example, stopping all cluster and queue manager activity, applying all upgrades and maintenance to all queue managers, then starting everything at the same time). Clusters are designed to still work with multiple versions of queue manager coexisting, so a well-planned, phased maintenance approach is recommended.

Have a backup plan:

- z/OS On z/OS, have you applied backwards migration PTFs?
- Have you taken backups?
- Avoid using new cluster functionality immediately: Wait until you are sure that all the queue managers are upgraded to the new level, and are certain that you are not going to roll any of them back. Using new cluster function in a cluster where some queue managers are still at an earlier level can lead to undefined behavior. For example, in the move to IBM WebSphere® MQ Version 7.1 from IBM WebSphere MQ Version 6.0, if a queue manager defines a cluster topic, IBM WebSphere MQ Version 6.0 queue managers will not understand the definition or be able to publish on this topic.

Migrate full repositories first. Although they can forward information that they do not understand, they cannot persist it, so it is not the recommended approach unless absolutely necessary. For more information, see Queue manager cluster migration.

Clustering: Using REFRESH CLUSTER best practices:

You use the **REFRESH CLUSTER** command to discard all locally held information about a cluster and rebuild that information from the full repositories in the cluster. You should not need to use this command, except in exceptional circumstances. If you do need to use it, there are special considerations about how you use it. This information is a guide based on testing and feedback from customers.

Only run REFRESH CLUSTER if you really need to do so

The IBM MQ cluster technology ensures that any change to the cluster configuration, such as a change to a clustered queue, automatically becomes known to any member of the cluster that needs to know the information. There is no need for further administrative steps to be taken to achieve this propagation of information.

If such information does not reach the queue managers in the cluster where it is required, for example a clustered queue is not known by another queue manager in the cluster when an application attempts to open it for the first time, it implies a problem in the cluster infrastructure. For example, it is possible that a channel cannot be started between a queue manager and a full repository queue manager. Therefore, any situation where inconsistencies are observed must be investigated. If possible, resolve the situation without using the **REFRESH CLUSTER** command.

In rare circumstances that are documented elsewhere in this product documentation, or when requested by IBM support, you can use the **REFRESH CLUSTER** command to discard all locally held information about a cluster and rebuild that information from the full repositories in the cluster.

Refreshing in a large cluster can affect performance and availability of the cluster

Use of the **REFRESH CLUSTER** command can be disruptive to the cluster while it is in progress, for example by creating a sudden increase in work for the full repositories as they process the repropagation of queue manager cluster resources. If you are refreshing in a large cluster (that is, many hundreds of queue managers) you should avoid use of the command in day-to-day work if possible and use alternative methods to correct specific inconsistencies. For example, if a cluster queue is not being correctly propagated across the cluster, an initial investigation technique of updating the clustered queue definition, such as altering its description, repropagates the queue configuration across the cluster. This process can help to identify the problem and potentially resolve a temporary inconsistency.

If alternative methods cannot be used, and you have to run **REFRESH CLUSTER** in a large cluster, you should do so at off-peak times or during a maintenance window to avoid impact on user workloads. You should also avoid refreshing a large cluster in a single batch, and instead stagger the activity as explained in "Avoid performance and availability issues when cluster objects send automatic updates."

Avoid performance and availability issues when cluster objects send automatic updates

After a new cluster object is defined on a queue manager, an update for this object is generated every 27 days from the time of definition, and sent to every full repository in the cluster and onwards to any other interested queue managers. When you issue the **`REFRESH CLUSTER`** command to a queue manager, you reset the clock for this automatic update on all objects defined locally in the specified cluster.

If you refresh a large cluster (that is, many hundreds of queue managers) in a single batch, or in other circumstances such as recreating a system from configuration backup, after 27 days all of those queue managers will re-advertise all of their object definitions to the full repositories at the same time. This could again cause the system to run significantly slower, or even become unavailable, until all the updates have completed. Therefore, when you have to refresh or re-create multiple queue managers in a large cluster, you should stagger the activity over several hours, or several days, so that subsequent automatic updates do not regularly impact system performance.

The system cluster history queue

When a **`REFRESH CLUSTER`** is performed, the queue manager takes a snapshot of the cluster state before the refresh and stores it on the `SYSTEM.CLUSTER.HISTORY.QUEUE` (SCHQ) if it is defined on the queue manager. This snapshot is for IBM service purposes only, in case of later problems with the system.

The SCHQ is defined by default on distributed queue managers on startup. For z/OS migration, the SCHQ must be manually defined.

Messages on the SCHQ expire after three months.

REFRESH CLUSTER considerations for publish/subscribe clusters

Clustering: Availability, multi-instance, and disaster recovery:

This topic provides guidance for planning and administering IBM MQ clusters. This information is a guide based on testing and feedback from customers.

IBM MQ Clustering itself is not a High Availability solution, but in some circumstances it can be used to improve the availability of services using IBM MQ, for example by having multiple instances of a queue on different queue managers. This section gives guidance on ensuring that the IBM MQ infrastructure is as highly available as possible so that it can be used in such an architecture.

Availability of cluster resources

The reason for the usual recommendation to maintain two full repositories is that the loss of one is not critical to the smooth running of the cluster. Even if both become unavailable, there is a 60 day grace period for existing knowledge held by partial repositories, although new or not previously accessed resources (queues for example) are not available in this event.

Using clusters to improve application availability

A cluster can help in designing highly available applications (for example a request/response type server application), by using multiple instances of the queue and application. If needed, priority attributes can give preference to the 'live' application unless a queue manager or channel for example become unavailable. This is powerful for switching over quickly to continue processing new messages when a problem occurs.

However, messages which were delivered to a particular queue manager in a cluster are held only on that queue instance, and are not available for processing until that queue manager is recovered. For this reason, for true data high availability you might want to consider other technologies such as multi-instance queue managers.

Multi-instance queue managers

Software High Availability (multi-instance) is the best built-in offering for keeping your existing messages available. See Using IBM MQ with high availability configurations, Create a multi-instance queue manager, and the following section for more information. Any queue manager in a cluster may be made highly available using this technique, as long as all queue managers in the cluster are running at least IBM WebSphere MQ Version 7.0.1. If any queue managers in the cluster are at previous levels, they might lose connectivity with the multi-instance queue managers if they fail over to a secondary IP.

As discussed previously in this topic, as long as two full repositories are configured, they are almost by their nature highly available. If you need to, IBM MQ software High Availability / multi-instance queue managers can be used for full repositories. There is no strong reason to use these methods, and in fact for temporary outages these methods might cause additional performance cost during the failover. Using software HA instead of running two full repositories is discouraged because in the event of a single channel outage, for example, it would not necessarily fail over, but might leave partial repositories unable to query for cluster resources.

Disaster recovery

Disaster recovery, for example recovering from when the disks storing a queue manager's data becomes corrupt, is difficult to do well; IBM MQ can help, but it cannot do it automatically. The only 'true' disaster recovery option in IBM MQ (excluding any operating system or other underlying replication technologies) is restoration from a backup. There are some cluster specific points to consider in these situations:

- Take care when testing disaster recovery scenarios. For example, if testing the operation of backup queue managers, be careful when bringing them online in the same network as it is possible to accidentally join the live cluster and start 'stealing' messages by hosting the same named queues as in the live cluster queue managers.
- Disaster recovery testing must not interfere with a running live cluster. Techniques to avoid interference include:
  - Complete network separation or separation at the firewall level.
  - z/OS Not starting channel initiation or the z/OS **chinit** address space.
  - Not issuing live TLS certificate to the disaster recovery system until, or unless, an actual disaster recovery scenario occurs.
- When restoring a backup of a queue manager in the cluster it is possible that the backup is out of sync with the rest of the cluster. The **REFRESH CLUSTER** command can resolve updates and synchronize with the cluster but the **REFRESH CLUSTER** command must be used as a last resort. See “Clustering: Using REFRESH CLUSTER best practices” on page 58. Review any in-house process documentation and IBM MQ documentation to see whether a simple step was missed before resorting to using the command.
- As for any recovery, applications must deal with replay and loss of data. It must be decided whether to clear the queues down to a known state, or if there is enough information elsewhere to manage replays.

Planning your distributed publish/subscribe network

You can create a network of queue managers where subscriptions created on one queue manager will receive matching messages published by an application connected to another queue manager in the network. To choose a suitable topology, you need to consider your requirements for manual control, network size, frequency of change, availability and scalability.

Before you begin

This task assumes that you understand what distributed publish/subscribe networks are, and how they work. For a technical overview, see Distributed publish/subscribe networks.

About this task

There are three basic topologies for a publish/subscribe network:
- Direct routed cluster
- Topic host routed cluster
- Hierarchy

For the first two topologies, the starting point is an IBM MQ cluster configuration. The third topology can be created with or without a cluster. See"Planning your distributed queues and clusters" on page 7for information about planning the underlying queue manager network.

A *Direct routed cluster* is the simplest topology to configure when a cluster is already present. Any topic that you define on any queue manager is automatically made available on every queue manager in the cluster, and publications are routed directly from any queue manager where a publishing application connects, to each of the queue managers where matching subscriptions exist. This simplicity of configuration relies on IBM MQ maintaining a high level of sharing of information and connectivity between every queue manager in the cluster. For small and simple networks (that is, a small number of queue managers, and a fairly static set of publishers and subscribers) this is acceptable. However, when used in larger or more dynamic environments the overhead might be prohibitive. See"Direct routing in publish/subscribe clusters" on page 66.

A *Topic host routed cluster* gives the same benefit as a direct routed cluster, by making any topic that you define on any queue manager in the cluster automatically available on every queue manager in the cluster. However, topic host routed clusters require you to carefully choose the queue managers that host each topic, because all information and publications for that topic pass through those topic host queue managers. This means that the system does not have to maintain channels and information flows between all queue managers. However it also means that publications might no longer be sent directly to subscribers, but might be routed through a topic host queue manager. For these reasons additional load might be put on the system, especially on the queue managers hosting the topics, so careful planning of the topology is required. This topology is particularly effective for networks that contain many queue managers, or that host a dynamic set of publishers and subscribers (that is, publishers or subscribers that are frequently added or removed). Additional topic hosts can be defined to improve availability of routes and to horizontally scale publication workload. See"Topic host routing in publish/subscribe clusters" on page 71.

A *Hierarchy* requires the most manual configuration to set up, and is the hardest topology to modify. You must manually configure the relationships between each queue manager in the hierarchy and its direct relations. After relationships are configured, publications will (as for the previous two topologies) be routed to subscriptions on other queue managers in the hierarchy. Publications are routed using the hierarchy relationships. This allows very specific topologies to be configured to suit different requirements, but it can also result in publications requiring many "hops" through intermediate queue managers to reach the subscriptions. There is always only one route through a hierarchy for a publication, so availability of every queue manager is critical. Hierarchies are typically only preferable where a single cluster cannot be configured; for example when spanning multiple organizations. See“Routing in publish/subscribe hierarchies” on page 96.

Where necessary, the above three topologies can be combined to solve specific topographical requirements. For an example, see Combining the topic spaces of multiple clusters.

To choose a suitable topology for your distributed publish/subscribe network, you need to consider the following broad questions:
- How big will your network be?
- How much manual control do you need over its configuration?
- How dynamic will the system be, both in terms of topics and subscriptions, and in terms of queue managers?
- What are your availability and scalability requirements?
- Can all queue managers connect directly to each other?

Procedure

- Estimate how big your network needs to be.
  1. Estimate how many topics you need.
  2. Estimate how many publishers and subscribers you expect to have.
  3. Estimate how many queue managers will be involved in publish/subscribe activities.

     See also“Publish/subscribe clustering: Best practices” on page 81, especially the following sections:
     – How to size your system
     – Reasons to limit the number of cluster queue managers involved in publish/subscribe activity
     – How to decide which topics to cluster

  If your network will have many queue managers, and handle many publishers and subscribers, you probably need to use a topic host routed cluster or a hierarchy. Direct routed clusters require almost no manual configuration, and can be a good solution for small or static networks.
- Consider how much manual control you need over which queue manager hosts each topic, publisher or subscriber.
  1. Consider whether some of your queue managers are less capable than others.
  2. Consider whether the communication links to some of your queue managers are more fragile than to others.
  3. Identify cases where you expect a topic to have many publications and few subscribers.
  4. Identify cases where you expect a topic to have many subscribers and few publications.

  In all topologies, publications are delivered to subscriptions on other queue managers. In a direct routed cluster those publications take the shortest path to the subscriptions. In a topic host routed cluster or a hierarchy, you control the route that publications take. If your queue managers differ in their capability, or have differing levels of availability and connectivity, you will probably want to assign specific workloads to specific queue managers. You can do this using either a topic host routed cluster or a hierarchy.

  In all topologies, co-locating the publishing applications on the same queue manager as the subscriptions whenever possible minimizes overheads and maximizes performance. For topic host routed clusters, consider putting publishers or subscribers on the queue managers that host the topic. This removes any extra “hops” between queue managers to pass a publication to a subscriber. This approach is particularly effective in cases where a topic has many publishers and few subscribers, or many subscribers and few publishers. See, for example, Topic host routing using centralized publishers or subscribers.

  See also“Publish/subscribe clustering: Best practices” on page 81, especially the following sections:
  – How to decide which topics to cluster
  – Publisher and subscription location

- Consider how dynamic the network activity will be.
  1. Estimate how frequently subscribers will be added and removed on different topics.

     Whenever a subscription is added or removed from a queue manager, and it is the first or last subscription for that specific topic string, that information is communicated to other queue managers in the topology. In a direct routed cluster and a hierarchy, this subscription information is propagated to every queue manager in the topology whether or not they have publishers on the topic. If the topology consists of many queue managers, this might be a significant performance overhead. In a topic host routed cluster, this information is only propagated to those queue managers that host a clustered topic that maps to the subscription's topic string.

     See also the Subscription change and dynamic topic strings section of"Publish/subscribe clustering: Best practices" on page 81.

     Note: In very dynamic systems, where the set of many unique topic strings is rapidly and constantly being changed, it might be best to switch the model to a "publish everywhere" mode. See Subscription performance in publish/subscribe networks.
  2. Consider how dynamic the queue managers are in the topology.

     A hierarchy requires each change in queue manager in the topology to be manually inserted or removed from the hierarchy, with care taken when changing queue managers at higher levels in the hierarchy. Queue managers in a hierarchy typically also use manually configured channel connections. You must maintain these connections, adding and removing channels as queue managers are added and removed from the hierarchy.

     In a publish/subscribe cluster, queue managers are automatically connected to any other queue manager that is required when they first join the cluster, and automatically become aware of topics and subscriptions.
- Consider your route availability and publication traffic scalability requirements.
  1. Decide whether you need to always have an available route from a publishing queue manager to a subscribing queue manager, even when a queue manager is unavailable.
  2. Consider how scalable you need the network to be. Decide whether the level of publication traffic is too high to be routed through a single queue manager or channel, and whether that level of publication traffic must be handled by a single topic branch or can be spread across multiple topic branches.
  3. Consider whether you need to maintain message ordering.

  Because a direct routed cluster sends messages directly from publishing queue managers to subscribing queue managers, you do not need to consider the availability of intermediate queue managers along the route. Similarly, scaling to the intermediate queue managers is not a consideration. However, as previously mentioned, the overhead of automatically maintaining channels and information flows between all queue managers in the cluster can significantly affect performance, especially in a large or dynamic environment.

  A topic host routed cluster can be tuned for individual topics. You can ensure that each branch of the topic tree that has a considerable publication workload is defined on a different queue manager, and that each queue manager is sufficiently performant and available for the expected workload for that branch of the topic tree. You can also improve availability and horizontal scaling further by defining each topic on multiple queue managers. This allows the system to route around unavailable topic host queue managers, and to workload balance publication traffic across them. However, when you define a given topic on multiple queue managers, you also introduce the following constraints:
  - You lose message ordering across publications.
  - You cannot use retained publications. See"Design considerations for retained publications in publish/subscribe clusters" on page 94.

  You cannot configure high availability or scalability of routing in a hierarchy through multiple routes.

  See also the Publication traffic section of"Publish/subscribe clustering: Best practices" on page 81.
- Based on these calculations, use the links provided to help you decide whether to use a topic host routed cluster, a direct routed cluster, a hierarchy, or a mixture of these topologies.

What to do next

You are now ready to configure your distributed publish/subscribe network.

Related information:

Configuring a queue manager cluster

Configuring distributed queuing

Configuring a publish/subscribe cluster

Connecting a queue manager to a publish/subscribe hierarchy

Designing publish/subscribe clusters

There are two basic publish/subscribe cluster topologies: *direct routing* and *topic host routing*. Each has different benefits. When you design your publish/subscribe cluster, choose the topology that best fits your expected network requirements.

For an overview of the two publish/subscribe cluster topologies, see Publish/subscribe clusters. To help you evaluate your network requirements, see “Planning your distributed publish/subscribe network” on page 61 and “Publish/subscribe clustering: Best practices” on page 81.

In general, both cluster topologies provide the following benefits:

- Simple configuration on top of a point-to-point cluster topology.
- Automatic handling of queue managers joining and leaving the cluster.
- Ease of scaling for additional subscriptions and publishers, by adding extra queue managers and distributing the additional subscriptions and publishers across them.

However, the two topologies have different benefits as the requirements become more specific.

Direct routed publish/subscribe clusters

With direct routing, any queue manager in the cluster sends publications from connected applications direct to any other queue manager in the cluster with a matching subscription.

A direct routed publish/subscribe cluster provides the following benefits:

- Messages destined for a subscription on a specific queue manager in the same cluster are transported directly to that queue manager and do not need to pass through an intermediate queue manager. This can improve performance in comparison with a topic host routed topology, or a hierarchical topology.
- Because all queue managers are directly connected to each other, there is no single point of failure in the routing infrastructure of this topology. If one queue manager is not available, subscriptions on other queue managers in the cluster are still able to receive messages from publishers on available queue managers.
- It is very simple to configure, especially on an existing cluster.

Things to consider when using a direct routed publish/subscribe cluster:

- All queue managers in the cluster become aware of all other queue managers in the cluster.
- Queue managers in a cluster that host one or more subscriptions to a clustered topic, automatically create cluster sender channels to all other queue managers in the cluster, even when those queue managers are not publishing messages on any clustered topics.
- The first subscription on a queue manager to a topic string under a clustered topic results in a message being sent to every other queue manager in the cluster. Similarly, the last subscription on a topic string to be deleted also results in a message. The more individual topic strings being used under a clustered topic, and the higher the rate of change of subscriptions, the more inter-queue manager communication occurs.

- Every queue manager in the cluster maintains the knowledge of subscribed topic strings that it is informed of, even when the queue manager is neither publishing nor subscribing to those topics.

For the above reasons, all queue managers in a cluster with a direct routed topic defined will incur an additional overhead. The more queue managers there are in the cluster, the greater the overhead. Likewise the more topic strings subscribed to, and the greater their rate of change, the greater the overhead. This can result in too much load on queue managers running on small systems in a large or dynamic direct routed publish/subscribe cluster. See Direct routed publish/subscribe performance for further information.

When you know that a cluster cannot accommodate the overheads of direct routed clustered publish/subscribe, you can instead use topic host routed publish/subscribe. Alternatively, in extreme situations, you can completely disable clustered publish/subscribe functionality by setting the queue manager attribute **PSCLUS** to `DISABLED` on every queue manager in the cluster. See "Inhibiting clustered publish/subscribe" on page 91. This prevents any clustered topic from being created, and therefore ensures that your network does not incur any overheads associated with clustered publish/subscribe.

Topic host routed publish/subscribe clusters

With topic host routing, the queue managers where clustered topics are administratively defined become routers for publications. Publications from non-hosting queue managers in the cluster are routed through the hosting queue manager to any queue manager in the cluster with a matching subscription.

A topic host routed publish/subscribe cluster provides the following extra benefits over a direct routed publish/subscribe cluster:
- Only queue managers on which topic host routed topics are defined are made aware of all other queue managers in the cluster.
- Only the topic host queue managers need to be able to connect to all other queue managers in the cluster, and will typically only connect to those where subscriptions exist. Therefore there are significantly fewer channels running between queue managers.
- Cluster queue managers that host one or more subscriptions to a clustered topic automatically create cluster sender channels only to queue managers that host a cluster topic that maps to the topic string of the subscription.
- The first subscription on a queue manager to a topic string under a clustered topic results in a message being sent to a queue manager in the cluster that hosts the clustered topic. Similarly, the last subscription on a topic string to be deleted also results in a message. The more individual topic strings being used under a clustered topic, and the higher the rate of change of subscriptions, the more inter-queue manager communication occurs, but only between subscription hosts and topic hosts.
- More control over the physical configuration. With direct routing, all queue managers have to participate in the publish/subscribe cluster, increasing their overheads. With topic host routing, only the topic host queue managers are aware of other queue managers and their subscriptions. You explicitly choose the topic host queue managers, therefore you can ensure that those queue managers are running on adequate equipment, and you can use less powerful systems for the other queue managers.

Things to consider when using a topic host routed publish/subscribe cluster:
- An extra "hop" between a publishing queue manager and a subscribing queue manager is introduced when the publisher or the subscriber is not located on a topic hosting queue manager. The latency caused by the extra "hop" can mean that topic host routing is less efficient that direct routing.
- On large clusters, topic host routing eases the significant performance and scaling issues that you can get with direct routing.
- You might choose to define all your topics on a single queue manager, or on a very small number of queue managers. If you do this, make sure the topic host queue managers are hosted on powerful systems with good connectivity.

- You can define the same topic on more than one queue manager. This improves the availability of the topic, and also improves scalability because IBM MQ workload balances publications for a topic across all hosts for that topic. Note, however, that defining the same topic on more than one queue manager loses message order for that topic.
- By hosting different topics on different queue managers, you can improve scalability without losing message order.

Distributed publish/subscribe troubleshooting

Direct routing in publish/subscribe clusters:

Publications from any publishing queue manager are routed direct to any other queue manager in the cluster with a matching subscription.

For an introduction to how messages are routed between queue managers in publish/subscribe hierarchies and clusters, see Distributed publish/subscribe networks.

A direct routed publish/subscribe cluster behaves as follows:

- All queue managers automatically know of all other queue managers.
- All queue managers with subscriptions to clustered topics create channels to all other queue managers in the cluster and inform them of their subscriptions.
- Messages published by an application are routed from the queue manager that it is connected to, direct to each queue manager where a matching subscription exists.

The following diagram shows a queue manager cluster that is not currently used for publish/subscribe or point-to-point activities. Note that every queue manager in the cluster connects only to and from the full repository queue managers.

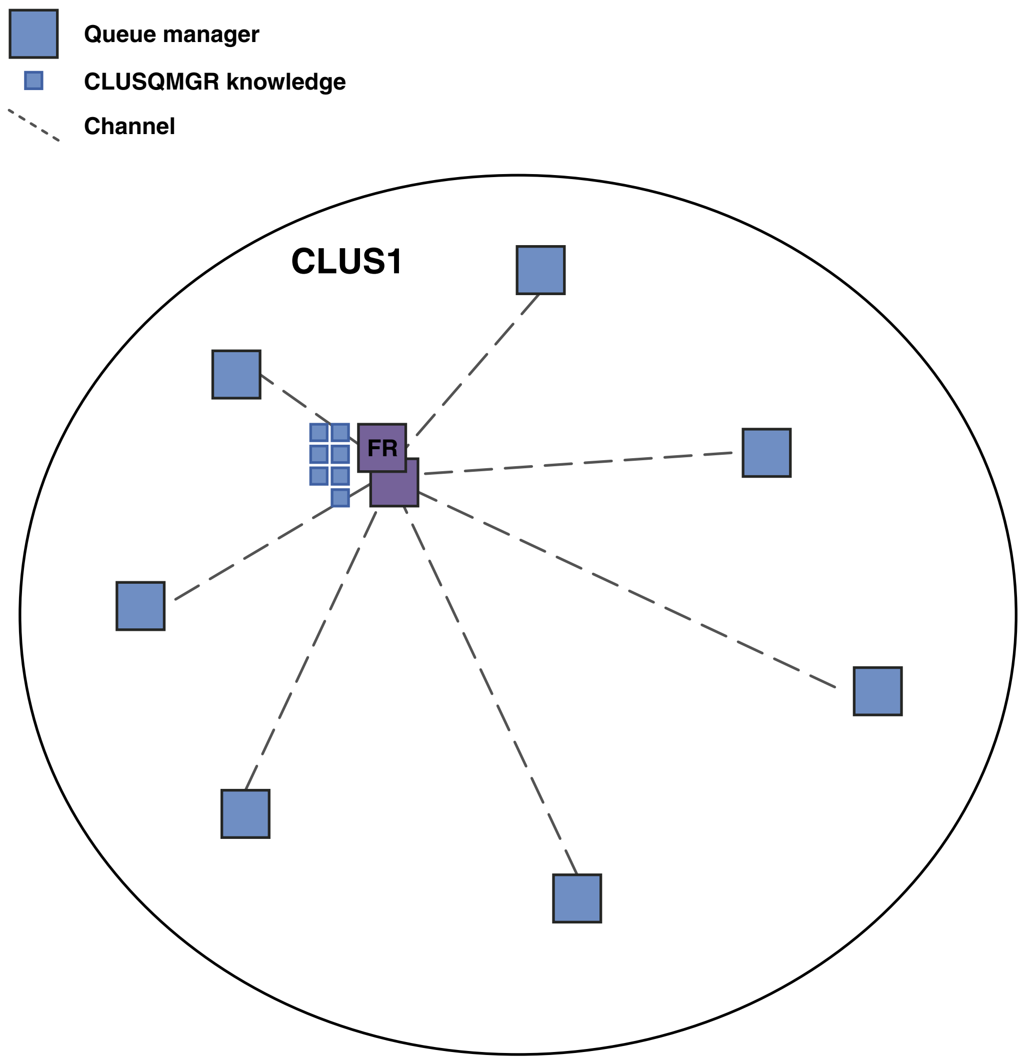

Figure 18. A queue manager cluster

For publications to flow between queue managers in a direct routed cluster, you cluster a branch of the topic tree as described in Configuring a publish/subscribe cluster, and specify *direct routing* (the default).

In a direct routed publish/subscribe cluster, you define the topic object on any queue manager in the cluster. When you do this, knowledge of the object, and knowledge of all other queue managers in the cluster, is automatically pushed to all queue managers in the cluster by the full repository queue managers. This happens before any queue manager references the topic:

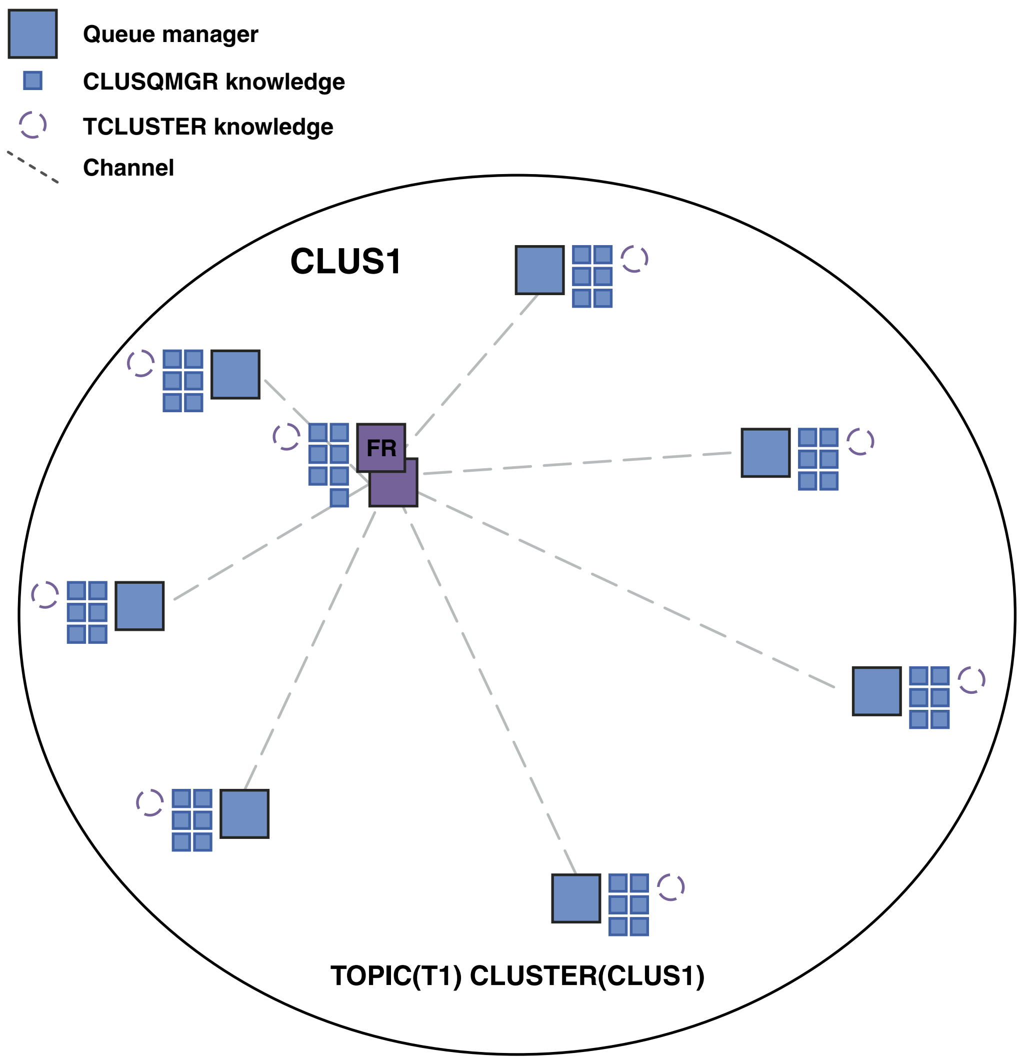

Figure 19. A direct routed publish/subscribe cluster

When a subscription is created, the queue manager that hosts the subscription establishes a channel to every queue manager in the cluster, and sends details of the subscription. This distributed subscription knowledge is represented by a proxy subscription on each queue manager. When a publication is produced on any queue manager in the cluster that matches that proxy subscription's topic string, a cluster channel is established from the publisher queue manager to each queue manager hosting a subscription, and the message is sent to each of them.

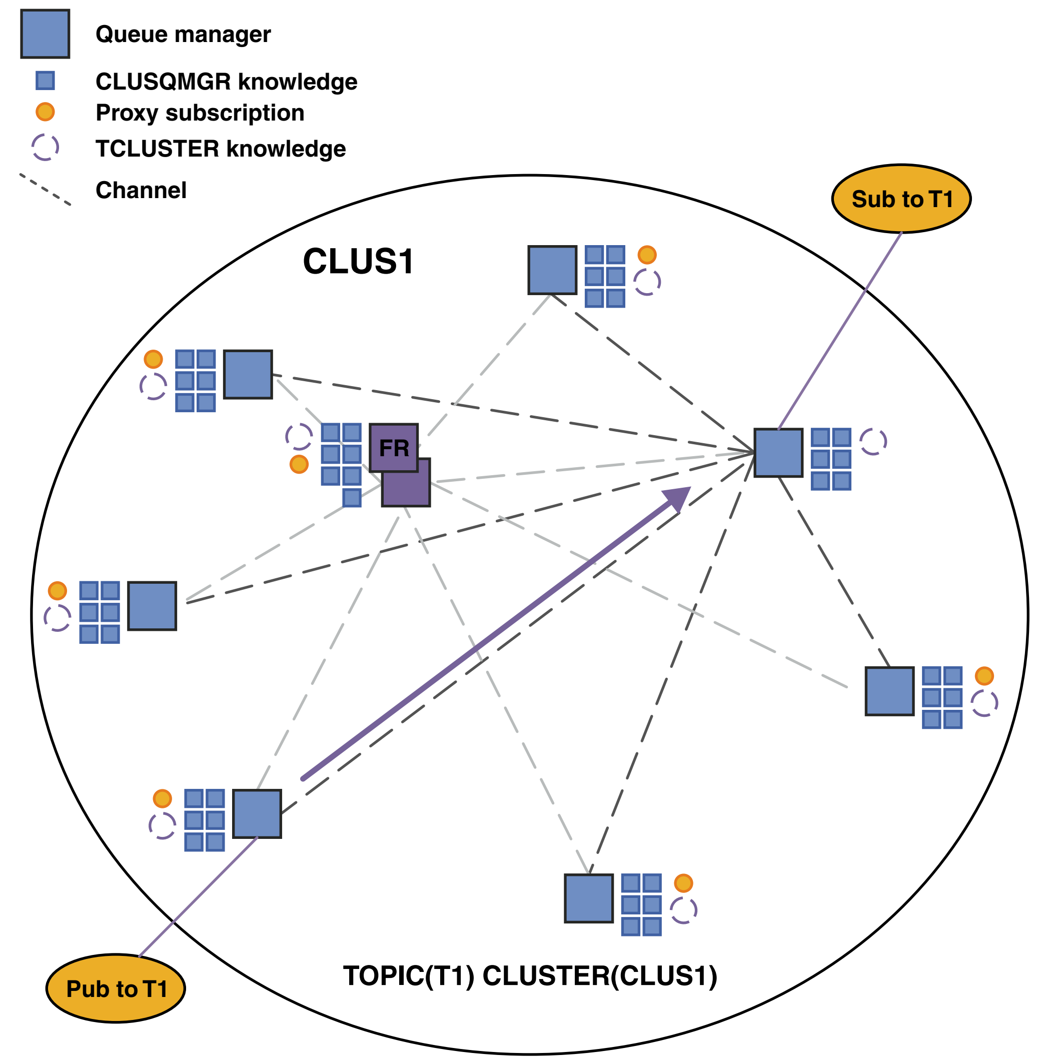

Figure 20. A direct routed publish/subscribe cluster with a publisher and a subscriber to a clustered topic

The direct routing of publications to subscription hosting queue managers simplifies configuration and minimizes the latency in delivering publications to subscriptions.

However, depending on the location of subscriptions and publishers, your cluster can quickly become fully interconnected, with every queue manager having a direct connection to every other queue manager. This might or might not be acceptable in your environment. Similarly, if the set of topic strings being subscribed to is changing frequently, the overhead of propagating that information between all queue managers can also become significant. All queue managers in a direct routed publish/subscribe cluster must be able to cope with these overheads.

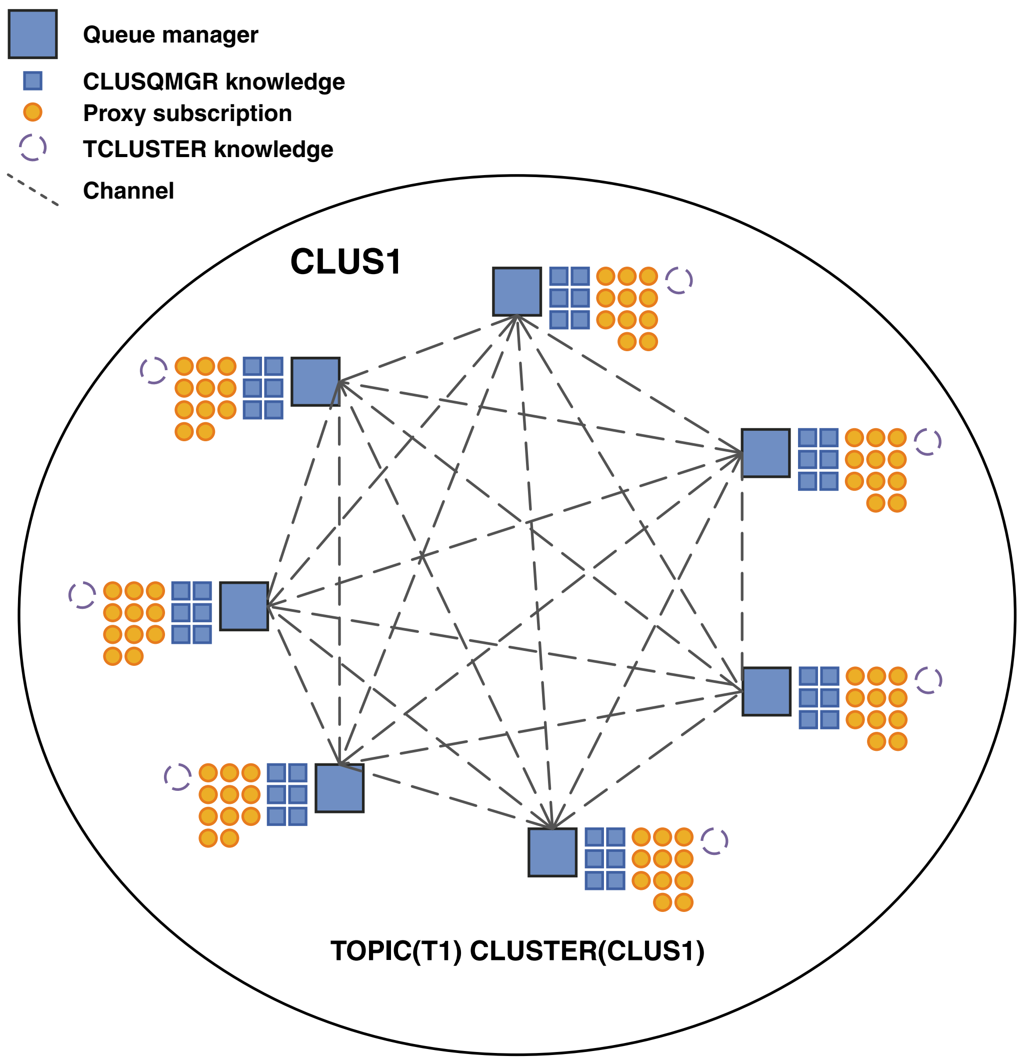

Figure 21. A direct routed publish/subscribe cluster that is fully interconnected

Summary and additional considerations

A direct routed publish/subscribe cluster needs little manual intervention to create or administer, and provides direct routing between publishers and subscribers. For certain configurations it is usually the most appropriate topology, notably clusters with few queue managers, or where high queue manager connectivity is acceptable and subscriptions are changing infrequently. However it also imposes certain constraints upon your system:

- The load on each queue manager is proportional to the total number of queue managers in the cluster. Therefore, in larger clusters, individual queue managers and the system as a whole can experience performance issues.
- By default, all clustered topic strings subscribed to are propagated throughout the cluster, and publications are propagated only to remote queue managers that have a subscription to the associated topic. Therefore rapid changes to the set of subscriptions can become a limiting factor. You can change this default behavior, and instead have all publications propagated to all queue managers, which removes the need for proxy subscriptions. This reduces the subscription knowledge traffic, but is likely to increase the publication traffic and the number of channels each queue manager establishes. See Subscription performance in publish/subscribe networks.

  Note: A similar restriction also applies to hierarchies.

- Because of the interconnected nature of publish/subscribe queue managers, it takes time for proxy subscriptions to propagate around all nodes in the network. Remote publications do not necessarily start being subscribed to immediately, so early publications might not be sent following a subscription to a new topic string. You can remove the problems caused by the subscription delay by having all publications propagated to all queue managers, which removes the need for proxy subscriptions. See Subscription performance in publish/subscribe networks.

  Note: This restriction also applies to hierarchies.

Before you use direct routing, explore the alternative approaches detailed in "Topic host routing in publish/subscribe clusters," and "Routing in publish/subscribe hierarchies" on page 96.

Topic host routing in publish/subscribe clusters:

Publications from non-hosting queue managers in the cluster are routed through the hosting queue manager to any queue manager in the cluster with a matching subscription.

For an introduction to how messages are routed between queue managers in publish/subscribe hierarchies and clusters, see Distributed publish/subscribe networks.

To understand the behavior and benefits of topic host routing it is best to first understand "Direct routing in publish/subscribe clusters" on page 66.

A topic host routed publish/subscribe cluster behaves as follows:
- Clustered administered topic objects are manually defined on individual queue managers in the cluster. These are referred to as *topic host queue managers*.
- When a subscription is made on a cluster queue manager, channels are created from the subscription host queue manager to the topic host queue managers, and proxy subscriptions are created only on the queue managers that host the topic.
- When an application publishes information to a topic, the connected queue manager always forwards the publication to one queue manager that hosts the topic, which passes it on to all queue managers in the cluster that have matching subscriptions to the topic.

This process is explained in more detail in the following examples.

Topic host routing using a single topic host

For publications to flow between queue managers in a topic host routed cluster, you cluster a branch of the topic tree as described in Configuring a publish/subscribe cluster, and specify *topic host routing*.

There are a number of reasons to define a topic host routed topic object on multiple queue managers in a cluster. However, for simplicity we start with a single topic host.

The following diagram shows a queue manager cluster that is not currently used for publish/subscribe or point-to-point activities. Note that every queue manager in the cluster connects only to and from the full repository queue managers.

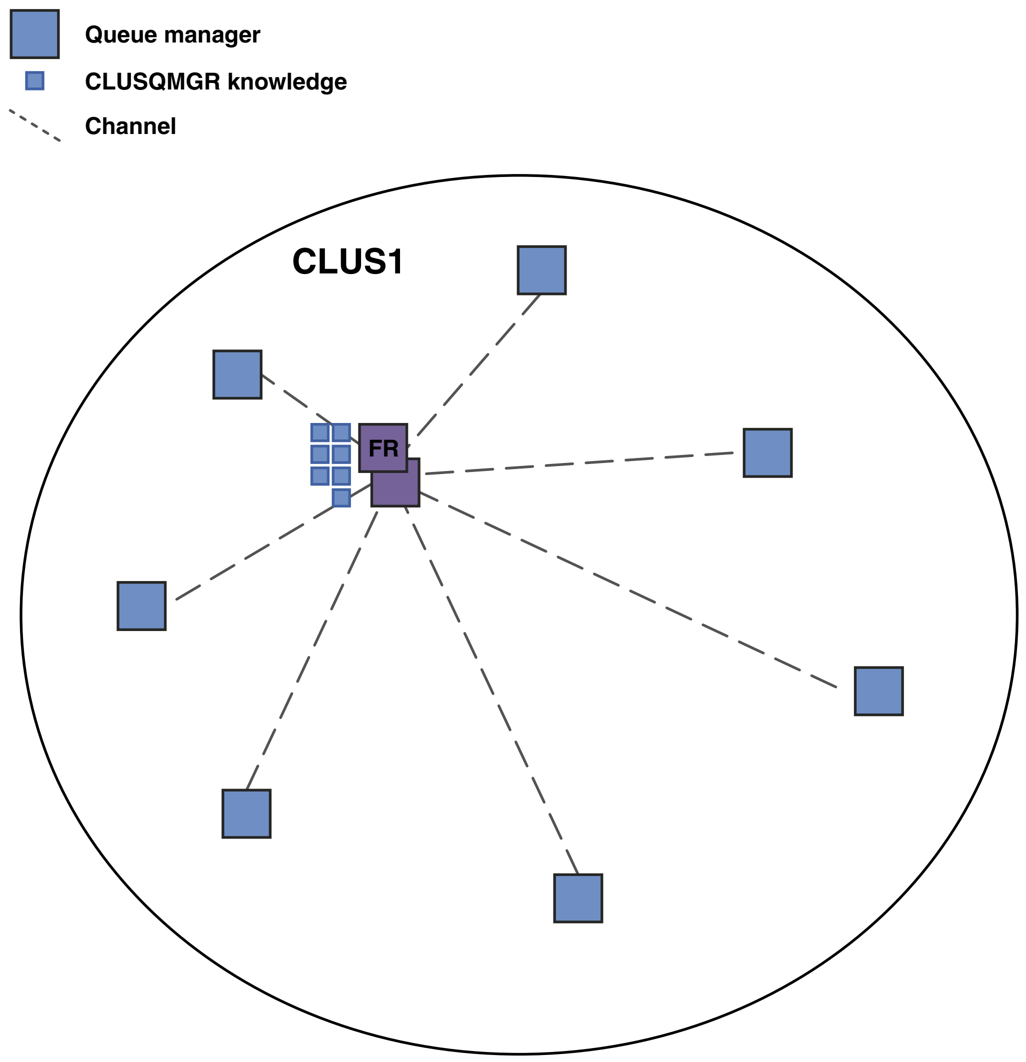

Figure 22. A queue manager cluster

In a topic host routed publish/subscribe cluster, you define the topic object on a specific queue manager in the cluster. Publish/subscribe traffic then flows through that queue manager, making it a critical queue manager in the cluster and increasing its workload. For these reasons it is not recommended to use a full repository queue manager, but to use another queue manager in the cluster. When you define the topic object on the host queue manager, knowledge of the object and its host is automatically pushed, by the full repository queue managers, to all the other queue managers in the cluster. Note that, unlike *direct routing*, each queue manager is not told about every other queue manager in the cluster.

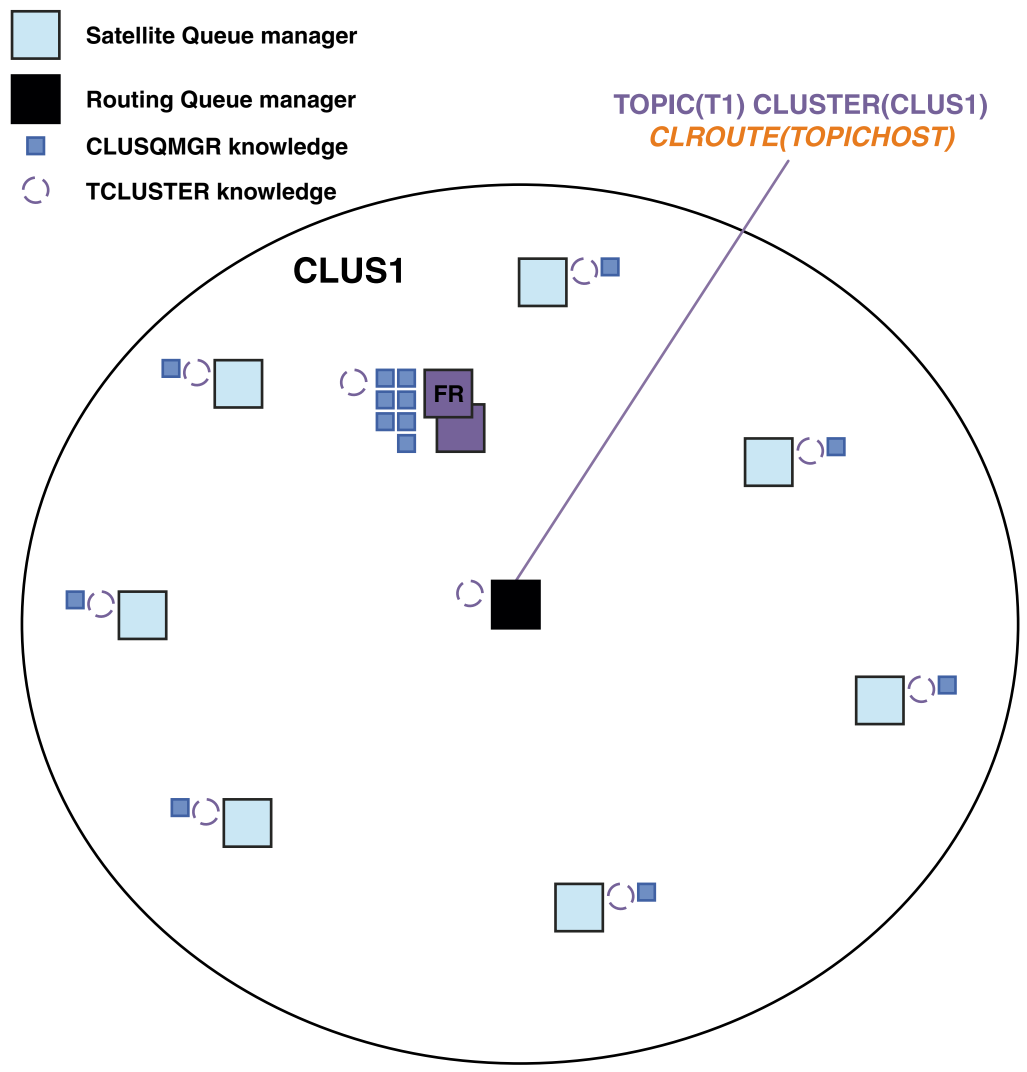

Figure 23. A topic host routed publish/subscribe cluster with one topic defined on one topic host

When a subscription is created on a queue manager, a channel is created between the subscribing queue manager and the topic host queue manager. The subscribing queue manager connects only to the topic host queue manager, and sends details of the subscription (in the form of a *proxy subscription*). The topic host queue manager does not forward this subscription information on to any further queue managers in the cluster.

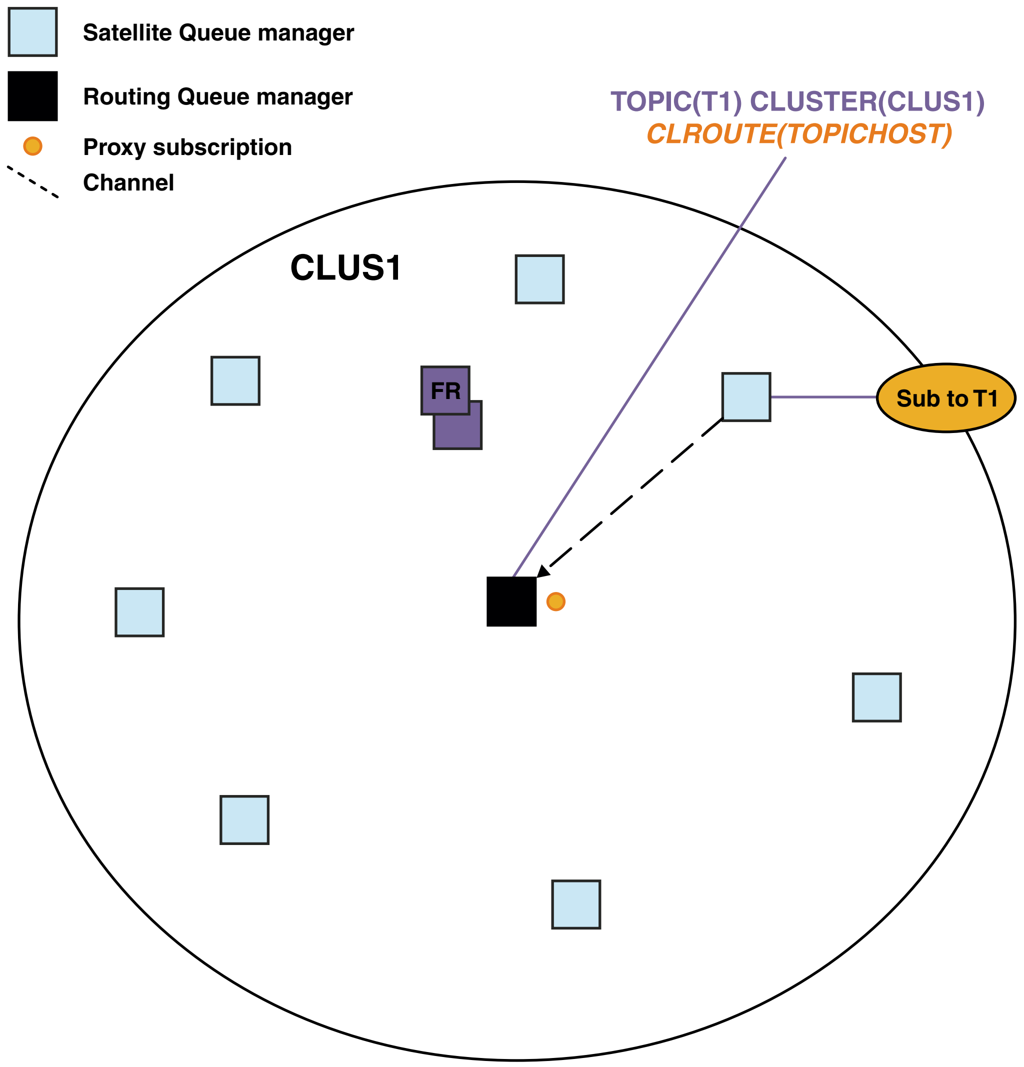

Figure 24. A topic host routed publish/subscribe cluster with one topic defined on one topic host, and one subscriber

When a publishing application connects to another queue manager and a message is published, a channel is created between the publishing queue manager and the topic host queue manager, and the message is forwarded to that queue manager. The publishing queue manager has no knowledge of any subscriptions on other queue managers in the cluster, so the message is forwarded to the topic host queue manager even if there are no subscribers to that topic in the cluster. The publishing queue manager connects only to the topic host queue manager. Publications are routed through the topic host to the subscribing queue managers, if any exist.

Subscriptions on the same queue manager as the publisher are satisfied directly, without first sending the messages to a topic host queue manager.

Note that, because of the critical role played by each topic host queue manager, you must choose queue managers that can handle the load, availability and connectivity requirements of topic hosting.

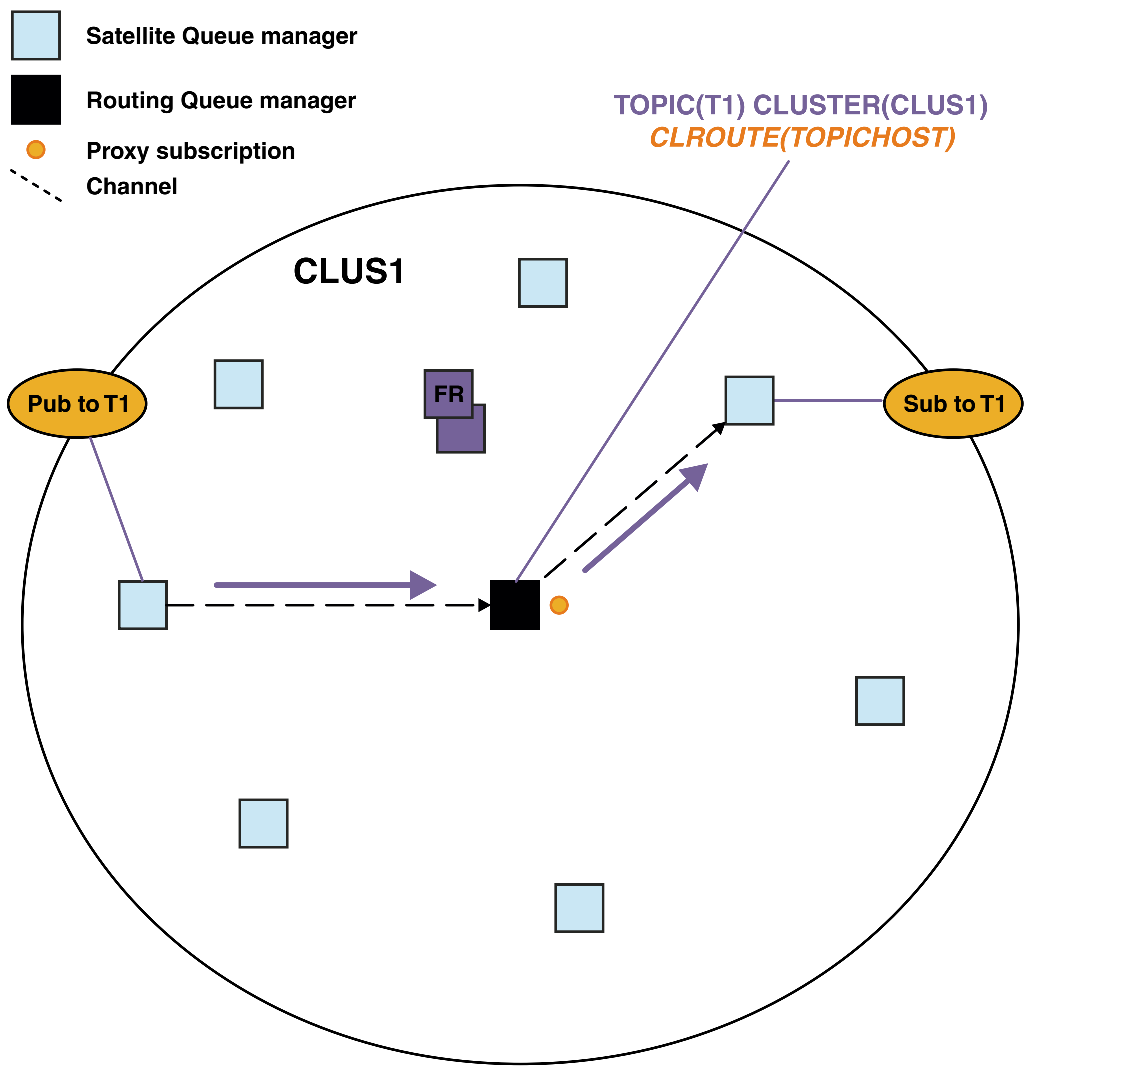

Figure 25. A topic host routed publish/subscribe cluster with one topic, one subscriber and one publisher

Dividing the topic tree across multiple queue managers

A routed topic hosting queue manager is only responsible for the subscription knowledge and publication messages that relate to the branch of the topic tree that its administered topic object is configured for. If different topics are used by different publish/subscribe applications in the cluster, you can configure different queue managers to host different clustered branches of the topic tree. This allows scaling by reducing the publication traffic, subscription knowledge and channels on each topic host queue manager in the cluster. You should use this method for distinct high volume branches of the topic tree:

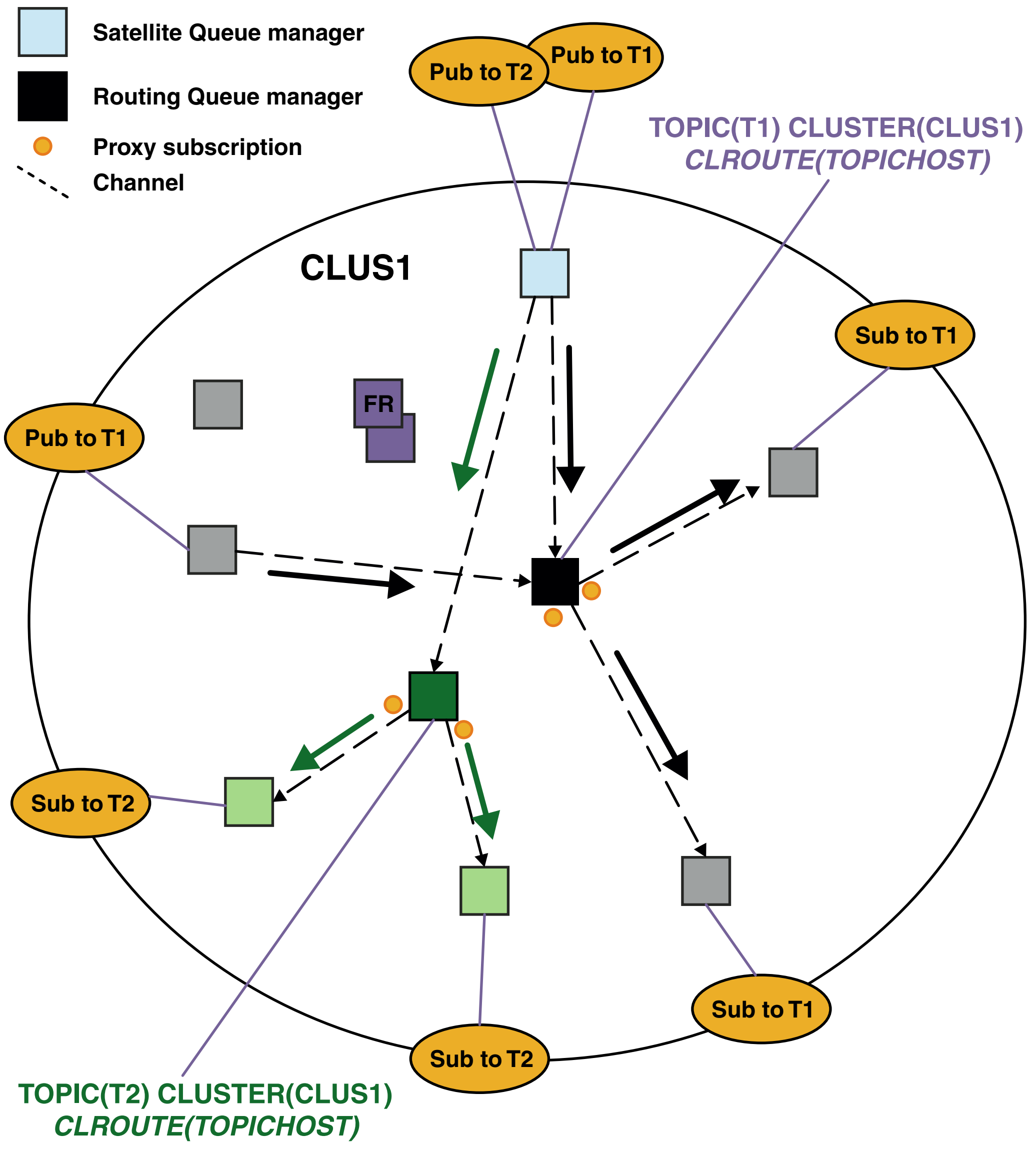

Figure 26. A topic host routed publish/subscribe cluster with two topics, each defined on one topic host

For example, using the topics described in Topic trees, if topic `T1` was configured with a topic string of `/USA/Alabama`, and topic `T2` was configured with a topic string of `/USA/Alaska`, then a message published to `/USA/Alabama/Mobile` would be routed through the queue manager hosting `T1`, and a message published to `/USA/Alaska/Juneau` would be routed through the queue manager hosting `T2`.

Note: You cannot make a single subscription span multiple clustered branches of the topic tree by using a wildcard higher in the topic tree than the points that are clustered. See Wildcard subscriptions.

Topic host routing using multiple topic hosts for a single topic

If a single queue manager has the responsibility for the routing of a topic, and that queue manager becomes unavailable or incapable of handling the workload, publications will not flow promptly to the subscriptions.

If you need greater resiliency, scalability and workload balancing than you get when you define a topic on just one queue manager, you can define a topic on more than one queue manager. Each individual message published is routed through a single topic host. When multiple matching topic host definitions exist, one of the topic hosts is chosen. The choice is made in the same way as for clustered queues. This allows messages to be routed to available topic hosts, avoiding any that are unavailable, and allows message load to be workload balanced across multiple topic host queue managers and channels. However, ordering across multiple messages is not maintained when you use multiple topic hosts for the same topic in the cluster.

The following diagram shows a topic host routed cluster in which the same topic has been defined on two queue managers. In this example, the subscribing queue managers send information about the subscribed topic to both topic host queue managers in the form of a proxy subscription:

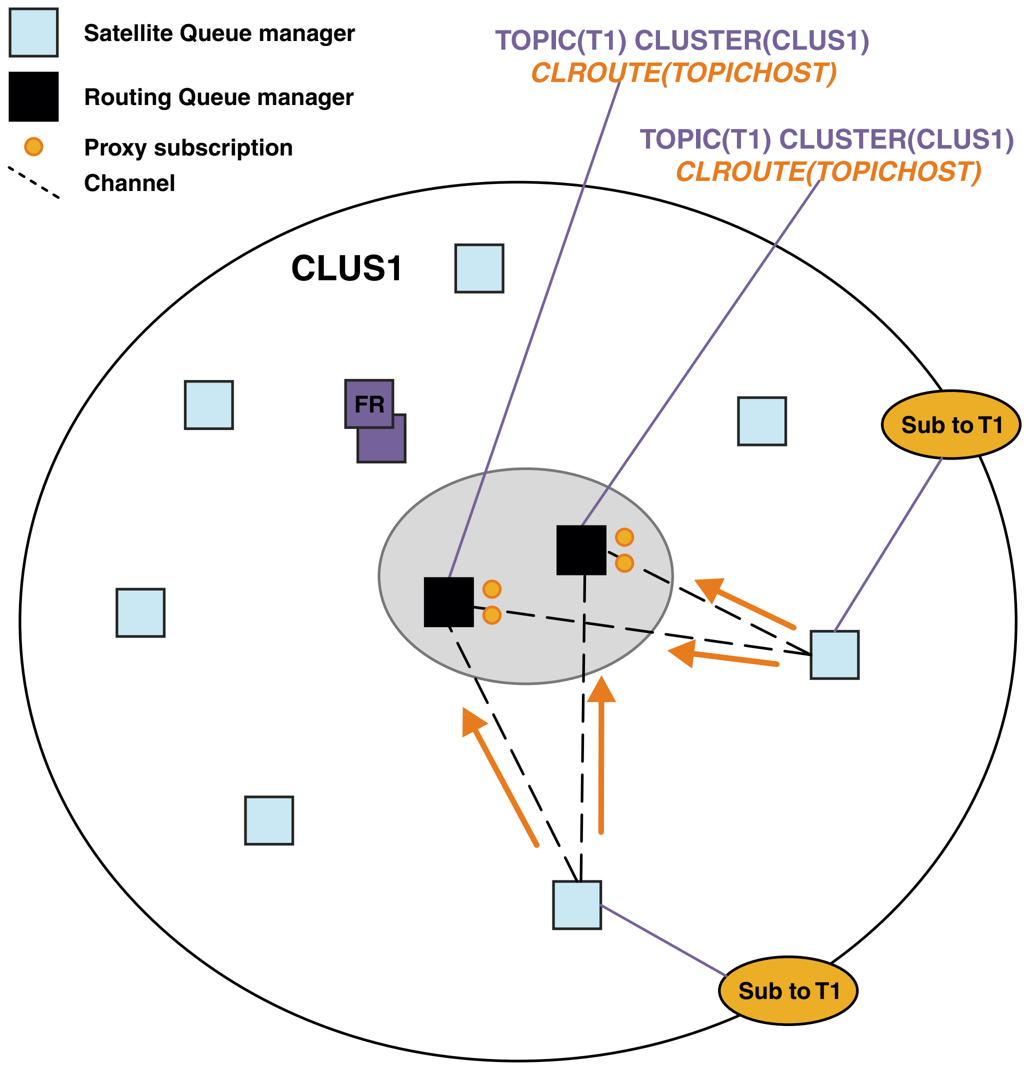

Figure 27. Creating proxy subscriptions in a multiple topic host publish/subscribe cluster

When a publication is made from a non-hosting queue manager, the queue manager sends a copy of the publication to *one* of the topic host queue managers for that topic. The system chooses the host based on the default behavior of the cluster workload management algorithm. In a typical system, this approximates to a round-robin distribution across each topic host queue manager. There is no affinity between messages from the same publishing application; this equates to using a cluster bind type of `NOTFIXED`.

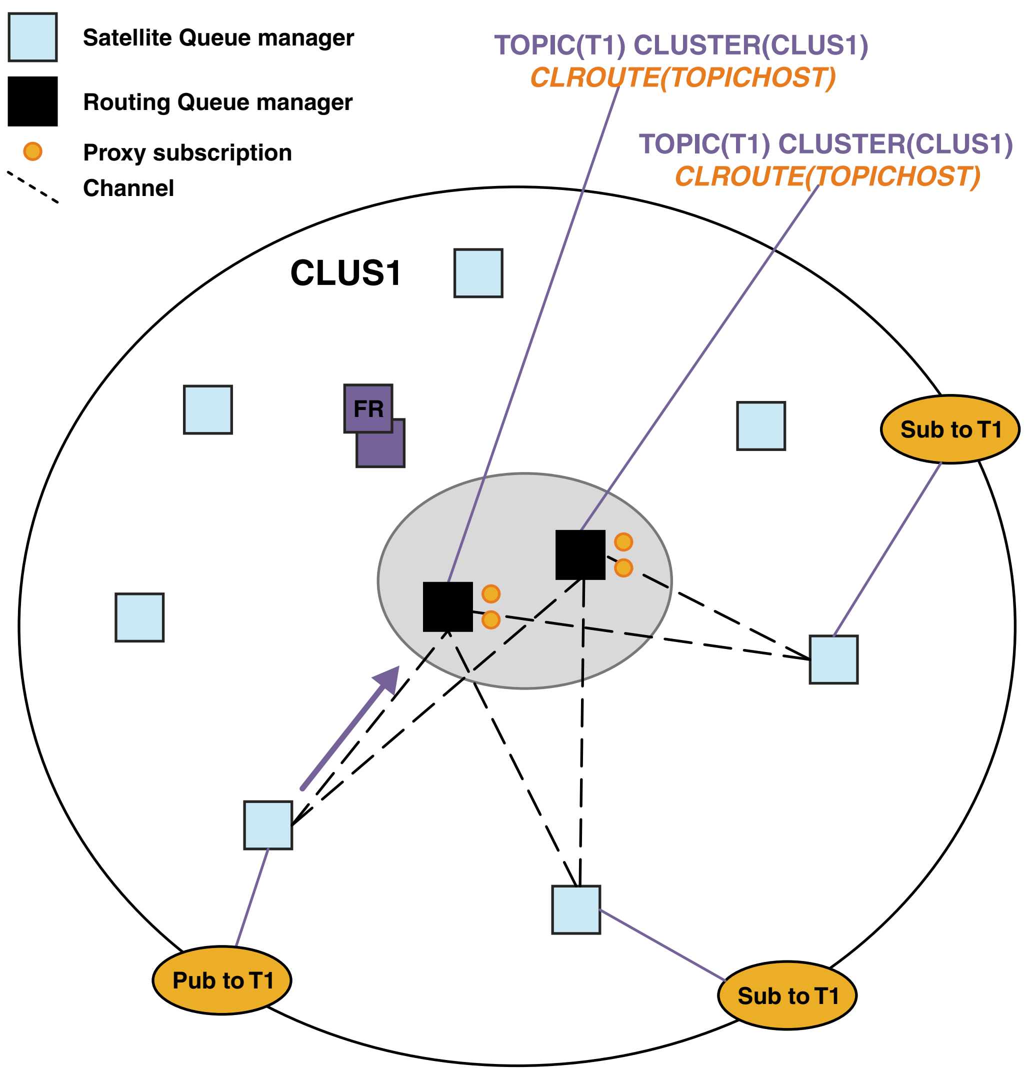

Figure 28. Receiving publications in a multiple topic host publish/subscribe cluster

Inbound publications to the chosen topic host queue manager are then forwarded to all queue managers that have registered a matching proxy subscription:

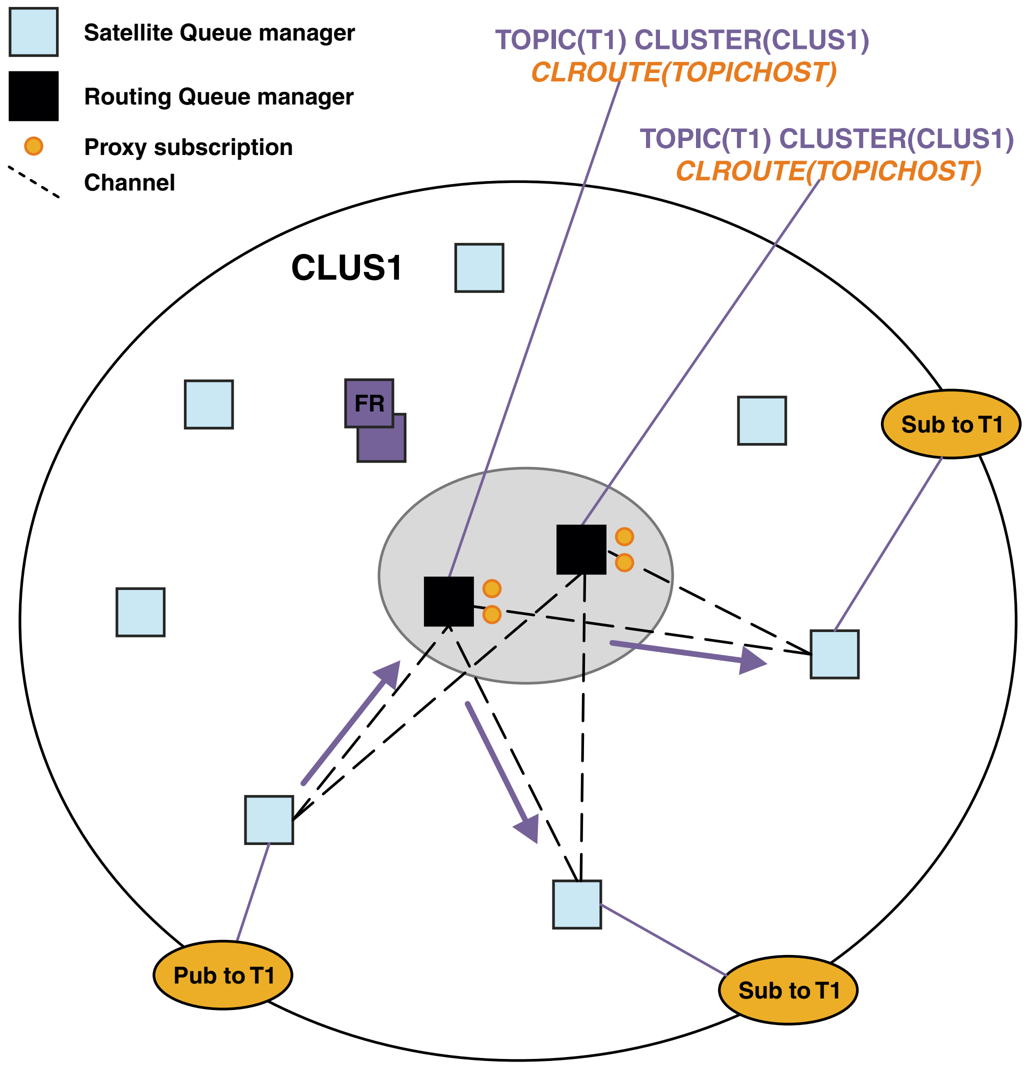

Figure 29. Routing publications to subscribers in a multiple topic host publish/subscribe cluster

Making subscriptions and publishers local to a topic host queue manager

The above examples show the routing between publishers and subscribers on queue managers that do not host administered routed topic objects. In these topologies, messages require multiple *hops* to reach the subscriptions.

Where the additional hop is not desirable, it might be appropriate to connect key publishers to topic hosting queue managers. However, if there are multiple topic hosts for a topic and only one publisher, all publication traffic will be routed through the topic host queue manager that the publisher is connected to.

Similarly, if there are key subscriptions, these could be located on a topic host queue manager. However, if there are multiple hosts of the routed topic, only a proportion of the publications will avoid the additional hop, with the remainder being routed through the other topic host queue managers first.

Topologies such as these are described further here: Topic host routing using centralized publishers or subscribers.

Note: Special planning is needed if changing the routed topic configuration when co-locating publishers or subscriptions with routed topic hosts. For example, see Adding extra topic hosts to a topic host routed cluster.

Summary and additional considerations

A topic host routed publish/subscribe cluster gives you precise control over which queue managers host each topic, and those queue managers become the *routing* queue managers for that branch of the topic tree. Moreover, queue managers without subscriptions or publishers have no need to connect with the topic host queue managers, and queue managers with subscriptions have no need to connect to queue managers that do not host a topic. This configuration can significantly reduce the number of connections between queue managers in the cluster, and the amount of information being passed between queue managers. This is especially true in large clusters where only a subset of queue managers are performing publish/subscribe work. This configuration also gives you some control over the load on individual queue managers in the cluster, so (for example) you can choose to host highly active topics on more powerful and more resilient systems. For certain configurations - notably larger clusters - it is usually a more appropriate topology than *direct routing*.

However, topic host routing also imposes certain constraints upon your system:

- System configuration and maintenance require more planning than for direct routing. You need to decide which points to cluster in the topic tree, and the location of the topic definitions in the cluster.
- Just as for direct routed topics, when a new topic host routed topic is defined, the information is pushed to the full repository queue managers, and from there direct to all members of the cluster. This event causes channels to be started to each member of the cluster from the full repositories if not already started.
- Publications are always sent to a host queue manager from a non-host queue manager, even if there are no subscriptions in the cluster. Therefore, you should use routed topics when subscriptions are typically expected to exist, or when the overhead of global connectivity and knowledge is greater than the risk of extra publication traffic.

  Note: As previously described, making publishers local to a topic host can mitigate this risk.
- Messages that are published on non-host queue managers do not go direct to the queue manager that hosts the subscription, they are always routed through a topic host queue manager. This approach can increase the total overhead to the cluster, and increase message latency and reduce performance.

  Note: As previously described, making subscriptions or publishers local to a topic host can mitigate this risk.
- Using a single topic host queue manager introduces a single point of failure for all messages that are published to a topic. You can remove this single point of failure by defining multiple topic hosts. However, having multiple hosts affects the order of published messages as received by subscriptions.
- Extra message load is incurred by topic host queue managers, because publication traffic from multiple queue managers needs to be processed by them. This load can be lessened: Either use multiple topic hosts for a single topic (in which case message ordering is not maintained), or use different queue managers to host routed topics for different branches of the topic tree.

Before you use topic host routing, explore the alternative approaches detailed in “Direct routing in publish/subscribe clusters” on page 66, and “Routing in publish/subscribe hierarchies” on page 96.

Publish/subscribe clustering: Best practices:

Using clustered topics makes extending the publish/subscribe domain between queue managers simple, but can lead to problems if the mechanics and implications are not fully understood. There are two models for information sharing and publication routing. Implement the model that best meets your individual business needs, and performs best on your chosen cluster.

The best practice information in the following sections does not provide a one size fits all solution, but rather shares common approaches to solving common problems. It assumes that you have a basic understanding of IBM MQ clusters, and of publish/subscribe messaging, and that you are familiar with the information in Distributed publish/subscribe networks and "Designing publish/subscribe clusters" on page 64.

When you use a cluster for point-to-point messaging, each queue manager in the cluster works on a need-to-know basis. That is, it only finds out about other cluster resources, such as other queue managers in the cluster and clustered queues, when applications connecting to them request to use them. When you add publish/subscribe messaging to a cluster, an increased level of sharing of information and connectivity between cluster queue managers is introduced. To be able to follow best practices for publish/subscribe clusters, you need to fully understand the implications of this change in behavior.

To allow you to build the best architecture, based on your precise needs, there are two models for information sharing and publication routing in publish/subscribe clusters: *direct routing* and *topic host routing*. To make the right choice, you need to understand both models, and the different requirements that each model satisfies. These requirements are discussed in the following sections, in conjunction with "Planning your distributed publish/subscribe network" on page 61:
- "Reasons to limit the number of cluster queue managers involved in publish/subscribe activity"
- "How to decide which topics to cluster" on page 82
- "How to size your system" on page 82
- "Publisher and subscription location" on page 83
- "Publication traffic" on page 84
- "Subscription change and dynamic topic strings" on page 84

Reasons to limit the number of cluster queue managers involved in publish/subscribe activity

There are capacity and performance considerations when you use publish/subscribe messaging in a cluster. Therefore, it is best practice to consider carefully the need for publish/subscribe activity across queue managers, and to limit it to only the number of queue managers that require it. After the minimum set of queue managers that need to publish and subscribe to topics are identified, they can be made members of a cluster that contains only them and no other queue managers.

This approach is especially useful if you have an established cluster already functioning well for point-to-point messaging. When you are turning an existing large cluster into a publish/subscribe cluster, it is a better practice to initially create a separate cluster for the publish/subscribe work where the applications can be tried, rather than using the current cluster. You can use a subset of existing queue managers that are already in one or more point-to-point clusters, and make this subset members of the new publish/subscribe cluster. However, the full repository queue managers for your new cluster must not be members of any other cluster; this isolates the additional load from the existing cluster full repositories.

If you cannot create a new cluster, and have to turn an existing large cluster into a publish/subscribe cluster, do not use a direct routed model. The topic host routed model usually performs better in larger clusters, because it generally restricts the publish/subscribe information sharing and connectivity to the set of queue managers that are actively performing publish/subscribe work, concentrating on the queue managers hosting the topics. The exception to that is if a manual refresh of the subscription information is invoked on a queue manager hosting a topic definition, at which point the topic host queue manager will connect to every queue manager in the cluster. See Resynchronization of proxy subscriptions.

If you establish that a cluster cannot be used for publish/subscribe due to its size or current load, it is good practice to prevent this cluster unexpectedly being made into a publish/subscribe cluster. Use the **PSCLUS** queue manager property to stop anyone adding a clustered topic on any queue manager in the cluster. See "Inhibiting clustered publish/subscribe" on page 91.

How to decide which topics to cluster

It is important to choose carefully which topics are added to the cluster: The higher up the topic tree these topics are, the more widespread their use becomes. This can result in more subscription information and publications being propagated than necessary. If there are multiple, distinct branches of the topic tree, where some need to be clustered and some do not, create administered topic objects at the root of each branch that needs clustering and add those to the cluster. For example, if branches `/A`, `/B` and `/C` need clustering, define a separate clustered topic objects for each branch.

Note: The system prevents you from nesting clustered topic definitions in the topic tree. You are only permitted to cluster topics at one point in the topic tree for each sub branch. For example, you cannot define clustered topic objects for `/A` and for `/A/B`. Nesting clustered topics can lead to confusion over which clustered object applies to which subscription, especially when subscriptions are using wildcards. This is even more important when using topic host routing, where routing decisions are precisely defined by your allocation of topic hosts.

If clustered topics must be added high up the topic tree, but some branches of the tree below the clustered point do not require the clustered behavior, you can use the subscription and publication scope attributes to reduce the level of subscription and publication sharing for further topics.

You should not put the topic root node into the cluster without considering the behavior that is seen. Make global topics obvious where possible, for example by using a high-level qualifier in the topic string: `/global` or `/cluster`.

There is a further reason for not wanting to make the root topic node clustered. This is because every queue manager has a local definition for the root node, the SYSTEM.BASE.TOPIC topic object. When this object is clustered on one queue manager in the cluster, all other queue managers are made aware of it. However, when a local definition of the same object exists, its properties override the cluster object. This results in those queue managers acting as if the topic was not clustered. To resolve this, you would need to cluster every definition of SYSTEM.BASE.TOPIC. You could do this for direct routed definitions, but not for topic host routed definitions, because it causes every queue manager to become a topic host.

How to size your system

Publish/subscribe clusters typically result in a different pattern of cluster channels to point-to-point messaging in a cluster. The point-to-point model is an 'opt in' one, but publish/subscribe clusters have a more indiscriminate nature with subscription fan-out, especially when using direct routed topics. Therefore, it is important to identify which queue managers in a publish/subscribe cluster will use cluster channels to connect to other queue managers, and under what circumstances.

The following table lists the typical set of cluster sender and receiver channels expected for each queue manager in a publish/subscribe cluster under normal running, dependent on the queue manager role in the publish/subscribe cluster.

Table 5. Cluster sender and receiver channels for each routing method.

Queue manager role	Direct cluster receivers	Direct cluster senders	Topic cluster receivers	Topic cluster senders
Full repository	AllQmgrs	AllQmgrs	AllQmgrs	AllQMgrs
Host of topic definition	n/a	n/a	AllSubs+AllPubs (1)	AllSubs (1)
Subscriptions created	AllPubs (1)	AllQMgrs	AllHosts	AllHosts
Publishers connected	AllSubs (1)	AllSubs (1)	AllHosts	AllHosts
No publishers or subscribers	AllSubs (1)	None (1)	None (2)	None (2)

Key:

AllQmgrs
A channel to and from every queue manager in the cluster.

AllSubs
A channel to and from every queue manager where a subscription has been created.

AllPubs
A channel to and from every queue manager where a publishing application has been connected.

AllHosts
A channel to and from every queue manager where a definition of the clustered topic object has been configured.

None No channels to or from other queue managers in the cluster for the sole purpose of publish/subscribe messaging.

Notes:

1. If a queue manager refresh of proxy subscriptions is made from this queue manager, a channel to and from all other queue managers in the cluster might be automatically created.
2. If a queue manager refresh of proxy subscriptions is made from this queue manager, a channel to and from any other queue managers in the cluster that host a definition of a clustered topic might be automatically created.

The previous table shows that topic host routing typically uses significantly less cluster sender and receiver channels than direct routing. If channel connectivity is a concern for certain queue managers in a cluster, for reasons of capacity or ability to establish certain channels (for example, through firewalls), topic host routing is therefore a preferred solution.

Publisher and subscription location

Clustered publish/subscribe enables messages published on one queue manager to be delivered to subscriptions on any other queue manager in the cluster. As for point-to-point messaging, the cost of transmitting messages between queue managers can be detrimental to performance. Therefore you should consider creating subscriptions to topics on the same queue managers as where messages are being published.

When using topic host routing within a cluster, it is important to also consider the location of the subscriptions and publishers with respect to the topic hosting queue managers. When the publisher is not connected to a queue manager that is a host of the clustered topic, messages published are always sent to a topic hosting queue manager. Similarly, when a subscription is created on a queue manager that is not a topic host for a clustered topic, messages published from other queue managers in the cluster are always sent to a topic hosting queue manager first. More specifically, if the subscription is located on a queue manager that hosts the topic, but there is one or more other queue managers that also host that same topic, a proportion of publications from other queue managers are routed through those other topic hosting queue managers. See Topic host routing using centralized publishers or subscribers for more information on designing a topic host routed publish/subscribe cluster to minimize the distance between publishers and subscriptions.

Publication traffic

Messages published by an application connected to one queue manager in a cluster are transmitted to subscriptions on other queue managers using cluster sender channels.

When you use direct routing, the messages published take the shortest path between queue managers. That is, they go direct from the publishing queue manager to each of the queue managers with subscriptions. Messages are not transmitted to queue managers that do not have subscriptions for the topic. See Proxy subscriptions in a publish/subscribe network.

Where the rate of publication messages between any one queue manager and another in the cluster is high, the cluster channel infrastructure between those two points must be able to maintain the rate. This might involve tuning the channels and transmission queue being used.

When you use topic host routing, each message published on a queue manager that is not a topic host is transmitted to a topic host queue manager. This is independent of whether one or more subscriptions exist anywhere else in the cluster. This introduces further factors to consider in planning:
- Is the additional latency of first sending each publication to a topic host queue manager acceptable?
- Can each topic host queue manager sustain the inbound and outbound publication rate? Consider a system with publishers on many different queue managers. If they all send their messages to a very small set of topic hosting queue managers, those topic hosts might become a bottleneck in processing those messages and routing them on to subscribing queue managers.
- Is it expected that a significant proportion of the published messages will not have a matching subscriber? If so, and the rate of publishing such messages is high, it might be best to make the publisher's queue manager a topic host. In that situation, any published message where no subscriptions exist in the cluster will not be transmitted to any other queue managers.

These problems might also be eased by introducing multiple topic hosts, to spread the publication load across them:
- Where there are multiple distinct topics, each with a proportion of the publication traffic, consider hosting them on different queue managers.
- If the topics cannot be separated onto different topic hosts, consider defining the same topic object on multiple queue managers. This results in publications being workload balanced across each of them for routing. However, this is only appropriate when publication message ordering is not required.

Subscription change and dynamic topic strings

Another consideration is the effect on performance of the system for propagating proxy subscriptions. Typically, a queue manager sends a proxy subscription message to certain other queue managers in the cluster when the first subscription for a specific clustered topic string (not just a configured topic object) is created on that queue manager. Similarly, a proxy subscription deletion message is sent when the last subscription for a specific clustered topic string is deleted.

For direct routing, each queue manager with subscriptions sends those proxy subscriptions to every other queue manager in the cluster. For topic host routing, each queue manager with subscriptions only sends the proxy subscriptions to each queue manager that hosts a definition for that clustered topic. Therefore, with direct routing, the more queue managers there are in the cluster, the higher the overhead of maintaining proxy subscriptions across them. Whereas, with topic host routing, the number of queue managers in the cluster is not a factor.

In both routing models, if a publish/subscribe solution consists of many unique topic strings being subscribed to, or the topics on a queue manager in the cluster are frequently being subscribed and unsubscribed, a significant overhead will be seen on that queue manager, caused by constantly generating messages distributing and deleting the proxy subscriptions. With direct routing, this is compounded by the need to send these messages to every queue manager in the cluster.

If the rate of change of subscriptions is too high to accommodate, even within a topic host routed system, see Subscription performance in publish/subscribe networks for information about ways to reduce proxy subscription overhead.

Defining cluster topics:

Cluster topics are administrative topics with the **`cluster`** attribute defined. Information about cluster topics is pushed to all members of a cluster, and combined with local topics to create portions of a topic space that spans multiple queue managers. This enables messages published on a topic on one queue manager to be delivered to subscriptions of other queue managers in the cluster.

When you define a cluster topic on a queue manager, the cluster topic definition is sent to the full repository queue managers. The full repositories then propagate the cluster topic definition to all queue managers within the cluster, making the same cluster topic available to publishers and subscribers at any queue manager in the cluster. The queue manager on which you create a cluster topic is known as a cluster topic host. The cluster topic can be used by any queue manager in the cluster, but any modifications to a cluster topic must be made on the queue manager where that topic is defined (the host) at which point the modification is propagated to all members of the cluster through the full repositories.

When you use direct routing, the location of the clustered topic definition does not directly affect the behavior of the system, because all queue managers in the cluster use the topic definition in the same way. You should therefore define the topic on any queue manager that will be a member of the cluster for as long as the topic is needed, and that is on a system reliable enough to regularly be in contact with the full repository queue managers.

When you use topic host routing, the location of the clustered topic definition is very important, because other queue managers in the cluster create channels to this queue manager and send subscription information and publications to it. To choose the best queue manager to host the topic definition, you need to understand topic host routing. See "Topic host routing in publish/subscribe clusters" on page 71.

If you have a clustered topic, and a local topic object, then the local topic takes precedence. See "Multiple cluster topic definitions of the same name" on page 88.

For information about the commands to use to display cluster topics, see the related information.

Clustered topic inheritance

Typically, publishing and subscribing applications in a clustered publish/subscribe topology expect to work the same, no matter which queue manager in the cluster they are connected to. This is why clustered administered topic objects are propagated to every queue manager in the cluster.

An administered topic object inherits its behavior from other administered topic objects higher in the topic tree. This inheritance occurs when an explicit value has not been set for a topic parameter.

In the case of clustered publish/subscribe, it is important to consider such inheritance because it introduces the possibility that publishers and subscribers will behave differently depending on which queue manager they connect to. If a clustered topic object leaves any parameters to inherit from higher topic objects, the topic might behave differently on different queue managers in the cluster. Similarly, locally defined topic objects defined below a clustered topic object in the topic tree will mean those lower topics are still clustered, but the local object might change its behavior in some way that differs from other queue managers in the cluster.

Wildcard subscriptions

Proxy subscriptions are created when local subscriptions are made to a topic string that resolves at, or below, a clustered topic object. If a wildcard subscription is made higher in the topic hierarchy than any cluster topic, it does not have proxy subscriptions sent around the cluster for the matching cluster topic, and therefore receives no publications from other members of the cluster. It does however receive publications from the local queue manager.

However, if another application subscribes to a topic string that resolves to or below the cluster topic, proxy subscriptions are generated and publications are propagated to this queue manager. On arrival the original, higher wildcard subscription is considered a legitimate recipient of those publications and receives a copy. If this behavior is not required, set **`WILDCARD(BLOCK)`** on the clustered topic. This makes the original wildcard not be considered a legitimate subscription, and stops it receiving any publications (local, or from elsewhere in the cluster) on the cluster topic, or its subtopics.

Cluster topic attributes:

When a topic object has the cluster name attribute set, the topic definition is propagated across all queue managers in the cluster. Each queue manager uses the propagated topic attributes to control the behavior of publish/subscribe applications.

A topic object has a number of attributes that apply to publish/subscribe clusters. Some control the general behavior of the publishing and subscribing applications and some control how the topic is used across the cluster.

A clustered topic object definition must be configured in a way that all queue managers in the cluster can correctly use it.

For example if the model queues to be used for managed subscriptions (`MDURMDL` and `MNDURMDL`) are set to a non-default queue name, that named model queue must be defined on all queue managers where managed subscriptions will be created.

Similarly, if any attribute is set to `ASPARENT`, the behavior of the topic will be dependent on the higher nodes in the topic tree (see Administrative topic objects) on each individual queue manager in the cluster. This might result in different behavior when publishing or subscribing from different queue managers.

The main attributes that directly relate to publish/subscribe behavior across the cluster are as follows:

CLROUTE

This parameter controls the routing of messages between queue managers where publishers are connected, and queue managers where matching subscriptions exist.

- You configure the route to be either direct between these queue managers, or through a queue manager that hosts a definition of the clustered topic. See Publish/subscribe clusters for more details.

- You cannot change the **CLROUTE** while the **CLUSTER** parameter is set. To change the **CLROUTE**, first set the **CLUSTER** property to be blank. This stops applications that use the topic from behaving in a clustered manner. This in turn results in a break in publications being delivered to subscriptions, so you should also quiesce publish/subscribe messaging while making the change.

PROXYSUB

This parameter controls when proxy subscriptions are made.

- FIRSTUSE is the default value, and causes proxy subscriptions to be sent in response to local subscriptions on a queue manager in a distributed publish/subscribe topology, and canceled when no longer required. For details about why you might want to change this attribute from the default value of FIRSTUSE, see Individual proxy subscription forwarding and *publish everywhere* .
- To enable *publish everywhere*, you set the **PROXYSUB** parameter to FORCE for a high-level topic object. This results in a single wildcard proxy subscription that matches all topics below this topic object in the topic tree.

Note: Setting the **PROXYSUB(FORCE)** attribute in a large or busy publish/subscribe cluster can result in excessive load on system resources. The **PROXYSUB(FORCE)** attribute is propagated to every queue manager, not just the queue manager that the topic was defined on. This causes every queue manager in the cluster to create a wildcarded proxy subscription.

A copy of a message to this topic, published on any queue manager in the cluster, is sent to every queue manager in the cluster - either directly, or through a topic host queue manager, depending on the **CLROUTE** setting.

When the topic is direct routed, every queue manager creates cluster sender channels to every other queue manager. When the topic is topic host routed, channels to each topic host queue manager are created from every queue manager in the cluster.

For more information about the **PROXYSUB** parameter when used in clusters, see Direct routed publish/subscribe performance.

PUBSCOBE and SUBSCOPE

These parameters determine whether this queue manager propagates publications to queue managers in the topology (publish/subscribe cluster or hierarchy) or restricts the scope to just its local queue manager. You can do the equivalent job programmatically using MQPMO_SCOPE_QMGR and MQSO_SCOPE_QMGR.

PUBSCOPE

If a cluster topic object is defined with **PUBSCOPE(QMGR)**, the definition is shared with the cluster, but the scope of publications that are based on that topic is local only and they are not sent to other queue managers in the cluster.

SUBSCOPE

If a cluster topic object is defined with **SUBSCOPE(QMGR)**, the definition is shared with the cluster, but the scope of subscriptions that are based on that topic is local only, therefore no proxy subscriptions are sent to other queue managers in the cluster.

These two attributes are commonly used together to isolate a queue manager from interacting with other members of the cluster on particular topics. The queue manager neither publishes or receives publications on those topics to and from other members of the cluster. This situation does not prevent publication or subscription if topic objects are defined on subtopics.

Setting **SUBSCOPE** to QMGR on a local definition of a topic does not prevent other queue managers in the cluster from propagating their proxy subscriptions to the queue manager if they are using a clustered version of the topic, with **SUBSCOPE(ALL)**. However, if the local definition also sets **PUBSCOPE** to QMGR those proxy subscriptions are not sent publications from this queue manager.

Subscription scope

Multiple cluster topic definitions of the same name:

You can define the same named cluster topic object on more than one queue manager in the cluster, and in certain scenarios this enables specific behavior. When multiple cluster topic definitions exist of the same name, the majority of properties should match. If they do not, errors or warnings are reported depending on the significance of the mismatch.

In general, if there is a mismatch in the properties of multiple cluster topic definitions, warnings are issued and one of the topic object definitions is used by each queue manager in the cluster. Which definition is used by each queue manager is not deterministic, or consistent across the queue managers in the cluster. Such mismatches should be resolved as quickly as possible.

During cluster setup or maintenance you sometimes need to create multiple cluster topic definitions that are not identical. However this is only ever useful as a temporary measure, and it is therefore treated as a potential error condition.

When mismatches are detected, the following warning messages are written to each queue manager's error log:

- Multi On Multiplatforms, AMQ9465 and AMQ9466.
- z/OS On z/OS, CSQX465I and CSQX466I.

The chosen properties for any topic string on each queue manager can be determined by viewing topic status rather than the topic object definitions, for example by using **DISPLAY TPSTATUS**.

In some situations, a conflict in configuration properties is severe enough to stop the topic object being created, or to cause the mismatched objects to be marked as invalid and not propagated across the cluster (See **CLSTATE** in DISPLAY TOPIC). These situations occur when there is a conflict in the cluster routing property (**CLROUTE**) of the topic definitions. Additionally, due to the importance of consistency across topic host routed definitions, further inconsistencies are rejected as detailed in subsequent sections of this article.

If the conflict is detected at the time that the object is defined, the configuration change is rejected. If detected later by the full repository queue managers, the following warning messages are written to the queue managers error logs:

- Multi On Multiplatforms: AMQ9879
- z/OS On z/OS: CSQX879E.

When multiple definitions of the same topic object are defined in the cluster, a locally defined definition takes precedence over any remotely defined one. Therefore, if any differences exist in the definitions, the queue managers hosting the multiple definitions behave differently from each other.

The effect of defining a non-cluster topic with the same name as a cluster topic from another queue manager

It is possible to define an administered topic object that is not clustered on a queue manager that is in a cluster, and simultaneously define the same named topic object as a clustered topic definition on a different queue manager. In this case, the locally defined topic object takes precedence over all remote definitions of the same name.

This has the effect of preventing the clustering behavior of the topic when used from this queue manager. That is, subscriptions might not receive publications from remote publishers, and messages from publishers might not be propagated to remote subscriptions in the cluster.

Careful consideration should be given before configuring such a system, because this can lead to confusing behavior.

Note: If an individual queue manager needs to prevent publications and subscriptions from propagating around the cluster, even when the topic has been clustered elsewhere, an alternative approach is to set the publication and subscription scopes to only the local queue manager. See "Cluster topic attributes" on page 86.

Multiple cluster topic definitions in a direct routed cluster

For direct routing, you do not usually define the same cluster topic on more than one cluster queue manager. This is because direct routing makes the topic available at all queue managers in the cluster, no matter which queue manager it was defined on. Moreover, adding multiple cluster topic definitions significantly increases system activity and administrative complexity, and with increased complexity comes a greater chance of human error:
- Each definition results in an additional cluster topic object being pushed out to the other queue managers in the cluster, including the other cluster topic host queue managers.
- All definitions for a specific topic in a cluster must be identical, otherwise it is difficult to work out which topic definition is being used by a queue manager.

It is also not essential that the sole host queue manager is continually available for the topic to function correctly across the cluster, because the cluster topic definition is cached by the full repository queue managers and by all other queue managers in their partial cluster repositories. For more information, see Availability of topic host queue managers that use direct routing.

For a situation in which you might need to temporarily define a cluster topic on a second queue manager, for example when the existing host of the topic is to be removed from the cluster, see Moving a cluster topic definition to a different queue manager.

If you need to alter a cluster topic definition, take care to modify it at the same queue manager it was defined on. Attempting to modify it from another queue manager might accidentally create a second definition of the topic with conflicting topic attributes.

Multiple cluster topic definitions in a topic host routed cluster

When a cluster topic is defined with a cluster route of *topic host*, the topic is propagated across all queue managers in the cluster just as for *direct* routed topics. Additionally, all publish/subscribe messaging for that topic is routed through the queue managers where that topic is defined. Therefore the location and number of definitions of the topic in the cluster becomes important (see "Topic host routing in publish/subscribe clusters" on page 71).

To ensure adequate availability and scalability it is useful, if possible, to have multiple topic definitions. See Availability of topic host queue managers that use topic host routing.

When adding or removing additional definitions of a *topic host* routed topic in a cluster, you should consider the flow of messages at the time of the configuration change. If messages are being published in the cluster to the topic at the time of the change, a staged process is required to add or remove a topic definition. See Moving a cluster topic definition to a different queue manager and Adding extra topic hosts to a topic host routed cluster.

As previously explained, the properties of the multiple definitions should match, with the possible exception of the **PUB** parameter, as described in the next section. When publications are routed through topic host queue managers it is even more important for multiple definitions to be consistent. Therefore, an inconsistency detected in either the topic string or cluster name is rejected if one or more of the topic definitions has been configured for topic host cluster routing.

Note: Cluster topic definitions are also rejected if an attempt is made to configure them above or below another topic in the topic tree, where the existing clustered topic definition is configured for topic host routing. This prevents ambiguity in the routing of publications with respect to wildcarded subscriptions.

Special handling for the PUB parameter

The **PUB** parameter is used to control when applications can publish to a topic. In the case of topic host routing in a cluster, it can also control which topic host queue managers are used to route publications. For this reason it is permitted to have multiple definitions of the same topic object in the cluster, with different settings for the PUB parameter.

If multiple remote clustered definitions of a topic have different settings for this parameter, the topic allows publications to be sent and delivered to subscriptions if the following conditions are met:
- There is not a matching topic object defined on the queue manager that the publisher is connected to that is set to `PUB(DISABLED)`.
- One or more of the multiple topic definitions in the cluster is set to `PUB(ENABLED)`, or one or more of the multiple topic definitions is set to `PUB(ASPARENT)` and the local queue managers where the publisher is connected and the subscription defined are set to `PUB(ENABLED)` at a higher point in the topic tree.

For topic host routing, when messages are published by applications connected to queue managers that are not topic hosts, messages are only routed to the topic hosting queue managers where the **PUB** parameter has not explicitly been set to `DISABLED`. You can therefore use the `PUB(DISABLED)` setting to quiesce message traffic through certain topic hosts. You might want to do this to prepare for maintenance or removal of a queue manager, or for the reasons described in Adding extra topic hosts to a topic host routed cluster.

Availability of cluster topic host queue managers:

Design your publish/subscribe cluster to minimize the risk that, should a topic host queue manager become unavailable, the cluster will no longer be able to process traffic for the topic. The effect of a topic host queue manager becoming unavailable depends on whether the cluster is using topic host routing or direct routing.

Availability of topic host queue managers that use direct routing

For direct routing, you do not usually define the same cluster topic on more than one cluster queue manager. This is because direct routing makes the topic available at all queue managers in the cluster, no matter which queue manager it was defined on.See Multiple cluster topic definitions in a direct routed cluster.

In a cluster, whenever the host of a clustered object (for example a clustered queue or clustered topic) becomes unavailable for a prolonged period of time, the other members of the cluster will eventually expire the knowledge of those objects. In the case of a clustered topic, if the cluster topic host queue manager becomes unavailable, the other queue managers continue to process publish/subscribe requests for the topic in a direct clustered way (that is, sending publications to subscriptions on remote queue managers) for at least 60 days from when the topic hosting queue manager was last in communication with the full repository queue managers. If the queue manager on which you defined the cluster topic object is never made available again, then eventually the cached topic objects on the other queue managers are deleted and the topic reverts to a local topic, in which case subscriptions cease to receive publications from applications connected to remote queue managers.

With the 60 day period to recover the queue manager on which you define a cluster topic object, there is little need to take special measures to guarantee that a cluster topic host remains available (note, however, that any subscriptions defined on the unavailable cluster topic host do not remain available). The 60 day period is sufficient to cater for technical problems, and is likely to be exceeded only because of administrative errors. To mitigate that possibility, if the cluster topic host is unavailable, all members of the cluster write error log messages hourly, stating that their cached cluster topic object was not refreshed. Respond to these messages by making sure that the queue manager on which the cluster topic object is defined, is running. If it is not possible to make the cluster topic host queue manager available again, define the same clustered topic definition, with exactly the same attributes, on another queue manager in the cluster.

Availability of topic host queue managers that use topic host routing

For topic host routing, all publish/subscribe messaging for a topic is routed through the queue managers where that topic is defined. For this reason, it is very important to consider the continual availability of these queue managers in the cluster. If a topic host becomes unavailable, and no other host exists for the topic, traffic from publishers to subscribers on different queue managers in the cluster immediately halts for the topic. If additional topic hosts are available, the cluster queue managers route new publication traffic through these topic hosts, providing continuous availability of message routes.

As for direct topics, after 60 days, if the first topic host is still unavailable, knowledge of that topic host's topic is removed from the cluster. If this is the last remaining definition for this topic in the cluster, all other queue managers cease to forward publications to any topic host for routing.

To ensure adequate availability and scalability it is therefore useful, if possible, to define each topic on at least two cluster queue managers. This gives protection against any given topic host queue manager becoming unavailable. See also Multiple cluster topic definitions in a topic host routed cluster.

If you cannot configure multiple topic hosts (for example because you need to preserve message ordering), and you cannot configure just one topic host (because the availability of a single queue manager must not affect the flow of publications to subscriptions across all queue managers in the cluster), consider configuring the topic as a direct routed topic. This avoids reliance on a single queue manager for the whole cluster, but does still require each individual queue manager to be available in order for it to process locally hosted subscriptions and publishers.

Inhibiting clustered publish/subscribe:

Introducing the first direct routed clustered topic into a cluster forces every queue manager in the cluster to become aware of every other queue manager, and potentially causes them to create channels to each other. If this is not desirable, you should instead configure topic host routed publish/subscribe. If the existence of a direct routed clustered topic might jeopardize the stability of the cluster, due to scaling concerns of each queue manager, you can completely disable clustered publish/subscribe functionality by setting **PSCLUS** to `DISABLED` on every queue manager in the cluster.

As described in"Direct routing in publish/subscribe clusters" on page 66, when you introduce a direct routed clustered topic into a cluster, all partial repositories are automatically notified of all other members of the cluster. The clustered topic might also create subscriptions at all other nodes (for example, where **PROXYSUB(FORCE)** is specified) and cause large numbers of channels to be started from a queue manager, even when there are no local subscriptions. This puts an immediate additional load on each queue manager in the cluster. For a cluster that contains many queue managers, this can cause a significant reduction in performance. Therefore the introduction of direct routed publish/subscribe to a cluster must be carefully planned.

When you know that a cluster cannot accommodate the overheads of direct routed publish/subscribe, you can instead use topic host routed publish/subscribe. For an overview of the differences, see "Designing publish/subscribe clusters" on page 64.

If you prefer to completely disable publish/subscribe functionality for the cluster, you can do so by setting the queue manager attribute **PSCLUS** to `DISABLED` on every queue manager in the cluster. This setting disables both direct routed and topic host routed publish/subscribe in the cluster, by modifying three aspects of queue manager functionality:

- An administrator of this queue manager is no longer able to define a Topic object as clustered.
- Incoming topic definitions or proxy subscriptions from other queue managers are rejected, and a warning message is logged to inform the administrator of incorrect configuration.
- Full repositories no longer automatically share information about every queue manager with all other partial repositories when they receive a topic definition.

Although **PSCLUS** is a parameter of each individual queue manager in a cluster, it is not intended to selectively disable publish/subscribe in a subset of queue managers in the cluster. If you selectively disable in this way, you will see frequent error messages. This is because proxy subscriptions and topic definitions are constantly seen and rejected if a topic is clustered on a queue manager where **PSCLUS** is enabled.

You should therefore aim to set **PSCLUS** to `DISABLED` on every queue manager in the cluster. However, in practice this state can be difficult to achieve and maintain, for example queue managers can join and leave the cluster at any time. At the very least, you must ensure that **PSCLUS** is set to `DISABLED` on all full repository queue managers. If you do this, and a clustered topic is subsequently defined on an `ENABLED` queue manager in the cluster, this does not cause the full repositories to inform every queue manager of every other queue manager, and so your cluster is protected from potential scaling issues across all queue managers. In this scenario, the origin of the clustered topic is reported in the error logs of the full repository queue managers.

If a queue manager participates in one or more publish/subscribe clusters, and also one or more point-to-point clusters, you must set **PSCLUS** to `ENABLED` on that queue manager. For this reason, when overlapping a point-to-point cluster with a publish subscribe cluster, you should use a separate set of full repositories in each cluster. This approach allows topic definitions and information about every queue manager to flow only in the publish/subscribe cluster.

To avoid inconsistent configurations when you change **PSCLUS** from `ENABLED` to `DISABLED`, no clustered topic objects can exist in any cluster of which this queue manager is a member. Any such topics, even remotely defined ones, must be deleted before changing **PSCLUS** to `DISABLED`.

For more information about **PSCLUS**, see ALTER QMGR (PSCLUS).

Related information:
Direct routed publish/subscribe cluster performance

Publish/subscribe and multiple clusters:

A single queue manager can be a member of more than one cluster. This arrangement is sometimes known as *overlapping clusters*. Through such an overlap, clustered queues can be made accessible from multiple clusters, and point-to-point message traffic can be routed from queue managers in one cluster to queue managers in another cluster. Clustered topics in publish/subscribe clusters do not provide the same capability. Therefore, their behavior must be clearly understood when using multiple clusters.

Unlike for a queue, you cannot associate a topic definition with more than one cluster. The scope of a clustered topic is confined to those queue managers in the same cluster as the topic is defined for. This allows publications to be propagated to subscriptions only on those queue managers in the same cluster.

A queue manager's topic tree

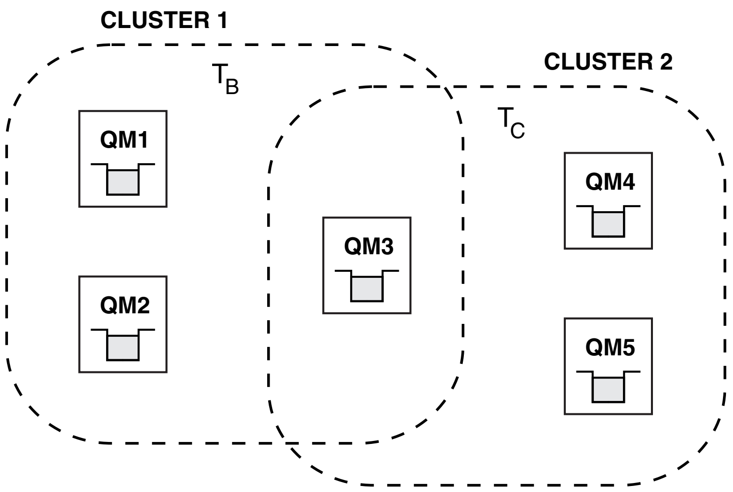

Figure 30. Overlapping clusters: Two clusters each subscribing to different topics

When a queue manager is a member of multiple clusters it is made aware of all clustered topics defined in each of those clusters. For example, in the previous figure QM3 is aware of both the T_B and T_C administered clustered topic objects, whereas QM1 is only aware of T_B. QM3 applies both topic definitions to its local topic, and therefore has a different behavor to QM1 for certain topics. For this reason it is important that clustered topics from different clusters do not interfere with each other. Interference can occur when one clustered topic is defined above or below another clustered topic in a different cluster (for example, they have topic strings of `/Sport` and `/Sport/Football`) or even for the same topic string in both. Another form of interference is when administered clustered topic objects are defined with the same object name in different clusters, but for different topic strings.

If such a configuration is made, the delivery of publications to matching subscriptions becomes very dependent on the relative locations of publishers and subscribers with respect to the cluster. For this reason, you cannot rely on such a configuration, and you should change it to remove the interfering topics.

When planning an overlapping cluster topology with publish/subscribe messaging, you can avoid any interference by treating the topic tree and clustered topic object names as if they span all overlapping clusters in the topology.

Integrating multiple publish/subscribe clusters

If there is a requirement for publish/subscribe messaging to span queue managers in different clusters, there are two options available:

- Connect the clusters together through the use of a publish/subscribe hierarchy configuration. See Combining the topic spaces of multiple clusters.
- Create an additional cluster that overlays the existing clusters and includes all queue managers that need to publish or subscribe to a particular topic.

With the latter option, you should consider carefully the size of the cluster and the most effective cluster routing mechanism. See"Designing publish/subscribe clusters" on page 64.

Design considerations for retained publications in publish/subscribe clusters:

There are a few restrictions to consider when designing a publish/subscribe cluster to work with retained publications.

Considerations

Consideration 1: The following cluster queue managers always store the latest version of a retained publication:

- The publisher's queue manager
- In a topic host routed cluster, the topic host (provided there is only one topic host for the topic, as explained in the next section of this article)
- All queue managers with subscriptions matching the topic string of the retained publication

Consideration 2: Queue managers do not receive updated retained publications while they have no subscriptions. Therefore any retained publication stored on a queue manager that no longer subscribes to the topic will become stale.

Consideration 3: On creating any subscription, if there is a local copy of a retained publication for the topic string, the local copy is delivered to the subscription. If you are the first subscriber for any given topic string, a matching retained publication is also delivered from one of the following cluster members:

- In a direct routed cluster, the publisher's queue manager
- In a topic host routed cluster, the topic hosts for the given topic

Delivery of a retained publication from a topic host or publishing queue manager to the subscribing queue manager is asynchronous to the `MQSUB` calls. Therefore, if you use the `MQSUBRQ` call, the latest retained publication might be missed until a subsequent call to `MQSUBRQ`.

Implications

For any publish/subscribe cluster, when a first subscription is made, the local queue manager might be storing a stale copy of a retained publication and this is the copy that is delivered to the new subscription. The existence of a subscription on the local queue manager means that this will resolve the next time the retained publication is updated.

For a topic host routed publish/subscribe cluster, if you configure more than one topic host for a given topic, new subscribers might receive the latest retained publication from a topic host, or they might receive a stale retained publication from another topic host (with the latest having been lost). For topic host routing, it is usual to configure multiple topic hosts for a given topic. However, if you expect applications to make use of retained publications, you should configure only one topic host for each topic.

For any given topic string, you should use only a single publisher, and ensure the publisher always uses the same queue manager. If you do not do this, different retained publications might be active at different queue managers for the same topic, leading to unexpected behavior. Because multiple proxy subscriptions are distributed, multiple retained publications might be received.

If you are still concerned about subscribers using stale publications, consider setting a message expiry when you create each retained publication.

You can use the **CLEAR TOPICSTR** command to remove a retained publication from a publish/subscribe cluster. In certain circumstances you might need to issue the command on multiple members of the publish/subscribe cluster, as described in **CLEAR TOPICSTR** .

Wildcard subscriptions and retained publications

If you are using wildcard subscriptions, the corresponding proxy subscriptions delivered to other members of the publish/subscribe cluster are wildcarded from the topic separator immediately prior to the first wildcard character. See Wildcards and cluster topics.

Therefore the wildcard used might match more topic strings, and more retained publications, than will match the subscribing application.

This increases the amount of storage needed for the retained publications, and you therefore need to ensure that the hosting queue managers have enough storage capacity.

Retained publications

Individual proxy subscription forwarding and publish everywhere

REFRESH CLUSTER considerations for publish/subscribe clusters:

Issuing the **REFRESH CLUSTER** command results in the queue manager temporarily discarding locally held information about a cluster, including any cluster topics and their associated proxy subscriptions.

The time taken from issuing the **REFRESH CLUSTER** command to the point that the queue manager regains a full knowledge of the necessary information for clustered publish/subscribe depends on the size of the cluster, the availability, and the responsiveness of the full repository queue managers.

During the refresh processing, disruption to publish/subscribe traffic in a publish/subscribe cluster occurs. For large clusters, use of the **REFRESH CLUSTER** command can disrupt the cluster while it is in progress, and again at 27 day intervals thereafter when the cluster objects automatically send status updates to all interested queue managers. See Refreshing in a large cluster can affect performance and availability of the cluster. For these reasons, the **REFRESH CLUSTER** command must be used in a publish/subscribe cluster only when under the guidance of your IBM Support Center.

The disruption to the cluster can appear externally as the following symptoms:

- Subscriptions to cluster topics on this queue manager are not receiving publications from publishers that are connected to other queue managers in the cluster.
- Messages that are published to cluster topics on this queue manager are not being propagated to subscriptions on other queue managers.
- Subscriptions to cluster topics on this queue manager created during this period are not consistently sending proxy subscriptions to other members of the cluster.
- Subscriptions to cluster topics on this queue manager deleted during this period are not consistently removing proxy subscriptions from other members of the cluster.
- 10-second pauses, or longer, in message delivery.
- **MQPUT** failures, for example, MQRC_PUBLICATION_FAILURE.

- Publications placed on the dead-letter queue with a reason of MQRC_UNKNOWN_REMOTE_Q_MGR

For these reasons publish/subscribe applications need to be quiesced before issuing the **REFRESH CLUSTER** command.

See also Usage notes for **REFRESH CLUSTER** and "Clustering: Using REFRESH CLUSTER best practices" on page 58.

After a **REFRESH CLUSTER** command is issued on a queue manager in a publish/subscribe cluster, wait until all cluster queue managers and cluster topics have been successfully refreshed, then resynchronize proxy subscriptions as described in Resynchronization of proxy subscriptions. When all proxy subscriptions have been correctly resynchronized, restart your publish/subscribe applications.

If a **REFRESH CLUSTER** command is taking a long time to complete, monitor it by looking at the CURDEPTH of `SYSTEM.CLUSTER.COMMAND.QUEUE`.

Related concepts:

"Clustering: Using REFRESH CLUSTER best practices" on page 58
You use the **REFRESH CLUSTER** command to discard all locally held information about a cluster and rebuild that information from the full repositories in the cluster. You should not need to use this command, except in exceptional circumstances. If you do need to use it, there are special considerations about how you use it. This information is a guide based on testing and feedback from customers.

Routing in publish/subscribe hierarchies

If your distributed queue manager topology is a publish/subscribe hierarchy, and a subscription is made on a queue manager, by default a proxy subscription is created on every queue manager in the hierarchy. Publications received on any queue manager are then routed through the hierarchy to each queue manager that hosts a matching subscription.

For an introduction to how messages are routed between queue managers in publish/subscribe hierarchies and clusters, see Distributed publish/subscribe networks.

When a subscription to a topic is made on a queue manager in a distributed publish/subscribe hierarchy, the queue manager manages the process by which the subscription is propagated to connected queue managers. *Proxy subscriptions* flow to all queue managers in the network. A proxy subscription gives a queue manager the information it needs to forward a publication to those queue managers that host subscriptions for that topic. Each queue manager in a publish/subscribe hierarchy is only aware of its direct relations. Publications put to one queue manager are sent, through its direct relations, to those queue managers with subscriptions. This is illustrated in the following figure, in which *Subscriber 1* registers a subscription for a particular topic on the *Asia* queue manager (1). Proxy subscriptions for this subscription on the *Asia* queue manager are forwarded to all other queue managers in the network (2,3,4).

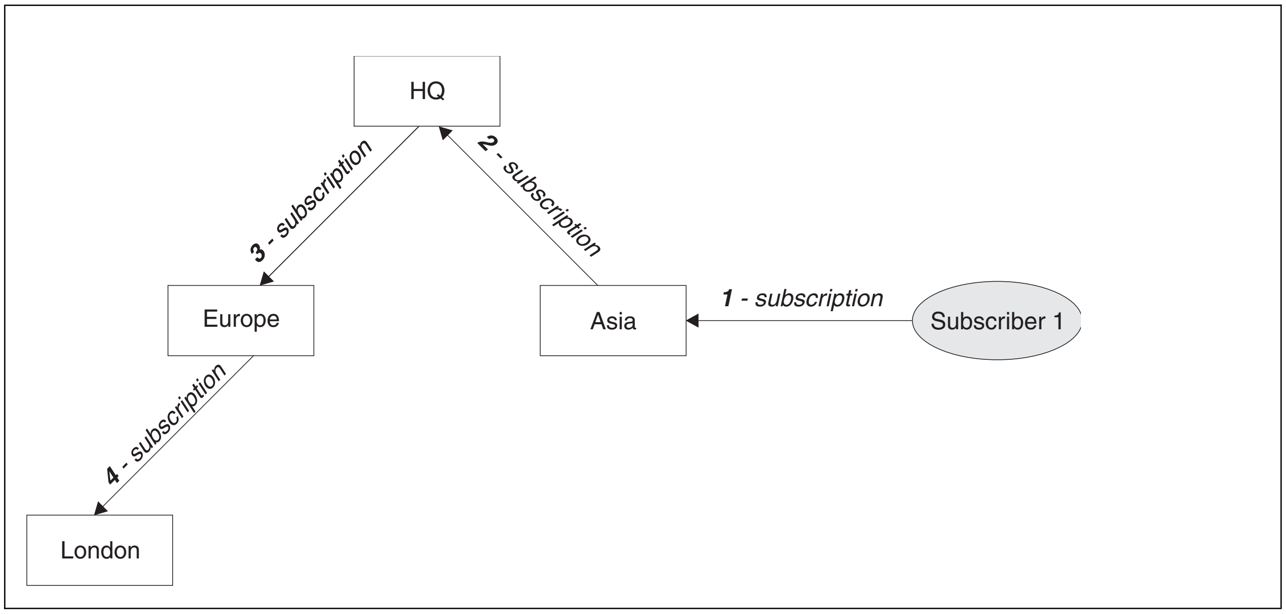

Figure 31. Propagation of subscriptions through a queue manager network

A queue manager consolidates all the subscriptions that are created on it, whether from local applications or from remote queue managers. It creates proxy subscriptions for the topics of the subscriptions with its neighbors, unless a proxy subscription already exists. This is illustrated in the following figure, in which *Subscriber 2* registers a subscription, to the same topic as in Figure 31, on the *HQ* queue manager (5). The subscription for this topic is forwarded to the *Asia* queue manager, so that it is aware that subscriptions exist elsewhere on the network (6). The subscription is not forwarded to the *Europe* queue manager, because a subscription for this topic has already been registered; see step 3 in Figure 31.

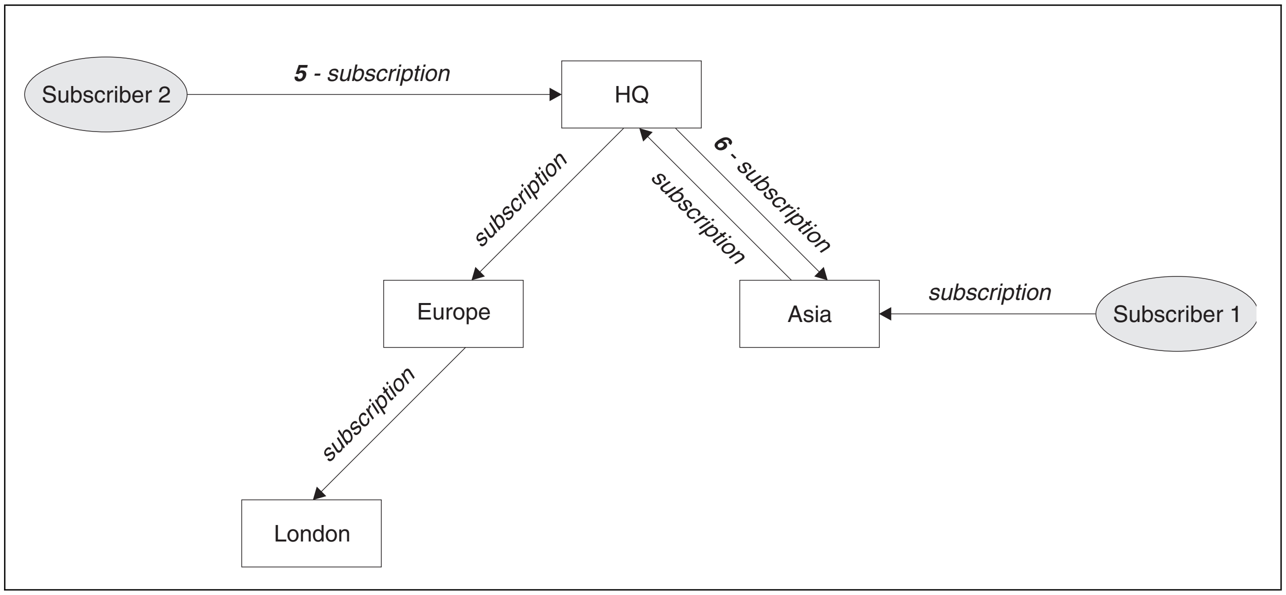

Figure 32. Multiple subscriptions

When an application publishes information to a topic, by default the receiving queue manager forwards it to all queue managers that have valid subscriptions to the topic. It might forward it through one or more intermediate queue managers. This is illustrated in the following figure, in which a publisher sends a publication, on the same topic as in Figure 32, to the *Europe* queue manager (7). A subscription for this topic exists from *HQ* to *Europe*, so the publication is forwarded to the *HQ* queue manager (8). However, no subscription exists from *London* to *Europe* (only from *Europe* to *London*), so the publication is not forwarded to the *London* queue manager. The *HQ* queue manager sends the publication directly to *Subscriber 2* and to the *Asia* queue manager (9). The publication is forwarded to *Subscriber 1* from *Asia* (10).

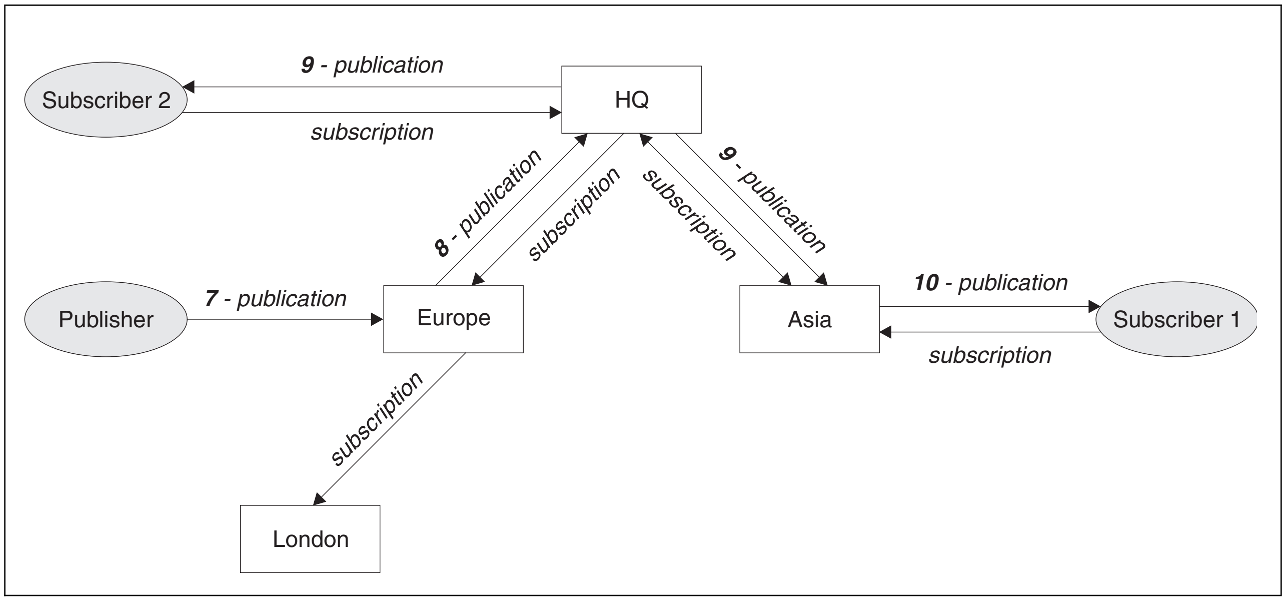

Figure 33. Propagation of publications through a queue manager network

When a queue manager sends any publications or subscriptions to another queue manager, it sets its own user ID in the message. If you are using a publish/subscribe hierarchy, and if the incoming channel is set up to put messages with the authority of the user ID in the message, then you must authorize the user ID of the sending queue manager. See Using default user IDs with a queue manager hierarchy.

Note: If you instead use publish/subscribe clusters, authorization is handled by the cluster.

Summary and additional considerations

A publish/subscribe hierarchy gives you precise control over the relationship between queue managers. After it has been created, it needs little manual intervention to administer. However it also imposes certain constraints upon your system:

- The higher nodes in the hierarchy, especially the root node, must be hosted on robust, highly available, and performant equipment. This is because more publication traffic is expected to flow through these nodes.
- The availability of every non-leaf queue manager in the hierarchy affects the ability of the network to flow messages from publishers to subscribers on other queue managers.
- By default, all topic strings subscribed to are propagated throughout the hierarchy, and publications are propagated only to remote queue managers that have a subscription to the associated topic. Therefore rapid changes to the set of subscriptions can become a limiting factor. You can change this default behavior, and instead have all publications propagated to all queue managers, which removes the need for proxy subscriptions. See Subscription performance in publish/subscribe networks.

  Note: A similar restriction also applies to direct routed clusters.
- Because of the interconnected nature of publish/subscribe queue managers, it takes time for proxy subscriptions to propagate around all nodes in the network. Remote publications do not necessarily start being subscribed to immediately, so early publications might not be sent following a subscription to a new topic string. You can remove the problems caused by the subscription delay by having all

publications propagated to all queue managers, which removes the need for proxy subscriptions. See Subscription performance in publish/subscribe networks.

Note: This restriction also applies to direct routed clusters.

- For a publish/subscribe hierarchy, adding or removing queue managers requires manual configuration to the hierarchy, with careful consideration to the location of those queue managers and their reliance on other queue managers. Unless you are adding or removing queue managers that are at the bottom of the hierarchy, and therefore have no further branches below them, you will also have to configure other queue managers in the hierarchy.

Before you use a publish/subscribe hierarchy as your routing mechanism, explore the alternative approaches detailed in "Direct routing in publish/subscribe clusters" on page 66 and "Topic host routing in publish/subscribe clusters" on page 71.

Distributed publish/subscribe system queues

Four system queues are used by queue managers for publish/subscribe messaging. You need to be aware of their existence only for problem determination and capacity planning purposes.

See Balancing producers and consumers in publish/subscribe networks for guidance on how to monitor these queues.

Table 6. Publish/subscribe system queues on Multiplatforms

System queue	Purpose
SYSTEM.INTER.QMGR.CONTROL	IBM MQ distributed publish/subscribe control queue
SYSTEM.INTER.QMGR.FANREQ	IBM MQ distributed publish/subscribe internal proxy subscription fan-out process input queue
SYSTEM.INTER.QMGR.PUBS	IBM MQ distributed publish/subscribe publications
SYSTEM.HIERARCHY.STATE	IBM MQ distributed publish/subscribe hierarchy relationship state

z/OS On z/OS, you set up the necessary system objects when you create the queue manager, by including the CSQ4INSX, CSQ4INSR and CSQ4INSG samples in the CSQINP2 initialization input data set. For more information, see Task 13: Customize the initialization input data sets.

The attributes of the publish/subscribe system queues are shown in Table 7.

Table 7. Attributes of publish/subscribe system queues

Attribute	Default value
DEFPSIST	Yes
DEFSOPT	EXC
MAXMSGL	Multi On Multiplatforms: The value of the MAXMSGL parameter of the ALTER QMGR command z/OS On z/OS: 104857600 (that is, 100 MB)
MAXDEPTH	999999999
SHARE	N/A
z/OS STGCLASS	This attribute is used only on z/OS platforms

Note: The only queue that contains messages put by applications is `SYSTEM.INTER.QMGR.PUBS`. **`MAXDEPTH`** is set to its maximum value for this queue to allow temporary build up of published messages during outages or times of excessive load. If the queue manager is running on a system where that depth of queue could not be contained, this should be adjusted.

Related information:

Distributed publish/subscribe troubleshooting

Distributed publish/subscribe system queue errors:

Errors can occur when distributed publish/subscribe queue manager queues are unavailable. This affects the propagation of subscription knowledge across the publish/subscribe network, and publication to subscriptions on remote queue managers.

If the fan-out request queue `SYSTEM.INTER.QMGR.FANREQ` is unavailable, the creation of a subscription might generate an error, and error messages will be written to the queue manager error log when proxy subscriptions need to be delivered to directly connected queue managers.

If the hierarchy relationship state queue `SYSTEM.HIERARCHY.STATE` is unavailable, an error message is written to the queue manager error log and the publish/subscribe engine is put into COMPAT mode. To view the publish/subscribe mode, use the command `DISPLAY QMGR PSMODE`.

If any other of the `SYSTEM.INTER.QMGR` queues are unavailable, an error message is written to the queue manager error log and, although function is not disabled, it is likely that publish/subscribe messages will build up on queues on this or remote queue managers.

If the publish/subscribe system queue or required transmission queue to a parent, child or publish/subscribe cluster queue manager is unavailable, the following outcomes occur:

- The publications are not delivered, and a publishing application might receive an error. For details of when the publishing application receives an error, see the following parameters of the **`DEFINE TOPIC`** command: **`PMSGDLV`** , **`NPMSGDLV`** , and **`USEDLQ`** .
- Received inter-queue manager publications are backed out to the input queue, and subsequently re-attempted. If the backout threshold is reached, the undelivered publications are placed on the dead letter queue. The queue manager error log will contain details of the problem.
- An undelivered proxy subscription is backed out to the fanout request queue, and subsequently attempted again. If the backout threshold is reached, the undelivered proxy subscription is not delivered to any connected queue manager, and is placed on the dead letter queue. The queue manager error log will contain details of the problem, including details of any necessary corrective administrative action required.
- Hierarchy relationship protocol messages fail, and the connection status is flagged as `ERROR`. To view the connection status, use the command **`DISPLAY PUBSUB`**.

Planning your storage and performance requirements on Multiplatforms

Multi

You must set realistic and achievable storage, and performance goals for your IBM MQ system. Use the links to find out about factors that affect storage and performance on your platform.

The requirements vary depending on the systems that you are using IBM MQ on, and what components you want to use.

For the latest information about supported hardware and software environments, see System Requirements for IBM MQ.

IBM MQ stores queue manager data in the file system. Use the following links to find out about planning and configuring directory structures for use with IBM MQ:
- “Planning file system support on Multiplatforms” on page 104
- “Requirements for shared file systems on Multiplatforms” on page 105
- “Sharing IBM MQ files on Multiplatforms” on page 114
- Linux UNIX “Directory structure on UNIX and Linux systems” on page 117
- Windows “Directory structure on Windows systems” on page 126
- IBM i “Directory structure on IBM i” on page 130

Linux UNIX Use the following links for information about system resources, shared memory, and process priority on UNIX and Linux:

- Calculating the size of the log

Related concepts:

"Planning an IBM MQ architecture" on page 1
When planning your IBM MQ environment, consider the support that IBM MQ provides for single and multiple queue manager architectures, and for point-to-point and publish/subscribe messaging styles. Also plan your resource requirements, and your use of logging and backup facilities.

z/OS "Planning your IBM MQ environment on z/OS" on page 138
When planning your IBM MQ environment, you must consider the resource requirements for data sets, page sets, Db2, Coupling Facilities, and the need for logging, and backup facilities. Use this topic to plan the environment where IBM MQ runs.

Related information:

Hardware and software requirements on UNIX and Linux

Hardware and software requirements on Windows

Disk space requirements on Multiplatforms

Multi

The storage requirements for IBM MQ depend on which components you install, and how much working space you need.

Disk storage is required for the optional components you choose to install, including any prerequisite components they require. The total storage requirement also depends on the number of queues that you use, the number and size of the messages on the queues, and whether the messages are persistent. You also require archiving capacity on disk, tape, or other media, as well as space for your own application programs.

The following table shows the approximate disk space required when you install various combinations of the product on different platforms. (Values are rounded up to the nearest 5 MB, where a MB is 1,048,576 bytes.)

IBM i

Notes:

1. On IBM i you cannot separate the native client from the server. The server figure in the table is for 5724H72*BASE without Java™, together with the English Language Load (2924). There are 22 possible unique language loads.
2. The figure in the table is for the native client 5725A49 *BASE without Java.
3. Java and JMS classes can be added to both server and client bindings. If you want to include these features add 110 MB.
4. Adding samples source to either the client or server adds an extra 10 MB.
5. Adding samples to Java and JMS classes adds an extra 5 MB.

Platform	Client installation [1]	Server installation [2]	IBM MQ MFT installation [3]	Full installation - LTS release [4]	Full installation - CD releases [4]
AIX AIX®	145 MB	190 MB	705 MB	915 MB	915 MB V 9.0.5 1410 MB
HP-UX HP-UX	225 MB	310 MB	1075 MB	1340 MB	N/A
IBM i IBM i	215 MB	450 MB	80 MB	655 MB	N/A
Linux Linux for System x (64 bit)	125 MB	170 MB	575 MB	935 MB	V 9.0.1 1500 MB V 9.0.2 1560 MB
Linux Linux on POWER® Systems - Little Endian	90 MB	125 MB	555 MB	685 MB	V 9.0.1 980 MB V 9.0.2 995 MB V 9.0.3 1000 MB V 9.0.4 1100 MB
Linux Linux for IBM Z	125 MB	160 MB	560 MB	665 MB	V 9.0.1 V 9.0.2 1050 MB V 9.0.3 1100 MB

Solaris Solaris SPARC	105 MB [5]	150 MB [5]	680 MB	820 MB	N/A
Windows Windows (64 bit installation) [6]	445 MB	555 MB	710 MB	1070 MB	V 9.0.1 V 9.0.2 1490 MB V 9.0.3 1310 MB

Usage notes

1. A client installation includes the following components:
   - Runtime
   - Client
2. A server installation includes the following components:
   - Runtime
   - Server
3. A Managed File Transfer installation includes the following components:
   - Managed File Transfer Service, Logger, Agent, Tools, and Base components
   - Runtime
   - Server
   - Java
   - JRE
4. A full installation includes all available components.
5. Solaris On Solaris platforms you must install silently to get this combination of components.
6. Windows Not all the components listed here are installable features on Windows systems; their functionality is sometimes included in other features. See IBM MQ features for Windows systems.

Planning file system support on Multiplatforms

Multi

Queue manager data is stored in the file system. A queue manager makes use of file system locking to prevent multiple instances of a multi-instance queue manager being active at the same time.

Shared file systems

Shared file systems enable multiple systems to access the same physical storage device concurrently. Corruption would occur if multiple systems accessed the same physical storage device directly without some means of enforcing locking and concurrency control. Operating systems provide local file systems with locking and concurrency control for local processes; network file systems provide locking and concurrency control for distributed systems.

Historically, networked file systems have not performed fast enough, or provided sufficient locking and concurrency control, to meet the requirements for logging messages. Today, networked file systems can provide good performance, and implementations of reliable network file system protocols such as *RFC 3530, Network File System (NFS) version 4 protocol*, meet the requirements for logging messages reliably.

Shared file systems and IBM MQ

Queue manager data for a multi-instance queue manager is stored in a shared network file system. On Microsoft UNIX, Linux, and Windows systems, the queue manager's data files and log files must be placed in shared network file system. IBM i On IBM i, journals are used instead of log files, and journals cannot be shared. Multi-instance queue managers on IBM i use journal replication, or switchable journals, to make journals available between different queue manager instances.

Prior to release v7.0.1, IBM MQ does not support queue manager data stored on networked storage accessed as a shared file system. If queue manager data is placed on shared networked storage, then you need to ensure the queue manager data is not accessed by another instance of the queue manager running at the same time.

From v7.0.1 onwards, IBM MQ uses locking to prevent multiple instances of the same multi-instance queue manager being active at the same time. The same locking also ensures that two separate queue managers cannot inadvertently use the same set of queue manager data files. Only one instance of a queue manager can have its lock at a time. Consequently, IBM MQ does support queue manager data stored on networked storage accessed as a shared file system.

Because not all the locking protocols of network file systems are robust, and because a file system might be configured for performance rather than data integrity, you must run the **amqmfsck** command to test whether a network file system will control access to queue manager data and logs correctly. This command applies only UNIX and IBM i systems. On Microsoft Windows, there is only one supported network file system and the **amqmfsck** command is not required.

Related tasks:

"Verifying shared file system behavior on Multiplatforms" on page 107

Run **amqmfsck** to check whether a shared file system on UNIX IBM i and IBM i systems meets the requirements for storing the queue manager data of a multi-instance queue manager. Run the IBM MQ MQI client sample program **amqsfhac** in parallel with **amqmfsck** to demonstrate that a queue manager maintains message integrity during a failure.

Requirements for shared file systems on Multiplatforms

Multi

Shared files systems must provide data write integrity, guaranteed exclusive access to files and release locks on failure to work reliably with IBM MQ.

There are three fundamental requirements that a shared file system must meet:

1. Data write integrity.

   Data write integrity is sometimes called "Write through to disk on flush". The queue manager must be able to synchronize with data being successfully committed to the physical device. In a transactional system, you need to be sure that some writes have been safely committed before continuing with other processing.

   More specifically, IBM MQ on UNIX platforms uses the *O_SYNC* open option and the `fsync()` system call to explicitly force writes to recoverable media, and the write operation is dependent upon these options operating correctly.

   Attention: Linux You should mount the file system with the `async` option, which still supports the option of synchronous writes and gives better performance than the `sync` option.

   Note, however, that if the file system has been exported from Linux, you must still export the file system using the `sync` option.

2. Guaranteed exclusive access to files.

   In order to synchronize multiple queue managers, there needs to be a mechanism for a queue manager to obtain an exclusive lock on a file.

3. Release locks on failure.

   If a queue manager fails, or if there is a communication failure with the file system, files locked by the queue manager need to be unlocked and made available to other processes without waiting for the queue manager to be reconnected to the file system.

   For multi-instance queue managers on Microsoft Windows, the networked storage must be accessed by the Common Internet File System (CIFS) protocol used by Microsoft Windows networks.

   For multi-instance queue managers on other supported platforms, the storage must be accessed by a network file system protocol which is Posix-compliant and supports lease-based locking. Network File

System Version 4 satisfies this requirement. Older file systems, such as Network File System Version 3, which do not have a reliable mechanism to release locks after a failure, must not be used with multi-instance queue managers.

A shared file system must meet these requirements for IBM MQ to operate reliably. If it does not, the queue manager data and logs get corrupted when using the shared file system in a multi-instance queue manager configuration.

You must check whether the shared file system you plan to use meets these requirements. You must also check whether the file system is correctly configured for reliability. Shared file systems sometimes provide configuration options to improve performance at the expense of reliability.

For further information, see Testing and support statement for IBM MQ multi-instance queue managers.

Under normal circumstances IBM MQ operates correctly with attribute caching and it is not necessary to disable caching, for example by setting NOAC on an NFS mount. Attribute caching can cause issues when multiple file system clients are contending for write access to the same file on the file system server, as the cached attributes used by each client might not be the same as those attributes on the server. An example of files accessed in this way are queue manager error logs for a multi-instance queue manager. The queue manager error logs might be written to by both an active and a standby queue manager instance and cached file attributes might cause the error logs to grow larger than expected, before rollover of the files occurs.

To help to check the file system, run the task Verifying shared file system behavior. This task checks if your shared file system meets requirements 2 and 3. You need to verify requirement 1 in your shared file system documentation, or by experimenting with logging data to the disk.

Disk faults can cause errors when writing to disk, which IBM MQ reports as First Failure Data Capture errors. You can run the file system checker for your operating system to check the shared file system for any disk faults. For example, on UNIX the file system checker is called fsck. On Windows platforms the file system checker is called CHKDSK, or SCANDISK.

Note: You should put only queue manager data on an NFS server. On the NFS, use the following three options with the mount command to make the system secure:

- **noexec**
  By using this option, you stop binary files from being run on the NFS, which prevents a remote user from running unwanted code on the system.
- **nosuid**
  By using this option, you prevent the use of the set-user-identifier and set-group-identifier bits, which prevents a remote user from gaining higher privileges.
- **nodev**
  By using this option, you stop character and block special devices from being used or defined, which prevents a remote user from getting out of a chroot jail.

Verifying shared file system behavior on Multiplatforms: Multi

Run **amqmfsck** to check whether a shared file system on UNIX IBM i and IBM i systems meets the requirements for storing the queue manager data of a multi-instance queue manager. Run the IBM MQ MQI client sample program **amqsfhac** in parallel with **amqmfsck** to demonstrate that a queue manager maintains message integrity during a failure.

Before you begin

You need a server with networked storage, and two other servers connected to it that have IBM MQ installed. You must have administrator (root) authority to configure the file system, and be an IBM MQ Administrator to run **amqmfsck**.

About this task

"Requirements for shared file systems on Multiplatforms" on page 105 describes the file system requirements for using a shared file system with multi-instance queue managers. The IBM MQ technote Testing and support statement for IBM MQ multi-instance queue managers lists the shared file systems that IBM has already tested with. The procedure in this task describes how to test a file system to help you assess whether an unlisted file system maintains data integrity.

Failover of a multi-instance queue manager can be triggered by hardware or software failures, including networking problems which prevent the queue manager writing to its data or log files. Mainly, you are interested in causing failures on the file server. But you must also cause the IBM MQ servers to fail, to test any locks are successfully released. To be confident in a shared file system, test all of the following failures, and any other failures that are specific to your environment:
1. Shutting down the operating system on the file server including syncing the disks.
2. Halting the operating system on the file server without syncing the disks.
3. Pressing the reset button on each of the servers.
4. Pulling the network cable out of each of the servers.
5. Pulling the power cable out of each of the servers.
6. Switching off each of the servers.

Create the directory on the networked storage that you are going to use to share queue manager data and logs. The directory owner must be an IBM MQ Administrator, or in other words, a member of the `mqm` group on UNIX. The user who runs the tests must have IBM MQ Administrator authority.

Use the example of exporting and mounting a file system in Create a multi-instance queue manager on Linux IBM i or Mirrored journal configuration on an ASP using ADDMQMJRN to help you through configuring the file system. Different file systems require different configuration steps. Read the file system documentation.

Procedure

In each of the checks, cause all the failures in the previous list while the file system checker is running. If you intend to run **amqsfhac** at the same time as **amqmfsck**, do the task, "Running **amqsfhac** to test message integrity" on page 112 in parallel with this task.
1. Mount the exported directory on the two IBM MQ servers.

   On the file system server create a shared directory `shared`, and a subdirectory to save the data for multi-instance queue managers, `qmdata`. For an example of setting up a shared directory for multi-instance queue managers on Linux, see Example in Create a multi-instance queue manager on Linux

2. Check basic file system behavior.

   On one IBM MQ server, run the file system checker with no parameters.

```
amqmfsck /shared/qmdata
```

Figure 34. On IBM MQ server 1

3. Check concurrently writing to the same directory from both IBM MQ servers.

   On both IBM MQ servers, run the file system checker at the same time with the `-c` option.

```
amqmfsck -c /shared/qmdata
```

Figure 35. On IBM MQ server 1

```
amqmfsck -c /shared/qmdata
```

Figure 36. On IBM MQ server 2

4. Check waiting for and releasing locks on both IBM MQ servers.

   On both IBM MQ servers run the file system checker at the same time with the `-w` option.

```
amqmfsck -w /shared/qmdata
```

Figure 37. On IBM MQ server 1

```
amqmfsck -w /shared/qmdata
```

Figure 38. On IBM MQ server 2

5. Check for data integrity.
   a. Format the test file.

      Create a large file in the directory being tested. The file is formatted so that the subsequent phases can complete successfully. The file must be large enough that there is sufficient time to interrupt the second phase to simulate the failover. Try the default value of 262144 pages (1 GB). The program automatically reduces this default on slow file systems so that formatting completes in about 60 seconds

```
amqmfsck -f /shared/qmdata
```

The server responds with the following messages:

```
Formatting test file for data integrity test.

Test file formatted with 262144 pages of data.
```

Figure 39. On IBM MQ server 1

   b. Write data into the test file using the file system checker while causing a failure.

      Run the test program on two servers at the same time. Start the test program on the server which is going to experience the failure, then start the test program on the server that is going to survive the failure. Cause the failure you are investigating.

The first test program stops with an error message. The second test program obtains the lock on the test file and writes data into the test file starting where the first test program left off. Let the second test program run to completion.

Table 8. Running the data integrity check on two servers at the same time

IBM MQ server 1	**IBM MQ server 2**
`amqmfsck -a /shared/qmdata`	
`Please start this program on a second machine with the same parameters.`	`amqmfsck -a /shared/qmdata`
	`Waiting for lock...`
`File lock acquired.`	`Waiting for lock...`
`Start a second copy of this program with the same parameters on another server.`	`Waiting for lock...`
`Writing data into test file.`	`Waiting for lock...`
`To increase the effectiveness of the test, interrupt the writing by ending the process, temporarily breaking the network connection to the networked storage, rebooting the server or turning off the power.`	`Waiting for lock...` `Waiting for lock...`
`Turn the power off here.`	

	`File lock acquired.`
	`Reading test file`
	`Checking the integrity of the data read.`
	`Appending data into the test file after data already found.`
	`The test file is full of data. It is ready to be inspected for data integrity.`

The timing of the test depends on the behavior of the file system. For example, it typically takes 30 - 90 seconds for a file system to release the file locks obtained by the first program following a power outage. If you have too little time to introduce the failure before the first test program has filled the file, use the `-x` option of **`amqmfsck`** to delete the test file. Try the test from the start with a larger test file.

c. Verify the integrity of the data in the test file.

```
amqmfsck -i /shared/qmdata
```

The server responds with the following messages:

```
File lock acquired

Reading test file checking the integrity of the data read.

The data read was consistent.

The tests on the directory completed successfully.
```

Figure 40. On IBM MQ server 2

6. Delete the test files.

```
amqmfsck -x /shared/qmdata

Test files deleted.
```

Figure 41. On IBM MQ server 2

The server responds with the message:

```
Test files deleted.
```

Results

The program returns an exit code of zero if the tests complete successfully, and non-zero otherwise.

Examples

The first set of three examples shows the command producing minimal output.

Successful test of basic file locking on one server

```
> amqmfsck /shared/qmdata
The tests on the directory completed successfully.
```

Failed test of basic file locking on one server

```
> amqmfsck /shared/qmdata
AMQ6245: Error Calling 'write()[2]' on file '/shared/qmdata/amqmfsck.lck' error '2'.
```

Successful test of locking on two servers

Table 9. Successful locking on two servers

IBM MQ server 1	IBM MQ server 2

`> amqmfsck -w /shared/qmdata`
`Please start this program on a second`
`machine with the same parameters.`
`Lock acquired.`
`Press Return`
`or terminate the program to release the lock.`	

	`> amqmfsck -w /shared/qmdata`
	`Waiting for lock...`

`[ Return pressed ]`
`Lock released.`	

Table 9. Successful locking on two servers (continued)

IBM MQ server 1	IBM MQ server 2

	`Lock acquired.`
	`The tests on the directory completed successfully`

The second set of three examples shows the same commands using verbose mode.

Successful test of basic file locking on one server

```
> amqmfsck -v /shared/qmdata
System call: stat("/shared/qmdata")'

amqmfsck (file system check)

Running **amqsfhac** *to test message integrity:*

amqsfhac checks that a queue manager using networked storage maintains data integrity following a failure.

Before you begin

You require four servers for this test. Two servers for the multi-instance queue manager, one for the file system, and one for running **amqsfhac** as a IBM MQ MQI client application.

Follow step 1 on page 107 in Procedure to set up the file system for a multi-instance queue manager.

About this task

Procedure

1. Create a multi-instance queue manager on another server, QM1, using the file system you created in step 1 on page 107 in Procedure.

   See Create a multi-instance queue manager.
2. Start the queue manager on both servers making it highly available.

   On server 1:
   ```
   strmqm -x QM1
   ```
   On server 2:
   ```
   strmqm -x QM1
   ```
3. Set up the client connection to run **amqsfhac**.

   a. Use the procedure in *Verifying an IBM MQ installation* for the platform, or platforms, that your enterprise use to set up a client connection, or the example scripts in Reconnectable client samples.
   b. Modify the client channel to have two IP addresses, corresponding to the two servers running QM1.

      In the example script, modify:

      ```
      DEFINE CHANNEL(CHANNEL1) CHLTYPE(CLNTCONN) TRPTYPE(TCP) +
      CONNAME('LOCALHOST(2345)') QMNAME(QM1) REPLACE
      ```

      To:

      ```
      DEFINE CHANNEL(CHANNEL1) CHLTYPE(CLNTCONN) TRPTYPE(TCP) +
      CONNAME('server1(2345),server2(2345)') QMNAME(QM1) REPLACE
      ```

      Where server1 and server2 are the host names of the two servers, and 2345 is the port that the channel listener is listening on. Usually this defaults to 1414. You can use 1414 with the default listener configuration.
4. Create two local queues on QM1 for the test. Run the following MQSC script:

   ```
   DEFINE QLOCAL(TARGETQ) REPLACE
   DEFINE QLOCAL(SIDEQ) REPLACE
   ```
5. Test the configuration with **amqsfhac**

   ```
   amqsfhac QM1 TARGETQ SIDEQ 2 2 2
   ```
6. Test message integrity while you are testing file system integrity.

   Run **amqsfhac** during step 5 on page 108 of Procedure.

   ```
   amqsfhac QM1 TARGETQ SIDEQ 10 20 0
   ```

   If you stop the active queue manager instance, **amqsfhac** reconnects to the other queue manager instance once it has become active. Restart the stopped queue manager instance again, so that you can reverse the failure in your next test. You will probably need to increase the number of iterations based on experimentation with your environment so that the test program runs for sufficient time for the failover to occur.

Results

An example of running **amqsfhac** in step 6 is shown in Figure 42 on page 114. The test is a success.

If the test detected a problem, the output would report the failure. In some test runs MQRC_CALL_INTERRUPTED might report “Resolving to backed out”. It makes no difference to the result. The outcome depends on whether the write to disk was committed by the networked file storage before or after the failure took place.

Sharing IBM MQ files on Multiplatforms

Multi

Some IBM MQ files are accessed exclusively by an active queue manager, other files are shared.

IBM MQ files are split into program files and data files. Program files are typically installed locally on each server running IBM MQ. Queue managers share access to data files and directories in the default data directory. They require exclusive access to their own queue manager directory trees contained in each of the `qmgrs` and `log` directories shown in Figure 43 on page 115.

Figure 43 on page 115 is a high-level view of the IBM MQ directory structure. It shows the directories which can be shared between queue managers and made remote. The details vary by platform. The dotted lines indicate configurable paths.

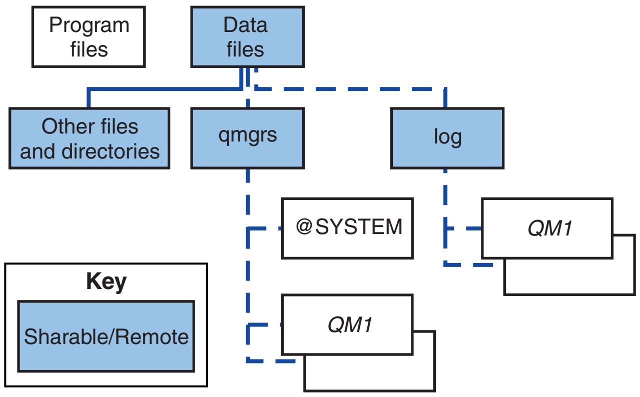

Figure 43. Overall view of IBM MQ directory structure

Program files

The program files directory is typically left in the default location, is local, and shared by all the queue managers on the server.

Data files

The data files directory is typically local in the default location, `/var/mqm` on UNIX and Linux systems and configurable on installation on Windows. It is shared between queue managers. You can make the default location remote, but do not share it between different installations of IBM MQ. The `DefaultPrefix` attribute in the IBM MQ configuration points to this path.

`qmgrs` From v7.0.1, there are two alternative ways to specify the location of queue manager data.

Using `Prefix`

The `Prefix` attribute specifies the location of the `qmgrs` directory. IBM MQ constructs the queue manager directory name from the queue manager name and creates it as a subdirectory of the `qmgrs` directory.

The `Prefix` attribute is located in the QueueManager stanza, and is inherited from the value in the `DefaultPrefix` attribute. By default, for administrative simplicity, queue managers typically share the same `qmgrs` directory.

The `QueueManager` stanza is in the `mqs.ini` file.

If you change the location of the `qmgrs` directory for any queue manager, you must change the value of its `Prefix` attribute.

The `Prefix` attribute for the `QM1` directory in Figure 43 for a UNIX and Linux platform is,

```
Prefix=/var/mqm
```

Using `DataPath`

The `DataPath` attribute specifies the location of the queue manager data directory.

The `DataPath` attribute specifies the complete path, including the name of the queue manager data directory. The `DataPath` attribute is unlike the `Prefix` attribute, which specifies an incomplete path to the queue manager data directory.

The `DataPath` attribute, if it is specified, is located in the QueueManager stanza. If it has been specified, it takes precedence over any value in the `Prefix` attribute.

The `QueueManager` stanza is in the `mqs.ini` file.

If you change the location of the queue manager data directory for any queue manager you must change the value of the `DataPath` attribute.

The `DataPath` attribute for the `QM1` directory in Figure 43 on page 115 for a UNIX or Linux platform is,

```
DataPath=/var/mqm/qmgrs/QM1
```

`log`

The log directory is specified separately for each queue manager in the `Log` stanza in the queue manager configuration. The queue manager configuration is in `qm.ini`.

***`DataPath`*`/`*`QmgrName`*`/@IPCC` subdirectories**

The *`DataPath`*`/`*`QmgrName`*`/@IPCC` subdirectories are in the shared directory path. They are used to construct the directory path for IPC file system objects. They need to distinguish the namespace of a queue manager when a queue manager is shared between systems. Before V7.0.1, a queue manager was only used on one system. One set of subdirectories was sufficient to define the directory path to IPC file system objects, see Figure 44.

```
DataPath/QmgrName/@IPCC/esem
```

Figure 44. Example IPC subdirectory, pre-V7.0.1

In V7.0.1, and later, the IPC file system objects have to be distinguished by system. A subdirectory, for each system the queue manager runs on, is added to the directory path, see Figure 45.

```
DataPath/QmgrName/@IPCC/esem/myHostName/
```

Figure 45. Example IPC subdirectory, V7.0.1 and subsequent releases

`myHostName` is up to the first 20 characters of the host name returned by the operating system. On some systems, the host name might be up to 64 characters in length before truncation. The generated value of *`myHostName`* might cause a problem for two reasons:

1. The first 20 characters are not unique.
2. The host name is generated by a DHCP algorithm that does not always allocate the same host name to a system.

In these cases, set *`myHostName`* using the environment variable, `MQC_IPC_HOST` ; see Figure 46.

```
export MQS_IPC_HOST= myHostName
```

Figure 46. Example: setting `MQC_IPC_HOST`

Other files and directories

Other files and directories, such as the directory containing trace files, and the common error log, are normally shared and kept on the local file system.

Up until v7.0.1, IBM MQ relied upon external management to guarantee queue managers exclusive access to the queue manager data and log files. From v7.0.1 onwards, with support of shared file systems, IBM MQ manages exclusive access to these files using file system locks. A file system lock allows only one instance of a particular queue manager to be active at a time.

When you start the first instance of a particular queue manager it takes ownership of its queue manager directory. If you start a second instance, it can only take ownership if the first instance has stopped. If the first queue manager is still running, the second instance fails to start, and reports the queue manager is running elsewhere. If the first queue manager has stopped, then the second queue manager takes over ownership of the queue manager files and becomes the running queue manager.

You can automate the procedure of the second queue manager taking over from the first. Start the first queue manager with the `strmqm -x` option that permits another queue manager to take over from it. The second queue manager then waits until the queue manager files are unlocked before attempting to take over ownership of the queue manager files, and start.

Directory structure on UNIX and Linux systems

Linux UNIX

The IBM MQ directory structure on UNIX and Linux systems can be mapped to different file systems for easier management, better performance, and better reliability.

Use the flexible directory structure of IBM MQ to take advantage of shared file systems for running multi-instance queue managers.

Use the command **crtmqm** *QM1* to create the directory structure shown in Figure 47 where `R` is the release of the product. It is a typical directory structure for a queue manager created on an IBM MQ system from IBM WebSphere MQ Version 7.0.1 onwards. Some directories, files and .ini attribute settings are omitted for clarity, and another queue manager name might be altered by mangling. The names of the file systems vary on different systems.

In a typical installation, every queue manager that you create points to common `log` and `qmgrs` directories on the local file system. In a multi-instance configuration, the `log` and `qmgrs` directories are on a network file system shared with another installation of IBM MQ.

Figure 47 shows the default configuration for IBM MQ v7.R on AIX where `R` is the release of the product. For examples of alternative multi-instance configurations, see"Example directory configurations on UNIX and Linux systems" on page 121.

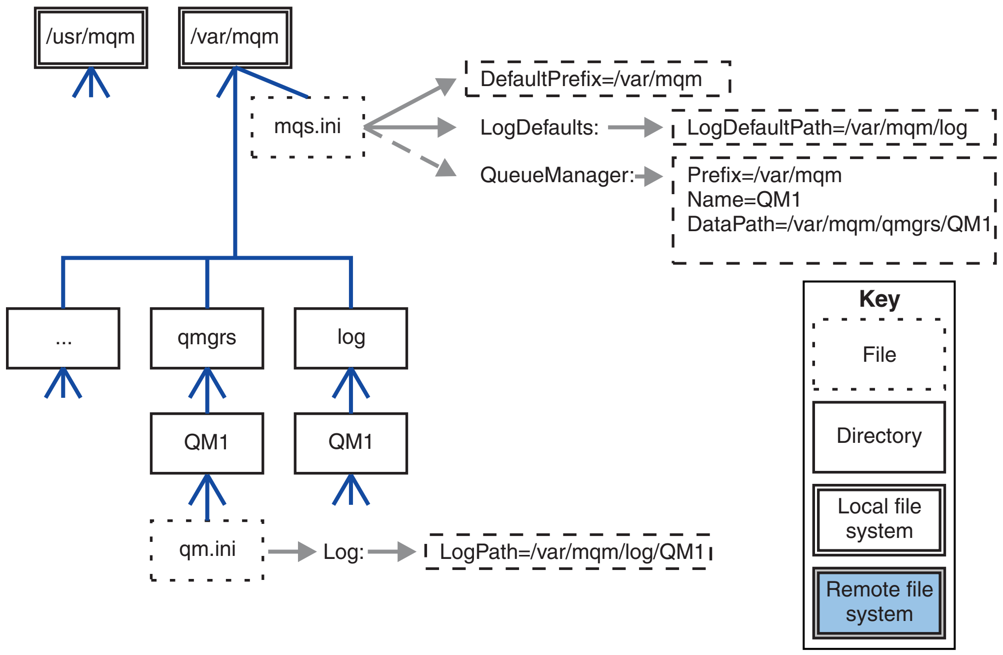

Figure 47. Example default IBM MQ directory structure for UNIX and Linux systems

The product is installed into `/usr/mqm` on AIX and `/opt/mqm` on the other systems, by default. The working directories are installed into the `/var/mqm` directory.

Note: If you created the `/var/mqm` file system prior to installing IBM MQ , ensure that the mqm user has full directory permissions, for example, file mode 755.

Note: The `/var/mqm/errors` directory should be a separate filesystem to prevent FFDCs produced by the queue manager from filling the filesystem that contains `/var/mqm`.

See Creating file systems on UNIX and Linux systems for more information.

The `log` and `qmgrs` directories are shown in their default locations as defined by the default values of the `LogDefaultPath` and `DefaultPrefix` attributes in the `mqs.ini` file. When a queue manager is created, by default the queue manager data directory is created in *`DefaultPrefix`*`/qmgrs`, and the log file directory in *`LogDefaultPath`*`/log`. `LogDefaultPath` and `DefaultPrefix` only effects where queue managers and log files are created by default. The actual location of a queue manager directory is saved in the `mqs.ini` file, and the location of the log file directory is saved in the `qm.ini` file.

The log file directory for a queue manager is defined in the `qm.ini` file in the `LogPath` attribute. Use the `-ld` option on the **`crtmqm`** command to set the `LogPath` attribute for a queue manager; for example, **`crtmqm`** `-ld` *`LogPath`* `QM1`. If you omit the `ld` parameter the value of `LogDefaultPath` is used instead.

The queue manager data directory is defined in the `DataPath` attribute in the `QueueManager` stanza in the `mqs.ini` file. Use the `-md` option on the **`crtmqm`** command to set the `DataPath` for a queue manager; for example, **`crtmqm -`** `md` *`DataPath`* `QM1`. If you omit the `md` parameter the value of the `DefaultPrefix` or `Prefix` attribute is used instead. `Prefix` takes precedence over `DefaultPrefix`.

Typically, create `QM1` specifying both the log and data directories in a single command.

```
 crtmqm
-md DataPath -ld
LogPath QM1
```

You can modify the location of a queue manager log and data directories of an existing queue manager by editing the `DataPath` and `LogPath` attributes in the `qm.ini` file when the queue manager is stopped.

The path to the `errors` directory, like the paths to all the other directories in `/var/mqm`, is not modifiable. However the directories can be mounted on different file systems, or symbolically linked to different directories.

Directory content on UNIX and Linux systems: Linux UNIX

Content of the directories associated with a queue manager.

For information about the location of the product files, see Choosing an installation location

For information about alternative directory configurations, see “Planning file system support on Multiplatforms” on page 104.

In Figure 48 on page 119, the layout is representative of IBM MQ after a queue manager has been in use for some time. The actual structure that you have depends on which operations have occurred on the queue manager.

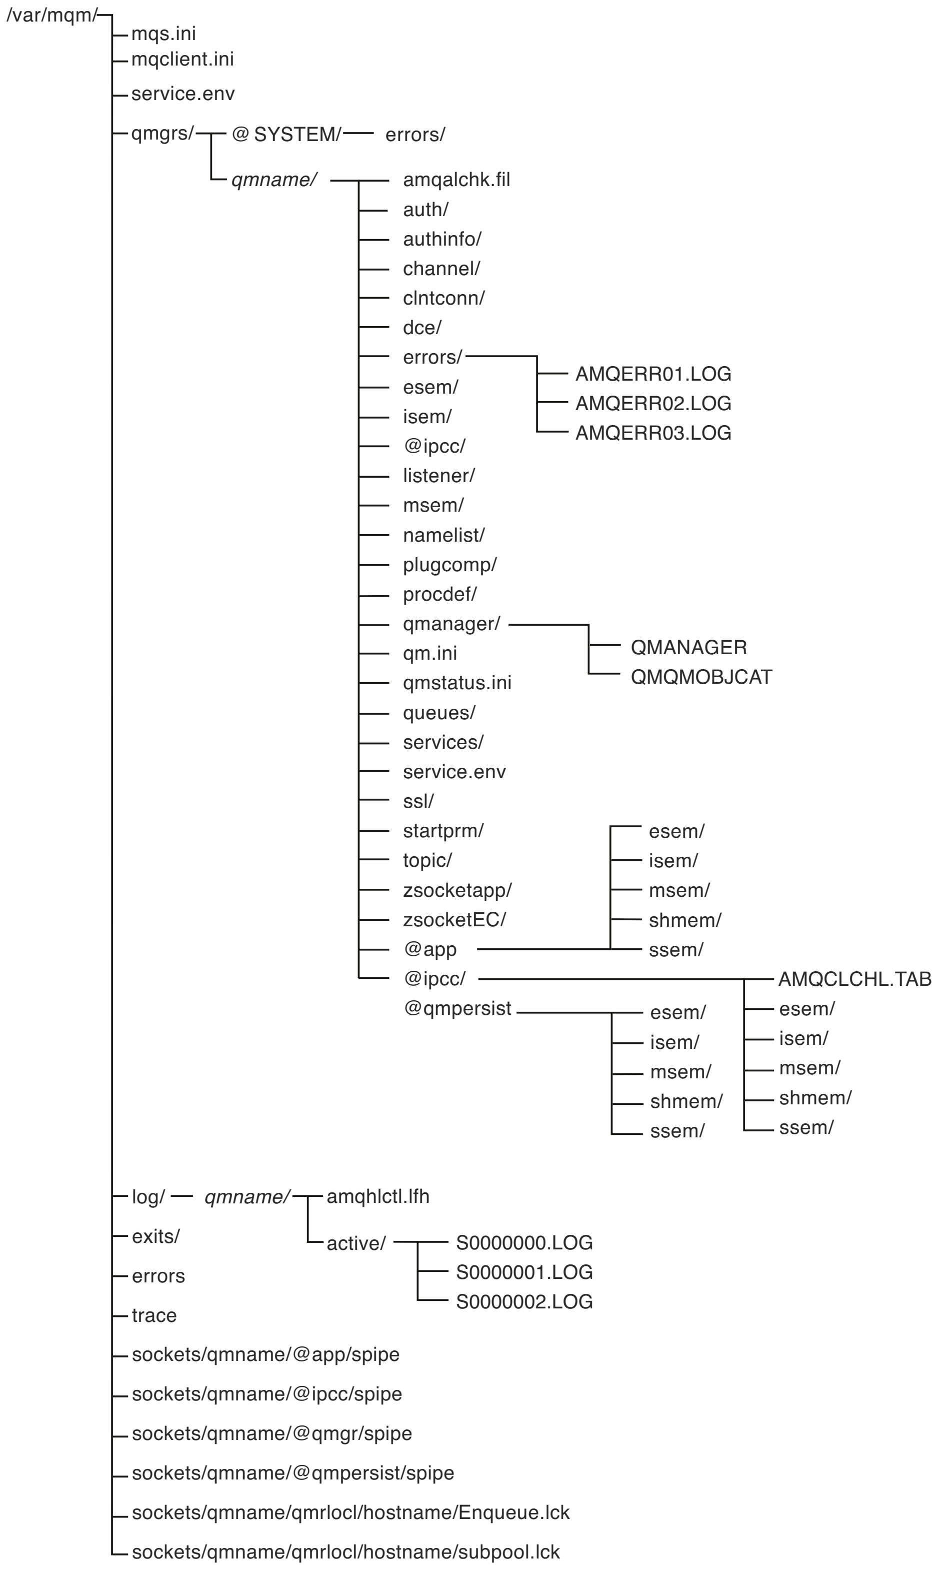

Figure 48. Default directory structure (UNIX) after a queue manager has been started

/var/mqm/

The `/var/mqm` directory contains configuration files and output directories that apply to an IBM MQ installation as a whole, and not to an individual queue manager.

Table 11. Documented content of the `/var/mqm` directory on UNIX

mqs.ini	IBM MQ installation wide configuration file, read when a queue manager starts. File path modifiable using the **AMQ_MQS_INI_LOCATION** environment variable. Ensure this is set and exported in the shell in which the **strmqm** command is run.
mqclient.ini	Default client configuration file read by IBM MQ MQI client programs. File path modifiable using the **MQCLNTCF** environment variable.
service.env	Contains machine scope environment variables for a service process. File path fixed.
errors/	Machine scope error logs, and FFST™ files. Directory path fixed. See also, FFST: IBM MQ for UNIX and Linux systems.
sockets/	Contains information for each queue manager for system use only.
trace/	Trace files. Directory path fixed.
web/	mqweb server directory.
exits/	Default directory containing user channel exit programs. Location modifiable in ApiExit stanzas in the mqs.ini file.
exits64/	

/var/mqm/qmgrs/*qmname***/**

`/var/mqm/qmgrs/`*qmname*`/` contains directories and files for a queue manager. The directory is locked for exclusive access by the active queue manager instance. The directory path is directly modifiable in the `mqs.ini` file, or by using the **md** option of the **crtmqm** command.

Table 12. Documented contents of the `/var/mqm/qmgrs/qmname` directory on UNIX

qm.ini	Queue manager configuration file, read when a queue manager starts.
errors/	Queue manager scope error logs. *qmname* = `@system` contains channel-related messages for an unknown or unavailable queue manager.
@ipcc/ AMQCLCHL.TAB	Default client channel control table, created by the IBM MQ server, and read by IBM MQ MQI client programs. File path modifiable using the **MQCHLLIB** and **MQCHLTAB** environment variables.
qmanager	Queue manager object file: `QMANAGER` Queue manager object catalog: `QMQMOBJCAT`

Table 12. Documented contents of the `/var/mqm/qmgrs/qmname` directory on UNIX (continued)

authinfo/	Each object defined within the queue manager is associated with a file in these directories. The file name approximately matches the definition name; see, Understanding IBM MQ file names.
channel/	
clntconn/	
listener/	
namelist/	
procdef/	
queues/	
services/	
topics/	
...	Other directories used by IBM MQ, such as @ipcc, to be modified only by IBM MQ.

`/var/mqm/log/`*`qmname`*`/`

`/var/mqm/log/`*`qmname`*`/` contains the queue manager log files. The directory is locked for exclusive access by the active queue manager instance. The directory path is modifiable in the `qm.ini` file, or by using the **`ld`** option of the **`crtmqm`** command.

Table 13. Documented contents of the `/var/mqm/log/qmname` directory on UNIX

amqhlctl.lfh	Log control file.
active/	This directory contains the log files numbered S0000000.LOG, S0000001.LOG, S0000002.LOG, and so on.

`opt/mqm`

`opt/mqm` is, by default, the installation directory on most platforms. See "Disk space requirements on Multiplatforms" on page 102 for more information on the amount of space that you need for the installation directory on the platform, or platforms, that your enterprise uses.

Example directory configurations on UNIX and Linux systems: ▶ Linux ▶ UNIX

Examples of alternative file system configurations on UNIX and Linux systems.

You can customize the IBM MQ directory structure in various ways to achieve a number of different objectives.

- Place the `qmgrs` and `log` directories on remote shared file systems to configure a multi-instance queue manager.
- Use separate file systems for the data and log directories, and allocate the directories to different disks, to improve performance by reducing I/O contention.
- Use faster storage devices for directories that have a greater effect on performance. Physical device latency is frequently a more important factor in the performance of persistent messaging than whether a device is mounted locally or remotely. The following list shows which directories are most and least performance sensitive.
  1. `log`
  2. `qmgrs`
  3. Other directories, including `/usr/mqm`
- Create the `qmgrs` and `log` directories on file systems that are allocated to storage with good resilience, such as a redundant disk array, for example.

- It is better to store the common error logs in `var/mqm/errors`, locally, rather than on a network file system, so that error relating to the network file system can be logged.

Figure 49 is a template from which alternative IBM MQ directory structures are derived. In the template, dotted lines represent paths that are configurable. In the examples, the dotted lines are replaced by solid lines that correspond to the configuration information stored in the AMQ_MQS_INI_LOCATION environment variable, and in the `mqs.ini` and `qm.ini` files.

Note: The path information is shown as it appears in the `mqs.ini` or `qm.ini` files. If you supply path parameters in the **`crtmqm`** command, omit the name of the queue manager directory: the queue manager name is added to the path by IBM MQ.

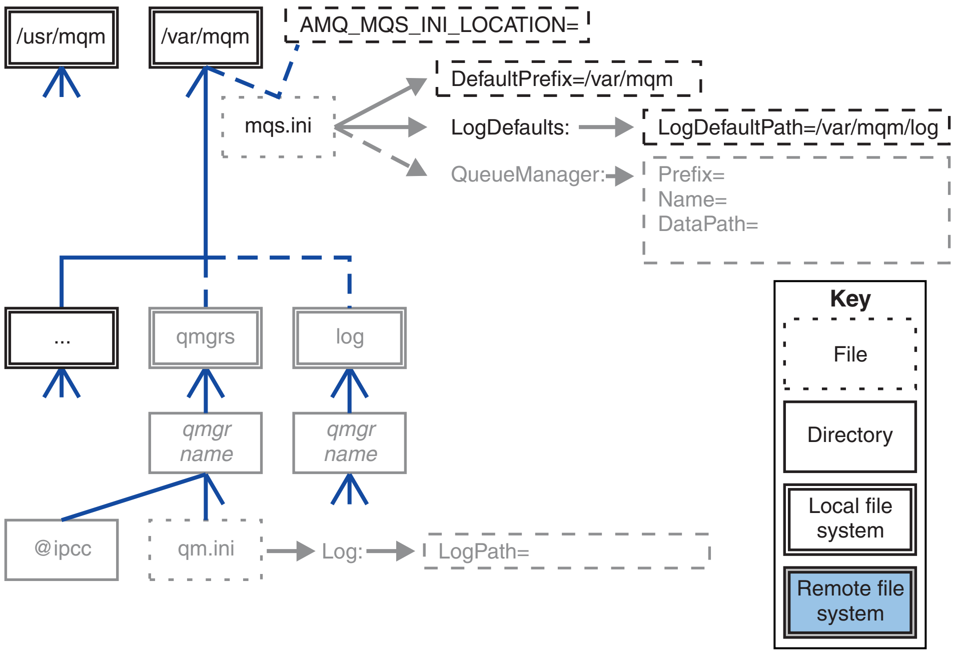

Figure 49. Directory structure pattern template

Examples of configured directory structures follow. The first example shows a typical default directory structure for IBM WebSphere MQ Version 7.0.1 created by issuing the **`crtmqm`** *QM1* command. The second example shows how a typical directory structure appears for a queue manager created using an IBM MQ release earlier than Version 7.0.1. The directory structure does not change.

Queue managers newly created in Version 7.0.1 have a different configuration file from earlier releases of Version 7. If you need to remove the Version 7.0.1 fix pack to revert to Version 7.0.0, Fix Pack 2, you need to re-create the configuration files. You might only need to use the Prefix attribute to define the path to the new queue manager data directory, or you might need to move the queue manager data directory and log directories to a different location. The safest way to reconfigure the queue manager is to save the queue manager data and log directories, delete and re-create the queue manager, and then replace the data and log directories in their new location, with the ones that have been saved.

Typical directory structure for Version 7.0.1 onwards

Figure 50 on page 123 is the default directory structure created in Version 7.0.1 by issuing the command **`crtmqm`** *QM1*.

The mqs.ini file has a stanza for the QM1 queue manager, created by referring to the value of DefaultPrefix. The Log stanza in the qm.ini file has a value for LogPath, set by reference to LogDefaultPath in mqs.ini.

Use the optional **crtmqm** parameters to override the default values of DataPath and LogPath.

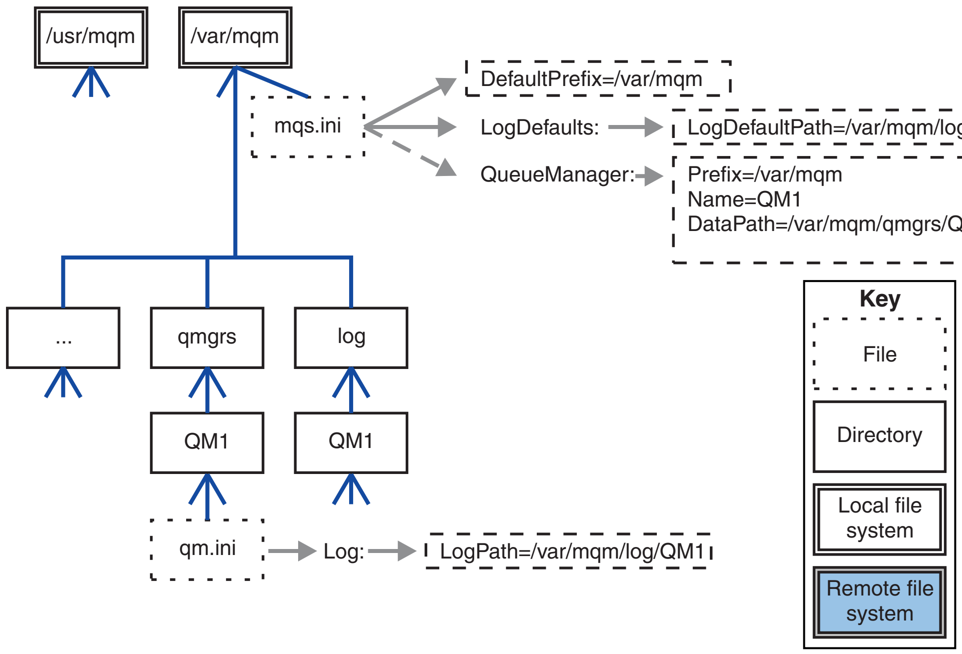

Figure 50. Example default IBM MQ directory structure for UNIX and Linux systems

Typical directory structure for releases earlier than Version 7.0.1

The DataPath attribute did not exist before Version 7.0.1; the attribute is not present in the mqs.ini file. The location of the qmgrs directory was configured using the Prefix attribute. The location of individual directories could be configured by using symbolic links to point to different file system locations.

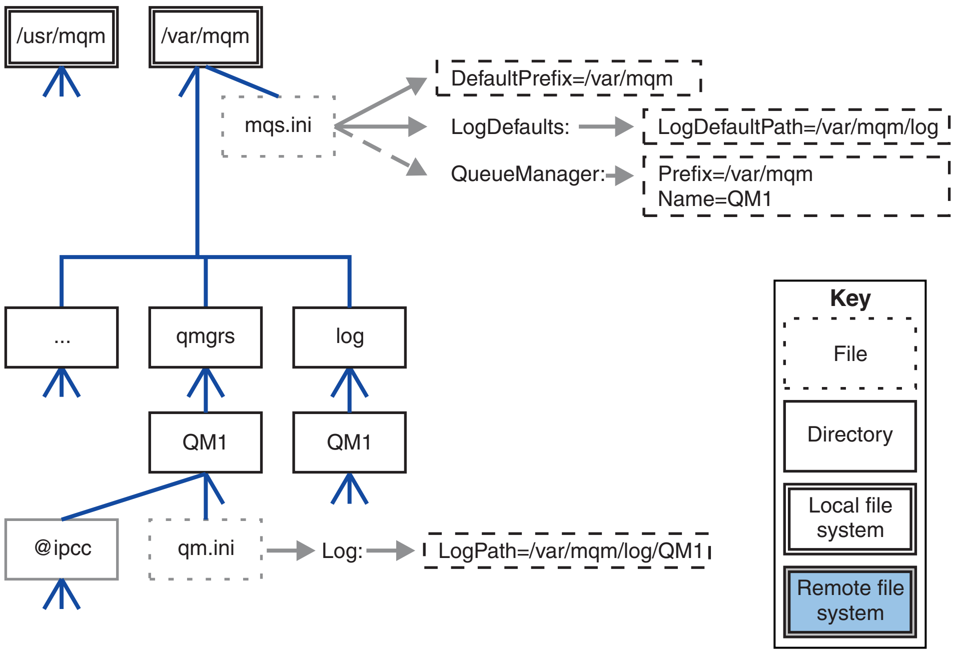

Figure 51. Typical directory structure for releases earlier than Version 7.0.1

Share default `qmgrs` and `log` directories (Version 7.0.1 onwards)

An alternative to "Share everything (Version 7.0.1 onwards)" on page 125, is to share the `qmgrs` and `log` directories separately (Figure 52). In this configuration, there is no need to set `AMQ_MQS_INI_LOCATION` as the default mqs.ini is stored in the local `/var/mqm` file system. The files and directories, such as `mqclient.ini` and `mqserver.ini` are also not shared.

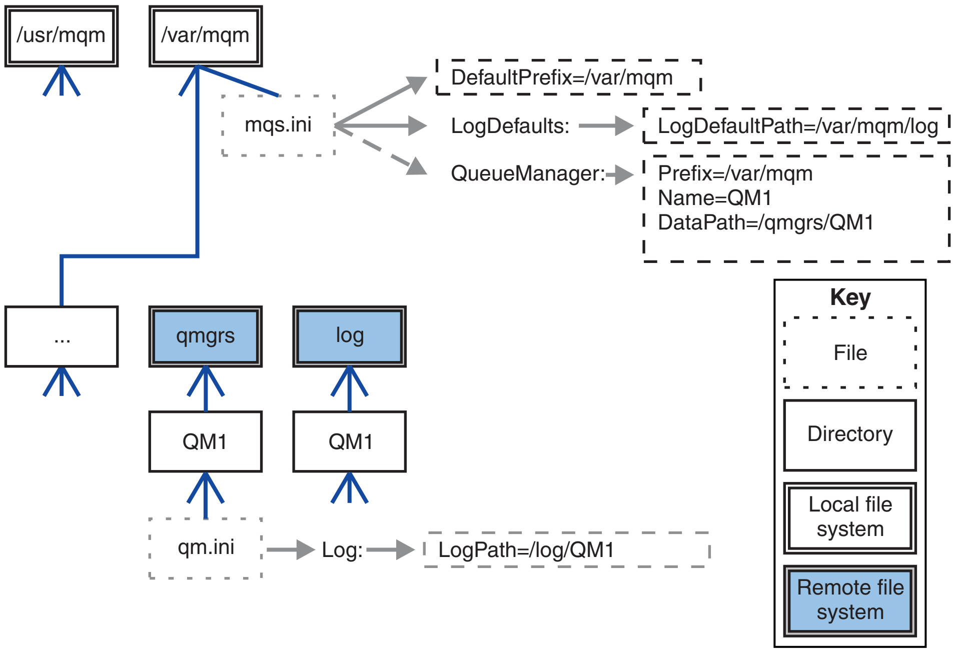

Figure 52. Share `qmgrs` and `log` directories

Share named `qmgrs` and `log` directories (Version 7.0.1 onwards)

The configuration in Figure 53 places the `log` and `qmgrs` in a common named remote shared file system called `/ha`. The same physical configuration can be created in two different ways.

1. Set `LogDefaultPath=/ha` and then run the command, **`crtmqm`** - `md` */ha/qmgrs* `QM1`. The result is exactly as illustrated in Figure 53.
2. Leave the default paths unchanged and then run the command, **`crtmqm`** - `ld` */ha/log* - `md` */ha/qmgrs* `QM1`.

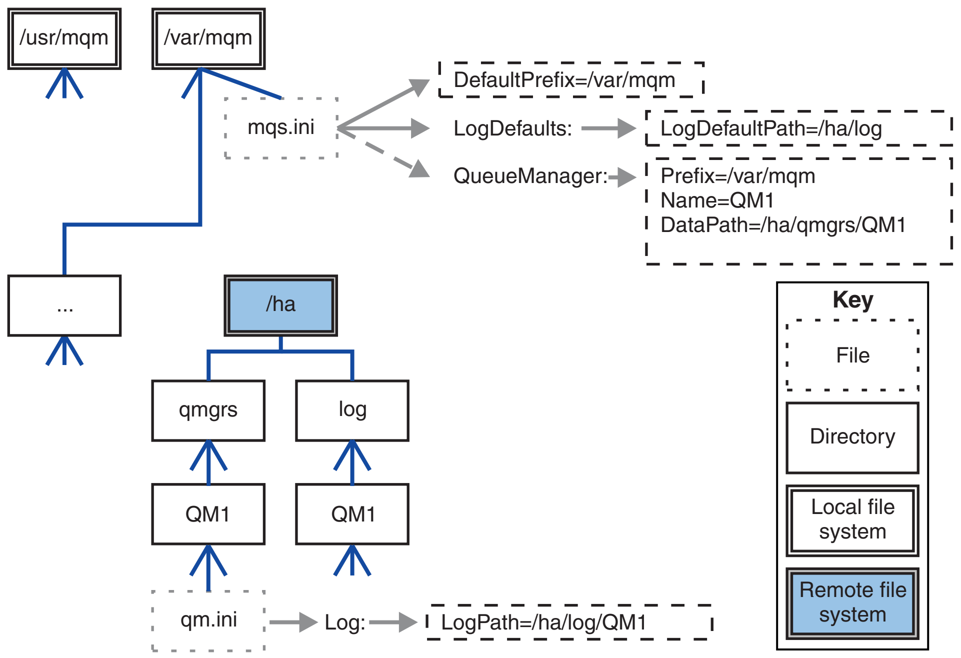

Figure 53. Share named `qmgrs` and `log` directories

Share everything (Version 7.0.1 onwards)

Figure 54 on page 126 is a simple configuration for system with fast networked file storage.

Mount `/var/mqm` as a remote shared file system. By default, when you start QM1, it looks for `/var/mqm`, finds it on the shared file system, and reads the `mqs.ini` file in `/var/mqm`. Rather than use the single `/var/mqm/mqs.ini` file for queue managers on all your servers, you can set the `AMQ_MQS_INI_LOCATION` environment variable on each server to point to different `mqs.ini` files.

Note: The contents of the generic error file in `/var/mqm/errors/` are shared between queue managers on different servers.

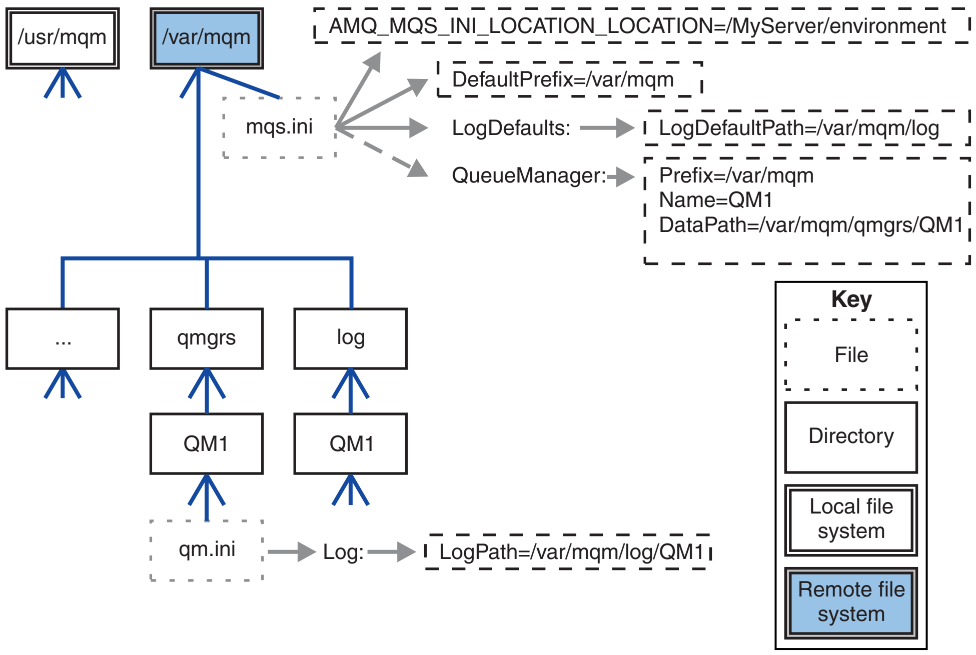

Figure 54. Share everything

Note that you cannot use this for multi-instance queue managers. The reason is that it is necessary for each host in a multi-instance queue manager to have its own local copy of `/var/mqm` to keep track of local data, such as semaphores and shared memory. These entities cannot be shared across hosts.

Directory structure on Windows systems

Windows

How to find queue manager configuration information and directories on Windows.

The default directories for IBM MQ for Windows installation are:

Program directory
`C:\Program Files\IBM\MQ`

Data directory
`C:\ProgramData\IBM\MQ`

Important: Windows For Windows installations, the directories are as stated, unless there is a previous installation of the product that still contains registry entries or queue managers, or both. In this situation, the new installation uses the old data directory location. For more information, see Program and data directory locations.

If you want to know which installation directory and which data directory is being used, run the dspmqver command.

The installation directory is listed in the **`InstPath`** field and the data directory is listed in the **`DataPath`** field.

Running the **`dspmqver`** command displays, for example, the following information:

```
>dspmqver
Name:        IBM MQ
Version:     9.0.0.0
Level:       p900-L160512.4
BuildType:   IKAP - (Production)
Platform:    IBM MQ for Windows (x64 platform)
Mode:        64-bit
O/S:         Windows 7 Professional x64 Edition, Build 7601: SP1
InstName:    Installation1
InstDesc:
Primary:     Yes
InstPath:    C:\Program Files\IBM\MQ
DataPath:    C:\ProgramData\IBM\MQ
MaxCmdLevel: 900
LicenseType: Production
```

Multi-instance queue managers

To configure a multi-instance queue manager, the log and data directories must be placed on networked storage, preferably on a different server to any of the servers that are running instances of the queue manager.

Two parameters are provided on the **crtmqm** command, **-md** and **-ld**, to make it easier specify the location of the queue manager data and log directories. The effect of specifying the **-md** parameter is fourfold:

1. The `mqs.ini` stanza `QueueManager\`*`QmgrName`* contains a new variable, *DataPath*, which points to the queue manager data directory. Unlike the *Prefix* variable, the path includes the name of the queue manager directory.
2. The queue manager configuration information stored in the mqs.ini file is reduced to *Name*, *Prefix*, *Directory* and *DataPath*.

Directory content: Windows

Lists the location and content of IBM MQ directories.

An IBM MQ configuration has three main sets of files and directories:

1. Executable, and other read-only files that are only updated when maintenance is applied. For example:
   - The readme file
   - The IBM MQ Explorer plug-in and help files
   - License files

   These files are described in Table 14 on page 128.
2. Potentially modifiable files and directories that are not specific to a particular queue manager. These files and directories are described in Table 15 on page 128.
3. Files and directories that are specific to each queue manager on a server. These files and directories are described in Table 16 on page 129.

Resource directories and files

The resource directories and files contain all the executable code and resources to run a queue manager. The variable, *FilePath*, in the installation specific IBM MQ configuration registry key, contains the path to the resource directories.

Table 14. Directories and files in the `FilePath` directory

File path	Contents
FilePath\bin	Commands and DLLs
FilePath\bin64	Commands and DLLs (64 bit)
FilePath\conv	Data conversion tables
FilePath\doc	Wizard help files
FilePath\MQExplorer	Explorer and Explorer help Eclipse plug-ins
FilePath\gskit8	Global security kit
FilePath\java	Java resources, including JRE
FilePath\licenses	License information
FilePath\Non_IBM_License	License information
FilePath\properties	Used internally
FilePath\Tivoli	
FilePath\tools	Development resources and samples
FilePath\web	Described in IBM MQ Console and REST API installation component file structure for non-editable files.
FilePath\Uninst	Used internally
FilePath\README.TXT	Readme file

Directories not specific to a queue manager

Some directories contain files, such as trace files and error logs, that are not specific to a specific queue manager. The *DefaultPrefix* variable contains the path to these directories. *DefaultPrefix* is part of the `AllQueueManagers` stanza.

Table 15. Directories and files in `DefaultPrefix` directory

File path	Contents
DefaultPrefix\config	Used internally
DefaultPrefix\conv	V 9.0.0 `ccsid_part2.tbl` and`ccsid.tbl` data conversion control file, described in Data conversion
DefaultPrefix\errors	Non queue manager error logs, `AMQERR` *nn*`.LOG`
DefaultPrefix\exits	Channel exit programs
DefaultPrefix\exits64	Channel exit programs (64 bit)
DefaultPrefix\ipc	Not used
DefaultPrefix\qmgrs	Described in Table 16 on page 129
DefaultPrefix\trace	Trace files
DefaultPrefix\web	Described in IBM MQ Console and REST API installation component file structure for user editable files
DefaultPrefix\amqmjpse.txt	Used internally

Queue manager directories

When you create a queue manager, a new set of directories, specific to the queue manager, is created.

If you create a queue manager with the **-md** *filepath* parameter, the path is stored in the *DataPath* variable in the queue manager stanza of the mqs.ini file. If you create a queue manager without setting the **-md** *filepath* parameter, the queue manager directories are created in the path stored in *DefaultPrefix*, and the path is copied into the *Prefix* variable in the queue manager stanza of the mqs.ini file.

Table 16. Directories and files in `DataPath` and `Prefix\qmgrs\QmgrName` directories

File path	Contents
DataPath\@ipcc	Default location for AMQCLCHL.TAB, the client connection table.
DataPath\authinfo	Used internally.
DataPath\channel	
DataPath\clntconn	
DataPath\errors	Error logs, AMQERR *nn*.LOG
DataPath\listener	Used internally.
DataPath\namelist	
DataPath\plugcomp	
DataPath\procdef	
DataPath\qmanager	
DataPath\queues	
DataPath\services	
DataPath\ssl	
DataPath\startprm	
DataPath\topic	
DataPath\active	
DataPath\active.dat	
DataPath\amqalchk.fil	
DataPath\master	
DataPath\master.dat	
DataPath\qm.ini	Queue manager configuration
DataPath\qmstatus.ini	Queue manager status
Prefix\qmgrs\QmgrName	Used internally
Prefix\qmgrs\@SYSTEM	Not used
Prefix\qmgrs\@SYSTEM\errors	

Directory structure on IBM i

▶ IBM i

A description of the IFS is given, and the IBM MQ IFS directory structure is described for server, client, and Java.

The integrated file system (IFS) is a part of IBM i that supports stream input/output and storage management similar to personal computer, UNIX and Linux operating systems, while providing an integrating structure over all information stored in the server.

On IBM i directory names begin with the character & (ampersand) instead of the character @ (at). For example, @system on IBM i is &system.

IFS root file system for IBM MQ server

When you install IBM MQ Server for IBM i, the following directories are created in the IFS root file system.

ProdData:

Overview

```
QIBM   '-- ProdData
          '-- mqm
           '-- doc
           '-- inc
           '-- lib
           '-- samp
           '-- licenses
          '-- LicenseDoc
           '-- 5724H72_V8R0M0
```

/QIBM/ProdData/mqm
Subdirectories below this contain all the product data, for example, C++ classes, trace format files, and license files. Data in this directory is deleted and replaced each time the product is installed.

/QIBM/ProdData/mqm/doc
A Command Reference for the CL commands is provided in HTML format and installed here.

/QIBM/ProdData/mqm/inc
The header files for compiling your C or C++ programs.

/QIBM/ProdData/mqm/lib
Auxiliary files used by MQ.

/QIBM/ProdData/mqm/samp
Further samples.

/QIBM/ProdData/mqm/licenses
License files. The two files for each language are named like LA_ *xx* and LI_ *xx* where *xx* is the 2 character language identifier for each language supplied.

Also the following directory stores license agreements files:

/QIBM/ProdData/LicenseDoc/5724H72_V8R0M0
License files. The files are named like 5724H72_V8R0M0_ *xx* where *xx* is the 2 or 5 character language identifier for each language supplied.

UserData:

Overview

```
QIBM   '-- UserData
           '-- mqm
            '-- errors
            '-- trace
            '-- qmgrs
            '-- &system
            '-- qmgrname1
            '-- qmgrname2
            '-- and so on
```

/QIBM/UserData/mqm
Subdirectories below this contain all user data relating to queue managers.

When you install the product, an mqs.ini file is created in directory /QIBM/UserData/mqm/ (unless it is already there from a previous installation).

When you create a queue manager, a qm.ini file is created in the directory /QIBM/UserData/mqm/qmgrs/ *QMGRNAME* / (where *QMGRNAME* is the name of the queue manager).

Data in the directories is retained when the product is deleted.

IFS root file system for IBM MQ MQI client

When you install IBM MQ MQI client for IBM i, the following directories created in the IFS root file system:

ProdData:

Overview

```
QIBM   '-- ProdData
           '-- mqm
            '-- lib
```

/QIBM/ProdData/mqm
Subdirectories below this directory contain all the product data. Data in this directory is deleted and replaced each time the product is replaced.

UserData:

Overview

```
QIBM   '-- UserData
           '-- mqm
            '-- errors
            '-- trace
```

/QIBM/UserData/mqm
Subdirectories below this directory contain all user data.

IFS root file system for IBM MQ Java

When you install IBM MQ Java on IBM i, the following directories are created in the IFS root file system:

ProdData:

Overview

```
QIBM   '-- ProdData
            '-- mqm
             '-- java
             '--samples
             '-- bin
             '-- lib
```

/QIBM/ProdData/mqm/java
Subdirectories below this contain all the product data, including Java classes. Data in this directory is deleted and replaced each time the product is replaced.

/QIBM/ProdData/mqm/java/samples
Subdirectories below this contain all the sample Java classes and data.

Libraries created by server and client installations

Installation of the IBM MQ server or client creates the following libraries:

- `QMQM`

  The product library.
- `QMQMSAMP`

  The samples library (if you choose to install the samples).
- `QMxxxx`

  Server only.

  Each time that you create a queue manager, IBM MQ automatically creates an associated library, with a name like `QMxxxx` where `xxxx` is derived from the queue manager name. This library contains objects specific to the queue manager, including journals and associated receivers. By default the name of this library is derived from the name of the queue manager prefixed with the characters QM. For example, for a queue manager called TEST, the library would be called QMTEST.

  Note: When you create a queue manager, you can specify the name of its library if you want to. For example:

  ```
  CRTMQM MQMNAME(TEST) MQMLIB(TESTLIB)
  ```

  You can use the WRKLIB command to list all the libraries that IBM MQ for IBM i has created. Against the queue manager libraries, you will see the text `QMGR: QMGRNAME`. The format of the command is:

  ```
  WRKLIB LIB(QM*)
  ```

  These queue manager-associated libraries are retained when the product is deleted.

Choosing circular or linear logging on Multiplatforms

Multi V 9.0.1

In IBM MQ, you can choose circular or linear logging. The following information gives you an overview of both types.

Advantages of circular logging

The main advantages of circular logging are that circular logging is:

- Easier to administer.

  Once you have configured circular logging correctly for your workload, no further administration is needed. Whereas, for linear logging, media images need to be recorded and log extents that are not required any more need to be archived or deleted.
- Better performing

  Circular logging performs better than linear logging, because circular logging is able to reuse log extents that have already been formatted. Whereas linear logging has to allocate new log extents and format them.

See Managing logs for further information.

Advantages of linear logging

The principal advantage of linear logging is that linear logging provides protection against more failures.

Neither circular nor linear logging protect against a corrupted or deleted log, or messages or queues that have been deleted by applications or the administrator.

Linear logging (but not circular) enables damaged objects to be recovered. So, linear logging provides protection against queue files being corrupted or deleted, as these damaged queues can be recovered from a linear log.

Both circular and linear protect against power loss and communications failure as described in Recovering from power loss or communication failures.

Other considerations

Whether you choose linear or circular depends on how much redundancy you require.

There is a cost to choosing more redundancy, that is linear logging, caused by the performance cost and the administration cost.

See Types of logging for more information.

Shared memory on AIX

AIX

If certain application types fail to connect because of an AIX memory limitation, in most cases this can be resolved by setting the environment variable EXTSHM=ON.

Some 32-bit processes on AIX might encounter an operating system limitation that affects their ability to connect to IBM MQ queue managers. Every standard connection to IBM MQ uses shared memory, but unlike other UNIX and Linux platforms, AIX allows 32-bit processes to attach only 11 shared memory sets.

Most 32-bit processes will not encounter this limit, but applications with high memory requirements might fail to connect to IBM MQ with reason code 2102: MQRC_RESOURCE_PROBLEM. The following application types might see this error:

- Programs running in 32-bit Java virtual machines
- Programs using the large or very large memory models
- Programs connecting to many queue managers or databases
- Programs that attach to shared memory sets on their own

AIX offers an extended shared memory feature for 32-bit processes that allows them to attach more shared memory. To run an application with this feature, export the environment variable EXTSHM=ON before starting your queue managers and your program. The EXTSHM=ON feature prevents this error in most cases, but it is incompatible with programs that use the SHM_SIZE option of the shmctl function.

IBM MQ MQI client applications and all 64-bit processes are unaffected by this limitation. They can connect to IBM MQ queue managers regardless of whether EXTSHM has been set.

IBM MQ and UNIX System V IPC resources

Linux UNIX

A queue manager uses some IPC resources. Use **`ipcs -a`** to find out what resources are being used.

This information applies to IBM MQ running on UNIX and Linux systems only.

IBM MQ uses System V interprocess communication (IPC) resources (*semaphores* and *shared memory segments*) to store and pass data between system components. These resources are used by queue manager processes and applications that connect to the queue manager. IBM MQ MQI clients do not use IPC resources, except for IBM MQ trace control. Use the UNIX command **`ipcs -a`** to get full information on the number and size of the IPC resources currently in use on the machine.

IBM MQ and UNIX Process Priority

Linux UNIX

Good practices when setting process priority *nice* values.

This information applies to IBM MQ running on UNIX and Linux systems only.

If you run a process in the background, that process can be given a higher *nice* value (and hence lower priority) by the invoking shell. This might have general IBM MQ performance implications. In highly-stressed situations, if there are many ready-to-run threads at a higher priority and some at a lower priority, operating system scheduling characteristics can deprive the lower priority threads of processor time.

It is good practice that independently started processes associated with queue managers, such as **runmqlsr**, have the same *nice* values as the queue manager they are associated with. Ensure the shell does not assign a higher *nice* value to these background processes. For example, in ksh, use the setting "`set +o bgnice`" to stop ksh from raising the *nice* value of background processes. You can verify the *nice* values of running processes by examining the *NI* column of a "ps -efl" listing.

Also, start IBM MQ application processes with the same *nice* value as the queue manager. If they run with different *nice* values, an application thread might block a queue manager thread, or vice versa, causing performance to degrade.

Planning your IBM MQ client environment on HP Integrity NonStop Server

NSS Client

When planning the environment in which the IBM MQ client for HP Integrity NonStop Server runs, you must consider the HP Integrity NonStop Server environment, and HP NonStop TMF.

First, familiarize yourself with the basic IBM MQ client for HP Integrity NonStop Server concepts. See the topics in IBM MQ client for HP Integrity NonStop Server technical overview.

Preparing the HP Integrity NonStop Server environment

NSS Client

Before installation, the environment must be prepared depending on whether the installation is to be verified immediately or not.

For the installation, you require the following items:
- A user ID that meets the requirements. For details about user ID requirements, see Setting up the user and group on HP Integrity NonStop Server .
- Verified locations in the OSS and Guardian file systems that can be for the installation files.
- An operational OSS shell and OSS file system. You can verify the file system by doing the following tasks:
  - Log on to the OSS environment (shell). Ensure that you have write access to the OSS installation root directory you intend to use.
  - Log on to the TACL environment using the user ID in the MQM group. Verify that the volume you intend to use meets the requirements and is accessible to you, and that the subvolume does not exist.

  You can login to both OSS or TACL using either an alias, if you have one, or your full principal.

If you intend to proceed immediately to verify that the installation is usable, you might also need the following optional items:

- An operational and accessible Local Sockets subsystem in the OSS environment.
- An operational TCP/IP subsystem.

If you intend to use TMF coordinated global units of work, you will need the following items:

- An operational TMF subsystem.
- An operational Pathway (TS/MP) subsystem.

Work with your systems administrator if you are in any doubt about the status of these critical subsystems.

IBM MQ and HP NonStop TMF

NSS Client

IBM MQ client for HP Integrity NonStop Server can participate in HP NonStop Transaction Management Facility (HP NonStop TMF) coordinated units of work. Coordinating transactions with HP NonStop TMF is only supported where the queue manager is at IBM WebSphere MQ Version 7.1 or later.

The IBM MQ provided TMF/Gateway converts transactions from TMF coordination into eXtended Architecture (XA) transaction coordination to communicate with the remote queue manager. The IBM MQ provided TMF/Gateway is the bridge between TMF and queue manager transactions, using the services provided by HP NonStop TMF, and has been designed to run in a Pathway environment.

HP NonStop TMF software provides transaction protection and database consistency in demanding environments. For more information about HP NonStop TMF, see HP NonStop TMF Introduction.

For information about how to configure the IBM MQ provided TMF/Gateway, see Configuring IBM MQ client for HP Integrity NonStop Server.

Using HP NonStop TMF

NSS Client

The HP NonStop Transaction Management Facility (TMF) is the native transaction manager on HP Integrity NonStop Server and is integrated with the file system and the relational database managers, SQL/MP, and SQL/MX.

IBM MQ client for HP Integrity NonStop Server can use TMF to coordinate global units of work.

To coordinate global units of work, TMF acts as the transaction manager, and an application must use the API provided by TMF to start, commit, and back out global units of work. An application starts a global unit of work by calling BEGINTRANSACTION, and then updates IBM MQ resources within the global unit of work by issuing MQPUT, MQPUT1, and MQGET calls within syncpoint control. The application can then commit the global unit of work by calling ENDTRANSACTION, or back it out by calling ABORTTRANSACTION.

An application that is using TMF transactions can only actively work on one transaction at any one time, however using RESUMETRANSACTION allows an application to switch from one active transaction to another, or to being associated with no TMF transaction, without completing or aborting the previously active transaction. Any calls to MQPUT, MQPUT1, or MQGET are made under the currently active TMF transaction, if present, or a local unit of work, if not present. Therefore, care must be taken within the application to ensure that these calls are being made within the correct unit of work.

Within a global unit of work, as well as updating IBM MQ resources, an application can update Enscribe files, SQL/MP databases, or SQL/MX databases.

Using global units of work

NSS Client

A global unit of work is implemented as a TMF transaction. An application starts a global unit of work by calling BEGINTRANSACTION, and either commits the unit of work by calling ENDTRANSACTION or backs out the unit of work by calling ABORTTRANSACTION. An application can use other TMF API calls as well.

An application can inherit a TMF transaction from another application. For example, an application (the first application) can perform work within the transaction before replying and passing the transaction back to a second application for further processing. Both the first and the second applications can therefore participate in the same global unit of work that involves updates to IBM MQ queues and updates to files and databases. The ability to pass a TMF transaction between applications means that several IBM MQ applications can perform messaging operations within the same global unit of work.

An application can manage and control multiple active TMF transactions at the same time. The transactions can be started by the application itself, or inherited from other applications, or both. This means that an application can participate in multiple global units of work at the same time.

The maximum number of concurrent active TMF transactions per process is 1000, which is an architectural limit. If an application is managing multiple TMF transactions, only one transaction can be current at any point in time. Alternatively, none of the transactions can be current. The application can use TMF API calls such as RESUMETRANSACTION, ACTIVATERECEIVETRANSID, and TMF_SET_TX_ID to move the state of being current from one transaction to another, or to designate that no transaction is current. The application uses this level of control to determine whether a messaging operation is performed within a local unit of work, a global unit of work, or outside of syncpoint control:

- If an application calls MQPUT, MQPUT1, or MQGET within syncpoint control when no TMF transaction is current, IBM MQ processes the call within a local unit of work.
- If an application calls MQPUT, MQPUT1, or MQGET within syncpoint control when the application has a current TMF transaction, IBM MQ processes the call within the global unit of work that is implemented by the current TMF transaction.
- If an application calls MQPUT, MQPUT1, or MQGET outside of syncpoint control, IBM MQ processes the call outside of syncpoint control, irrespective of whether the application has a current TMF transaction at the time of the call.

IBM MQ never changes the state of an application's TMF transaction during an MQI call, except when a software or hardware failure occurs during processing and IBM MQ or the operating system determines that the transaction must be backed out to preserve data integrity. Every MQI call restores the transaction state of the application just before returning control to the application.

Avoiding long running transactions

NSS Client

Avoid designing applications in which TMF transactions remain active for more than a few tens of seconds. Long running transactions can cause the circular audit trail of TMF to fill up. Because TMF is a critical system-wide resource, TMF protects itself by backing out application transactions that are active for too long.

Suppose that the processing within an application is driven by getting messages from a queue, and that the application gets a message from the queue and processes the message within a unit of work. Typically, an application calls MQGET with the wait option and within syncpoint control to get a message from the queue.

If the application is using a global unit of work instead, the specified wait interval on the MQGET call must be short to avoid a long running transaction. This means that the application might need to issue the MQGET call more than once before it retrieves a message.

Planning your IBM MQ environment on z/OS

z/OS

When planning your IBM MQ environment, you must consider the resource requirements for data sets, page sets, Db2, Coupling Facilities, and the need for logging, and backup facilities. Use this topic to plan the environment where IBM MQ runs.

Before you plan your IBM MQ architecture, familiarize yourself with the basic IBM MQ for z/OS concepts, see the topics in IBM MQ for z/OS concepts.

Related concepts:

"Planning an IBM MQ architecture" on page 1
When planning your IBM MQ environment, consider the support that IBM MQ provides for single and multiple queue manager architectures, and for point-to-point and publish/subscribe messaging styles. Also plan your resource requirements, and your use of logging and backup facilities.

IBM MQ Technical overview

Configuring z/OS

Administering IBM MQ for z/OS

Planning your storage and performance requirements on z/OS

z/OS

You must set realistic and achievable storage, and performance goals for your IBM MQ system. Use this topic help you understand the factors which affect storage, and performance.

This topic contains information about the storage and performance requirements for IBM MQ for z/OS. It contains the following sections:

- z/OS performance options for IBM MQ
- Determining z/OS workload management importance and velocity goals
- "Library storage" on page 140
- "System LX usage" on page 140
- "Address space storage" on page 140
- "Data storage" on page 144

See, “Where to find more information about storage and performance requirements” on page 145 for more information.

z/OS performance options for IBM MQ

With workload management, you define performance goals and assign a business importance to each goal. You define the goals for work in business terms, and the system decides how much resource, such as processor and storage, should be given to the work to meet its goal. Workload management controls the dispatching priority based on the goals you supply. Workload management raises or lowers the priority as needed to meet the specified goal. Thus, you need not fine-tune the exact priorities of every piece of work in the system and can focus instead on business objectives.

The three kinds of goals are:

Response time
How quickly you want the work to be processed

Execution velocity
How fast the work should be run when ready, without being delayed for processor, storage, I/O access, and queue delay

Discretionary
A category for low priority work for which there are no performance goals

Response time goals are appropriate for end-user applications. For example, CICS® users might set workload goals as response time goals. For IBM MQ address spaces, velocity goals are more appropriate. A small amount of the work done in the queue manager is counted toward this velocity goal but this work is critical for performance. Most of the work done by the queue manager counts toward the performance goal of the end-user application. Most of the work done by the channel initiator address space counts toward its own velocity goal. The receiving and sending of IBM MQ messages, which the channel initiator accomplishes, is typically important for the performance of business applications using them.

Determining z/OS workload management importance and velocity goals

For full information about workload management and defining goals through the service definition, see *z/OS MVS Planning: Workload Management*.

This section suggests how to set the z/OS workload management importance and velocity goals relative to other important work in your system.

Use the following service classes:

The default SYSSTC service class
- VTAM and TCP/IP address spaces
- IRLM address space (IRLMPROC)

Note: The VTAM, TCP/IP, and IRLM address spaces must have a higher dispatching priority than all the DBMS address spaces, their attached address spaces, and their subordinate address spaces. Do not allow workload management to reduce the priority of VTAM, TCP/IP, or IRLM to (or below) that of the other DBMS address spaces

A high velocity goal and importance of 1 for a service class with a name that you define, such as PRODREGN, for the following:
- IBM MQ queue manager and channel initiator address spaces
- Db2 (all address spaces, except for the Db2-established stored procedures address space)
- CICS (all region types)

- IMS™ (all region types except BMPs)

  A high velocity goal is good for ensuring that startups and restarts are performed as quickly as possible for all these address spaces.

The velocity goals for CICS and IMS regions are only important during startup or restart. After transactions begin running, workload management ignores the CICS or IMS velocity goals and assigns priorities based on the response time goals of the transactions that are running in the regions. These transaction goals should reflect the relative priority of the business applications they implement. They might typically have an importance value of 2. Any batch applications using MQ should similarly have velocity goals and importance reflecting the relative priority of the business applications they implement. Typically the importance and velocity goals will be less than those for PRODREGN.

Library storage

You must allocate storage for the product libraries. The exact figures depend on your configuration, but an estimate of the space required by the distribution libraries is 80 MB. The target libraries require about 72 MB. Additionally, you require space for the SMP/E libraries.

The target libraries used by IBM MQ for z/OS use PDS or PDSE formats. Ensure that any PDSE target libraries are not shared outside a sysplex. For more information about the required libraries and their sizes and the required format, see the *Program Directory for IBM MQ for z/OS*, which can be downloaded from the from the IBM Publications Center (see IBM MQ Version 9.0 PDF documentation).

System LX usage

Each defined IBM MQ subsystem reserves one system linkage index (LX) at IPL time, and a number of non-system linkage indexes when the queue manager is started. The system linkage index is reused when the queue manager is stopped and restarted. Similarly, distributed queuing reserves one non-system linkage index. In the unlikely event of your z/OS system having inadequate system LXs defined, you might need to take these reserved system LXs into account.

Address space storage

z/OS

Use this topic for basic guidance on address space requirements for the IBM MQ components.

Storage requirements can be divided into the following categories:
- Common storage
- Queue manager private region storage usage
- Channel initiator storage usage

For more details see, Suggested regions sizes.

With 31-bit address space, a virtual line marks the 16-megabyte address, and 31-bit addressable storage is often known as “above the (16MB) line”. With 64-bit address space there is a second virtual line called the bar that marks the 2-gigabyte address. The bar separates storage below the 2-gigabyte address, called “below the bar”, from storage above the 2-gigabyte address, called “above the bar”. Storage below the bar uses 31-bit addressability, storage above the bar uses 64-bit addressability.

You can specify the limit of 31-bit storage by using the REGION parameter on the JCL, and the limit of above the bar storage by using the MEMLIMIT parameter. These specified values can be overridden by MVS exits.

Common storage

Each IBM MQ for z/OS subsystem has the following approximate storage requirements:

- CSA 4 KB
- ECSA 800 KB, plus the size of the trace table that is specified in the TRACTBL parameter of the CSQ6SYSP system parameter macro. For more information, see Using CSQ6SYSP.

In addition, each concurrent IBM MQ logical connection requires about 5 KB of ECSA. When a task ends, other IBM MQ tasks can reuse this storage. IBM MQ does not release the storage until the queue manager is shut down, so you can calculate the maximum amount of ECSA required by multiplying the maximum number of concurrent logical connections by 5 KB. Concurrent logical connections are the number of:

- Tasks (TCBs) in Batch, TSO, z/OS UNIX and Linux System Services, IMS, and Db2 SPAS regions that are connected to IBM MQ, but not disconnected.
- CICS transactions that have issued an IBM MQ request, but have not terminated
- JMS Connections, Sessions, TopicSessions or QueueSessions that have been created (for bindings connection), but not yet destroyed or garbage collected.
- Active IBM MQ channels.

You can set a limit to the common storage, used by logical connections to the queue manager, with the ACELIM configuration parameter. The ACELIM control is primarily of interest to sites where Db2 stored procedures cause operations on IBM MQ queues.

When driven from a stored procedure, each IBM MQ operation can result in a new logical connection to the queue manage. Large Db2 units of work, for example due to table load, can result in an excessive demand for common storage.

ACELIM is intended to limit common storage use and to protect the z/OS system. Using ACELIM causes IBM MQ failures when the limit is exceeded. See the ACELIM section in Using CSQ6SYSP for more information.

Use SupportPac MP1B to format the SMF 115 subtype 3 records produced by STATISTICS CLASS(2) trace.

The amount of storage currently in the subpool controlled by the ACELIM value is indicated in the output, on the line titled *ACE/PEB*. SupportPac MP1B indicates the number of bytes in use.

Increase the normal value by a sufficient margin to provide space for growth and workload spikes. Divide the new value by 1024 to yield a maximum storage size in KB for use in the ACELIM configuration.

The channel initiator typically requires ECSA usage of up to 160 KB.

Queue manager private region storage usage

IBM MQ for z/OS can use storage above the 2 GB bar for some internal control blocks. You can have buffer pools in this storage, which gives you the potential to configure much larger buffer pools if sufficient storage is available. Typically buffer pools are the major internal control blocks that use storage above the 2 GB bar.

Each buffer pool size is determined at queue manager initialization time, and storage is allocated for the buffer pool when a page set that is using that buffer pool is connected. A new parameter LOCATION (ABOVE|BELOW) is used to specify where the buffers are allocated. You can use the ALTER BUFFPOOL command to dynamically change the size of buffer pools.

To use above the bar (64 Bit) storage, you can specify a value for MEMLIMIT parameter (for example MEMLIMIT=3G) on the **`EXEC PGM=CSQYASCP`** parameter in the queue manager JCL. Your installation might have a default value set.

You should specify a MEMLIMIT and specify a sensible storage size rather than MEMLIMIT=NOLIMIT to prevent potential problems. If you specify NOLIMIT or a very large value, then an ALTER BUFFPOOL command with a large size, can use up all of the available z/OS virtual storage, which will lead to paging in your system.

Start with a MEMLIMIT=3G and increase this size when you need to increase the size of your buffer pools.

Specify MEMLIMIT= 2 GB plus the size of the buffer pools above the bar, rounded up to the nearest GB. For example, for 2 buffer pools configured with LOCATION ABOVE, buffer pool 1 has 10,000 buffers, buffer pool 2 has 50,000 buffers. Memory usage above the bar equals 60,000 (total number of buffers) * 4096 = 245,760,000 bytes = 199.3 MB, rounded up to 200MB as a multiple of 4MB. All buffer pools regardless of LOCATION will make use of 64 bit storage for control structures. As the number of buffer pools and number of buffers in those pools increase this can become significant. A good rule of thumb is that each buffer requires an additional 200 bytes of 64 bit storage. For a configuration with 10 buffer pools each with 20,000 buffers that would require: 200 * 10 * 20,000 = 40,000,000 equivalent to 40 MB. You can specify 3 GB for the MEMLIMIT size, which will allow scope for growth (40MB + 200MB + 2 GB which rounds up to 3 GB).

For some configurations there can be significant performance benefits to using buffer pools that have their buffers permanently backed by real storage. You can achieve this by specifying the FIXED4KB value for the PAGECLAS attribute of the buffer pool. However, you should only do this if there is sufficient real storage available on the LPAR, otherwise other address spaces might be affected. For information about when you should use the FIXED4KB value for PAGECLAS, see IBM MQ Support Pac MP16: IBM MQ for z/OS - Capacity planning & tuning

To minimize paging, consider real storage in addition to the virtual storage that is used by the queue manager and the channel initiator.

Before you use storage above the bar, you should discuss with your MVS systems programmer to ensure that there is sufficient auxiliary storage for peak time usage, and sufficient real storage requirements to prevent paging.

Note:
The size of memory dump data sets might have to be increased to handle the increased virtual storage.

Making the buffer pools so large that there is MVS paging might adversely affect performance. You might consider using a smaller buffer pool that does not page, with IBM MQ moving the message to and from the page set.

You can monitor the address space storage usage from the CSQY220I message that indicates the amount of private region storage in use above and below the 2 GB bar, and the remaining amount.

Channel initiator storage usage

There are two areas of channel initiator storage usage that you must consider:
- Private region
- Accounting and statistics

Private region storage usage

You should specify REGION=0M for the CHINIT to allow it to use the maximum below the bar storage. The storage available to the channel initiator limits the number of concurrent connections the CHINIT can have.

Every channel uses approximately 170 KB of extended private region in the channel initiator address space. Storage is increased by message size if messages larger than 32 KB are transmitted. This increased storage is freed when:

- A sending or client channel requires less than half the current buffer size for 10 consecutive messages.
- A heartbeat is sent or received.

The storage is freed for reuse within the Language Environment, however, is not seen as free by the z/OS virtual storage manager. This means that the upper limit for the number of channels is dependent on message size and arrival patterns, and on limitations of individual user systems on extended private region size. The upper limit on the number of channels is likely to be approximately 9000 on many systems because the extended region size is unlikely to exceed 1.6 GB. The use of message sizes larger than 32 KB reduces the maximum number of channels in the system. For example, if messages that are 100 MB long are transmitted, and an extended region size of 1.6 GB is assumed, the maximum number of channels is 15.

The channel initiator trace is written to a dataspace. The size of the database storage, is controlled by the **`TRAXTBL`** parameter. See ALTER QMGR.

Accounting and statistics storage usage

You should allow the channel initiator access to a minimum of 256 MB of virtual storage, and you can do this by specifying `MEMLIMIT=256M`.

If you do not set the MEMLIMIT parameter in the channel initiator JCL, you can set the amount of virtual storage above the bar using the MEMLIMIT parameter in the `SMFPRMxx` member of SYS1.PARMLIB, or from the IEFUSI exit.

If you set the MEMLIMIT to restrict the above bar storage below the required level, the channel initiator issues the CSQX124E message and class 4 accounting and statistics trace will not be available.

Suggested region sizes

The following table shows suggested values for region sizes.

Table 17. Suggested definitions for JCL region sizes

Definition setting	System
Queue manager	REGION=0M, MEMLIMIT=3G
Channel initiator	REGION=0M

Managing the MEMLIMIT and REGION size

Other mechanisms, for example the **`MEMLIMIT`** parameter in the SMFPRMxx member of SYS1.PARMLIB or the IEFUSI exit might be used at your installation to provide a default amount of virtual storage above the bar for z/OS address spaces. See the z/OSMVS Programming: Extended Addressability Guide for full details about limiting storage above the bar.

Data storage

z/OS

Use this topic when planning your data storage requirements for log data sets, Db2 storage, coupling facility storage, and page data sets.

Work with your storage administrator to determine where to put the queue manager data sets. For example, your storage administrator may give you specific DASD volumes, or SMS storage classes, data classes, and management classes for the different data set types.

- Log data sets must be on DASD. These logs can have high I/O activity with a small response time and do not need to be backed up.
- Archive logs can be on DASD or tape. After they have been created, they might never be read again except in an abnormal situation, such as recovering a page set from a backup. They should have a long retention date.
- Page sets might have low to medium activity and should be backed up regularly. On a high use system, they should be backed up twice a day.
- BSDS data sets should be backed up daily; they do not have high I/O activity.

All data sets are similar to those used by Db2, and similar maintenance procedures can be used for IBM MQ.

See the following sections for details of how to plan your data storage:

- **Logs and archive storage**

  "How long do I need to keep archive logs" on page 169 describes how to determine how much storage your active log and archive data sets require, depending on the volume of messages that your IBM MQ system handles and how often the active logs are offloaded to your archive data sets.
- **Db2 storage**

  "Db2 storage" on page 162 describes how to determine how much storage Db2 requires for the IBM MQ data.
- **coupling facility storage**

  "Defining coupling facility resources" on page 153 describes how to determine how large to make your coupling facility structures.
- **Page set and message storage**

  "Planning your page sets and buffer pools" on page 145 describes how to determine how much storage your page data sets require, depending on the sizes of the messages that your applications exchange, on the numbers of these messages, and on the rate at which they are created or exchanged.

Planning your page sets and buffer pools

z/OS

Information to help you with planning the initial number, and sizes of your page data sets, and buffer pools.

This topic contains the following sections:
- "Plan your page sets"
  - Page set usage
  - Number of page sets
  - Size of page sets
- "Calculate the size of your page sets" on page 146
  - Page set zero
  - Page set 01 - 99
  - Calculating the storage requirement for messages
- "Enabling dynamic page set expansion" on page 149
- "Defining your buffer pools" on page 150

Plan your page sets

Page set usage

For short-lived messages, few pages are normally used on the page set and there is little or no I/O to the data sets except at startup, during a checkpoint, or at shutdown.

For long-lived messages, those pages containing messages are normally written out to disk. This operation is performed by the queue manager in order to reduce restart time.

Separate short-lived messages from long-lived messages by placing them on different page sets and in different buffer pools.

Number of page sets

Using several large page sets can make the role of the IBM MQ administrator easier because it means that you need fewer page sets, making the mapping of queues to page sets simpler.

Using multiple, smaller page sets has a number of advantages. For example, they take less time to back up, and I/O can be carried out in parallel during backup and restart. However, consider that this adds a significant performance cost to the role of the IBM MQ administrator, who is required to map each queue to one of a much greater number of page sets.

Define at least five page sets, as follows:
- A page set reserved for object definitions (page set zero)
- A page set for system-related messages
- A page set for performance-critical long-lived messages
- A page set for performance-critical short-lived messages
- A page set for all other messages

"Defining your buffer pools" on page 150 explains the performance advantages of distributing your messages on page sets in this way.

Size of page sets

Define sufficient space in your page sets for the expected peak message capacity. Consider for any unexpected peak capacity, such as when a build-up of messages develops because a queue server program is not running. You can be do this by allocating the page set with secondary extents or, alternatively, by enabling dynamic page set expansion. For more information, see "Enabling dynamic page set expansion" on page 149.

When planning page set sizes, consider all messages that might be generated, including non-application message data. For example, trigger messages, event messages and any report messages that your application has requested.

The size of the page set determines the time taken to recover a page set when restoring from a backup, because a large page set takes longer to restore.

Note: Recovery of a page set also depends on the time the queue manager takes to process the log records written since the backup was taken; this time period is determined by the backup frequency. For more information, see "Planning for backup and recovery" on page 176.

Note: Page sets larger than 4 GB require the use of SMS extended addressability.

Calculate the size of your page sets

For queue manager object definitions (for example, queues and processes), it is simple to calculate the storage requirement because these objects are of fixed size and are permanent. For messages however, the calculation is more complex for the following reasons:
- Messages vary in size.
- Messages are transitory.
- Space occupied by messages that have been retrieved is reclaimed periodically by an asynchronous process.

Large page sets of greater than 4 GB that provide extra capacity for messages if the network stops, can be created if required. It is not possible to modify the existing page sets. Instead, new page sets with extended addressability and extended format attributes, must be created. The new page sets must be the same physical size as the old ones, and the old page sets must then be copied to the new ones. If backward migration is required, page set zero must not be changed. If page sets less than 4 GB are adequate, no action is needed.

Page set zero

For page set zero, the storage required is:

```
   (maximum number of local queue definitions x 1010)
      (excluding shared queues)
+  (maximum number of model queue definitions x 746)
+  (maximum number of alias queue definitions x 338)
+  (maximum number of remote queue definitions x 434)
+  (maximum number of permanent dynamic queue definitions x 1010)
+  (maximum number of process definitions x 674)
+  (maximum number of namelist definitions x 12320)
+  (maximum number of message channel definitions x 2026)
+  (maximum number of client-connection channel definitions x 5170)
+  (maximum number of server-connection channel definitions x 2026)
+  (maximum number of storage class definitions x 266)
+  (maximum number of authentication information definitions x 1010)
+  (maximum number of administrative topic definitions x 15000)
+  (total length of topic strings defined in administrative topic definitions)
```

Divide this value by 4096 to determine the number of records to specify in the cluster for the page set data set.

You do not need to allow for objects that are stored in the shared repository, but you must allow for objects that are stored or copied to page set zero (objects with a disposition of GROUP or QMGR).

The total number of objects that you can create is limited by the capacity of page set zero. The number of local queues that you can define is limited to 524 287.

Page sets 01 - 99

For page sets 01 - 99, the storage required for each page set is determined by the number and size of the messages stored on that page set. (Messages on shared queues are not stored on page sets.)

Divide this value by 4096 to determine the number of records to specify in the cluster for the page set data set.

Calculating the storage requirement for messages

This section describes how messages are stored on pages. Understanding this can help you calculate how much page set storage you must define for your messages. To calculate the approximate space required for all messages on a page set you must consider maximum queue depth of all the queues that map to the page set and the average size of messages on those queues.

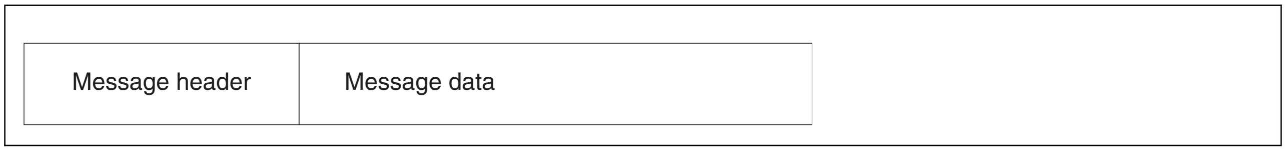
Note: The sizes of the structures and control information given in this section are liable to change between major releases. For details specific to your release of IBM MQ, refer to SupportPac MP16 - WebSphere MQ for z/OS Capacity planning & tuning and MP1E / MP1F / MP1G - WebSphere MQ for z/OS Vx.x.x Performance report

You must allow for the possibility that message "gets" might be delayed for reasons outside the control of IBM MQ (for example, because of a problem with your communications protocol). In this case, the "put" rate of messages might far exceed the "get" rate. This can lead to a large increase in the number of messages stored in the page sets and a consequent increase in the storage size demanded.

Each page in the page set is 4096 bytes long. Allowing for fixed header information, each page has 4057 bytes of space available for storing messages.

When calculating the space required for each message, the first thing you must consider is whether the message fits on one page (a short message) or whether it needs to be split over two or more pages (a long message). When messages are split in this way, you must allow for additional control information in your space calculations.

For the purposes of space calculation, a message can be represented as the following:



The message header section contains the message descriptor and other control information, the size of which varies depending on the size of the message. The message data section contains all the actual message data, and any other headers (for example, the transmission header or the IMS bridge header).

A minimum of two pages are required for page set control information which, is typically less than 1% of the total space required for messages.

Short messages

A short message is defined as a message that fits on one page.

From IBM WebSphere MQ Version 7.0.1, small messages are stored one on each page.

Long messages

If the size of the message data is greater than 3596 bytes, but not greater than 4 MB, the message is classed as a long message. When presented with a long message, IBM MQ stores the message on a series of pages, and stores control information that points to these pages in the same way that it would store a short message. This is shown in Figure 55:

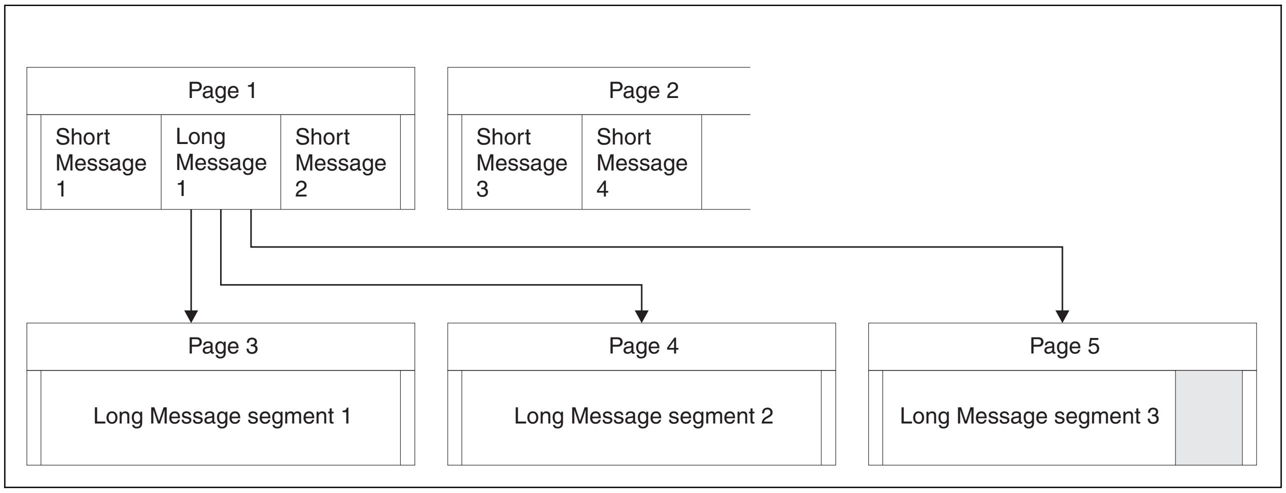


Figure 55. How IBM MQ stores long messages on page sets

Very long messages

Very long messages are messages with a size greater than 4 MB. These are stored so that each 4 MB uses 1037 pages. Any remainder is stored in the same way as a long message, as described above.

Enabling dynamic page set expansion

z/OS

Page sets can be extended dynamically while the queue manager is running. A page set can have 119 extents, and can be spread over multiple disk volumes.

Each time a page set expands, a new data set extent is used. The queue manager continues to expand a page set when required, until the maximum number of extents has been reached, or until no more storage is available for allocation on eligible volumes.

Once page set expansion fails for one of the reasons above, the queue manager marks the page set for no further expansion attempts. This marking can be reset by altering the page set to EXPAND(SYSTEM).

Page set expansion takes place asynchronously to all other page set activity, when 90% of the existing space in the page set is allocated.

The page set expansion process formats the newly allocated extent and makes it available for use by the queue manager. However, none of the space is available for use, until the entire extent has been formatted. This means that expansion by a large extent is likely to take some time, and putting applications might 'block' if they fill the remaining 10% of the page set before the expansion has completed.

Sample thlqual.SCSQPROC(CSQ4PAGE) shows how to define the secondary extents.

To control the size of new extents, you use one of the following options of the EXPAND keyword of the DEFINE PSID and ALTER PSID commands:
- USER
- SYSTEM
- NONE

USER

Uses the secondary extent size specified when the page set was allocated. If a value was not specified, or if a value of zero was specified, dynamic page set expansion cannot occur.

Page set expansion occurs when the space in the page is 90% used, and is performed asynchronously with other page set activity.

This may lead to expansion by more than a single extent at a time.

Consider the following example: you allocate a page set with a primary extent of 100000 pages and a secondary extent of 5000 pages. A message is put that requires 9999 pages. If the pageset is already using 85,000 pages, writing the message crosses the 90% full boundary (90,000 pages). At this point, a further secondary extent is allocated to the primary extent of 100,000 pages, taking the page set size to 105,000 pages. The remaining 4999 pages of the message continue to be written. When the used page space reaches 94,500 pages, which is 90% of the updated page set size of 105,000 pages, another 5000 page extent is allocated, taking the page set size to 110,000 pages. At the end of the MQPUT, the pageset has expanded twice, and 94,500 pages are used. None of the ages in the second page set expansion have been used, although they were allocated.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set. Only one extent is required to reach this size.

SYSTEM

Ignores the secondary extent size that was specified when the page set was defined. Instead, the queue manager sets a value that is approximately 10% of the current page set size. The value is rounded up to the nearest cylinder of DASD.

If a value was not specified, or if a value of zero was specified, dynamic page set expansion can still occur. The queue manager sets a value that is approximately 10% of the current page set size. The new value is rounded up depending on the characteristics of the DASD.

Page set expansion occurs when the space in the page set is approximately 90% used, and is performed asynchronously with other page set activity.

At restart, if a previously used page set has been replaced with a data set that is smaller, it is expanded until it reaches the size of the previously used data set.

NONE

No further page set expansion is to take place.

Defining your buffer pools

Use this topic to help plan the number of buffer pools you should define, and their settings.

This topic is divided into the following sections:

1. "Decide on the number of buffer pools to define"
2. "Decide on the initial characteristics of each buffer pool" on page 151
3. "Monitor the performance of buffer pools under expected load" on page 152
4. "Adjust buffer pool characteristics" on page 152

Decide on the number of buffer pools to define

You should define four buffer pools initially:

Buffer pool 0

Use for object definitions (in page set zero) and performance critical, system related message queues, such as the SYSTEM.CHANNEL.SYNCQ queue and the SYSTEM.CLUSTER.* queues.

Use the remaining three buffer pools for user messages.

Buffer pool 1

Use for important long-lived messages.

Long-lived messages are those that remain in the system for longer than two checkpoints, at which time they are written out to the page set. If you have many long-lived messages, this buffer pool should be relatively small, so that page set I/O is evenly distributed (older messages are written out to DASD each time the buffer pool becomes 85% full).

If the buffer pool is too large, and the buffer pool never gets to 85% full, page set I/O is delayed until checkpoint processing. This might affect response times throughout the system.

If you expect few long-lived messages only, define this buffer pool so that it is sufficiently large to hold all these messages.

Buffer pool 2

Use for performance-critical, short-lived messages.

There is normally a high degree of buffer reuse, using few buffers. However, you should make this buffer pool large to allow for unexpected message accumulation, for example, when a server application fails.

Buffer pool 3

Use for all other (typically, performance noncritical) messages.

Queues such as the dead-letter queue, SYSTEM.COMMAND.* queues and SYSTEM.ADMIN.* queues can also be mapped to buffer pool 3.

Where virtual storage constraints exist, and buffer pools need to be smaller, buffer pool 3 is the first candidate for size reduction.

You might need to define additional buffer pools in the following circumstances:
- If a particular queue is known to require isolation, perhaps because it exhibits different behavior at various times.
  - Such a queue might either require the best performance possible under the varying circumstances, or need to be isolated so that it does not adversely affect the other queues in a buffer pool.
  - Each such queue can be isolated into its own buffer pool and pageset.
- You want to isolate different sets of queues from each other for class-of-service reasons.
  - Each set of queues might then require one, or both, of the two types of buffer pools 1 or 2, as described in Table 20 on page 152, necessitating creation of several buffer pools of a specific type.

CD In IBM MQ Version 9.0 for z/OS, the maximum number of buffer pools that you can define depends on the OPMODE parameter. If IBM MQ Version 8.0 new functions are enabled, a maximum of 100 buffer pools can be defined. Otherwise, a maximum of 16 buffer pools can be defined.

Decide on the initial characteristics of each buffer pool

Having decided on the number of buffer pools that you require, you now need to decide the initial characteristics of those buffer pools. The available characteristics are affected by OPMODE, and are summarized in Table 19.

Table 19. Buffer pool characteristics by OPMODE setting

Parameter name/ OPMODE setting	**Maximum number of buffers in a single buffer pool**	**Maximum number of buffer pools**	**Maximum total number of buffers in queue manager**	**Buffer pool location**	**Buffer pool page class**
DEFINE or ALTER BUFFPOOL parameter	BUFFERS			LOCATION (ABOVE/ BELOW)	PAGECLAS (4KB/FIXED4KB)
CD IBM MQ Version 8.0 new functions not enabled	500 000	16	Limited by available space below the bar. Likely to be less than 262 144	BELOW bar	Pageable (4KB)
CD IBM MQ Version 8.0 functions enabled	999 999 999	100	99 999 999 900 (If MEMLIMIT /IEFUSI exit allows)	ABOVE or BELOW bar	Pageable (4KB) or page-fixed (FIXED4KB)

If you are using the four buffer pools described in "Decide on the number of buffer pools to define" on page 150, then Table 20 on page 152 gives two sets of values for the size of the buffer pools.

The first set is suitable for a test system, the other for a production system or a system that will become a production system eventually. Regardless of the OPMODE setting, the values assume that the buffer pools will be located below the bar, and that the buffers will be pageable.

Table 20. Suggested definitions for buffer pool settings

Definition setting	Test system	Production system
BUFFPOOL 0	1 050 buffers	50 000 buffers
BUFFPOOL 1	1 050 buffers	20 000 buffers
BUFFPOOL 2	1 050 buffers	50 000 buffers
BUFFPOOL 3	1 050 buffers	20 000 buffers

If you need more than the four suggested buffer pools, select the buffer pool (1 or 2) that most accurately describes the expected behavior of the queues in the buffer pool, and size it using the information in Table 20.

CD It might be that you will need to reduce the size of some of the other buffer pools, or reconsider the number of buffer pools, especially if you have not enabled IBM MQ Version 8.0 new functions with OPMODE.

Monitor the performance of buffer pools under expected load

You can monitor the usage of buffer pools by analyzing buffer pool performance statistics. In particular, you should ensure that the buffer pools are large enough so that the values of QPSTSOS, QPSTSTLA, and QPSTDMC remain at zero.

For further information, see Buffer manager data records.

Adjust buffer pool characteristics

Use the following points to adjust the buffer pool settings from "Decide on the initial characteristics of each buffer pool" on page 151, if required.

Use the performance statistics from "Monitor the performance of buffer pools under expected load" as guidance.

Note: CD These points all assume that IBM MQ Version 8.0 new functions have been enabled with OPMODE, with the exception of point 2.

1. If you are migrating from an earlier version of IBM MQ, only change your existing settings if you have more real storage available.
2. In general, bigger buffer pools are better for performance, and buffer pools can be much bigger if they are above the bar.

   However, at all times you should have sufficient real storage available so that the buffer pools are resident in real storage. It is better to have smaller buffer pools that do not result in paging, than big ones that do.

   Additionally, there is no point having a buffer pool that is bigger than the total size of the pagesets that use it, although you should take into account pageset expansion if it is likely to occur.
3. Aim for one buffer pool per pageset, as this provides better application isolation.
4. If you have sufficient real storage, such that your buffer pools will never be paged out by the operating system, consider using page-fixed buffers in your buffer pool.

   This is particularly important if the buffer pool is likely to undergo much I/O, as it saves the CPU cost associated with page-fixing the buffers before the I/O, and page-unfixing them afterwards.
5. There are several benefits to locating buffer pools above the bar even if they are small enough to fit below the bar. These are:
   - 31 bit virtual storage constraint relief - for example more space for common storage.

  - If the size of a buffer pool needs to be increased unexpectedly while it is being heavily used, there is less impact and risk to the queue manager, and its workload, by adding more buffers to a buffer pool that is already above the bar, than moving the buffer pool to above the bar and then adding more buffers.
6. Tune buffer pool zero and the buffer pool for short-lived messages (buffer pool 2) so that the 15% free threshold is never exceeded (that is, QPSTCBSL divided by QPSTNBUF is always greater than 15%). If more than 15% of buffers remain free, I/O to the page sets using these buffer pools can be largely avoided during normal operation, although messages older than two checkpoints are written to page sets.

   Attention: The optimum value for these parameters is dependent on the characteristics of the individual system. The values given are intended only as a guideline and might not be appropriate for your system.
7. SYSTEM.* queues which get very deep, for example SYSTEM.CHANNEL.SYNCQ, might benefit from being placed in their own buffer pool, if sufficient storage is available.

IBM MQ SupportPac MP16 - WebSphere MQ for z/OS Capacity planning & tuning provides further information about tuning buffer pools.

Planning your coupling facility and offload storage environment

z/OS

Use this topic when planning the initial sizes, and formats of your coupling facility (CF) structures, and shared message data set (SMDS) environment or Db2 environment.

This section contains information about the following topics:
- "Defining coupling facility resources"
  - Deciding your offload storage mechanism
  - Planning your structures
  - Planning the size of your structures
  - Mapping shared queues to structures
- "Planning your shared message data set (SMDS) environment" on page 158
- "Planning your Db2 environment" on page 162

Defining coupling facility resources

If you intend to use shared queues, you must define the coupling facility structures that IBM MQ will use in your CFRM policy. To do this you must first update your CFRM policy with information about the structures, and then activate the policy.

Your installation probably has an existing CFRM policy that describes the Coupling Facilities available. The IXCMIAPU z/OS utility is used to modify the contents of the policy based on textual statements you provide. The utility is described in the *MVS Setting up a Sysplex* manual. You must add statements to the policy that define the names of the new structures, the Coupling Facilities that they are defined in, and what size the structures are.

The CFRM policy also determines whether IBM MQ structures are duplexed and how they are reallocated in failure scenarios. Shared queue recovery contains recommendations for configuring CFRM for System Managed Rebuild processing.

Deciding your offload storage environment

The message data for shared queues can be offloaded from the coupling facility and stored in either a Db2 table or in an IBM MQ managed data set called a *shared message data set* (SMDS). Messages which are too large to store in the coupling facility (that is, larger than 63 KB) must always be offloaded, and smaller messages may optionally be offloaded to reduce coupling facility space usage.

For more information, see Specifying offload options for shared messages.

Planning your structures

A queue-sharing group requires a minimum of two structures to be defined. The first structure, known as the administrative structure, is used to coordinate IBM MQ internal activity across the queue-sharing group. No user data is held in this structure. It has a fixed name of *qsg-name* CSQ_ADMIN (where *qsg-name* is the name of your queue-sharing group). Subsequent structures are used to hold the messages on IBM MQ shared queues. Each structure can hold up to 512 shared queues.

Using multiple structures

A queue-sharing group can connect to up to 64 coupling facility structures. One of these structures must be the administration structure, one of these structures might be the SYSAPPL structure. So you can use up to 63 (62 with SYSAPPL) structures for IBM MQ data. You might choose to use multiple structures for any of the following reasons:

- You have some queues that are likely to hold a large number of messages and so require all the resources of an entire coupling facility.
- You have a requirement for a large number of shared queues, so they must be split across multiple structures because each structure can contain only 512 queues.
- RMF reports on the usage characteristic of a structure suggest that you should distribute the queues it contains across a number of Coupling Facilities.
- You want some queue data to held in a physically different coupling facility from other queue data for data isolation reasons.
- Recovery of persistent shared messages is performed using structure level attributes and commands, for example BACKUP CFSTRUCT. To simplify backup and recovery, you could assign queues that hold nonpersistent messages to different structures from those structures that hold persistent messages.

When choosing which Coupling Facilities to allocate the structures in, consider the following points:

- Your data isolation requirements.
- The volatility of the coupling facility (that is, its ability to preserve data through a power outage).
- Failure independence between the accessing systems and the coupling facility, or between Coupling Facilities.
- The level of coupling facility Control Code (CFCC) installed on the coupling facility (IBM MQ requires Level 9 or higher).

Planning the size of your structures

The administrative structure (*qsg-name* CSQ_ADMIN) must be large enough to contain 1000 list entries for each queue manager in the queue-sharing group. When a queue manager starts, the structure is checked to see if it is large enough for the number of queue managers currently *defined* to the queue-sharing group. Queue managers are considered as being defined to the queue-sharing group if they have been added by the CSQ5PQSG utility. You can check which queue managers are defined to the group with the MQSC DISPLAY GROUP command.

Table 21 on page 155 shows the minimum required size for the administrative structure for various numbers of queue managers defined in the queue-sharing group. These sizes were established for a CFCC level 14 coupling facility structure; for higher levels of CFCC, they probably need to be larger.

Table 21. Minimum administrative structure sizes

Number of queue managers defined in queue-sharing group	Required storage
1	6144 KB
2	6912 KB
3	7976 KB
4	8704 KB
5	9728 KB
6	10496 KB
7	11520 KB
8	12288 KB
9	13056 KB
10	14080 KB
11	14848 KB
12	15616 KB
13	16640 KB
14	17408 KB
15	18176 KB
16	19200 KB
17	19968 KB
18	20736 KB
19	21760 KB
20	22528 KB
21	23296 KB
22	24320 KB
23	25088 KB
24	25856 KB
25	27136 KB
26	27904 KB
27	28672 KB
28	29696 KB
29	30464 KB
30	31232 KB
31	32256 KB

When you add a queue manager to an existing queue-sharing group, the storage requirement might have increased beyond the size recommended in Table 21. If so, use the following procedure to estimate the required storage for the CSQ_ADMIN structure: Issue MQSC command `/pf DISPLAY CFSTATUS(*)`, where /cpf is for an existing member of the queue-sharing group, and extract the ENTSMAX information for the CSQ_ADMIN structure. If this number is less than 1000 times the total number of queue managers you want to define in the queue-sharing group (as reported by the DISPLAY GROUP command), increase the structure size.

The size of the structures required to hold IBM MQ messages depends on the likely number and size of the messages to be held on a structure concurrently, together with an estimate of the likely number of concurrent units of work.

The graph in Figure 56 shows how large you should make your CF structures to hold the messages on your shared queues. To calculate the allocation size you need to know

- The average size of messages on your queues
- The total number of messages likely to be stored in the structure

Find the number of messages along the horizontal axis. (Ticks are at multiples of 2, 5, and 8.) Select the curve that corresponds to your message size and determine the required value from the vertical axis. For example, for 200 000 messages of length 1 KB gives a value in the range 256 through 512MB.

Table 22 on page 157 provides the same information in tabular form.

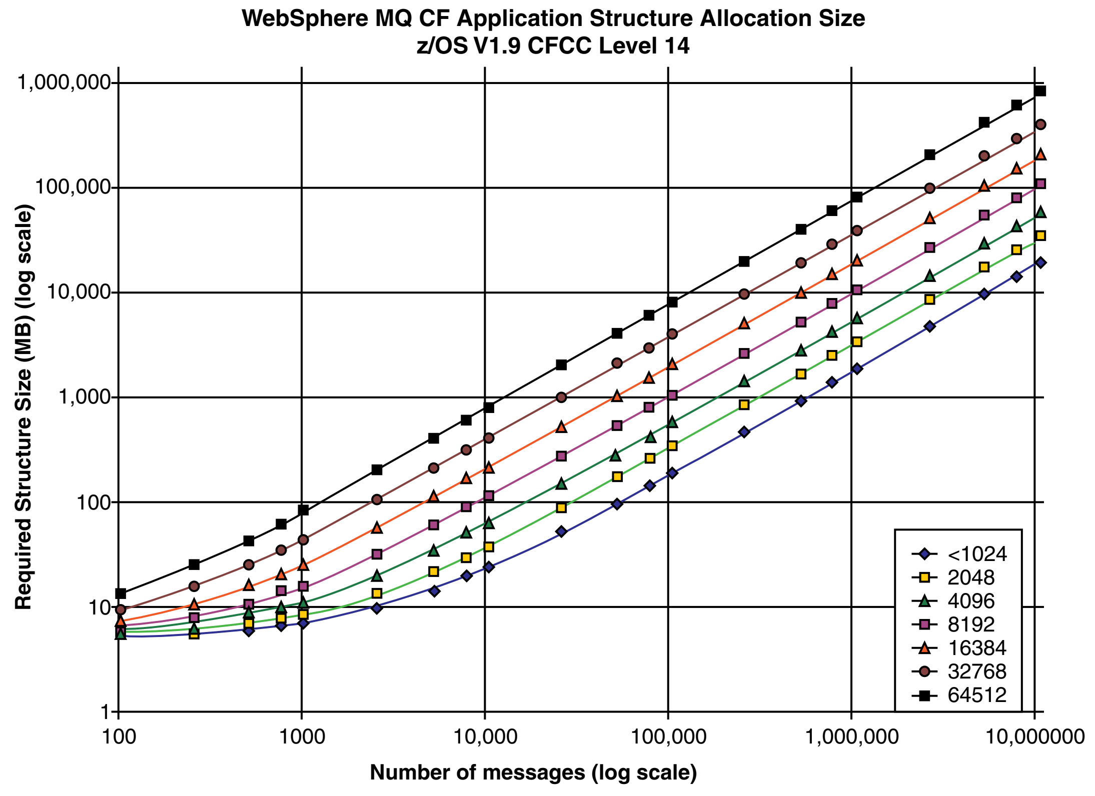

Figure 56. Calculating the size of a coupling facility structure

Use this table to help calculate how large to make your coupling facility structures:

Table 22. Calculating the size of a coupling facility structure

Number of messages	1 KB	2 KB	4 KB	8 KB	16 KB	32 KB	63 KB
100	6	6	7	7	8	10	14
1000	8	9	12	17	27	48	88
10000	25	38	64	115	218	423	821
100000	199	327	584	1097	2124	4177	8156

Your CFRM policy should include the following statements:

`INITSIZE` is the size in KB that XES allocates to the structure when the first connector connects to it. `SIZE` is the maximum size that the structure can attain. `FULLTHRESHOLD` sets the percentage value of the threshold at which XES issues message IXC585E to indicate that the structure is getting full. A best practice is to ensure that `INITSIZE` and `SIZE` are within a factor of 2.

For example, with the figures determined previously, you might include the following statements:

```
STRUCTURE NAME(structure-name)
INITSIZE(value from graph in KB, that is, multiplied by 1024)
SIZE(something larger)
FULLTHRESHOLD(85)
```

```
STRUCTURE NAME(QSG1APPLICATION1)
INITSIZE(272144) /* 256 MB */
SIZE(524288) /* 512 MB */
FULLTHRESHOLD(85)
```

If the structure use reaches the threshold where warning messages are issued, intervention is required. You might use IBM MQ to inhibit `MQPUT` operations to some of the queues in the structure to prevent applications from writing more messages, start more applications to get messages from the queues, or quiesce some of the applications that are putting messages to the queue.

Alternatively, you can use XES facilities to alter the structure size in place. The following z/OS command:

```
SETXCF START,ALTER,STRNAME= structure-name,SIZE= newsize
```

alters the size of the structure to *`newsize`*, where *`newsize`* is a value that is less than the value of SIZE specified on the CFRM policy for the structure, but greater than the current coupling facility size.

You can monitor the use of a coupling facility structure with the MQSC DISPLAY GROUP command.

If no action is taken and a queue structure fills up, an MQRC_STORAGE_MEDIUM_FULL return code is returned to the application. If the administration structure becomes full, the exact symptoms depend on which processes experience the error, but they might include the following problems:
- No responses to commands.
- Queue manager failure as a result of problems during commit processing.

Starting in V7.0.1 certain system queues are provided with CFSTRUCT attributes which specify an application structure CSQSYSAPPL prefixed with the queue-sharing group name. The CSQSYSAPPL structure is an application structure for system queues. For details of creating the coupling facility structures see Task 10: Set up the coupling facility.

With the default definitions, the SYSTEM.QSG.CHANNEL.SYNCQ and SYSTEM.QSG.UR.RESOLUTION.QUEUE use this structure. Table 3 demonstrates an example of how to estimate the message data sizes for the default queues.

Table 23. Table showing CSQSYSAPPL usage against sizing.

qsg-name **CSQSYSAPPL usage**	**sizing**
SYSTEM.QSG.CHANNEL.SYNCQ	2 messages of 500 bytes per active instance of a shared channel
SYSTEM.QSG.UR.RESOLUTION.QUEUE	1000 messages of 2 KB

The suggested initial structure definition values are as follows:

```
STRUCTURE NAME(qsgname CSQSYSAPPL)
INITSIZE(20480)          /* 20 MB */
SIZE(30720)            /* 30 MB */
FULLTHRESHOLD(85)
```

These values can be adjusted depending on your use of shared channels and group units of recovery.

Mapping shared queues to structures

The CFSTRUCT attribute of the queue definition is used to map the queue to a structure.

IBM MQ adds the name of the queue-sharing group to the beginning of the CFSTRUCT attribute. For a structure defined in the CFRM policy with name *qsg-name* SHAREDQ01, the definition of a queue that uses this structure is:

```
DEFINE QLOCAL( myqueue ) QSGDISP(SHARED) CFSTRUCT(SHAREDQ01)
```

Planning your shared message data set (SMDS) environment

z/OS

If you are using queue-sharing groups with SMDS offloading, IBM MQ needs to connect to a group of shared message data sets. Use this topic to help understand the data set requirements, and configuration required to store IBM MQ message data.

A *shared message data set* (described by the keyword SMDS) is a data set used by a queue manager to store offloaded message data for shared messages stored in a coupling facility structure.

When this form of data offloading is enabled, the **CFSTRUCT** requires an associated group of shared message data sets, one data set for each queue manager in the queue-sharing group. The group of shared message data sets is defined to IBM MQ using the **DSGROUP** parameter on the **CFSTRUCT** definition. Additional parameters can be used to supply further optional information, such as the number of buffers to use and expansion attributes for the data sets.

Each queue manager can write to the data set which it owns, to store shared message data for messages written via that queue manager, and can read all of the data sets in the group

A list describing the status and attributes for each data set associated with the structure is maintained internally as part of the **CFSTRUCT** definition, so each queue manager can check the definition to find out which data sets are currently available.

This data set information can be displayed using the **DISPLAY CFSTATUS TYPE(SMDS)** command to display current status and availability, and the **DISPLAY SMDS** command to display the parameter settings for the data sets associated with a specified **CFSTRUCT**.

Individual shared message dta sets are effectively identified by the combination of the owning queue manager name (usually specified using the **SMDS** keyword) and the **CFSTRUCT** structure name.

This section describes the following topics:

- The DSGROUP parameter
- The DSBLOCK parameter
- Shared message data set characteristics
- Shared message data set space management
- Access to shared message data sets
- Creating a shared message data set
- Shared message data set performance and capacity considerations
- Activating a shared message data set

See DEFINE CFSTRUCT for details of these parameters.

For information on managing your shared message data sets, see Managing shared message data sets for further details.

The DSGROUP parameter

The **DSGROUP** parameter on the **CFSTRUCT** definition identifies the group of data sets in which large messages for that structure are to be stored. Additional parameters may be used to specify the logical block size to be used for space allocation purposes and values for the buffer pool size and automatic data set expansion options.

The **DSGROUP** parameter must be set up before offloading to data sets can be enabled.
- If a new **CFSTRUCT** is being defined at **CFLEVEL(5)** and the option **OFFLOAD(SMDS)** is specified or assumed, then the **DSGROUP** parameter must be specified on the same command.
- If an existing **CFSTRUCT** is being altered to increase the **CFLEVEL** to **CFLEVEL(5)** and the option **OFFLOAD(SMDS)** is specified or assumed, then the **DSGROUP** parameter must be specified on the same command if it is not already set.

The DSBLOCK parameter

Space within each data set is allocated to queues as logical blocks of a fixed size (usually 256 KB) specified using the **DSBLOCK** parameter on the **CFSTRUCT** definition, then allocated to individual messages as ranges of pages of 4 KB (corresponding to the physical block size and control interval size) within each logical block. The logical block size also determines the maximum amount of message data that can be read or written in a single I/O operation, which is the same as the buffer size for the SMDS buffer pool.

A larger value of the **DSBLOCK** parameter can improve performance for very large messages by reducing the number of separate I/O operations. However, a smaller value decreases the amount of buffer storage required for each active request. The default value for the **DSBLOCK** parameter is 256 KB, which provides a reasonable balance between these requirements, so specifying this parameter might not normally be necessary.

Shared message data set characteristics

A shared message data set is defined as a VSAM linear data set (LDS). Each offloaded message is stored in one or more blocks in the data set. The stored data is addressed directly by information in the coupling facility entries, like an extended form of virtual storage. There is no separate index or similar control information stored in the data set itself.

The direct addressing scheme means that for messages which fit into one block, only a single I/O operation is needed to read or write the block. When a message spans more than one block, the I/O operations for each block can be fully overlapped to minimize elapsed time, provided that sufficient buffers are available.

The shared message data set also contains a small amount of general control information, consisting of a header in the first page, which includes recovery and restart status information, and a space map checkpoint area which is used to save the free block space map at queue manager normal termination.

Shared message data set space management

As background information for capacity, performance and operational considerations, it might be useful to understand the concepts of how space in shared message data sets is managed by the queue managers.

Free space in each shared message data set is tracked by its owning queue manager using a space map which indicates the number of pages in use within each logical block. The space map is maintained in main storage while the data set is open and saved in the data set when it is closed normally. (In recovery situations the space map is automatically rebuilt by scanning the messages in the coupling facility structure to find out which data set pages are currently in use).

When a shared message with offloaded message data is being written, the queue manager allocates a range of pages for each message block. If there is a partly used current logical block for the specified queue, the queue manager allocates space starting at the next free page in that block, otherwise it allocates a new logical block. If the whole message does not fit within the current logical block, the queue manager splits the message data at the end of the logical block and allocates a new logical block for the next message block. This is repeated until space has been allocated for the whole message. Any unused space in the last logical block is saved as the new current logical block for the queue. When the data set is closed normally, any unused pages in current logical blocks are returned to the space map before it is saved.

When a shared message with offloaded message data has been read and is ready to be deleted, the queue manager processes the delete request by transferring the coupling facility entry for the message to a clean-up list monitored by the owning queue manager (which may be the same queue manager). When entries arrive on this list, the owning queue manager reads and deletes the entries and returns the freed ranges of pages to the space map. When all used pages in a logical block have been freed the block becomes available for reuse.

Access to shared message data sets

Each shared message data set must be on shared direct access storage which is accessible to all queue managers in the queue-sharing group.

During normal running, each queue manager opens its own shared message data set for read/write access, and opens any active shared message data sets for other queue managers for read-only access, so it can read messages stored by those queue managers. This means that each queue manager userid requires at least UPDATE access to its own shared message data set and READ access to all other shared message data sets for the structure.

If it is necessary to recover shared message data sets using **RECOVER CFSTRUCT**, the recovery process can be executed from any queue manager in the queue-sharing group. A queue manager which may be used to perform recovery processing requires UPDATE access to all data sets that it may need to recover

Creating a shared message data set

Each shared message data set should normally be created before the corresponding **CFSTRUCT** definition is created or altered to enable the use of this form of message offloading, as the **CFSTRUCT** definition changes will normally take effect immediately, and the data set will be required as soon as a queue manager attempts to access a shared queue which has been assigned to that structure. A sample job to allocate and pre-format a shared message data set is provided in SCSQPROC(CSQ4SMDS). The job must be customized and run to allocate a shared message data set for each queue manager which uses a CFSTRUCT with OFFLOAD(SMDS).

If the queue manager finds that offload support has been enabled and tries to open its shared message data set but it has not yet been created, the shared message data set will be flagged as unavailable. The queue manager will then be unable to store any large messages until the data set has been created and the queue manager has been notified to try again, for example using the **START SMDSCONN** command.

A shared message data set is created as a VSAM linear data set using an Access Method Services **DEFINE CLUSTER** command. The definition must specify **SHAREOPTIONS(2 3)** to allow one queue manager to open it for write access and any number of queue managers to read it at the same time. The default control interval size of 4 KB must be used. If the data set may need to expand beyond 4 GB, it must be defined using an SMS data class which has the VSAM extended addressability attribute.

Each shared message data set can either be empty or pre-formatted to binary zeros (using **CSQJUFMT** or a similar utility such as the sample job SCSQPROC(CSQ4SMDS)), before its initial use. If it is empty or only partly formatted when it is opened, the queue manager automatically formats the remaining space to binary zeros.

Shared message data set performance and capacity considerations

Each shared message data set is used to store offloaded data for shared messages written to the associated **CFSTRUCT** by the owning queue manager, from regions within the same system. The stored data for each message includes a descriptor (currently about 350 bytes), the message headers and the message body. Each offloaded message is stored in one or more pages (physical blocks of size 4 KB) in the data set.

The data set space required for a given number of offloaded messages can therefore be estimated by rounding up the overall message size (including the descriptor) to the next multiple of 4 KB and then multiplying by the number of messages.

As for a page set, when a shared message data set is almost full, it can optionally be expanded automatically. The default behavior for this automatic expansion can be set using the **DSEXPAND** parameter on the **CFSTRUCT** definition. This setting can be overridden for each queue manager using the **DSEXPAND** parameter on the **ALTER SMDS** command. Automatic expansion is triggered when the data set reaches 90% full and more space is required. If expansion is allowed but an expansion attempt is rejected by VSAM because no secondary space allocation was specified when the data set was defined, expansion is retried using a secondary allocation of 20% of the current size of the data set.

Provided that the shared message data set is defined with the extended addressability attribute, the maximum size is only limited by VSAM considerations to a maximum of 16 TB or 59 volumes. This is significantly larger than the 64 GB maximum size of a local page set.

Activating a shared message data set

When a queue manager has successfully connected to an application coupling facility structure, it checks whether that structure definition specifies offloading using an associated **DSGROUP** parameter. If so, the queue manager allocates and opens its own shared message data set for write access, then it opens for read access any existing shared message data sets owned by other queue managers.

When a shared message data set is opened for the first time (before it has been recorded as active within the queue-sharing group), the first page will not yet contain a valid header. The queue manager fills in header information to identify the queue-sharing group, the structure name and the owning queue manager.

After the header has been completed, the queue manager registers the new shared message data set as active and broadcasts an event to notify any other active queue managers about the new data set.

Every time a queue manager opens a shared message data set it validates the header information to ensure that the correct data set is still being used and that it has not been damaged.

Planning your Db2 environment

z/OS

If you are using queue-sharing groups, IBM MQ needs to attach to a Db2 subsystem that is a member of a data sharing group. Use this topic to help understand the Db2 requirements used to hold IBM MQ data.

IBM MQ needs to know the name of the data sharing group that it is to connect to, and the name of a Db2 subsystem (or Db2 group) to connect to, to reach this data sharing group. These names are specified in the QSGDATA parameter of the CSQ6SYSP system parameter macro (described in Using CSQ6SYSP).

Within the data sharing group, shared Db2 tables are used to hold:
- Configuration information for the queue-sharing group.
- Properties of IBM MQ shared and group objects.
- Optionally, data relating to offloaded IBM MQ messages.

V 9.0.4 IBM MQ provides sample jobs for defining the Db2 tablespaces, tables, and indexes. Two sets of sample jobs are provided:
- One for compatibility with earlier versions of IBM MQ
- One for use with Db2 V12 and later, which exploits Universal Table Spaces (UTS)

Since Db2 V11, various types of table space, used by earlier versions of IBM MQ, have been flagged as deprecated. Where possible, when setting up a new data sharing group you are encouraged to choose the set of jobs which exploit Db2 UTS.

V 9.0.4 Use of preexisting table space types remains supported. There is no non-disruptive migration path from these non-preferred table spaces to UTS. Tables must be unloaded, redefined in UTS, and reloaded, necessitating an IBM MQ queue-sharing group outage.

By default Db2 uses the user ID of the person running the jobs as the owner of the Db2 resources. If this user ID is deleted then the resources associated with it are deleted, and so the table is deleted. Consider using a group ID to own the tables, rather than an individual user ID. You can do this by adding `GROUP=groupname` onto the JOB card, and specifying `SET CURRENT SQLID='groupname'` before any SQL statements.

IBM MQ uses the RRS Attach facility of Db2. This means that you can specify the name of a Db2 group that you want to connect to. The advantage of connecting to a Db2 group attach name (rather than a specific Db2 subsystem), is that IBM MQ can connect (or reconnect) to any available Db2 subsystem on the z/OS image that is a member of that group. There must be a Db2 subsystem that is a member of the data sharing group active on each z/OS image where you are going to run a queue-sharing IBM MQ subsystem, and RRS must be active.

Db2 storage

For most installations, the amount of Db2 storage required is about 20 or 30 cylinders on a 3390 device. However, if you want to calculate your storage requirement, the following table gives some information to help you determine how much storage Db2 requires for the IBM MQ data. The table describes the length of each Db2 row, and when each row is added to or deleted from the relevant Db2 table. Use this information together with the information about calculating the space requirements for the Db2 tables and their indexes in the *Db2 for z/OS Installation Guide*.

Table 24. Planning your Db2 storage requirements

Db2 table name	Length of row	A row is added when:	A row is deleted when:
CSQ.ADMIN_B_QSG	252 bytes	A queue-sharing group is added to the table with the ADD QSG function of the CSQ5PQSG utility.	A queue-sharing group is removed from the table with the REMOVE QSG function of the CSQ5PQSG utility. (All rows relating to this queue-sharing group are deleted automatically from all the other Db2 tables when the queue-sharing group record is deleted.)
CSQ.ADMIN_B_QMGR	Up to 3828 bytes	A queue manager is added to the table with the ADD QMGR function of the CSQ5PQSG utility.	A queue manager is removed from the table with the REMOVE QMGR function of the CSQ5PQSG utility.
CSQ.ADMIN_B_STRUCTURE	1454 bytes	The first local queue definition, specifying the QSGDISP(SHARED) attribute, that names a previously unknown structure within the queue-sharing group is defined.	The last local queue definition, specifying the QSGDISP(SHARED) attribute, that names a structure within the queue-sharing group is deleted.
CSQ.ADMIN_B_SCST	342 bytes	A shared channel is started.	A shared channel becomes inactive.
CSQ.ADMIN_B_SSKT	254 bytes	A shared channel that has the NPMSPEED(NORMAL) attribute is started.	A shared channel that has the NPMSPEED(NORMAL) attribute becomes inactive.
CSQ.ADMIN_B_STRBACKUP	514 bytes	A new row is added to the CSQ.ADMIN_B_STRUCTURE table. Each entry is a dummy entry until the BACKUP CFSTRUCT command is run, which overwrites the dummy entries.	A row is deleted from the CSQ.ADMIN_B_STRUCTURE table.
CSQ.OBJ_B_AUTHINFO	3400 bytes	An authentication information object with QSGDISP(GROUP) is defined.	An authentication information object with QSGDISP(GROUP) is deleted.
CSQ.OBJ_B_QUEUE	Up to 3707 bytes	• A queue with the QSGDISP(GROUP) attribute is defined. • A queue with the QSGDISP(SHARED) attribute is defined. • A model queue with the DEFTYPE(SHAREDYN) attribute is opened.	• A queue with the QSGDISP(GROUP) attribute is deleted. • A queue with the QSGDISP(SHARED) attribute is deleted. • A dynamic queue with the DEFTYPE(SHAREDYN) attribute is closed with the DELETE option.
CSQ.OBJ_B_NAMELIST	Up to 15127 bytes	A namelist with the QSGDISP(GROUP) attribute is defined.	A namelist with the QSGDISP(GROUP) attribute is deleted.
CSQ.OBJ_B_CHANNEL	Up to 14127 bytes	A channel with the QSGDISP(GROUP) attribute is defined.	A channel with the QSGDISP(GROUP) attribute is deleted.
CSQ.OBJ_B_STGCLASS	Up to 2865 bytes	A storage class with the QSGDISP(GROUP) attribute is defined.	A storage class with the QSGDISP(GROUP) attribute class is deleted.

Table 24. Planning your Db2 storage requirements (continued)

Db2 table name	Length of row	A row is added when:	A row is deleted when:
CSQ.OBJ_B_PROCESS	Up to 3347 bytes	A process with the QSGDISP(GROUP) attribute is defined.	A process with the QSGDISP(GROUP) attribute is deleted.
CSQ.OBJ_B_TOPIC	Up to 14520 bytes	A topic object with QSGDISP(GROUP) attribute is defined.	A topic object with QSGDISP(GROUP) attribute is deleted.
CSQ.EXTEND_B_QMGR	Less than 430 bytes	A queue manager is added to the table with the ADD QMGR function of the CSQ5PQSG utility.	A queue manager is removed from the table with the REMOVE QMGR function of the CSQ5PQSG utility.
CSQ.ADMIN_B_MESSAGES	87 bytes	For large message PUT (1 per BLOB).	For large message GET (1 per BLOB).
CSQ.ADMIN_MSGS_BAUX1 CSQ.ADMIN_MSGS_BAUX2 CSQ.ADMIN_MSGS_BAUX3 CSQ.ADMIN_MSGS_BAUX4		These 4 tables contain message payload for large messages added into one of these 4 tables for each BLOB of the message. BLOBS are up to 511 KB in length, so if the message size is > 711 KB, there will be multiple BLOBs for this message.	

The use of large numbers of shared queue messages of size greater than 63 KB can have significant performance implications on your IBM MQ system. For more information, see SupportPac MP16, Capacity Planning and Tuning for IBM MQ for z/OS, at: Business Integration - IBM MQ SupportPacs.

Planning your logging environment

z/OS

Use this topic to plan the number, size and placement of the logs, and log archives used by IBM MQ.

Logs are used to:
- Write recovery information about persistent messages
- Record information about units of work using persistent messages
- Record information about changes to objects, such as define queue
- Backup CF structures

and for other internal information.

The IBM MQ logging environment is established using the system parameter macros to specify options, such as: whether to have single or dual active logs, what media to use for the archive log volumes, and how many log buffers to have.

These macros are described in Task 14: Create the bootstrap and log data sets and Task 17: Tailor your system parameter module.

Note: If you are using queue-sharing groups, ensure that you define the bootstrap and log data sets with SHAREOPTIONS(2 3).

This section contains information about the following topics:

Log data set definitions

z/OS

Use this topic to decide on the most appropriate configuration for your log data sets.

This topic contains information to help you answer the following questions:
- Should your installation use single or dual logging?
- How many active log data sets do you need?
- “How large should the active logs be?” on page 166
- Active log placement

Should your installation use single or dual logging?

In general you should use dual logging for production, to minimize the risk of losing data. If you want your test system to reflect production, both should use dual logging, otherwise your test systems can use single logging.

With single logging data is written to one set of log data sets. With dual logging data is written to two sets of log data sets, so in the event of a problem with one log data set, such as the data set being accidentally deleted, the equivalent data set in the other set of logs can be used to recover the data.

With dual logging you require twice as much DASD as with single logging.

If you are using dual logging, then also use dual BSDSs and dual archiving to ensure adequate provision for data recovery.

Dual active logging adds a small performance cost.

Attention: Always use dual logging and dual BSDSs rather than dual writing to DASD (mirroring). If a mirrored data set is accidentally deleted, both copies are lost.

If you use persistent messages, single logging can increase maximum capacity by 10-30% and can also improve response times.

Single logging uses 2 - 31 active log data sets, whereas dual logging uses 4 - 62 active log data sets to provide the same number of active logs. Thus single logging reduces the amount of data logged, which might be important if your installation is I/O constrained.

How many active log data sets do you need?

The number of logs depends on the activities of your queue manager. For a test system with low throughput, three active log data sets might be suitable. For a high throughput production system you might want the maximum number of logs available, so, if there is a problem with offloading logs you have more time to resolve the problems.

You must have at least three active log data sets, but it is preferable to define more. For example, if the time taken to fill a log is likely to approach the time taken to archive a log during peak load, define more logs.

You should also define more logs to offset possible delays in log archiving. If you use archive logs on tape, allow for the time required to mount the tape.

Consider having enough active log space to keep a day's worth of data, in case the system is unable to archive because of lack of DASD or because it cannot write to tape.

It is possible to dynamically define new active log data sets as a way of minimizing the effect of archive delays or problems. New data sets can be brought online rapidly, using the DEFINE LOG command to avoid queue manager 'stall' due to lack of space in the active log.

If you want to define more than 31 active log data sets, you must configure your logging environment to use a version 2 format BSDS. Once a version 2 format BSDS is in use, up to 310 active log data sets can be defined for each log copy ring. See “Planning to increase the maximum addressable log range” on page 171 for information on how you convert to a version 2 format BSDS.

You can tell whether your queue manager is using a version 2 or higher BSDS, either by running the print log map utility (CSQJU004), or from the CSQJ034I message issued during queue manager initialization. An end of log RBA range of `FFFFFFFFFFFFFFFF`, in the CSQJ034I message, indicates that a version 2, or higher, format BSDS is in use.

When a queue manager is using a version 2, or higher, format BSDS it is possible to use the DEFINE LOG command to dynamically add more than 31 active log data sets to a log copy ring.

How large should the active logs be?

From IBM MQ Version 8.0, the maximum supported active log size, when archiving to disk, is 4 GB. In previous releases of the product, the maximum supported active log size when archiving to disk is 3 GB.

When archiving to tape the maximum active log size is 4 GB.

You should create active logs of at least 1 GB in size for production and test systems.

Important: You need to be careful when allocating data sets, because IDCAMS rounds up the size you allocate.

To allocate a 3 GB log specify one of the following options:
- Cylinders(4369)
- Megabytes(3071)
- TRACKS(65535)
- RECORD(786420)

Any one of these allocates 2.99995 GB.

To allocate a 4GB log specify one of the following options:
- Cylinders(5825)
- Megabytes(4095)
- TRACKS(87375)
- RECORD(1048500)

Any one of these allocates 3.9997 GB.

When using striped data sets, where the data set is spread across multiple volumes, the specified size value is allocated on each DASD volume used for striping. So, if you want to use 4 GB logs and four volumes for striping, you should specify:
- CYLinders(1456)
- Megabytes(1023)

Setting these attributes allocates 4*1456 = 5824 Cylinders or 4 * 1023 = 4092 Megabytes.

Note: Striping is supported when using extended format data sets. This is usually set by the storage manager.

Active log placement

For performance reasons you should consider striping your active log data sets. The I/O is spread across multiple volumes and reduces the I/O response times, leading to higher throughput. See the preceding text for information about allocating the size of the active logs when using striping.

You should review the I/O statistics using reports from RMF or a similar product., Perform the review of these statistics monthly (or more frequently) for the IBM MQ data sets, to ensure there are no delays due to the location of the data sets.

In some situations, there can be much IBM MQ page set I/O, and this can impact the IBM MQ log performance if they are located on the same DASD.

If you use dual logging, ensure that each set of active and archive logs is kept apart. For example, allocate them on separate DASD subsystems, or on different devices.

This reduces the risk of them both being lost if one of the volumes is corrupted or destroyed. If both copies of the log are lost, the probability of data loss is high.

When you create a new active log data, set you should preformat it using CSQJUFMT. If the log is not preformatted, the queue manager formats the log the first time it is used, which impacts the performance.

With older DASD with large spinning disks, you had to be careful which volumes were used to get the best performance.

With modern DASD, where data is spread over many PC sized disks, you do not need to worry so much about which volumes are used.

Your storage manager should be checking the enterprise DASD to review and resolve any performance problems. For availability, you might want to use one set of logs on one DASD subsystem, and the dual logs on a different DASD subsystem.

Planning your log archive storage

z/OS

Use this topic to understand the different ways of maintaining your archive log data sets.

You can place archive log data sets on standard-label tapes, or DASD, and you can manage them by data facility hierarchical storage manager (DFHSM). Each z/OS logical record in an archive log data set is a VSAM control interval from the active log data set. The block size is a multiple of 4 KB.

Archive log data sets are dynamically allocated, with names chosen by IBM MQ. The data set name prefix, block size, unit name, and DASD sizes needed for such allocations are specified in the system parameter module. You can also choose, at installation time, to have IBM MQ add a date and time to the archive log data set name.

It is not possible to specify with IBM MQ, specific volumes for new archive logs, but you can use Storage Management routines to manage this. If allocation errors occur, offloading is postponed until the next time offloading is triggered.

If you specify dual archive logs at installation time, each log control interval retrieved from the active log is written to two archive log data sets. The log records that are contained in the pair of archive log data sets are identical, but the end-of-volume points are not synchronized for multivolume data sets.

Should your archive logs reside on tape or DASD?

When deciding whether to use tape or DASD for your archive logs, there are a number of factors that you should consider:

- Review your operating procedures before deciding about tape or disk. For example, if you choose to archive to tape, there must be enough tape drive when they are required. After a disaster, all subsystems might want tape drives and you might not have as many free tape drives as you expect.
- During recovery, archive logs on tape are available as soon as the tape is mounted. If DASD archives have been used, and the data sets migrated to tape using hierarchical storage manager (HSM), there is a delay while HSM recalls each data set to disk. You can recall the data sets before the archive log is used. However, it is not always possible to predict the correct order in which they are required.
- When using archive logs on DASD, if many logs are required (which might be the case when recovering a page set after restoring from a backup) you might require a significant quantity of DASD to hold all the archive logs.
- In a low-usage system or test system, it might be more convenient to have archive logs on DASD to eliminate the need for tape mounts.
- Both issuing a RECOVER CFSTRUCT command, and backing out a persistent unit of work, result in the log being read backwards. Tape drives with hardware compression perform badly on operations that read backwards. Plan sufficient log data on DASD to avoid reading backwards from tape.

Archiving to DASD offers faster recoverability but is more expensive than archiving to tape. If you use dual logging, you can specify that the primary copy of the archive log go to DASD and the secondary copy go to tape. This increases recovery speed without using as much DASD, and you can use the tape as a backup.

Archiving to tape

If you choose to archive to a tape device, IBM MQ can extend to a maximum of 20 volumes.

If you are considering changing the size of the active log data set so that the set fits on one tape volume, note that a copy of the BSDS is placed on the same tape volume as the copy of the active log data set. Adjust the size of the active log data set downward to offset the space required for the BSDS on the tape volume.

If you use dual archive logs on tape, it is typical for one copy to be held locally, and the other copy to be held off-site for use in disaster recovery.

Archiving to DASD volumes

IBM MQ requires that you catalog all archive log data sets allocated on non-tape devices (DASD). If you choose to archive to DASD, the CATALOG parameter of the CSQ6ARVP macro must be YES. If this parameter is NO, and you decide to place archive log data sets on DASD, you receive message CSQJ072E each time an archive log data set is allocated, although IBM MQ still catalogs the data set.

If the archive log data set is held on DASD, the archive log data sets can extend to another volume; multivolume is supported.

If you choose to use DASD, make sure that the primary space allocation (both quantity and block size) is large enough to contain either the data coming from the active log data set, or that from the corresponding BSDS, whichever is the larger of the two.

This minimizes the possibility of unwanted z/OS `X'B37'` or `X'E37'` abend codes during the offload process. The primary space allocation is set with the PRIQTY (primary quantity) parameter of the CSQ6ARVP macro.

From IBM MQ Version 8.0, archive log data sets can exist on large or extended-format sequential data sets. SMS ACS routines can now use DSNTYPE(LARGE) or DSNTYPE(EXT). These were not supported before Version 8.0.

IBM MQ supports allocation of archive logs as extended format data sets. When extended format is used, the maximum archive log size is increased from 65535 tracks to the maximum active log size of 4GB. Archive logs are eligible for allocation in the extended addressing space (EAS) of extended address volumes (EAV).

Where the required hardware and software levels are available, allocating archive logs to a data class defined with COMPACTION using zEDC might reduce the disk storage required to hold archive logs. For more information, see IBM MQ for z/OS: Reducing storage occupancy with IBM zEnterprise Data Compression (zEDC).

Refer to Using the zEnterprise Data Compression (zEDC) enhancements for details on hardware and software levels, as well as example RACF profile changes.

The z/OS data set encryption feature can be applied to archive logs for queue managers running at IBM MQ Version 8.0 or later. These archive logs must be allocated through Automatic Class Selection (ACS) routines to a data class defined with EXTENDED attributes, and a data set key label that ensures the data is AES encrypted.

Using SMS with archive log data sets

If you have MVS™/DFP storage management subsystem (DFSMS) installed, you can write an Automatic Class Selection (ACS) user-exit filter for your archive log data sets, which helps you convert them for the SMS environment.

Such a filter, for example, can route your output to a DASD data set, which DFSMS can manage. You must exercise caution if you use an ACS filter in this manner. Because SMS requires DASD data sets to be cataloged, you must make sure the CATALOG DATA field of the CSQ6ARVP macro contains YES. If it does not, message CSQJ072E is returned; however, the data set is still cataloged by IBM MQ.

For more information about ACS filters, see DFP Storage Administration Reference.

How long do I need to keep archive logs

z/OS

Use the information in this section to help you plan your backup strategy.

You specify how long archive logs are kept in days , using the ARCRETN parameter in USING CSQ6ARVP or the SET SYSTEM command. After this period the data sets can be deleted by z/OS.

You can manually delete archive log data sets when they are no longer needed.

- The queue manager might need the archive logs for recovery.

  The queue manager can only keep the most recent 1000 archives in the BSDS, When the archive logs are not in the BSDS they cannot be used for recovery, and are only of use for audit, analysis, or replay type purposes.
- You might want to keep the archive logs so that you can extract information from the logs. For example, extracting messages from the log, and reviewing which user ID put or got the message.

The BSDS contains information on logs and other recovery information. This data set is a fixed size. When the number of archive logs reaches the value of MAXARCH in CSQ6LOGP, or when the BSDS fills up, the oldest archive log information is overwritten.

There are utilities to remove archive log entries from the BSDS, but in general, the BSDS wraps and overlays the oldest archive log record.

When is an archive log needed

You need to back up your page sets regularly. The frequency of backups determines which archive logs are needed in the event of losing a page set.

You need to back up your CF structures regularly. The frequency of backups determines which archive logs are needed in the event of losing data in the CF structure.

The archive log might be needed for recovery. The following information explains when the archive log might be needed, where there are problems with different IBM MQ resources.

Loss of Page set 0
: You must recover your system from your backup and restart the queue manager.

  You need the logs from when the backup was taken, plus up to three active logs.

Loss of any other page set
: You must recover your system from your backup and restart the queue manager.

  You need the logs from when the backup was taken, plus up to three active logs.

All LPARS lose connectivity to a structure, or the structure is unavailable
: Use the RECOVER CFSTRUCT command to read from the last CF backup on the logs.

  If you have been doing frequent backups of the CF, the data should be in active logs.

  You should not need archive logs.

Administration structure rebuild
: If you need to rebuild the administration structure, the information is read from the last checkpoint of the log for each queue manager.

  If a queue manager is not active, another queue manager reads the log.

  You should not need archive logs.

Loss of an SMDS data set
: If you lose an SMDS data set, or the data set gets corrupted, the data set becomes unusable and the status for it is set to FAILED. The CF structure is unchanged.

  In order to restore the SMDS data set, you need to:

  1. Redefine the SMDS data set, and
  2. Fail and then recover the CF structure.

     Issuing the RECOVER CFSTRUCT command twice achieves this process.

     Issuing the command the first time sets the structure state to failed; issuing the command a second time does the actual recovery.

     Note: All non persistent messages on the CF structure will be lost; all persistent messages will be restored.

  You will need the logs from the time the BACKUP CFSTRUCT command was issued, so this might require archive logs.

  If all LPARs lose connectivity to the structure, the structure is re-created, possibly in an alternative CF. Note that your structure CFRM PREFLIST attribute must contain multiple CFs.

  Note: All non persistent messages will be lost; all persistent messages will be re-created by:

  1. Reading the log for the last CF backup
  2. Reading the logs from all queue managers that have used the structure, and
  3. Merging updates since the backup

  You require the logs from all queue managers that have accessed the structure since the last backup (back to the time when the backup was taken) plus the structure backup itself in the log of the queue manager that took the backup.

BSDS

Do you need single or dual BSDS?

If you are using dual active logs you should use dual BSDS.

How big does the BSDS need to be?

The BSDS does not need to be very large, and a primary and secondary of one cylinder should be sufficient.

Planning to increase the maximum addressable log range

z/OS

You can increase the maximum addressable log range by configuring your queue manager to use a larger log relative byte address (RBA).

For an overview of the change to the log RBA for IBM MQ Version 8.0 , see Larger log Relative Byte Address.

If the queue manager is not in a queue-sharing group, you can upgrade the queue manager to CD IBM MQ Version 9.0, enable Version 8.0 new functions, and convert it to use 8 byte log RBA values at any time. Once a queue manager has been converted to use 8 byte log RBA values, it is not possible to revert it to COMPAT mode.

For queue managers in a queue-sharing group, you can upgrade each queue manager in turn to CD IBM MQ Version 9.0 and enable Version 8.0 new function. Once all the queue managers in the group are at IBM MQ Version 8.0 new function mode, you can change each queue manager in turn to use 8 byte log RBA values. It is not essential to change all the queue managers at the same time.

When a queue manager in a queue-sharing group has been converted to use 8 byte log RBA values, other queue managers in the queue-sharing group can use the logs of the converted queue manager, even though they have not yet been converted to use 8 byte log RBA values. This is useful, for example, for peer recovery.

Note: A queue manager that has been converted to use 8 byte log RBA values can read logs that have data written with 6 byte or 8 byte log RBA values. Therefore, its active logs and archive logs can be used to recover page sets and coupling facility (CF) structures.

Undoing the change

The change cannot be backed out.

How long does it take?

The change requires a queue manager restart. Stop the queue manager, run the CSQJUCNV utility against the bootstrap data set (BSDS), or data sets, to create new data sets, rename these bootstrap data sets, and restart the queue manager.

What impact does this have?

- With 8 byte log RBA in use, every write of data to the log data sets has additional bytes. Therefore, for a workload consisting of persistent messages there is a small increase in the amount of data written to the logs.
- Data written to a page set, or coupling facility (CF) structure, is not affected.

Implementing the larger log Relative Byte Address

Planning for Managed File Transfer

z/OS

Use this topic as guidance on how you need to set up your system to run Managed File Transfer (MFT). The queue manager needs to be a the same or higher level than the MFT code.

Common configurations

There are three common Managed File Transfer (MFT) configurations:
1. A single queue manager with one or more agents using local connections. This might be used to put the contents of a data set into IBM MQ queues.
2. A single queue manager with an MFT client on a distributed machine using client bindings.
3. Two queue managers connected by channels, and one or more agents on each machine. These agents can be client or local bindings.

MFT can use multiple queue managers:
- One or more queue managers to transfer the data.
- A commands queue manager that issues requests. For example, a request to start a transfer is sent to this queue manager, and the associated commands are routed to the MFT agents.
- A coordination queue manager that manages the work.

Notes:
1. You can use the same queue manager for transferring data, commands and coordination.
2. This setup, although the simplest, might not be the most efficient because all the workload is on one queue manager.

If you have an existing Managed File Transfer configuration, your command and coordination queue manager might already exist.

If you do not have an existing Managed File Transfer configuration, you can use one queue manager for transferring data, commands, and coordination. Note that even if you do this, it is possible to set up multiple configurations on the same machine.

If you are using multiple queue managers you need to set up channels between the queue managers. You can either do this by using clustering or by using point-to-point connections. Managed File Transfer status and activity can be logged, and can be stored in either a Db2 or Oracle database.

Managed File Transfer is written in Java, with some shell scripts and JCL to configure and operate the program.

Important: You must be familiar with UNIX System Services (USS) in order to configure Managed File Transfer. For example:
- The file directory structure, with names such as `/u/userID/myfile.txt`
- USS commands, for example:
  - `cd` (change directory)
  - `ls` (list)
  - `chmod` (change the file permissions)
  - `chown` (change file ownership or groups which can access the file or directory)

You require the following products in USS to be able to configure and run MFT:

1. Java, for example, in directory `/java/java71_bit64_GA/J7.1_64/`
2. IBM MQ Version 8.0 , for example, in directory `/mqm/V8R0M0`
3. If you want to use Db2 for status and history, you need to install Db2 JDBC libraries, for example, in directory `/db2/db2v10/jdbc/libs`.

Product registration

At startup Managed File Transfer checks the registration in `sys1.parmlib`(IFAPRDxx) concatenation. The following code is an example of how you register MFT:

```
PRODUCT OWNER('IBM CORP')
NAME('WS MQ FILE TRANS')
ID(5655-MFT)
VERSION(*) RELEASE(*) MOD(*)
FEATURENAME('WS MQ FILE TRANS')
STATE(ENABLED)
```

Disk space

You will need 100 MB of DASD for PDSEs and a minimum of 50 MB in USS. If you used trace to diagnose problems, you need additional disk space in USS, for example 50 MB.

Security

You need to identify which user IDs are going to be used for MFT configuration and for MFT operation.

You need to identify the files or queues you transfer, and which user IDs are going to be submitting transfer requests to MFT.

When you customize the agents and logger, you specify the group of users that is allowed to run MFT services, or do MFT administration.

You should set up this group before you start customizing MFT. As MFT uses IBM MQ queues, if you have security enabled in the queue manager, MFT requires access to the following resources:

Table 25. MQADMIN resource class

Name	Access required
QUEUE.SYSTEM.FTE.EVENT.agent_name	Update
QUEUE.SYSTEM.FTE.COMMAND.agent_name	Update
CONTEXT.SYSTEM.FTE.COMMAND.agent_name	Update
QUEUE.SYSTEM.FTE.STATE.agent_name	Update
QUEUE.SYSTEM.FTE.DATA.agent_name	Update
QUEUE.SYSTEM.FTE.REPLY.agent_name	Update
QUEUE.SYSTEM.FTE.AUTHAGT1.agent_name	Update
QUEUE.SYSTEM.FTE.AUTHTRN1.agent_name	Update
QUEUE.SYSTEM.FTE.AUTHOPS1.agent_name	Update
QUEUE.SYSTEM.FTE.AUTHSCH1.agent_name	Update
QUEUE.SYSTEM.FTE.AUTHMON1.agent_name	Update
QUEUE.SYSTEM.FTE.AUTHADM1.agent_name	Update

Table 26. MQQUEUE resource class

Name	Access required
SYSTEM.FTE.AUTHAGT1.agent_name	Update
SYSTEM.FTE.AUTHTRN1.agent_name	Update
SYSTEM.FTE.AUTHOPS1.agent_name	Update
SYSTEM.FTE.AUTHSCH1.agent_name	Update
SYSTEM.FTE.AUTHMON1.agent_name	Update

You can use user sandboxing to determine which parts of the file system the user who requests the transfer can access.

To enable user sandboxing, add the `userSandboxes=true` statement to the *agent.properties* file for the agent that you want to restrict, and add appropriate values to the `MQ_DATA_PATH/mqft/config/coordination_qmgr_name/agents/agent_name/UserSandboxes.xml` file.

See Working with user sandboxes for further information.

This user ID is configured in `UserSandboxes.xml` files.

This XML file has information like user ID, or user ID* and a list of resource that can be used (included), or cannot be used (excluded). You need to define specific user IDs that can access which resources: for example:

Table 27. Example user ID together with access to specific resources

User ID	Access	Include or Exclude	Resource
Admin*	Read	Include	`/home/user/**`
Admin*	Read	Exclude	`/home/user/private/**`
Sysprog	Read	Include	`/home/user/**`
Admin*	Read	Include	Application.reply.queue

Notes:

1. If `type=queue` is specified, the resource is either a queue name, or `queue@qmgr`.
2. If the resource begins with `//`, the resource is a data set; otherwise the resource is a file in USS.
3. The user ID is the user ID from the MQMD structure, so this might not reflect the user ID that actually puts the message.
4. For requests on the local queue manager you can use MQADMIN CONTEXT.* to limit which users can set this value.
5. For requests coming in over a remote queue manager, you have to assume that the distributed queue managers have security enabled to prevent unauthorized setting of the user ID in the MQMD structure.
6. A user ID of SYSPROG1 on a Linux machine, is the same user ID SYSPROG1 for the security checking on z/OS.

How many agents do I need?

The agents do the work in transferring data, and when you make a request to transfer data you specify the name of an agent.

By default an agent can process 25 send and 25 receive requests concurrently. You can configure these processes. See Managed File Transfer configuration options on z/OS for more information.

If the agent is busy then work is queued. The time taken to process a request depends on multiple factors, for example, the amount of data to be sent, the network bandwidth, and the delay on the network.

You might want to have multiple agents to process work in parallel.

You can also control which resources an agent can access, so you might want some agents to work with a limited subset of data.

If you want to process requests with different priority you can use multiple agents and use workload manager to set the priority of the jobs.

Running the agents

Typically the agents are long running processes. The processes can be submitted as jobs that run in batch, or as started tasks.

Planning for channel initiator SMF data

z/OS

You need to plan the implementation of SMF data for the channel initiator (CHINIT).

The CHINIT produces two types of record:
- Statistics data with information about the CHINIT and the tasks within it.
- Channel accounting data with information similar to the DIS CHSTATUS command.

You start collecting statistics data using:
```
/CPF START TRACE(S) class(4)
```

and stop it using
```
/CPF STOP TRACE(S) class(4)
```

You start collecting accounting data using:
```
/CPF START TRACE(A) class(4)
```

and stop it using
```
/CPF STOP TRACE(A) class(4)
```

The SMF records are produced when:
- The time interval in the STATIME ZPARM parameter has elapsed, or if STATIME is zero, on the SMF broadcast. The request to collect SMF data for the CHINIT and the queue manager are synchronized.
- A `STOP TRACE(A) CLASS(4)` or `STOP TRACE(S) CLASS(4)` command is issued, or
- When the CHINIT is shut down. At this point any SMF is written out.

The statistics SMF data normally fits into one SMF record, however, multiple SMF records might be created if a large number of tasks are in use.

Accounting data is gathered for each channel for which it is enabled (using the STATCHL attribute) and normally fits into one SMF record. However, multiple SMF records might be created if a large number of channels are active.

If a channel stops in the interval, accounting data is written to SMF the next time the SMF processing runs. If a client connects, does some work and disconnects, then reconnects and disconnects, there are two sets of channel accounting data produced.

You can control which channels have information written to SMF:
1. By using the STATCHL option on the channel and queue manager.
2. For client channels, note that, you must set STATCHL at the queue manager level.
3. For automatically defined cluster sender channels, you must set STATACLS.

The cost of using the CHINIT SMF data is small. Typically the increase in CPU usage is under a few percent, and often within measurement error.

Before you use this function you need to work with your z/OS systems programmer to ensure that SMF has the capacity for the additional records, and that they change their processes for extracting SMF records to include the new SMF data.

For CHINIT statistics the SMF record type is 115 and sub-type 231.

For CHINIT accounting the SMF record type is 116 and sub-type 10.

You can write your own programs to process this data, or use the SupportPac MP1B that contains a program, MQSMF, for printing the data, and creating data in Comma Separated Values (CSV) suitable for importing into a spread sheet.

If you are experiencing issues with capturing channel initiator SMF data, see Dealing with issues when capturing SMF data for the channel initiator (CHINIT) for further information.

Planning for backup and recovery

z/OS

Developing backup and recovery procedures at your site is vital to avoid costly and time-consuming losses of data. IBM MQ provides means for recovering both queues and messages to their current state after a system failure.

This topic contains the following sections:
- "Recovery procedures" on page 177
- "Tips for backup and recovery" on page 177
- "Recovering page sets" on page 179
- "Recovering CF structures" on page 180
- "Achieving specific recovery targets" on page 181
- "Backup considerations for other products" on page 183
- "Recovery and CICS" on page 183
- "Recovery and IMS" on page 183
- "Preparing for recovery on an alternative site" on page 184
- "Example of queue manager backup activity" on page 184

Recovery procedures

Develop the following procedures for IBM MQ:

- Creating a point of recovery.
- Backing up page sets.
- Backing up CF structures.
- Recovering page sets.
- Recovering from out-of-space conditions (IBM MQ logs and page sets).
- Recovering CF structures.

See Administering IBM MQ for z/OS for information about these.

Become familiar with the procedures used at your site for the following:

- Recovering from a hardware or power failure.
- Recovering from a z/OS component failure.
- Recovering from a site interruption, using off-site recovery.

Tips for backup and recovery

z/OS

Use this topic to understand some backup and recovery tasks.

The queue manager restart process recovers your data to a consistent state by applying log information to the page sets. If your page sets are damaged or unavailable, you can resolve the problem using your backup copies of your page sets (if all the logs are available). If your log data sets are damaged or unavailable, it might not be possible to recover completely.

Consider the following points:

- Periodically take backup copies
- Do not discard archive logs you might need
- Do not change the DDname to page set association

Periodically take backup copies

A *point of recovery* is the term used to describe a set of backup copies of IBM MQ page sets and the corresponding log data sets required to recover these page sets. These backup copies provide a potential restart point in the event of page set loss (for example, page set I/O error). If you restart the queue manager using these backup copies, the data in IBM MQ is consistent up to the point that these copies were taken. Provided that all logs are available from this point, IBM MQ can be recovered to the point of failure.

The more recent your backup copies, the quicker IBM MQ can recover the data in the page sets. The recovery of the page sets is dependent on all the necessary log data sets being available.

In planning for recovery, you need to determine how often to take backup copies and how many complete backup cycles to keep. These values tell you how long you must keep your log data sets and backup copies of page sets for IBM MQ recovery.

When deciding how often to take backup copies, consider the time needed to recover a page set. The time needed is determined by the following:

- The amount of log to traverse.
- The time it takes an operator to mount and remove archive tape volumes.
- The time it takes to read the part of the log needed for recovery.

- The time needed to reprocess changed pages.
- The storage medium used for the backup copies.
- The method used to make and restore backup copies.

In general, the more frequently you make backup copies, the less time recovery takes, but the more time is spent making copies.

For each queue manager, you should take backup copies of the following:
- The archive log data sets
- The BSDS copies created at the time of the archive
- The page sets
- Your object definitions
- Your CF structures

To reduce the risk of your backup copies being lost or damaged, consider:
- Storing the backup copies on different storage volumes to the original copies.
- Storing the backup copies at a different site to the original copies.
- Making at least two copies of each backup of your page sets and, if you are using single logging or a single BSDS, two copies of your archive logs and BSDS. If you are using dual logging or BSDS, make a single copy of both archive logs or BSDS.

Before moving IBM MQ to a production environment, fully test and document your backup procedures.

Backing up your object definitions

Create backup copies of your object definitions. To do this, use the MAKEDEF feature of the COMMAND function of the utility program (described in Using the COMMAND function of CSQUTIL).

You should do this whenever you take backup copies of your queue manager data sets, and keep the most current version.

Backing up your coupling facility structures

If you have set up any queue-sharing groups, even if you are not using them, you must take periodic backups of your CF structures. To do this, use the IBM MQ BACKUP CFSTRUCT command. You can use this command only on CF structures that are defined with the RECOVER(YES) attribute. If any CF entries for persistent shared messages refer to offloaded message data stored in a shared message data set (SMDS) or Db2, the offloaded data is retrieved and backed up together with the CF entries. Shared message data sets should not be backed up separately.

It is recommended that you take a backup of all your CF structures about every hour, to minimize the time it takes to restore a CF structure.

You could perform all your CF structure backups on a single queue manager, which has the advantage of limiting the increase in log use to a single queue manager. Alternatively, you could perform backups on all the queue managers in the queue-sharing group, which has the advantage of spreading the workload across the queue-sharing group. Whichever strategy you use, IBM MQ can locate the backup and perform a RECOVER CFSTRUCT from any queue manager in the queue-sharing group. The logs of all the queue managers in the queue-sharing group need to be accessed to recover the CF structure.

Backing up your message security policies

If you are using Advanced Message Security to create a backup of your message security policies, create a backup using the message security policy utility (CSQ0UTIL) to run **`dspmqspl`** with the -export parameter, then save the policy definitions that are output to the EXPORT DD.

You should create a backup of your message security policies whenever you take backup copies of your queue manager data sets, and keep the most current version.

Do not discard archive logs you might need

IBM MQ might need to use archive logs during restart. You must keep sufficient archive logs so that the system can be fully restored. IBM MQ might use an archive log to recover a page set from a restored backup copy. If you have discarded that archive log, IBM MQ cannot restore the page set to its current state. When and how you discard archive logs is described in Discarding archive log data sets.

You can use the `/cpf DIS USAGE TYPE(ALL)` command to display the log RBA, and log range sequence number (LRSN) that you need to recover your queue manager's page sets and the queue-sharing group's structures. You should then use the print log map utility (CSQJU004) to print bootstrap data set (BSDS) information for the queue manager to locate the logs containing the log RBA.

For structures, you need to run the CSQJU004 utility on each queue manager in the queue-sharing group to locate the logs containing the LRSN. You need these logs and any later logs to be able to recover the page sets and structures.

Do not change the DDname to page set association

IBM MQ associates page set number 00 with DDname CSQP0000, page set number 01 with DDname CSQP0001, and so on, up to CSQP0099. IBM MQ writes recovery log records for a page set based on the DDname that the page set is associated with. For this reason, you must not move page sets that have already been associated with a PSID DDname.

Recovering page sets

z/OS

Use this topic to understand the factors involved when recovering pages sets, and how to minimize restart times.

A key factor in recovery strategy concerns the time for which you can tolerate a queue manager outage. The total outage time might include the time taken to recover a page set from a backup, or to restart the queue manager after an abnormal termination. Factors affecting restart time include how frequently you back up your page sets, and how much data is written to the log between checkpoints.

To minimize the restart time after an abnormal termination, keep units of work short so that, at most, two active logs are used when the system restarts. For example, if you are designing an IBM MQ application, avoid placing an `MQGET` call that has a long wait interval between the first in-syncpoint MQI call and the commit point because this might result in a unit of work that has a long duration. Another common cause of long units of work is batch intervals of more than 5 minutes for the channel initiator.

You can use the DISPLAY THREAD command to display the RBA of units of work and to help resolve the old ones.

How often must you back up a page set?

Frequent page set backup is essential if a reasonably short recovery time is required. This applies even when a page set is very small or there is a small amount of activity on queues in that page set.

If you use persistent messages in a page set, the backup frequency should be in hours rather than days. This is also the case for page set zero.

To calculate an approximate backup frequency, start by determining the target total recovery time. This consists of the following:

1. The time taken to react to the problem.
2. The time taken to restore the page set backup copy.

   If you use SnapShot backup/restore, the time taken to perform this task is a few seconds. For information about SnapShot, see the *DFSMSdss Storage Administration Guide*.
3. The time the queue manager requires to restart, including the additional time needed to recover the page set.

   This depends most significantly on the amount of log data that must be read from active and archive logs since that page set was last backed up. All such log data must be read, in addition to that directly associated with the damaged page set.

   Note: When using *fuzzy backup* (where a snapshot is taken of the logs and page sets while a unit of work is active), it might be necessary to read up to three additional checkpoints, and this might result in the need to read one or more additional logs.

When deciding on how long to allow for the recovery of the page set, the factors that you need to consider are:

- The rate at which data is written to the active logs during normal processing depends on how messages arrive in your system, in addition to the message rate.

  Messages received or sent over a channel result in more data logging than messages generated and retrieved locally.
- The rate at which data can be read from the archive and active logs.

  When reading the logs, the achievable data rate depends on the devices used and the total load on your particular DASD subsystem.

  With most tape units, it is possible to achieve higher data rates for archived logs with a large block size. However, if an archive log is required for recovery, all the data on the active logs must be read also.

Recovering CF structures

z/OS

Use this topic to understand the recovery process for CF structures.

At least one queue manager in the queue-sharing group must be active to process a RECOVER CFSTRUCT command. CF structure recovery does not affect queue manager restart time, because recovery is performed by an already active queue manager.

The recovery process consists of two logical steps that are managed by the RECOVER CFSTRUCT command:

1. Locating and restoring the backup.
2. Merging all the logged updates to persistent messages that are held on the CF structure from the logs of all the queue managers in the queue-sharing group that have used the CF structure, and applying the changes to the backup.

The second step is likely to take much longer because a lot of log data might need to be read. You can reduce the time taken if you take frequent backups, or if you recover multiple CF structures at the same time, or both.

The queue manager performing the recovery locates the relevant backups on all the other queue managers' logs using the data in Db2 and the bootstrap data sets. The queue manager replays these backups in the correct time sequence across the queue-sharing group, from just before the last backup through to the point of failure.

The time it takes to recover a CF structure depends on the amount of recovery log data that must be replayed, which in turn depends on the frequency of the backups. In the worst case, it takes as long to read a queue manager's log as it did to write it. So if, for example, you have a queue-sharing group containing six queue managers, an hour's worth of log activity could take six hours to replay. In general it takes less time than this, because reading can be done in bulk, and because the different queue manager's logs can be read in parallel. As a starting point, we recommend that you back up your CF structures every hour.

All queue managers can continue working with non-shared queues and queues in other CF structures while there is a failed CF structure. If the administration structure has also failed, at least one of the queue managers in the queue-sharing group must be started before you can issue the RECOVER CFSTRUCT command.

Backing up CF structures can require considerable log writing capacity, and can therefore impose a large load on the queue manager doing the backup. Choose a lightly loaded queue manager for doing backups; for busy systems, add an additional queue manager to the queue-sharing group and dedicate it exclusively for doing backups.

Achieving specific recovery targets

z/OS

Use this topic for guidance on how you can achieve specific recovery target times by adjusting backup frequency.

If you have specific recovery targets to achieve, for example, completion of the queue manager recovery and restart processing in addition to the normal startup time within *xx* seconds, you can use the following calculation to estimate your backup frequency (in hours):

```
Formula (A)
                    Required restart time * System recovery log read rate
                          (in secs)                  (in MB/sec)
Backup frequency  = -----------------------------------------------------
   (in hours)                Application log write rate (in MB/hour)
```

Note: The examples given next are intended to highlight the need to back up your page sets frequently. The calculations assume that most log activity is derived from a large number of persistent messages. However, there are situations where the amount of log activity is not easily calculated. For example, in a queue-sharing group environment, a unit of work in which shared queues are updated in addition to other resources might result in UOW records being written to the IBM MQ log. For this reason, the Application log write rate in Formula (A) can be derived accurately only from the observed rate at which the IBM MQ logs fill.

For example, consider a system in which IBM MQ MQI clients generate a total load of 100 persistent messages a second. In this case, all messages are generated locally.

If each message is of user length 1 KB, the amount of data logged each hour is approximately:

```
100 * (1 + 1.3) KB * 3600 = approximately 800 MB

where
      100           = the message rate a second
      (1 + 1.3) KB  = the amount of data logged for
                      each 1 KB of persistent messages
```

Consider an overall target recovery time of 75 minutes. If you have allowed 15 minutes to react to the problem and restore the page set backup copy, queue manager recovery and restart must then complete within 60 minutes (3600 seconds) applying formula (A). Assuming that all required log data is on RVA2-T82 DASD, which has a recovery rate of approximately 2.7 MB a second, this necessitates a page set backup frequency of at least every:

```
3600 seconds * 2.7 MB a second / 800 MB an hour = 12.15 hours
```

If your IBM MQ application day lasts approximately 12 hours, one backup each day is appropriate. However, if the application day lasts 24 hours, two backups each day is more appropriate.

Another example might be a production system in which all the messages are for request-reply applications (that is, a persistent message is received on a receiver channel and a persistent reply message is generated and sent down a sender channel).

In this example, the achieved batch size is one, and so there is one batch for every message. If there are 50 request replies a second, the total load is 100 persistent messages a second. If each message is 1 KB in length, the amount of data logged each hour is approximately:

```
50((2 * (1+1.3) KB) + 1.4 KB + 2.5 KB) * 3600 = approximately 1500 MB

where:
 50                 = the message pair rate a second
 (2 * (1 + 1.3) KB) = the amount of data logged for each message pair
 1.4 KB             = the overhead for each batch of messages
                      received by each channel
 2.5 KB             = the overhead for each batch of messages sent
                      by each channel
```

To achieve the queue manager recovery and restart within 30 minutes (1800 seconds), again assuming that all required log data is on RVA2-T82 DASD, this requires that page set backup is carried out at least every:

```
1800 seconds * 2.7 MB a second / 1500 MB an hour = 3.24 hours
```

Periodic review of backup frequency

Monitor your IBM MQ log usage in terms of MB an hour. Periodically perform this check and amend your page set backup frequency if necessary.

Backup considerations for other products

z/OS

If you are using IBM MQ with CICS or IMS then you must also consider the implications for your backup strategy with those products. The data facility hierarchical storage manager (DFHSM) manages data storage, and can interact with the storage used by IBM MQ.

Backup and recovery with DFHSM

The data facility hierarchical storage manager (DFHSM) does automatic space-availability and data-availability management among storage devices in your system. If you use it, you need to know that it moves data to and from the IBM MQ storage automatically.

DFHSM manages your DASD space efficiently by moving data sets that have not been used recently to alternative storage. It also makes your data available for recovery by automatically copying new or changed data sets to tape or DASD backup volumes. It can delete data sets, or move them to another device. Its operations occur daily, at a specified time, and allow for keeping a data set for a predetermined period before deleting or moving it.

You can also perform all DFHSM operations manually. The *Data Facility Hierarchical Storage Manager User's Guide* explains how to use the DFHSM commands. If you use DFHSM with IBM MQ, note that DFHSM does the following:

- Uses cataloged data sets.
- Operates on page sets and logs.
- Supports VSAM data sets.

Recovery and CICS

The recovery of CICS resources is not affected by the presence of IBM MQ. CICS recognizes IBM MQ as a non-CICS resource (or external resource manager), and includes IBM MQ as a participant in any syncpoint coordination requests using the CICS resource manager interface (RMI). For more information about CICS recovery, see the *CICS Recovery and Restart Guide*. For information about the CICS resource manager interface, see the *CICS Customization Guide*.

Recovery and IMS

IMS recognizes IBM MQ as an external subsystem and as a participant in syncpoint coordination. IMS recovery for external subsystem resources is described in the *IMS Customization Guide*.

Preparing for recovery on an alternative site

z/OS

If a total loss of an IBM MQ computing center, you can recover on another IBM MQ system at a recovery site.

To recover an IBM MQ system at a recovery site, you must regularly back up the page sets and the logs. As with all data recovery operations, the objectives of disaster recovery are to lose as little data, workload processing (updates), and time as possible.

At the recovery site:

- The recovery IBM MQ queue manager **must** have the same name as the lost queue manager.
- Ensure the system parameter module used on the recovery queue manager contains the same parameters as the lost queue manager.

The process for disaster recovery is described in the Administering IBM MQ for z/OS.

Example of queue manager backup activity

z/OS

This topic shows as an example of queue manager backup activity.

When you plan your queue manager backup strategy, a key consideration is retention of the correct amount of log data. Managing the logs describes how to determine which log data sets are required, by reference to the system recovery RBA of the queue manager. IBM MQ determines the system recovery RBA using information about the following:

- Currently active units of work.
- Page set updates that have not yet been flushed from the buffer pools to disk.
- CF structure backups, and whether this queue manager's log contains information required in any recovery operation using them.

You must retain sufficient log data to be able to perform media recovery. While the system recovery RBA increases over time, the amount of log data that must be retained only decreases when subsequent backups are taken. CF structure backups are managed by IBM MQ, and so are taken into account when reporting the system recovery RBA. This means that in practice, the amount of log data that must be retained only reduces when page set backups are taken.

Figure 57 on page 185 shows an example of the backup activity on a queue manager that is a member of a queue-sharing group, how the recovery RBA varies with each backup, and how that affects the amount of log data that must be retained. In the example the queue manager uses local and shared resources: page sets, and two CF structures, STRUCTURE1 and STRUCTURE2.

Full page set backup

Figure 57. Example of queue manager backup activity.

Example of queue manager backup activity.

This is what happens at each point in time:

Point in time T1

A fuzzy backup is created of your page sets, as described in How to back up and recover page sets.

The system recovery RBA of the queue manager is the lowest of the following:

- The recovery RBAs of the page sets being backed up at this point.
- The lowest recovery RBA required to recover the CF application structures. This relates to the recovery of backups of STRUCTURE1 and STRUCTURE2 created earlier.
- The recovery RBA for the oldest currently active unit of work within the queue manager (UOWB1).

The system recovery RBA for this point in time is given by messages issued by the DISPLAY USAGE command, which is part of the fuzzy backup process.

Point in time T2

Backups of the CF structures are created. CF structure STRUCTURE1 is backed up first, followed by STRUCTURE2.

The amount of log data that must be retained is unchanged, because the same data as determined from the system recovery RBA at T1 is still required to recover using the page set backups taken at T1.

Point in time T3

Another fuzzy backup is created.

The system recovery RBA of the queue manager is the lowest of the following:

- The recovery RBAs of the page sets being backed up at this point.
- The lowest recovery RBA required to recover CF structure STRUCTURE1, because STRUCTURE1 was backed up before STRUCTURE2.
- The recovery RBA for the oldest currently active unit of work within the queue manager (UOWA1).

The system recovery RBA for this point in time is given by messages issued by the DISPLAY USAGE command, which is part of the fuzzy backup process.

You can now reduce the log data retained, as determined by this new system recovery RBA.

Point in time T4

A backup is taken of CF structure STRUCTURE2. The recovery RBA for the recovery of the oldest required CF structure backup relates to the backup of CF structure STRUCTURE1, which was backed up at time T2.

The creation of this CF structure backup has no effect on the amount of log data that must be retained.

Point in time T5

A backup is taken of CF structure STRUCTURE1. The recovery RBA for recovery of the oldest required CF structure backup now relates to recovery of CF structure STRUCTURE2, which was backed up at time T4.

The creation of this CF structure backup has no effect on amount of log data that must be retained.

Point in time T6

A full backup is taken of your page sets as described in How to back up and recover page sets.

The system recovery RBA of the queue manager is the lowest of the following:

- The recovery RBAs of the page sets being backed up at this point.
- The lowest recovery RBA required to recover the CF structures. This relates to recovery of CF structure STRUCTURE2.
- The recovery RBA for the oldest currently active unit of work within the queue manager. In this case, there are no current units of work.

The system recovery RBA for this point in time is given by messages issued by the DISPLAY USAGE command, which is part of the full backup process.

Again, the log data retained can be reduced, because the system recovery RBA associated with the full backup is more recent.

Planning your z/OS UNIX or UNIX System Services environment

z/OS

Certain processes within the IBM MQ queue manager (MSTR) and the channel initiator (CHIN) use z/OS UNIX or UNIX System Services (USS) for their normal processing. Plan your configuration if you do not want to use the default USS configuration.

No special action or customization is necessary in order for IBM MQ to use UNIX services as long as a system-wide default OMVS segment has been set up.

Users who do not want IBM MQ to invoke USS, using the guest or default UID and OMVS segment, need only model a new OMVS segment based on the default segment, as IBM MQ requires no special permissions, and does not run within UNIX as a superuser.

Note: Although the MSTR and CHIN jobs make use of USS facilities (for example, to interface with TCP/IP services), they do not need to access any of the content of the USS filesystem shipped by IBM MQ. As a result, the MSTR and CHIN jobs do not require any configuration to specify the path for the USS filesystem.

The content of the IBM MQ directory in the USS filesystem is used by applications connecting to IBM MQ. For example, applications using the IBM MQ classes for Java or IBM MQ classes for JMS interfaces.

See the following topics for the relevant configuration instructions:

- Environment variables relevant to IBM MQ classes for Java
- IBM MQ classes for Java libraries

- Setting environment variables
- Configuring the Java Native Interface (JNI) libraries

Planning your z/OS TCP/IP environment

z/OS

To get the best throughput through your network, you must use TCP/IP send and receive buffers with a size of 64 KB, or greater. With this size, the system optimizes its buffer sizes.

See Dynamic right sizing for high latency networks for more information.

You can check your system buffer size by using the following Netstat command, for example:

```
TSO NETSTAT ALL (CLIENT csq1CHIN
```

The results display much information, including the following two values:

```
ReceiveBufferSize: 0000065536
SendBufferSize: 0000065536
```

65536 is 64 KB. If your buffer sizes are less than 65536, you must work with your network team to increase the **TCPSENDBFRSIZE** and **TCPRCVBUFRSIZE** values in the `PROFILE DDName` in the TCPIP procedure. For example, you might use the following command:

```
TCPCONFIG TCPSENDBFRSZE 65536 TCPRCVBUFRSIZE 65536
```

If you are unable to change your system-wide **TCPSENDBFRSIZE** or **TCPRCVBUFRSIZE** settings, contact your IBM Software Support center.

Planning to use the IBM MQ Console and REST API on z/OS

z/OS V 9.0.2

The IBM MQ Console and REST API are WebSphere Application Server Liberty (Liberty) applications running in a server known as `mqweb`. The `mqweb` server runs as a started task. The MQ Console allows a web browser to be used to administer queue managers, and the REST API provides a simple programmatic interface for applications to do queue manager administration. V 9.0.4 From Version 9.0.4, the REST API also performs messaging.

The MQ Console and REST API can only directly interact with queue managers running at the same Version, Release, and Modification (VRM) . For example, the MQ Console and REST API shipped with Version 9.0.3 can only interact with local queue managers at Version 9.0.3, and the MQ Console and REST API shipped with Version 9.0.4 can only interact with local queue managers at Version 9.0.4.

Migration

If you have only one queue manager, you can run the `mqweb` server as a started task called MQWEB, and change the libraries it uses when you migrate your queue manager.

If you have more than one queue manager, during migration you can start a Version 9.0.3 and a Version 9.0.4 `mqweb` server, using started tasks named MQWB0903 and MQWB0904 respectively.

Note that these are example names for the started tasks, you can use any name you want.

When you migrate the queue managers, the queue managers become available in the Version 9.0.4 `mqweb` server.

Once you have migrated all the queue managers to Version 9.0.4, you can delete the Version 9.0.3 mqweb server.

V 9.0.4 In Version 9.0.4 and later, you can administer queue managers at a different version from the mqweb server by configuring a gateway queue manager. For more information, see Remote administration using the REST API.

Note: You still need at least one queue manager at the same version as the mqweb server, to act as the gateway queue manager.

HTTP ports

The mqweb server uses at least one, and up to two ports for HTTP:
- One for HTTPS; this value defaults to 9443
- One for HTTP; HTTP is not enabled by default, but if enabled, will use port 9080 by default

Notes:
1. If the default ports are already in use, you need to allocate other ports.
2. If you have more than one mqweb server running simultaneously for more than one version of IBM MQ, you need to allocate separate ports for each version.

You can use the command `tso netstat tcp tcpip portlist (port 9080)` to display information about a port - in this case, 9080.

Installation and configuration files

You need to install the IBM MQ for z/OS Unix System Services Web Components feature, which will install the files needed to run the mqweb server in USS. You need to be familiar with USS to be able to configure and manage the mqweb server.

If you have installed IBM MQ on one system, and run IBM MQ on a different system, you should copy the IBM MQ ZFS created during the installation to the processing system, and mount it read only.

If the directory where the IBM MQ files are to be stored is `/mqm/v904`, you can use the `df -P/mqm/v904` command to display the free and available space. Note that IBM MQ requires 646516 one kilobyte pages.

You need to create, and decide upon the location for, a Liberty user directory when you configure the mqweb server. This directory contains configuration and log files, and the location can be something similar to `/var/mqm/web/mqweb904`.

Security

The MQ Console and REST API, issue commands to the queue manager using the PCF interface. The user ID of the mqweb server needs authority to issue IBM MQ commands and access certain queues. These details are described in IBM MQ Console - required command security profiles.

If you are using the SAF interface for authentication, you need a Liberty Angel process running. If you already have a Liberty Profile running on the LPAR, the Angel process might already be running. See Enabling z/OS authorized services on Liberty for z/OS, and Configuring the Liberty Angel process and z/OS authorized services for more information.

The mqweb started task user ID needs:
- A uid to be able to use USS.
- Access to the `hlq.SCSQAUTH` and `hlq.SCSQANL*` data sets in the IBM MQ installation.

- Read access to the IBM MQ installation files in USS.
- Read and write access to the Liberty user directory.
- Access to various security profiles. See Configuring System Authorization Facility interface for more information.

The Liberty server use the default security prefix BBGZDFLT for its security definitions. If this is already being used, you might want to use a different prefix.

Installing and uninstalling IBM MQ

Before you start installing IBM MQ, consider how you want to use it. Use these topics to help you to prepare for installation, install the product, and verify the installation. There is also information to help you to uninstall the product.

About this task

To get started with installing IBM MQ, see the topics for the platform, or platforms, that your enterprise uses. For concepts and considerations relating to installation, see "IBM MQ installation overview" on page 192.

You can also apply and remove maintenance to IBM MQ. See Maintenance tasks in the Maintaining and migrating section.

Attention: The information in this section applies to both Continuous Delivery (CD) and Long Term Support (LTS) releases.

Any information that applies specifically to an LTS or CD release is marked with the appropriate icon.

Procedure

1. To find information on installing IBM MQ, see the appropriate sections for the platform, or platforms, that your enterprise uses:
   - AIX "Installing and uninstalling IBM MQ on AIX" on page 215
   - NSS Client "Installing and uninstalling IBM MQ client for HP Integrity NonStop Server" on page 249
   - HP-UX "Installing and uninstalling IBM MQ on HP-UX" on page 263
   - Linux "Installing IBM MQ on Linux using rpm" on page 340
   - Solaris "Installing and uninstalling IBM MQ on Solaris" on page 398
   - Windows "Installing and uninstalling IBM MQ on Windows" on page 435
   - z/OS "Installing IBM MQ for z/OS" on page 547
2. To find out about concepts and considerations relating to installation, see "IBM MQ installation overview" on page 192.

IBM MQ installation overview

An overview of concepts and considerations for installing IBM MQ, with links to instructions on how to install, verify, and uninstall IBM MQ on each of the supported platforms.

Related concepts:

"Multiple installations on UNIX, Linux, and Windows" on page 200
On UNIX, Linux, and Windows, it is possible to have more than one copy of IBM MQ on a system.

"Installation considerations for MQ Telemetry" on page 538
From IBM WebSphere MQ Version 7.1, MQ Telemetry is a component of the main IBM MQ product, and is no longer a separate plugin. You can choose to install MQ Telemetry when you first install IBM MQ, or when you modify an existing IBM MQ installation. To get a set of client libraries that help you write messaging applications for telemetry, download the IBM Messaging Telemetry Clients SupportPac.

IBM MQ components and features

You can select the components or features that you require when you install IBM MQ.

Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. For more information, see "License requirements" on page 194 and IBM MQ license information.

Also review the information on hardware and software requirements for the platform on which you are planning to install IBM MQ. For more information, see "Where to find product requirements and support information" on page 195.

Multi

Installation of IBM MQ on Multiplatforms

IBM MQ can be installed as a server or a client. The installation images can be downloaded (see "Installation with a download image" on page 211), or IBM MQ can be installed from a DVD.

An IBM MQ server is an installation of one or more queue managers that provide queuing services to one or more clients. All the IBM MQ objects, for example queues, exist only on the queue manager machine (the IBM MQ server machine), and not the client. An IBM MQ server can also support local IBM MQ applications.

An IBM MQ MQI client is a component that allows an application running on one system to communicate with a queue manager running on another system. The output from the call is sent back to the client, which passes it back to the application.

For detailed explanations of all the components that you can install, see:

- AIX "IBM MQ components for AIX" on page 216
- HP-UX "IBM MQ components for HP-UX" on page 264
- IBM i "IBM MQ components for IBM i" on page 298
- Linux "IBM MQ rpm components for Linux systems" on page 341

- Linux “IBM MQ Debian components for Linux Ubuntu systems” on page 364
- Solaris “IBM MQ components for Solaris systems” on page 398
- Windows “IBM MQ features for Windows systems” on page 436

For information about how to install IBM MQ on each supported platform, see the links in the following table:

Table 28. Where to find IBM MQ installation information for each platform

Platform	IBM MQ server	IBM MQ client
AIX AIX	“Installing IBM MQ server on AIX” on page 225	“Installing an IBM MQ client on AIX” on page 231
NSS Client HP Integrity NonStop Server	Not applicable	“Installing and uninstalling IBM MQ client for HP Integrity NonStop Server” on page 249

Windows Windows	“Installing IBM MQ server on Windows” on page 453	“Installing an IBM MQ client on Windows” on page 481

Multi

Installing IBM MQ clients and servers on the same system

It is possible to have both a server and a client installation on the same system. If you install from a DVD, to install an IBM MQ client on a system that is already running an IBM MQ server, you must use the appropriate Server DVD. You can use a Client DVD to install an IBM MQ client only on a system that is not running an IBM MQ server.

If you install an IBM MQ client from a Client DVD and later decide to install the IBM MQ server on the same system, you must first remove all the client components from the system, then use the appropriate Server DVD to install both the server and client components. You cannot install an IBM MQ server on a system that already has client components installed from a Client DVD.

Remember that even if your client and server are installed on the same system, you must still define the MQI channel between them. See Defining MQI channels for details.

Advanced Message Security, Managed File Transfer and MQ Telemetry

Advanced Message Security, Managed File Transfer and MQ Telemetry are separately installed components of IBM MQ. Make sure that you purchase a license for using IBM MQ Advanced before installing any of these components (see IBM MQ license information).

z/OS

Installation of IBM MQ on z/OS

For information on installation options for IBM MQ for z/OS, see "Installing IBM MQ for z/OS" on page 547.

V 9.0.0 For information on installation options for IBM MQ Advanced for z/OS, see "Installing IBM MQ Advanced for z/OS" on page 560.

Related concepts:

"Installation location on Multiplatforms" on page 198
You can install IBM MQ into the default location. Alternatively, you can install into a custom location during the installation process. The location where IBM MQ is installed is known as the *MQ_INSTALLATION_PATH*.

"Primary installation on UNIX, Linux, and Windows" on page 202
On systems that support multiple installations of IBM MQ (UNIX, Linux, and Windows), the primary installation is the one to which IBM MQ system-wide locations refer. Having a primary installation is optional, but convenient.

"Installation name on UNIX, Linux, and Windows" on page 197
Each installation of IBM MQ on UNIX, Linux, and Windows, has a unique identifier known as an installation name. The installation name is used to associate things such as queue managers and configuration files with an installation.

Related tasks:

Multi "Installing IBM MQ Advanced for Multiplatforms" on page 519
Installation tasks associated with IBM MQ Advanced for Multiplatforms are grouped in this section.

License requirements

You must have purchased sufficient licenses for your installation. The details of the license agreement is stored on your system at installation time so that you can read it at any time. IBM MQ supports IBM License Metric Tool (ILMT).

Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. See IBM MQ license information for more details.

License files

At installation, the license agreement files are copied into the `/licenses` directory under the *MQ_INSTALLATION_PATH*. You can read them at any time.

IBM i On IBM i, you can use the WRKSFWAGR command to view the software licenses.

ILMT

ILMT automatically detects IBM MQ, if you are using it, and checks with it each time a queue manager is started. You do not need to take any further action. You can install ILMT before or after IBM MQ.

The automatic detection applies to both the IBM MQ server and IBM MQ Java products.

Planning considerations for installation on Multiplatforms

Multi

Before you install IBM MQ, you must choose which components to install and where to install them. You must also make some platform-specific choices.

Before you start installing, consider how you want to use IBM MQ and review the information in this section, and also the information in the general Planning section.

NSS Client Note that HP Integrity NonStop Server uses a different installer from the other platforms, and a multi-installation layout.

When planning your installation, make sure that you check the hardware and software requirements for your system. For more information, see "Where to find product requirements and support information" on page 195.

Note: z/OS This information is about planning an installation on IBM MQ for Multiplatforms. For information about planning an installation on z/OS, see “Planning to install IBM MQ for z/OS” on page 550.

Installation name on UNIX, Linux, and Windows

ULW

Each installation of IBM MQ on UNIX, Linux, and Windows, has a unique identifier known as an installation name. The installation name is used to associate things such as queue managers and configuration files with an installation.

You can choose the installation name and make it meaningful to you. For example, you might call a test system *testMQ*.

If you do not specify an installation name when the product is installed, a default installation name is automatically assigned. For the first installation, this name is *Installation1*. For the second installation, the name is *Installation2*, and so on. The installation name *Installation0* is reserved for an installation of IBM WebSphere MQ Version 7.0.1. The installation name cannot be changed after the product is installed.

UNIX Linux On UNIX and Linux systems, the first IBM MQ installation is automatically given an installation name of *Installation1*. For subsequent installations, you can use the **`crtmqinst`** command to set the installation name before installing the product.

Windows On Windows systems, you can choose the installation name during the installation process.

The installation name can be up to 16 bytes and must be a combination of alphabetic and numeric characters in the ranges a-z, A-Z, and 0-9. You cannot use blank characters. The installation name must be unique, regardless of whether uppercase or lowercase characters are used. For example, the names `INSTALLATIONNAME` and `InstallationName` are not unique.

You can find out what installation name is assigned to an installation in a particular location using the **`dspmqinst`** command.

Installation descriptions

Each installation can also have an installation description. This description can give more detailed information about an installation in cases where the installation name cannot provide enough information. These descriptions can be up to 64 single-byte characters, or 32 double-byte characters. The default installation description is blank. You can set the installation description using the **`setmqinst`** command.

crtmqinst

Installation location on Multiplatforms

Multi

You can install IBM MQ into the default location. Alternatively, you can install into a custom location during the installation process. The location where IBM MQ is installed is known as the *MQ_INSTALLATION_PATH*.

Default location

The default location for the IBM MQ product code is shown in the following table:

Table 29. Installation location of IBM MQ

Platform	Installation location
AIX AIX	`/usr/mqm`
Linux HP-UX Solaris Linux , HP-UX, and Solaris	`/opt/mqm`
IBM i IBM i	`/QIBM/ProdData/mqm`
Windows Windows systems	`C:\Program Files\IBM\MQ`
Windows Windows data directories	`C:\ProgramData\IBM\MQ`

Important: Windows For Windows installations, the directories are as stated, unless there is a previous installation of the product that still contains registry entries or queue managers, or both. In this situation, the new installation uses the old data directory location. For more information, see Program and data directory locations.

IBM i On IBM i, IBM MQ can only be installed in the default location. For more information about the directory structure of IBM i, see Directory structure on IBM i

UNIX Linux On UNIX and Linux systems, working data is stored in `/var/mqm`, but you cannot change this location. For more information about the directory structure of UNIX and Linux systems, see Directory structure on UNIX and Linux systems.

Custom location installation

For an installation into a custom location, the path specified must either be an empty directory, or a path that does not exist. The length of the path is limited to 256 bytes. Permissions on the path must be such that the user mqm and users in the mqm group can access the directories.

- UNIX Linux On UNIX and Linux systems, the path must not contain spaces.
- AIX On AIX, the product is installed into a User Specified Installation Location (USIL), which can be either an existing USIL or a new USIL that is automatically created by the installation process. If a custom location is specified, the product location is the path specified during installation, plus `/usr/mqm`.

  For example, the path specified is `/usr/custom_location`. The *`MQ_INSTALLATION_PATH`* is `/usr/custom_location/usr/mqm`.

  Access permissions for the USIL directory should be set to rwx for user and r-x for group and others (755).
- HP-UX Linux Solaris Windows On Windows, Linux, HP-UX, and Solaris, the product location is the same path as specified during installation.

  For example, on Linux, the path specified is `/opt/custom_location`. The *`MQ_INSTALLATION_PATH`* is `/opt/custom_location`.
- Linux Solaris HP-UX On Linux, Solaris, and HP-UX, you can install IBM MQ into a non empty MQ_INSTALLATION_PATH directory.

  Linux Solaris On Linux and Solaris you do this by setting the environment variable AMQ_OVERRIDE_EMPTY_INSTALL_PATH to 1 before starting the installation.

  HP-UX On HP-UX you need to create the file `/tmp/AMQ_OVERRIDE_EMPTY_INSTALL_PATH` before starting the installation.

  Note, that a non empty directory in this context, indicates a directory which contains system files and directories.

For each installation, all of the IBM MQ components that you require must be installed in the same location.

For more information about how to install to a custom location, see the installation topics for the appropriate platform.

Additional location restrictions

New IBM MQ installations should not be located in the following paths:
- In a path that is a subdirectory of another existing installation.
- In a path that is part of the direct path to an existing installation.
- In a path that is a subdirectory of the default location, for example:
  - AIX /usr/mqm on AIX
  - HP-UX Linux Solaris /opt/mqm on Linux, Solaris and HP-UX platforms
- In a directory or subdirectory that is, or might later be used by another product, for example, an IBM Db2 installation, or operating system component.

HP-UX Linux Solaris An installation should not be located in /opt/mqm/v80, /opt/mqm/v75, /opt/mqm/inst2/mq71, or other directory located under /opt/mqm on Linux, Solaris and HP-UX platforms.

If IBM MQ is installed in /opt/IBM/MQ/installations/1, you cannot install in /opt/IBM/MQ/installations/1/a. Additionally, you should not install a new installation to /opt/IBM/MQ. However, you can install a new installation in /opt/IBM/MQ/installations/2 or /opt/IBM/MQnew because neither of these is a part of the direct path /opt/IBM/MQ/installations/1.

You must not install to any directory located under /opt/IBM/db2.

The reason an installation should not be located in a path that is a subdirectory of the default location is to avoid the risk if you later decide to install IBM MQ into the default location, and cannot then do so. If you do subsequently install into the default location, because IBM MQ has full access rights over the installation directory, existing files might be replaced or deleted. Scripts that you might subsequently run to uninstall IBM MQ might remove the installation directory at the end of the script.

Multiple installations on UNIX, Linux, and Windows

ULW

On UNIX, Linux, and Windows, it is possible to have more than one copy of IBM MQ on a system.

You can choose where each copy of IBM MQ is installed, but each copy must be in a separate installation location. A maximum of 128 installations of IBM MQ can exist on a single machine at a time. One installation can be an installation of IBM WebSphere MQ Version 7.0.1, Fix Pack 6, or later. You have a choice:

- Keep the simplicity of maintaining and managing a single installation of IBM MQ on a machine.
- Take advantage of the flexibility that is offered by enabling multiple IBM MQ installations.

Decisions to make before installing

Before you install multiple copies of IBM MQ, you must make several decisions:

Will you have a copy of IBM WebSphere MQ Version 7.0.1 on the system?
When IBM WebSphere MQ Version 7.0.1, Fix Pack 6, or later, is installed on the system, there are a number of restrictions to consider:

- Linux UNIX On UNIX and Linux systems, IBM WebSphere MQ Version 7.0.1 must be installed in the default location.

- IBM WebSphere MQ Version 7.0.1 must be the first installation on a system. You cannot install IBM WebSphere MQ Version 7.0.1 after installing Version 7.1, or later. If you uninstall version Version 7.0.1, it cannot be reinstalled while a later version of IBM MQ is installed.
- IBM WebSphere MQ Version 7.0.1 is automatically the primary installation. You cannot select another installation as the primary installation while IBM WebSphere MQ Version 7.0.1 is installed.

Where will you install each copy of IBM MQ ?
You can choose the installation location for your installations at Version 7.1, or later. For more information, see "Installation location on Multiplatforms" on page 198.

Do you need a primary installation?
A primary installation is an installation to which system-wide locations refer.

For more information, see "Primary installation on UNIX, Linux, and Windows" on page 202.

How will your applications connect?
You need to consider how your applications locate the appropriate IBM MQ libraries. For more information, see Connecting applications in a multiple installation environment, and Connecting .NET applications in a multiple installation environment.

Do your existing exits need changing?
If IBM MQ is not installed in the default location, your exits need to be updated. For more information, see Writing exits and installable services on UNIX, Linux, and Windows.

Which queue manager will be associated with which installation?
Each queue manager is associated with a particular installation. The installation that a queue manager is associated with limits that queue manager so that it can be administered only by commands from that installation. For more information, see Associating a queue manager with an installation.

How will you set up your environment to work with each installation?
With multiple installations on a system, you need to consider how you will work with particular installations, and how you will issue commands from that installation. You can either specify the full path to the command, or you can use the **`setmqenv`** or **`crtmqenv`** command to set environment variables. Setting the environment variables allows you to omit the path to the commands for that installation. For more information, see setmqenv, and crtmqenv.

When you have answered these questions, you can install IBM MQ after you have read "IBM MQ installation overview" on page 192.

If you have existing installations of IBM MQ and you want to use the multiple installation capability to migrate from one version of IBM MQ to another version, see one of the following platform-specific topics:

- ULW Multi-installation queue manager coexistence on UNIX, Linux, and Windows
- NSS Client "Planning your client installation on HP Integrity NonStop Server" on page 252

The IBM message service client for .NET support pack and multiple installations

For multiple version support, on IBM WebSphere MQ Version 7.1 or later, the *Java and .NET Messaging and Web Services* feature must be installed with the IBM MQ product. For more information about installing the .NET feature, see Installing IBM MQ classes for .NET.

Primary installation on UNIX, Linux, and Windows

ULW

On systems that support multiple installations of IBM MQ (UNIX, Linux, and Windows), the primary installation is the one to which IBM MQ system-wide locations refer. Having a primary installation is optional, but convenient.

Before IBM WebSphere MQ Version 7.1, only one instance of the product could be installed at any time. On Windows systems, several global environment variables were set to point to that installation. On UNIX and Linux systems, symbolic links were added to `/usr/lib`, `/usr/bin`, and `/usr/include`, also pointing at that single installation.

From Version 7.1, you can install multiple versions of IBM MQ on UNIX, Linux, and Windows. It is possible to have more than one installation of IBM MQ on one of these systems at any time and, optionally, to configure one of these installations as the primary installation. Environment variables and symbolic links pointing to a single installation are less meaningful when multiple versions exist. However, some functions require these system-wide locations to work. For example, custom user scripts for administering IBM MQ, and third party products. These functions work only on the primary installation.

Linux UNIX On UNIX and Linux systems, if you set an installation as the primary installation, symbolic links to the external libraries and control commands of that installation are added into `/usr/lib`, and `/usr/bin`. If you do not have a primary installation, the symbolic links are not created. For a list of the symbolic links that are made to the primary installation, see "External library and control command links to primary installation on UNIX and Linux" on page 206.

Windows On Windows systems, the global environmental variables point to the directories into which the primary installation was installed. These environment variables are used to locate IBM MQ libraries, control commands, and header files. Additionally, on Windows systems, some features of the operating system require the central registration of interface libraries that are then loaded into a single process. With multiple versions of IBM MQ, there would be conflicting sets of IBM MQ libraries. The features would try to load these conflicting sets of libraries into a single process. Therefore, such features can be used only with the primary installation. For details about some of the features that are limited to use with the primary installation, see "Features that can be used only with the primary installation on Windows" on page 209.

If you have an installation of IBM WebSphere MQ Version 7.0.1 on the system, this installation is automatically the primary installation. The primary installation cannot be changed while Version 7.0.1 is installed. If all the installations on the system are at Version 7.1, or later, you can choose whether to have a primary installation. Consider the options in Table 30 on page 203.

Table 30. Primary installation options

Options	Valid installation configurations		More information
	Primary	Non-primary	
Single installation of Version 7.1, or later.	Version 7.1, or later.	None	If you want to continue working with a single installation in the same way as previous releases, configure your installation as the primary installation. For information about this option, see Single installation of IBM WebSphere MQ Version 7.1, or later, configured as the primary installation
	None	Version 7.1, or later.	If you want to continue working with a single installation, but do not want symbolic links or global environment variables created for you, configure your installation as non-primary. For information about the implications of this option, see Single installation of IBM WebSphere MQ Version 7.1, or later, configured as non-primary
Multiple installations: Version 7.0.1 and Version 7.1, or later.	Version 7.0.1	Version 7.1, or later.	If you want to have multiple installations of IBM MQ, with one at Version 7.0.1, the Version 7.0.1 installation is automatically the primary installation. While IBM WebSphere MQ Version 7.0.1 is installed, you cannot change which installation is the primary installation. For information about this option and its implications, see Multiple installations of IBM MQ, one at Version 7.0.1
Multiple installations: Version 7.1, or later.	Version 7.1, or later.	Version 7.1, or later.	If you want to have multiple installations of IBM MQ at Version 7.1 or greater, you can choose whether to make one of the installations primary. For information about this option, see Multiple installations of IBM WebSphere MQ Version 7.1, or later
	None	Version 7.1, or later.

Single installation of IBM WebSphere MQ Version 7.1, or later, configured as the primary installation
Marking an IBM MQ installation as primary adds symbolic links, or global environment variables to the system so that the IBM MQ commands and libraries used by applications are automatically available with minimum system setup required.

Single installation of IBM WebSphere MQ Version 7.1, or later, configured as non-primary
If you install IBM WebSphere MQ Version 7.1, or later, as non-primary you might have to configure a library path for applications to load IBM MQ libraries. On Windows, some product capabilities are available only when IBM MQ is configured as primary.

Multiple installations of IBM WebSphere MQ Version 7.1, or later
You can choose to have one of the IBM WebSphere MQ Version 7.1 installations configured as the primary installation. Your choice depends on how applications locate libraries.

Multiple installations of IBM MQ, one at Version 7.0.1
IBM WebSphere MQ Version 7.1, or later, can coexist with IBM WebSphere MQ Version 7.0.1 with some limitations.

Changing the primary installation

Single installation of Version 7.1, or later, configured as the primary installation: ULW

Marking an IBM MQ installation as primary adds symbolic links, or global environment variables to the system so that the IBM MQ commands and libraries used by applications are automatically available with minimum system setup required.

You decide where to install IBM MQ.

Where possible, configure applications and scripts to use the system search path to find the IBM MQ control commands or IBM MQ libraries. This configuration of applications and scripts provides maximum flexibility for undertaking future tasks such as migrating to the next release of IBM MQ, or installing a second installation. For more information about options for connecting your applications, see Connecting applications in a multiple installation environment.

Windows On Windows, the first installation is automatically configured as the primary installation.

Linux UNIX On UNIX and Linux platforms, the first installation onto a system must be manually configured to be the primary installation.

Set the primary installation using the **setmqinst** command. For more information, see Uninstalling, upgrading, and maintaining the primary installation.
Related information:
Changing the primary installation
Choosing an installation location
Planning your installation
Choosing an installation name

Single installation of Version 7.1, or later, configured as non-primary: ULW

If you install IBM WebSphere MQ Version 7.1, or later, as non-primary you might have to configure a library path for applications to load IBM MQ libraries. On Windows, some product capabilities are available only when IBM MQ is configured as primary.

Linux UNIX
UNIX and Linux systems

The implications of running a non-primary installation on UNIX and Linux are:
- Applications that locate their IBM MQ libraries using an embedded library path, for example, RPATH, cannot find those libraries if the following conditions are true:
  - IBM MQ is installed in a different directory from the directory specified in the RPATH
  - There are no symbolic links in /usr
- Where applications locate their libraries using an external library path, for example, LD_LIBRARY_PATH, you must configure the external library path to include the *MQ_INSTALLATION_PATH*/lib or *MQ_INSTALLATION_PATH*/lib64 directory. The **setmqenv** and **crtmqenv** commands can configure a number of environment variables in the current shell, including the external library path.
- Most IBM MQ processes run as setuid/setgid. As a result, when loading user exits they ignore the external library path. User exits that reference IBM MQ libraries can find those libraries only if they are found in the library path embedded within them. They would be resolved if there were a symbolic link in /usr. User exits that are intended to be run on IBM WebSphere MQ Version 7.1, or later can now be

built so that they do not refer to IBM MQ libraries at all. Instead they rely on IBM MQ to pass in function pointers to the IBM MQ functions that the exit can then use. For more information, see Writing exits and installable services on UNIX, Linux, and Windows.

For more information about options for connecting your applications, see Connecting applications in a multiple installation environment.

On UNIX and Linux platforms, the first installation onto a system is not automatically configured as the primary installation. However, a single symbolic link is included in `/usr/bin` to locate the **`dspmqver`** command. If you do not want any symbolic links, you must remove this link using the following command:

```
setmqinst -x -p MQ_INSTALLATION_PATH
```

Windows

Windows systems

The implications of running a non-primary installation on Windows are:
- Applications normally find their libraries using the external library path, `PATH`. There is no concept of an embedded library path or explicit library location. If the installation is non-primary, the global `PATH` environment variable does not contain the IBM MQ installation directory. For applications to find IBM MQ libraries, update the `PATH` environment variable to reference the IBM MQ installation directory. The **`setmqenv`** and **`crtmqenv`** commands can configure a number of environment variables in the current shell, including the external library path.
- Some product capabilities are available only when an installation is configured as the primary installation; see Features that can be used only with the primary installation on Windows.

By default, on Windows, the first installation is automatically configured as primary. You must manually deselect it as the primary installation.

setmqenv

crtmqenv

Choosing an installation name

Multiple installations of Version 7.1, or later: ULW

You can choose to have one of the IBM WebSphere MQ Version 7.1 installations configured as the primary installation. Your choice depends on how applications locate libraries.

The IBM MQ libraries, such as mqm, which ship with IBM WebSphere MQ Version 7.1 automatically use libraries of the level required by the queue manager to which they are connecting. This means that provided an application locates its IBM MQ libraries from a IBM WebSphere MQ Version 7.1 installation, it can connect to any queue manager on that system. Having one IBM WebSphere MQ Version 7.1 installation configured as primary ensures that if the application finds its IBM MQ interface library, the application can connect to any queue manager.

For more information about connecting applications in a multiple installation environment, see Connecting applications in a multiple installation environment.

The primary installation is not automatically changed when you uninstall the primary installation. If you want another installation to be the primary installation, you must manually set the primary installation using the **setmqinst** command. For more information, see Uninstalling, upgrading, and maintaining the primary installation.

Related information:

Changing the primary installation

Choosing an installation location

Multiple installations

Planning your installation

Choosing an installation name

Multiple installations, one at Version 7.0.1: ULW

IBM WebSphere MQ Version 7.1, or later, can coexist with IBM WebSphere MQ Version 7.0.1 with some limitations.

- On UNIX and Linux systems, Version 7.0.1 can be installed only in a fixed, default location, so you cannot install Version 7.1, or later, in that default location.
- IBM WebSphere MQ Version 7.0.1 is automatically configured as the primary installation. On UNIX and Linux systems, symbolic links are automatically created to the appropriate IBM MQ directories. On Windows, everything that the product provided is registered globally. IBM WebSphere MQ Version 7.0.1 must be installed in this way to work. So where IBM WebSphere MQ Version 7.0.1 is installed, a IBM WebSphere MQ Version 7.1, or later, installation cannot be made primary.

The libraries from IBM WebSphere MQ Version 7.1, or later, can work with any queue manager running under IBM WebSphere MQ Version 7.0.1, or later. If an application needs to connect to queue managers running under Version 7.0.1 as well as later versions, it can continue to operate normally if the following conditions are true:

- It locates IBM WebSphere MQ Version 7.1, or later, libraries at run time.
- It uses only functions available in Version 7.0.1.

For more information about connecting applications in a multiple installation environment, see Connecting applications in a multiple installation environment.

The primary installation is not automatically changed when you uninstall IBM WebSphere MQ Version 7.0.1. If you want another installation to be the primary installation, you must manually set the primary installation using the **setmqinst** command. For more information, see Uninstalling, upgrading, and maintaining the primary installation.

External library and control command links to primary installation on UNIX and Linux: Linux UNIX

On UNIX and Linux platforms the primary installation is the one to which links from the `/usr` file system are made. However, only a subset of those links created with previous releases are now made.

No links are created from `/usr/include` to any installation and only links to external libraries and documented control commands are made from `/usr/lib`, and where appropriate, `/usr/lib64` (external libraries) and `/usr/bin` (control commands).

In order to run these commands you must complete the following steps:

1. provide a full path to the command in an available IBM MQ installation,
2. use the `setmqenv` script to update your shell environment,
3. manually add the bin directory from an IBM MQ installation directory to your PATH,
4. run the **`setmqinst`** command as root to make one of your existing IBM MQ installations the primary installation.

External libraries

Links are made to the following external libraries, both 32-bit and 64-bit:
- libmqm
- libmqm_r
- libmqmxa
- libmqmxa_r
- libmqmax
- libmqmax_r
- libmqmcb

Some Windows operating-system features can be used only with the primary installation. This restriction is due to the central registration of interface libraries, which might conflict as a result of multiple versions of IBM MQ being installed.

Features that can be used only with the primary installation on Windows: Windows

Some Windows operating-system features can be used only with the primary installation. This restriction is due to the central registration of interface libraries, which might conflict as a result of multiple versions of IBM MQ being installed.

The .NET monitor

The IBM MQ .NET monitor can run in two different modes: transactional and non-transactional. The transactional mode uses MSDTC transaction coordination and requires that the .NET monitor is registered with COM+. The .NET monitor from the primary installation is the only .NET monitor that is registered with COM+.

Any attempt to run the .NET monitor in transactional mode with a non-primary installation results in the failure of the .NET monitor to enlist with MSDTC. The .NET monitor receives an `MQRC_INSTALLATION_MISMATCH` error, which in turn results in an AMQ8377 error message on the console.

COM/ActiveX interface classes

The COM/ActiveX interface classes are registered only for the primary installation. If there is an installation of IBM WebSphere MQ Version 7.0.1 on the system, the COM/ActiveX interface classes registered are not capable of connecting to queue managers running under other installations. If the primary installation is an installation of IBM WebSphere MQ Version 7.1 or later, the interface classes can connect to queue managers associated with any installation. Server COM/ActiveX applications are limited by this restriction, but client applications can connect to any queue manager.

Any attempt to start a COM/ActiveX application that uses libraries from installations other than the primary installation results in failure with an `MQRC_Q_MGR_NOT_AVAILABLE` error.

Related concepts:

"Primary installation on UNIX, Linux, and Windows" on page 202

On UNIX and Linux platforms the primary installation is the one to which links from the `/usr` file system are made. However, only a subset of those links created with previous releases are now made.

Uninstalling, upgrading, and maintaining the primary installation: ULW

On all platforms, if you uninstall the primary installation, it ceases to be the primary installation. You must run the **`setmqinst`** command to select a new primary installation. On Windows, if you update the primary installation, it continues to be the primary installation. If you apply a fix pack to the primary installation, it continues to be the primary installation.

Be cautious about the effect uninstalling or upgrading the primary installation has on applications. Applications might be using the linkage library of the primary installation to switch to the linkage library of another installation. If such an application is running, you might not be able to uninstall the primary installation. The operating system might have locked the link library of the primary installation on behalf of the application. If the primary installation has been uninstalled, an application that loads the IBM MQ libraries it requires by linking to the primary installation is not able to start.

The solution is to switch the primary installation to another installation before uninstalling. Stop, and restart applications that are linked through the previous primary installation before uninstalling it.

Windows

If you update the primary installation, it stops being the primary installation at the beginning of the update procedure. If, by the end of the update procedure, you have not made another installation primary, the upgraded installation is made primary again.

Maintenance

If you apply a fix pack to the primary installation, it stops being the primary installation at the beginning of the maintenance procedure. If, by the end of the maintenance procedure, you have not made another installation primary, the upgraded installation is made primary again.

Related concepts:

"Primary installation on UNIX, Linux, and Windows" on page 202
On systems that support multiple installations of IBM MQ (UNIX, Linux, and Windows), the primary installation is the one to which IBM MQ system-wide locations refer. Having a primary installation is optional, but convenient.

Changing the primary installation

IBM MQ maintenance tasks

Server-to-server links on UNIX, Linux, and Windows

For verifying a server-to-server verification, the communication links between the two systems must be checked. Before you can do the verification, you must ensure that the communications protocol is installed and configured on both systems.

The examples used in the verification tasks listed in this topic for UNIX, Linux, and Windows use TCP/IP.

The various communication protocols used by the supported platforms are as follows.

UNIX
: IBM MQ supports both TCP and SNA. If you do not use TCP, see Setting up communication on UNIX and Linux systems.

Linux
: IBM MQ for Linux supports TCP on all Linux platforms. On x86 platforms and Power platforms, SNA is also supported. If you want to use the SNA LU6.2 support on these platforms, you need the IBM Communications Server for Linux Version 6.2. The Communications Server is available as a PRPQ product from IBM. For more details, see Communications Server.

  If you do not use TCP, see Setting up communication on UNIX and Linux systems.

Windows **Windows**

IBM MQ for Windows supports TCP, SNA, NetBios, and SPX. If you do not use TCP, see Setting up communication for Windows.

Installation with a download image

Multi

You can perform an installation of IBM MQ from an installation image downloaded from Passport Advantage®.

Before you start installing, consider how you want to use IBM MQ and review the general Planning section.

Go to the Passport Advantage and Passport Advantage Express® web site for further information on how you:

- Acquire new IBM software licenses.
- Renew Software Subscription and Support and Fixed Term Licenses.
- Buy and renew technical support for some Selected Open Source and other non-warranted applications.
- Subscribe to IBM SaaS offerings and acquire IBM Appliances.

Passport Advantage is designed for larger enterprises and enterprises with multiple sites.

Passport Advantage Express is designed for smaller enterprises and single-site enterprises.

Downloading IBM MQ Version 9.0

Redistributable clients

Linux Windows

The IBM MQ redistributable client is a collection of runtime files that are provided in a `.zip` or `.tar` file that can be redistributed to third parties under redistributable license terms, which provides a simple way of distributing applications and the runtime files that they require in a single package.

What are the IBM MQ redistributable clients?

From IBM MQ Version 8.0.0, Fix Pack 4, native redistributable client runtime libraries are provided for Linux x86-64 and Windows 64-bit platforms to make it simple to distribute both applications and the required IBM MQ runtime libraries. A third package, which is not platform-specific, contains the runtime files that are required for the Java/JMS applications, including the IBM MQ resource adapter for JMS applications that are running under an application server.

The redistributable client that is supplied with IBM MQ is also a non-installed and relocatable image. Maintenance of a redistributable, non-installed image, is achieved through replacement; that is, you download newer versions of the runtime components when they are shipped.

A *redistributable* client implies distributing the required run time with an application both inside and outside of your environment.

A *relocatable* client implies putting the files somewhere else other than a fixed default location. For example, instead of installing into `/opt/` installing into `/usr/local`.

A *non-installed* client implies that you are not required to lay down client files, and that these files can be copied as required.

The IBM IPLA license agreement is extended for IBM MQ to enable you to download a number of additional runtime files from Fix Central.

Supported languages

You can use the files that are contained in the redistributable images to run the following client applications:
- C
- C++
- COBOL
- Java
- Java JMS
- Both fully managed and unmanaged .NET

Limitations

GSKit objects
No new GSKit objects are being shipped. Only the runtime files are shipped, both in a regular installation and with the redistributable client.

IBM JREs
No IBM JREs are being provided with the redistributable client.

If you want to run Java/JMS applications, you must provide your own runtime environment. Your JRE, that applications run under, must meet the current SOE requirements and are bound by any restrictions or limitations that apply.

Developing applications
All other files that support the development and distribution of applications (including copybooks, header files, and sample source code) are not included in the redistributable client and are not licensed for redistribution.

If you need to develop IBM MQ applications, you still need to perform a traditional installation so that you obtain the SDK files that are required to build client applications.

Windows **Windows C runtime libraries**
You might have these libraries on your machine already, but if you do not, you need to download and install the following Microsoft C/C++ runtime libraries:

- Microsoft Visual C++ Redistributable 2008
- Microsoft Visual C++ Redistributable 2012

The download links for the redistributable downloads for each of these libraries can be found at The latest supported Visual C++ downloads .

For more information about installing redistributable clients, see:

- Linux "Redistributable clients on Linux" on page 374
- Windows "Redistributable clients on Windows" on page 493

Before you install IBM MQ, you must choose which components to install and where to install them. You must also make some platform-specific choices.

"Installation location on Multiplatforms" on page 198
You can install IBM MQ into the default location. Alternatively, you can install into a custom location during the installation process. The location where IBM MQ is installed is known as the *MQ_INSTALLATION_PATH*.

Windows ".NET application runtime - Windows only" on page 494
Considerations when using the .NET application.

Related information:

Configuring the Redistributable Managed File Transfer Agent

Installation considerations for redistributable clients

Linux Windows

The Linux x86-64 image is shipped in a `LinuxX64.tar.gz` file, and the Windows 64-bit image is shipped in a `Win64.zip` file.

File names

The archive or `.zip` file names describe the file contents and equivalent maintenance levels.

CD For example, for Continuous Delivery, in IBM MQ Version 9.0.4 the client images are available under the following file names:

Linux **Linux x86-64**
`9.0.4.0-WS-MQC-Redist-LinuxX64.tar.gz`

Windows **Windows**
`9.0.4.0-WS-MQC-Redist-Win64.zip`

Linux Windows z/OS **Java**
`9.0.4.0-WS-MQC-Redist-Java.zip`

LTS For Long Term Support, in IBM MQ Version 9.0.0, Fix Pack 2 the client images are available under the following file names:

Linux **Linux x86-64**
`9.0.0.2-WS-MQC-Redist-LinuxX64.tar.gz`

Windows **Windows**
`9.0.0.2-WS-MQC-Redist-Win64.zip`

Java `9.0.0.2-WS-MQC-Redist-Java.zip`

Choosing the runtime files to distribute with an application

A script file named **genmqpkg** is provided by the redistributable client under the `bin` directory.

You can use the **genmqpkg** script to generate a smaller subset of files that are tailored to the needs of the application, for which the files are intended to be distributed.

You are asked a series of interactive `Yes` or `No` questions to determine the runtime requirements for an IBM MQ application.

Finally, **genmqpkg** asks you to supply a new target directory, where the script duplicates the required directories and files.

Important: IBM support is only able to provide assistance with the full, unmodified set of files contained within the redistributable client packages.

Other considerations

The default data path of a non-installed client is:

Linux **Linux x86-64**
`$HOME/IBM/MQ/data`

Windows **Windows**
`%HOMEDRIVE%\%HOMEPATH%\IBM\MQ\data`

Important: A redistributable client runtime co-exists with a full IBM MQ client or server installation, provided that they are installed in different locations. However, unpacking a redistributable image into the same location as a full IBM MQ installation is not supported.

On Linux the `ccsid.tbl` used to define the supported CCSID conversions is traditionally expected to be found in the `UserData` directory structure, along with error logs, trace files, and so on. The `UserData` directory structure is populated by unpacking the redistributable client, and so, if the file is not found in its usual location, the redistributable client falls back to locate the file in the `/lib` subdirectory of the installation.

Classpath changes

The classpath used by **`dspmqver`**, **`setmqenv`**, and **`crtmqenv`** commands adds the `com.ibm.mq.allclient.jar` to the environment, immediately following the `com.ibm.mq.jar` and `com.ibm.mqjms.jar`.

An example of **`dspmqver`** output from the redistributable client on Linux:

```
Name:        IBM MQ
Version:     8.0.0.4
Level:       p800-804-L150909
BuildType:   IKAP - (Production)
Platform:    IBM MQ for Linux (x86-64 platform)
Mode:        64-bit
O/S:         Linux 2.6.32.59-0.7-default
InstName:    MQNI08000004
InstDesc:    IBM MQ V8.0.0.4 (Redistributable)
Primary:     No
InstPath:    /Development/johndoe/unzip/unpack
DataPath:    /u/johndoe/IBM/MQ/data
MaxCmdLevel: 802
```

An example of **`dspmqver`** output from the redistributable client on Windows:

```
Name:        IBM MQ
Version:     8.0.0.4
Level:       p800-804-L150909
BuildType:   IKAP - (Production)
Platform:    IBM MQ for Windows (x64 platform)
Mode:        64-bit
O/S:         Windows 7 Professional x64 Edition, Build 7601: SP1
InstName:    MQNI08000004
InstDesc:    IBM MQ V8.0.0.4 (Redistributable)
Primary:     No
InstPath:    C:\Users\johndoe\Desktop\Redist
DataPath:    C:\Users\johndoe\IBM\MQ\data
MaxCmdLevel: 802
```

Related concepts:

Installing and uninstalling IBM MQ on AIX

AIX

Installation tasks that are associated with installing IBM MQ on AIX systems are grouped in this section.

About this task

To prepare for installation and to install the IBM MQ components, complete the following tasks.

For information about how to uninstall IBM MQ, see "Uninstalling or modifying IBM MQ on AIX" on page 247.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See "Checking requirements on AIX" on page 218.
2. Plan your installation.

- As part of the planning process, you must choose which components to install and where to install them. See "IBM MQ components for AIX."
- You must also make some platform-specific choices. See "Planning to install IBM MQ on AIX" on page 220.

3. Prepare your system for installation of IBM MQ. See "Preparing the system on AIX" on page 221.
4. Install IBM MQ server. See "Installing IBM MQ server on AIX" on page 225.
5. Optional: Install an IBM MQ client. See "Installing an IBM MQ client on AIX" on page 231.
6. Verify your installation. See "Verifying an IBM MQ installation on AIX" on page 233.

IBM MQ components for AIX

AIX

You can select the components that you require when you install IBM MQ.

Important: See IBM MQ license information for details of what each purchase of IBM MQ entitles you to install.

On AIX each component of IBM MQ is represented by a fileset. Table 31 shows the filesets that are available when installing an IBM MQ server or client on an AIX system:

Table 31. IBM MQ filesets for AIX systems

Component	Description	Server media	Client media	Fileset name
Runtime	Contains files that are common to both server and client installations. **Note:** This component must be installed.	✓	✓	mqm.base.runtime
Server	You can use the server to run queue managers on your system and connect to other systems over a network. Provides messaging and queuing services to applications, and support for IBM MQ client connections.	✓		mqm.server.rte
Standard Client	The IBM MQ MQI client is a small subset of IBM MQ, without a queue manager, that uses the queue manager and queues on other (server) systems. It can be used only when the system it is on is connected to another system that is running a full server version of IBM MQ. The client and the server can be on the same system if required.	✓	✓	mqm.client.rte
SDK	The SDK is required for compiling applications. It includes sample source files, and the bindings (files .H, .LIB, .DLL, and others), that you need to develop applications to run on IBM MQ.	✓	✓	mqm.base.sdk
Sample programs	The sample application programs are needed if you want to check your IBM MQ installation using the verification procedures.	✓	✓	mqm.base.samples
Java messaging	The files needed for messaging using Java (includes Java Message Service).	✓	✓	mqm.java.rte
Man pages	UNIX man pages, in U.S. English, for: control commands MQI calls MQSC commands	✓	✓	mqm.man.en_US.data

Table 31. IBM MQ filesets for AIX systems (continued)

Component	**Description**	**Server media**	**Client media**	**Fileset name**
Java JRE	A Java Runtime Environment that is used by those parts of IBM MQ that are written in Java.	✓	✓	mqm.jre.rte
Message Catalogs	For available languages, see the table of message catalogs that follows.	✓	✓	
IBM Global Security Kit	IBM Global Security Kit V8 Certificate and TLS, Base Runtime.	✓	✓	mqm.gskit.rte
Telemetry Service	MQ Telemetry supports the connection of Internet Of Things (IOT) devices (that is, remote sensors, actuators and telemetry devices) that use the IBM MQ Telemetry Transport (MQTT) protocol. The telemetry service, which is also know as the MQXR service, enables a queue manager to act as an MQTT server, and communicate with MQTT client apps. A set of MQTT client libraries is also available in the IBM Messaging Telemetry Clients SupportPac. These libraries help you write the MQTT client apps that IOT devices use to communicate with MQTT servers. See also "Installation considerations for MQ Telemetry" on page 538.	✓		mqm.xr.service
Managed File Transfer	MQ Managed File Transfer transfers files between systems in a managed and auditable way, regardless of file size or the operating systems used. For information about the function of each component, see Managed File Transfer product options.	✓		mqm.ft.agent mqm.ft.base mqm.ft.logger mqm.ft.service mqm.ft.tools
Advanced Message Security	Provides a high level of protection for sensitive data flowing through the IBM MQ network, while not impacting the end applications. You must install this component on all IBM MQ installations that host queues you want to protect. You must install the IBM Global Security Kit component on any IBM MQ installation that is used by a program that puts or gets messages to or from a protected queue, unless you are using only Java client connections. You must install the **Java JRE** component to install this component.	✓		mqm.ams.rte
V 9.0.0 AMQP Service	Install this component to make AMQP channels available. AMQP channels support MQ Light APIs. You can use AMQP channels to give AMQP applications access to the enterprise-level messaging facilities provided by IBM MQ.	✓		mqm.amqp.rte
V 9.0.4 REST API and Console	Adds HTTP based administration for IBM MQ through the REST API and IBM MQ Console.	✓		mqm.web.rte

Table 32. IBM MQ message catalogs for AIX systems

Message catalog language	Component name
Brazilian Portuguese	mqm.msg.pt_BR
Czech	mqm.msg.cs_CZ
French	mqm.msg.fr_FR
German	mqm.msg.de_DE
Hungarian	mqm.msg.hu_HU
Italian	mqm.msg.it_IT
Japanese	mqm.msg.ja_JP, mqm.msg.Ja_JP
Korean	mqm.msg.ko_KR
Polish	mqm.msg.pl_PL
Russian	mqm.msg.ru_RU
Spanish	mqm.msg.es_ES
Simplified Chinese	mqm.msg.zh_CN, mqm.msg.Zh.CN
Traditional Chinese	mqm.msg.zh_TW, mqm.msg.Zh_TW
U.S. English	mqm.msg.en_US

Before you install IBM MQ, you must choose which components to install and where to install them. You must also make some platform-specific choices.

Checking requirements on AIX

AIX

Before you install IBM MQ on AIX, you must check for the latest information and system requirements.

About this task

A summary of the tasks that you must complete to check system requirements is listed here with links to further information.

Procedure

1. Check that you have the latest information, including information on hardware and software requirements. See "Where to find product requirements and support information" on page 195.
2. Check that your systems meet the initial hardware and software requirements for AIX. See "Hardware and software requirements on AIX systems" on page 219.

   The supported hardware and software environments are occasionally updated. See System Requirements for IBM MQ for the latest information.
3. Check that your systems have sufficient disk space for the installation. See Disk space requirements.
4. Check that you have the correct licenses. See "License requirements" on page 194 and IBM MQ license information.

What to do next

When you have completed these tasks, you are ready to start preparing your system for installation. For the next steps in installing IBM MQ, see "Preparing the system on AIX" on page 221.

Related concepts:

"IBM MQ installation overview" on page 192
An overview of concepts and considerations for installing IBM MQ, with links to instructions on how to install, verify, and uninstall IBM MQ on each of the supported platforms.

Related information:

IBM MQ maintenance tasks

Hardware and software requirements on AIX systems

AIX

Before you install IBM MQ, check that your system meets the hardware and operating system software requirements for the particular components you intend to install.

For hardware and software requirements, see System Requirements for IBM MQ.

IBM MQ does not support host names that contain spaces. If you install IBM MQ on a system with a host name that contains spaces, you are unable to create any queue managers.

Java Message Service and SOAP transport

If you want to use Java Message Service and SOAP support, you need an IBM Java 7 SDK and Runtime Environment Version 7.0 or later.

V 9.0.0 Java 8 is bundled with IBM MQ Version 9.0 but client components are built with Java 7 compatibility flags on.

For development, a JDK is required, and a JRE is required for running. The JRE does not need to be the JRE installed with IBM MQ, but has to be one from the supported list.

For a list of supported JDKs, see System Requirements for IBM MQ.

For further information about SOAP with IBM MQ, see IBM MQ transport for SOAP.

You can check the version installed using the following command:

```
java -version
```

Transport Layer Security (TLS)

If you want to use the TLS support, you need the IBM Global Security Kit (GSKit) V8 package. This package is supplied with IBM MQ as one of the components available for installation.

Unicode support on AIX

If you need to convert data to and from Unicode on your system, you must install the following file sets:

```
bos.iconv.ucs.com   Unicode converters for AIX sets
bos.iconv.ucs.ebcdic Unicode converters for EBCDIC sets
bos.iconv.ucs.pc   Unicode converters for PC sets
```

Check that the server environment meets the prerequisites for installing IBM MQ for Windows and install any prerequisite software that is missing from your system from the server DVD.

Related tasks:

"Checking requirements on Windows" on page 444
Before you install IBM MQ on Windows, you must check for the latest information and system requirements.

Planning to install IBM MQ on AIX

AIX

Before you install IBM MQ on AIX, you must choose which components to install and where to install them. You must also make some platform-specific choices.

About this task

The following steps provide links to additional information to help you with planning your installation of IBM MQ on AIX.

As part of your planning activities, make sure that you review the information on hardware and software requirements for the platform on which you are planning to install IBM MQ. For more information, see "Checking requirements on AIX" on page 218.

Procedure

- Decide which IBM MQ components and features to install. See "IBM MQ components and features" on page 192.

  Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. For more information, see "License requirements" on page 194 and IBM MQ license information.
- Review the options for naming your installation. In some cases, you can choose an installation name to use instead of the default name. See "Installation name on UNIX, Linux, and Windows" on page 197.
- Review the options and restrictions for choosing an installation location for IBM MQ. For more information, see "Installation location on Multiplatforms" on page 198.
- If you plan to install multiple copies of IBM MQ, see "Multiple installations on UNIX, Linux, and Windows" on page 200.
- If you already have a primary installation, or plan to have one, see "Primary installation on UNIX, Linux, and Windows" on page 202.
- Make sure that the communications protocol needed for server-to-server verification is installed and configured on both systems that you plan to use. For more information, see "Server-to-server links on UNIX, Linux, and Windows" on page 210.

Preparing the system on AIX

AIX

On AIX systems, you might have to complete several tasks before you install IBM MQ. You might also want to complete other tasks, depending on your installation intentions.

About this task

The tasks that you perform to prepare your systems for installation are listed here. Complete the appropriate tasks for your platform before installing.

Procedure

1. Set up a user ID of the name mqm, with a primary group of mqm. See "Setting up the user and group on AIX."
2. Create file systems for both the product code and working data to be stored. See "Creating file systems on AIX" on page 223.
3. Configure any additional settings needed for your AIX system. See "Configuring and tuning the operating system on AIX" on page 224.

What to do next

When you have completed the tasks to prepare the system, you are ready to start installing IBM MQ. To install a server, see "Installing IBM MQ server on AIX" on page 225. To install a client, see "Installing an IBM MQ client on AIX" on page 231.

Related information:

Planning

Maintaining and migrating

IBM MQ maintenance tasks

Setting up the user and group on AIX

AIX

On AIX systems, IBM MQ requires a user ID of the name mqm, with a primary group of mqm. The mqm user ID owns the directories and files that contain the resources associated with the product.

Creating the user ID and group

Set the primary group of the mqm user to the group mqm.

If you are installing IBM MQ on multiple systems you might want to ensure each UID and GID of mqm has the same value on all systems. If you are planning to configure multi-instance queue managers, it is essential the UID and GID are the same from system to system. It is also important to have the same UID and GID values in virtualization scenarios.

AIX

You can use the System Management Interface Tool (smit), for which you require root authority.

1. To create the mqm group, display the required window using this sequence:

   ```
   Security & Users
   Groups
   Add a Group
   ```

   Set the group name field to mqm.
2. To create the user mqm, display the required window using this sequence:

```
Security & Users
Users
Add a User
```

Set the user name field to mqm.

3. To add a password to the new user ID, display the required window using this sequence:

   ```
   Security & Users
   Passwords
   Change a User's Password
   ```

   Set the password as required.

Adding existing user IDs to the group

If you want to run administration commands, for example **crtmqm** (create queue manager) or **strmqm** (start queue manager), your user ID must be a member of the mqm group. This user ID must not be longer than 12 characters.

Users do not need mqm group authority to run applications that use the queue manager; it is needed only for the administration commands.

AIX

You can use smit to add an existing user ID to the mqm group. Display the required menu using this sequence:

```
Security & Users
Users
Change / Show Characteristics of a User
```

Type the name of the user in the **User Name** field and press **Enter**. Add mqm to the **Group SET** field, which is a comma-separated list of the groups to which the user belongs. Users do not need to have their primary group set to mqm. If mqm is in their set of groups, they can use the administration commands.

Log files created by MQ Telemetry service

The **umask** setting of the user ID that creates a queue manager will determine the permissions of the Telemetry log files generated for that queue manager. Even though the ownership of the log files will be set to mqm.

Related concepts:

"Creating file systems on AIX" on page 223
Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

When installing IBM MQ on AIX systems, there are some additional settings that must be configured.

Related information:

"Configuring and tuning the operating system on Solaris" on page 409
Configure Solaris systems with the resource limits required by IBM MQ.

Creating file systems on AIX

AIX

Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

Determining the size of a server installations file system

To determine the size of the /var/mqm file system for a server installation, consider:
- The maximum number of messages in the system at one time.
- Contingency for message buildups, if there is a system problem.
- The average size of the message data, plus 500 bytes for the message header.
- The number of queues.
- The size of log files and error messages.
- The amount of trace that is written to the /var/mqm/trace directory.

Storage requirements for IBM MQ also depend on which components you install, and how much working space you need. For more details, see Disk space requirements.

Creating a file system for the working data

Before you install IBM MQ, create and mount a file system called /var/mqm which is owned by the user mqm in the group mqm; see "Setting up the user and group on AIX" on page 221. This file system is used by all installations of IBM MQ on a system. If possible, use a partition strategy with a separate volume for the IBM MQ data. This means that other system activity is not affected if a large amount of IBM MQ work builds up. Configure the directory permissions to permit the mqm user to have full control, for example, file mode 755. These permissions will then be updated during the IBM MQ installation to match the permissions required by the queue manager.

Creating separate file systems for errors and logs

You can also create separate file systems for your log data (/var/mqm/log) and error files (/var/mqm/errors). If possible, place these directories on different physical disks from the queue manager data (/var/mqm/qmgrs) and from each other.

If you create separate file systems the /var/mqm/errors directory can be NFS mounted. However, if you choose to NFS-mount /var/mqm/errors, the error logs might be lost if the network fails.

You can protect the stability of your queue manager by having separate file systems for:
- /var/mqm/errors
- /var/mqm/trace
- /var/mqm/qmgrs
- /var/mqm/log

In the case of /var/mqm/errors, it is rare that this directory receives large quantities of data. But it is sometimes seen, particularly if there is a severe system problem leading to IBM MQ writing a lot of diagnostic information in to .FDC files. In the case of /var/mqm/trace, files are only written here when you use **strmqtrc** to start tracing IBM MQ.

You can obtain better performance of normal IBM MQ operations (for example, syncpoints, MQPUT, MQGET of persistent messages) by placing the following on separate disks:
- /var/mqm/qmgrs

- /var/mqm/log

In the rare event that you need to trace an IBM MQ system for problem determination, you can reduce performance impact by placing the /var/mqm/trace file system on a separate disk.

If you are creating separate file systems, allow a minimum of 30 MB of storage for /var/mqm, 100 MB of storage for /var/mqm/log, and 10 MB of storage for /var/mqm/errors. The 100 MB minimum allowance of storage for /var/mqm/log is the absolute minimum required for a single queue manager and is not a recommended value. The size of a file system must be scaled according to the number of queue managers that you intend to use, the number of pages per log file, and the number of log files per queue manager.

If you want to use individual queues that hold more than 2 GB of data, you must enable /var/mqm to use large files.

For more information about file systems, see File system support.

The size of the log file depends on the log settings that you use. The minimum sizes are for circular logging using the default settings. For more information about log sizes, see Calculating the size of the log.

Related concepts:

"Setting up the user and group on AIX" on page 221
On AIX systems, IBM MQ requires a user ID of the name mqm, with a primary group of mqm. The mqm user ID owns the directories and files that contain the resources associated with the product.

Related tasks:

"Configuring and tuning the operating system on AIX"
When installing IBM MQ on AIX systems, there are some additional settings that must be configured.

Configuring and tuning the operating system on AIX

AIX

When installing IBM MQ on AIX systems, there are some additional settings that must be configured.

About this task

When you install IBM MQ on AIX systems, you must configure the following operating system settings:
- File descriptors
- System resource limits

Procedure

- Increase the process limit for the number of file descriptors.

  When running a multi-threaded process such as the agent process, you might reach the soft limit for file descriptors. This limit gives you the IBM MQ reason code MQRC_UNEXPECTED_ERROR (2195) and, if there are enough file descriptors, an IBM MQ FFST file.

  To avoid this problem, increase the process limit for the number of file descriptors. You must alter the nofiles attribute in /etc/security/limits to 10,000 for the mqm user ID, or in the default stanza. To alter the number of file descriptors, complete the following steps:

  1. Check the maximum number of file descriptors available to a process running as mqm:
     ```
     lsuser -a nofiles mqm
     ```
  2. Set the value to at least 10240:
     ```
     chuser nofiles_hard=10240 mqm
     chuser nofiles=10240 mqm
     ```
- Set the system resource limit for data segment and stack segment to unlimited using the following commands in a command prompt:

```
ulimit -d unlimited
ulimit -s unlimited
```

Attention: For an mqm user ID other than root, the value unlimited might not be permitted.

What to do next

You can check your system configuration using the mqconfig command.

For more information on configuring your system, see the technote How to configure UNIX and Linux systems for IBM MQ.

Related concepts:

"Setting up the user and group on AIX" on page 221
On AIX systems, IBM MQ requires a user ID of the name mqm, with a primary group of mqm. The mqm user ID owns the directories and files that contain the resources associated with the product.

"Creating file systems on AIX" on page 223
Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

Installing IBM MQ server on AIX

AIX

You can install an IBM MQ server on AIX either interactively or silently.

Before you begin

- Before you start the installation procedure, make sure that you complete the necessary steps that are outlined in "Preparing the system on AIX" on page 221.
- IBM MQ can be installed into System Workload Partitions (WPARs) with both shared and private file systems. For installation into private file systems, IBM MQ can be installed directly into the System WPAR by using the procedure that is outlined in this topic. There are some limitations for shared /usr file systems:
  - The **dspmqinst** and **dspmqver** commands might report the primary installation incorrectly when compared with the symbolic links in /usr/bin. To synchronize the reporting of the primary installation in a System WPAR and the global environment, run **setmqinst** with the **-i** or **-x** parameter, on the individual zones.
  - You cannot change the primary installation within a WPAR. You must change the primary installation through the global environment, which has appropriate write access to /usr/bin.

  Note: During installation to a non-default location, ATTENTION messages that relate to **errupdate** or **trcupdate** are produced. These messages are not errors. However, AIX system trace for IBM MQ is not supported for installations in a non-default location, and IBM MQ trace must be used for problem determination.
- If you install a copy of IBM MQ server for AIX by using Electronic Software Download, obtained from Passport Advantage, you need to:
  - Decompress the tar file, by using the following command:
    ```
    decompress   WS_MQ_V9.0_TRIAL_FOR_AIX_ML.tar.Z
    ```
  - Extract the installation files from the tar file, by using the following command:
    ```
    tar -xvf   WS_MQ_V9.0_TRIAL_FOR_AIX_ML.tar
    ```
  - Use the installation tools **installp** or **smit** to install the IBM MQ server for AIX.

Tip: If you find that the Function keys do not work in SMIT, try pressing Esc and the Function key number to emulate the required Function key.

About this task

IBM MQ is supplied as a set of filesets that are installed by using the standard AIX installation tools. The procedure uses the system management interface tool (SMIT), but you can choose to use **installp**, **geninstall** or the web-based System Manager. You can select which components you want to install. The components and file sets are listed in "IBM MQ components for AIX" on page 216.

This procedure installs IBM MQ into the default location of /usr/mqm.

If you want to install IBM MQ in any one of the following situations:
- As the first installation on your system by using **installp**
- As the first installation on your system, and you are installing the product to a location that is not the default location
- Alongside an existing installation

Use the procedure that is described in "Installing the IBM MQ server silently on AIX" on page 227.

If you want to carry out a side-by-side installation, alongside an existing installation of IBM MQ in the default location, the existing installation must be IBM WebSphere MQ Version 7.0.1, Fix Pack 6, or later.

You must install the second version of the product in a location that is not the default. To create the non-default installation location you must use the **mkusil** command, which is available only from the command line.

You can then use **installp** (see "Installing the IBM MQ server silently on AIX" on page 227), or SMIT if you select the **Relocatable Software Installation** menu item.

If you want to carry out a single stage migration, refer to Single-stage migration from Version 7.0.1 or later to the latest version on UNIX, Linux, and Windows.

Procedure

1. Log in as root, or switch to the superuser by using the **su** command.
2. Set your current directory to the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Select the required smit window by using the following sequence:
   ```
   Software Installation and Maintenance
   Install and Update Software
   Install and Update from ALL Available Software
   ```
4. Specify the input directory in the **INPUT device / directory for software** field.
   a. Enter a period character **.**
   b. Press the **Enter** key
5. List the software in the **SOFTWARE to install** field:
   a. Enter **.**
   b. Press **F4**
6. Select the filesets to install from the list. If you require messages in a language different from the language that is specified by the locale that is selected on your system, ensure that you include the appropriate message catalog. Enter **ALL** to install all applicable filesets.
7. View the license agreement:
   a. Change **Preview new LICENSE agreements?** to **yes**
   b. Press **Enter**

8. Accept the license agreements and install IBM MQ:
   a. Change **ACCEPT new license agreements?** to **yes**
   b. Change **Preview new LICENSE agreements?** to **no**
   c. Press **Enter**

What to do next

- If you chose this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:
  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```
  where *MQ_INSTALLATION_PATH* represents the directory where IBM MQ is installed.

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. For more information, see "Verifying an IBM MQ installation on AIX" on page 233.

Changing the primary installation

Installing the IBM MQ server silently on AIX

AIX

You can carry out a non-interactive installation of the IBM MQ server from the command line using the AIX **installp** command. A non-interactive installation is also known as a silent, or unattended installation.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on AIX" on page 221.

Note: During installation, errors relating to **errupdate** or **trcupdate** might occur. This can caused by installing to a non-default location, if so these errors can be safely ignored. However, native trace for IBM MQ is only supported when installed in the default location.

About this task

You can use this method to install to a non-default location, and can select which components you want to install. The components and filesets are listed in "IBM MQ components and features" on page 192.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Set your current directory to the location of the installation file. The location might be the mount point of the CD, a network location, or a local file system directory.
3. Install the product in one of the following ways:
   - Install the whole product in the default location:
     ```
     installp -acgXYd . all
     ```
   - Install selected file sets in the default location:
     ```
     installp -acgXYd . list of file sets
     ```
   - Install the whole product in a non-default location using the -R flag:
     ```
     installp -R USIL_Directory -acgXYd . all
     ```
   - Install selected file sets in a non-default location using the -R flag:
     ```
     installp -R USIL_Directory -acgXYd . list of file sets
     ```

   where *USIL_Directory* is a directory which exists before the command is run; it must not contain any spaces or usr/mqm. IBM MQ is installed underneath the directory specified. For example, if /USIL1 is specified, the IBM MQ product files are located in /USIL1/usr/mqm. This location is known as the *MQ_INSTALLATION_PATH*.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:
  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```
  where *MQ_INSTALLATION_PATH* represents the directory where IBM MQ is installed.

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ . For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. See "Verifying an IBM MQ installation on AIX" on page 233, for more information.

Changing the primary installation

User Specified Installation Location (USIL)

Converting a trial license on AIX

AIX

Convert a trial license to a full license without reinstalling IBM MQ.

When the trial license expires, the "count-down" displayed by the **strmqm** command informs you the license has expired, and the command does not run.

Before you begin

1. IBM MQ is installed with a trial license.
2. You have access to the installation media of a fully licensed copy of IBM MQ.

About this task

Run the **setmqprd** command to convert a trial license to a full license.

If you do not want to apply a full license to your trial copy of IBM MQ, you can uninstall it at any time.

Procedure

1. Obtain the full license from the fully licensed installation media.

   The full license file is `amqpcert.lic`. On AIX, it is in the `/`*MediaRoot*`/licenses` directory on the installation media.
2. Run the **setmqprd** command from the installation that you are upgrading:

   ```
   MQ_INSTALLATION_PATH/bin/setmqprd /MediaRoot/licenses/amqpcert.lic
   ```

Related information:
setmqprd

Displaying messages in your national language on AIX

AIX

To display messages from a different national language message catalog, you must install the appropriate catalog and set the **LANG** environment variable.

About this task

Messages in the language specified by the locale selected on your machine at installation time are installed by default.

To find out which language is currently in use, run the **locale** command.

If this returns a language which is not one of the national languages provided by IBM MQ, you must select a national language, otherwise you will not get a message catalog installed on your system.

Message catalogs for all languages are installed in *MQ_INSTALLATION_PATH*/msg/*language identifier*, where *language identifier* is one of the identifiers in Table 33. If you require messages in a different language, perform the following steps:

Procedure

1. Install the appropriate message catalog (see "IBM MQ components and features" on page 192).
2. To select messages in a different language, ensure the **LANG** environment variable is set to the identifier for the language you want to install:

Table 33. Language identifiers

Identifier	**Language**
cs_CZ	Czech
de_DE	German
es_ES	Spanish
fr_FR	French
hu_HU	Hungarian
it_IT	Italian
ja_JP	Japanese
ko_KR	Korean
pl_PL	Polish
pt_BR	Brazilian Portuguese
ru_RU	Russian
zh_CN	Simplified Chinese
zh_TW	Traditional Chinese

AIX has some additional message catalogs:

Table 34. AIX specific language identifiers

Identifier	Language
Ja_JP	Japanese
Zh_CN	Simplified Chinese
Zh_TW	Traditional Chinese

Installing an IBM MQ client on AIX

AIX

You can interactively install the IBM MQ client for AIX using `smit`.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on AIX" on page 221.

About this task

IBM MQ is supplied as a set of filesets that are installed using the standard AIX installation tools. The procedure uses the System Management Interface Tool (`smit`), but you can choose to use **`installp`**, **`geninstall`** or the web-based System Manager. You can select which components you want to install. The components and filesets are listed in "IBM MQ components for AIX" on page 216. You must install at least the Runtime and Client components.

This procedure installs IBM MQ into the default location. If you want to install to a non-default location, you must use **`installp`**, see "Installing an IBM MQ client silently on AIX" on page 232.

Procedure

1. Log in as root, or switch to the superuser using the **`su`** command.
2. Make your current directory the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Select the required `smit` window using the following sequence:
   ```
   Software Installation and Maintenance
   Install and Update Software
   Install and Update from ALL Available Software
   ```
4. Click **List** to display the input device or directory for the software and select the location that contains the installation images.
5. Select the **SOFTWARE to install** field to obtain a list of available filesets, and select the filesets you want to install. Ensure that you include the appropriate message catalog if you require messages in a language different from the language specified by the locale specified on your system. Enter **ALL** to install all applicable filesets.
6. Change **Preview new LICENSE agreements?** to **yes** and press Enter to view the license agreements.
7. If you have a previous version of the product on your system, change the **Automatically install requisite software** to **no**.
8. Change **ACCEPT new license agreements?** to **yes** and press Enter to accept the license agreements.
9. Change **Preview new LICENSE agreements?** to **no** and press Enter to install IBM MQ.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

```
MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
```

You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.

- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see "Testing communication between a client and a server on AIX" on page 246.

Related tasks:

"Uninstalling or modifying IBM MQ on AIX" on page 247
On AIX, you can uninstall the IBM MQ server or client using the System Management Interface Tool (SMIT) or the **installp** command. You can also modify an installation by uninstalling a subset of the file sets.

Installing an IBM MQ client silently on AIX

AIX

You can carry out a non-interactive, or silent, installation of an IBM MQ client from the command line using the AIX **installp** command.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on AIX" on page 221.

Note: Installation to a non-default location is not supported on systems that have the AIX Trusted Computing Base (TCB) enabled.

About this task

You can use this method to install to a non-default location, and can select which components you want to install. The components and filesets are listed in "IBM MQ components and features" on page 192. You must install at least the Runtime and Client components.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Set your current directory to the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Install the product in one of the following ways:
   - Install the whole product in the default location:
     ```
     installp -acgXYd . all
     ```
   - Install selected filesets in the default location:
     ```
     installp -acgXYd . list of file sets
     ```
   - Install the whole product in a non-default location using the -R flag:
     ```
     installp -R USIL_Directory -acgXYd . all
     ```
   - Install selected filesets in a non-default location using the -R flag:
     ```
     installp -R USIL_Directory -acgXYd . list of file sets
     ```

   where the directory specified with the `-R` flag is an AIX User Specified Installation Location (USIL) directory which exists before the command is run; it must not contain any spaces or `usr/mqm`.

IBM MQ is installed underneath the directory specified. For example, if `/USIL1` is specified, the IBM MQ product files are located in `/USIL1/usr/mqm`. This location is known as the *MQ_INSTALLATION_PATH*.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see "Testing communication between a client and a server on AIX" on page 246.

Verifying an IBM MQ installation on AIX

AIX

The topics in this section provide instructions on how to verify a server or a client installation of IBM MQ on AIX systems.

About this task

You can verify a local (stand-alone) server installation or a server-to-server installation of the IBM MQ server:
- A local server installation has no communication links with other IBM MQ installations.
- A server-to-server installation does have links to other installations.

You can also verify that your IBM MQ MQI client installation completed successfully and that the communication link is working.

Procedure

- To verify a local server installation, see "Verifying a local server installation on AIX" on page 234.
- To verify a server-to-server installation, see "Verifying a server-to-server installation on AIX" on page 237.
- To verify a client installation, see "Verifying a client installation using the command line on AIX" on page 243.

Verifying a local server installation on AIX

AIX

You can use either the command line or the postcard application to verify a local (stand-alone) installation on HP-UX.

About this task

You can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a local server installation using the command line on AIX."
- To use the postcard application to verify an installation, see "Verifying a local server installation using the command line on AIX."

Verifying a local server installation using the command line on AIX: AIX

On AIX systems, you can verify a local server installation by using the command line to create a simple configuration of one queue manager and one queue. You can also verify an installation using the postcard application.

Before you begin

To verify the installation, you must first install the samples package.

Before beginning the verification procedure, you might want to check that you have the latest fixes for your system. For more information about where to find the latest updates, see "Checking requirements on AIX" on page 218.

About this task

Use the following steps to configure your default queue manager from the command line. After the queue manager is configured, use the `amqsput` sample program to put a message on the queue. You then use the `amqsget` sample program to get the message back from the queue.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On an AIX system, log in as a user in the `mqm` group.
2. Set up your environment:
   a. Set up environment variables for use with a particular installation by entering one the following command:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```
      where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.
   b. Check that the environment is set up correctly by entering the following command:

```
dspmqver
```

If the command completes successfully, and the expected version number and installation name are returned, the environment is set up correctly.

3. Create a queue manager called `QMA` by entering the following command:
   ```
   crtmqm QMA
   ```
   Messages indicate when the queue manager is created, and when the default IBM MQ objects are created.
4. Start the queue manager by entering the following command:
   ```
   strmqm QMA
   ```
   A message indicates when the queue manager starts.
5. Start MQSC by entering the following command:
   ```
   runmqsc QMA
   ```
   A message indicates when MQSC starts. MQSC has no command prompt.
6. Define a local queue called `QUEUE1` by entering the following command:
   ```
   DEFINE QLOCAL (QUEUE1)
   ```
   A message indicates when the queue is created.
7. Stop MQSC by entering the following command:
   ```
   end
   ```
   Messages are shown, followed by the command prompt.

Note: Subsequent steps require that the samples package is installed.

8. Change into the *`MQ_INSTALLATION_PATH`*`/samp/bin` directory, which contains the sample programs. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
9. Put a message on the queue by entering the following commands
   ```
   ./amqsput QUEUE1 QMA
   ```
   The following messages are shown:
   ```
   Sample AMQSPUT0 start
   target queue is QUEUE1
   ```
10. Type some message text on one or more lines, where each line is a different message. Enter a blank line to end the message input. The following message is shown:
    ```
    Sample AMQSPUT0 end
    ```
    Your messages are now on the queue and the command prompt is shown.
11. Get the messages from the queue, by entering the following command:
    ```
    ./amqsget QUEUE1 QMA
    ```
    The sample program starts, and your messages are displayed.

Results

You have successfully verified your local installation.

Verifying a local server installation using the Postcard application on AIX: AIX

Sending messages successfully between two Postcard applications verifies a local installation.

Before you begin

The postcard application is Java based and requires a system with the ability to view a graphical display.

You must ensure that you are a member of the IBM MQ administrators group (`mqm`).

Note: Using Postcard to verify an IBM MQ installation is only possible if there is one IBM MQ installation on that box. The Default Configuration wizard will not create a default configuration if a queue manager already exists on the box. The Default Configuration wizard will run on any installation on a box but only one default configuration can be created per box. Using Postcard to verify second and subsequent installations of IBM MQ on the same box is not possible.

To verify that the local installation is working, you can run two instances of the Postcard application on the same server. The postcard application can send messages to, and receive messages from, other postcard applications. Successful sending and receiving of messages verifies that IBM MQ is installed and working correctly on the server.

Procedure

1. Log on as a user in group `mqm`.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *MQ_INSTALLATION_PATH*/java/bin. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:
      ```
      ./postcard
      ```
   b. From the IBM MQ Explorer:
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.
3. At the Postcard - Sign On window, type in a nickname to use to send messages within the Postcard application (for example, `User1`).
4. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Launching the Default Configuration creates a default queue manager.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

When your selection is complete, click **OK** to display your first Postcard window.

5. Run a second instance of the Postcard application by following the steps used to open the first instance of the Postcard application.
6. The Postcard - Sign On panel is displayed again. Type in a second nickname to use to send messages within this second Postcard application (for example, `User2`).
7. Repeat the selection of the queue manager that you want to use as the mailbox (as described in step 4). The queue manager you select for this second Postcard must be the same queue manager as used for the first instance of the Postcard application.
8. In the first Postcard, (User1), enter the nickname (`User2`) for the second Postcard application in the **To:** field. Because the sender and receiver are on the same server, you can leave the **On:** field blank.
9. Type a message in the **Message:** field and click **Send**.
10. The **Postcards sent and received** area of the Postcard shows details of the message. In the sending Postcard, the message is displayed as sent. In the receiving Postcard, the message is displayed as received.
11. In the receiving Postcard, (User2), double-click the message in the **Postcards sent and received** area to view it. When this message arrives, it verifies that IBM MQ is correctly installed.

What to do next

Depending on your situation, you might want to do the following tasks:

- Install IBM MQ on other servers. Follow the installation procedure for the appropriate platform. Ensure that you use the **Join Default Cluster** window in the Default Configuration wizard to add the other servers to the cluster on your first server.
- Install the IBM MQ MQI client on other servers.
- Continue with further administration tasks, see Administering IBM MQ.

Verifying a server-to-server installation on AIX

AIX

You can use either the command line or the postcard application to verify a server-to-server installation on AIX.

Before you begin

For a server-to-server verification, the communication links between the two systems must be checked. Before you can do the verification, you must therefore ensure that the communications protocol is installed and configured on both systems.

On AIX, IBM MQ supports both TCP and SNA.

The examples in this task use TCP/IP. If you do not use TCP, see Setting up communication on UNIX and Linux.

About this task

For a server-to server installation, you can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see “Verifying a server-to-server installation using the command line on AIX.”
- To use the postcard application to verify an installation, see “Verifying a server-to-server installation using the Postcard application on AIX” on page 241.

Verifying a server-to-server installation using the command line on AIX: AIX

You can verify a server-to-server installation using two servers, one as a sender and one as a receiver.

Before you begin

- Make sure that TCP/IP and IBM MQ are installed on both servers (see “Verifying a server-to-server installation on AIX” on page 237).
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Decide which installation is the sender server and which installation is the receiver server. The installations might be on the same system, or on different systems.

About this task

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On the **receiver** server:
   a. On AIX, log in as a user in the mqm group.
   b. Check which ports are free, for example by running **netstat**. For more information about this command, see the documentation of your operating system.

      If port 1414 is not in use, make a note of 1414 to use as the port number in step 2 h. Use the same number for the port for your listener later in the verification. If it is in use, note a port that is not in use; for example 1415.
   c. Set up the environment for the installation you are using by entering the following command at the command prompt:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   d. Create a queue manager called QMB by entering the following command at the command prompt:
      ```
      crtmqm QMB
      ```
      Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.
   e. Start the queue manager by entering the following command:
      ```
      strmqm QMB
      ```
      A message tells you when the queue manager has started.
   f. Start MQSC by entering the following command:
      ```
      runmqsc QMB
      ```
      A message tells you that MQSC has started. MQSC has no command prompt.
   g. Define a local queue called RECEIVER.Q by entering the following command:
      ```
      DEFINE QLOCAL (RECEIVER.Q)
      ```

A message tells you the queue has been created.

h. Define a listener by entering the following command:

```
DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT ( PORT_NUMBER )
```

Where *port_number* is the name of the port the listener runs on. This number must be the same as the number used when defining your sender channel.

i. Start the listener by entering the following command:

```
START LISTENER (LISTENER1)
```

Note: Do not start the listener in the background from any shell that automatically lowers the priority of background processes.

j. Define a receiver channel by entering the following command:

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (RCVR) TRPTYPE (TCP)
```

A message tells you when the channel has been created.

k. End MQSC by typing:

```
end
```

Some messages are displayed, followed by the command prompt.

2. On the **sender** server:

a. As the sender server is an AIX system, log in as a user in the `mqm` group.

b. Set up the environment for the installation you are using by entering the following command at the command prompt:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.

c. Create a queue manager called `QMA` by entering the following command at the command prompt:

```
crtmqm QMA
```

Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.

d. Start the queue manager, by entering the following command:

```
strmqm QMA
```

A message tells you when the queue manager has started.

e. Start MQSC by entering the following command:

```
runmqsc QMA
```

A message tells you that an MQSC session has started. MQSC had no command prompt.

f. Define a local queue called `QMB` (to be used as a transmission queue) by entering the following command:

```
DEFINE QLOCAL (QMB) USAGE (XMITQ)
```

A message tells you when the queue has been created.

g. Define a local definition of the remote queue with by entering the following command:

```
DEFINE QREMOTE (LOCAL.DEF.OF.REMOTE.QUEUE) RNAME (RECEIVER.Q) RQMNAME ('QMB') XMITQ (QMB)
```

h. Define a sender channel by entering one of the following commands:

con-name is the TCP/IP address of the receiver system. If both installations are on the same system, the *con-name* is `localhost`. *port* is the port you noted in 1 b. If you do not specify a port, the default value of 1414 is used.

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (SDR) CONNAME ('CON-NAME(PORT)') XMITQ (QMB) TRPTYPE (TCP)
```

i. Start the sender channel by entering the following command:

```
START CHANNEL(QMA.QMB)
```

The receiver channel on the receiver server starts automatically when the sender channel starts.

j. Stop MQSC by entering the following command:

```
end
```

Some messages are displayed, followed by the command prompt.

k. If the sender server is a UNIX or Linux system, change into the *MQ_INSTALLATION_PATH*/samp/bin directory. This directory contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.

l. If both the sender server and receiver server are installations on the same system, check that the queue managers have been created on different installations by entering the following command:

```
dspmq -o installation
```

If the queue managers are on the same installation, move either QMA to the sender installation or QMB to the receiver installation by using the **setmqm** command. For more information, see setmqm.

m. Put a message on the local definition of the remote queue, which in turn specifies the name of the remote queue. Enter one of the following commands:

- On Windows:

  ```
  amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
  ```

- On UNIX and Linux:

  ```
  ./amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
  ```

A message tells you that amqsput has started.

n. Type some message text on one or more lines, followed by a blank line. A message tells you that amqsput has ended. Your message is now on the queue and the command prompt is displayed again.

3. On the **receiver** server:

a. As your receiver server is an AIX system, change into the *MQ_INSTALLATION_PATH*/samp/bin directory. This directory contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.

b. Get the message from the queue on the receiver by entering the following command:

```
./amqsget RECEIVER.Q QMB
```

The sample program starts, and your message is displayed. After a pause, the sample ends. Then the command prompt is displayed.

Results

You have now successfully verified the server-to-server installation.

Verifying a server-to-server installation using the Postcard application on AIX: AIX

You can use two instances of the Postcard application to verify that a server-to-server installation is working.

Before you begin

You can use the Postcard application on two servers, one instance of the Postcard application on each server, to verify that a server-to-server installation is working. Successful sending and receiving of messages verifies that IBM MQ is successfully installed, and that communication between the two servers is working correctly.

Note:
- If the system has multiple IBM MQ installations, ensure that Postcard has not been run before on any installations on that server. As the default configuration can only exist on one IBM MQ installation per system, the Default Configuration wizard and Postcard can not be used for verification of a second or any subsequent installation.
- The two server installations must be on different systems to do a server-to-server verification using the postcard application. To verify a server-to-server installation on the same machine, you can use the command line.
- Make sure that TCP/IP and IBM MQ are installed on both servers.
- Make sure that your systems are able to view a graphical display.
- Make sure that you are a member of the IBM MQ administrators group (`mqm`) on each server.
- Check that one of the following scenarios applies:
  - Neither server has had any queue managers created.
  - Use the Default Configuration wizard to create default queue managers on each server and link them to the default cluster.

    Details on how to use the Default Configuration wizard are provided in this topic.
  - Both servers have existing queue managers and these queue managers are in the same cluster.

    If your queue managers are not in the same cluster, create new queue managers on both servers. Then create a cluster, and ensure that the queue managers that you create on each server belong to that cluster.
  - You have configured channels to communicate between the two servers.

    For instructions on how to set up the channels, see "Verifying a server-to-server installation using the command line on AIX" on page 238. After you have set up the channels, follow the instructions in this topic to verify your server-to-server installation.

Procedure
1. On the first server, log on as a user in group `mqm`.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *`MQ_INSTALLATION_PATH`*`/java/bin`. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:
         ```
         ./postcard
         ```
   b. From the IBM MQ Explorer:
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.

3. At the Postcard - Sign On window, type a nickname to use to send messages within the Postcard application. For example, `User1` for the first server, and `User2` for the second server.
4. When you have completed the wizard, you are taken back to the Postcard - Sign On window.
5. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Work through the Default Configuration wizard. When you get to the option to join the queue manager to the default cluster, tick the check box. On the next screen:
     - For the first server, select **yes, make it the repository for the cluster**.
     - For the second server, select **No another computer has already joined the cluster as a repository**. When requested, enter the location of the repository, by typing the name of the sender server.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK**.
6. Complete steps 1 - 5 for the second server.
7. In the Postcard on the first server:
   a. Enter the nickname (`user2`) for the Postcard application on the second server in the **To:** field.
   b. Enter the queue manager on the second server in the **On:** field.
   c. Type a message in the **Message:** field and click **Send**.
8. In the Postcard on the second server:
   a. In the **Postcards sent and received**, double-click the message marked as received to view the message from the first server.
   b. Optional: Send a postcard to the first server by adapting the instructions in step 7. You must enter details of the first server in the **To:** field and the **On:** field.

   The messages verify that IBM MQ is correctly installed and that your communication link between the two servers is working correctly.

Verifying a client installation using the command line on AIX

AIX

You can verify a client installation using the command line. On the server you create a queue manager, a local queue, a listener, and a server-connection channel. You must also apply security rules to allow the client to connect and make use of the queue defined. On the client you create a client-connection channel, and then use the sample PUT and GET programs to complete the verification procedure.

About this task

The verification procedure shows how to create a queue manager called `queue.manager.1`, a local queue called `QUEUE1`, and a server-connection channel called `CHANNEL1` on the server.

It shows how to create the client-connection channel on the IBM MQ MQI client workstation. It then shows how to use the sample programs to put a message onto a queue, and get the message from the queue.

The example does not address any client security issues. See Setting up IBM MQ MQI client security for details if you are concerned with IBM MQ MQI client security issues.

The verification procedure assumes that:
- The full IBM MQ server product has been installed on a server.
- The server installation is accessible on your network.
- The IBM MQ MQI client software has been installed on a client system.
- The IBM MQ sample programs have been installed.
- TCP/IP has been configured on the server and client systems. For more information, see Configuring connections between the server and client.

Procedure

1. Set up the server using the command line, using the instructions in "Setting up the server using the command line on AIX."
2. Set up the client, using the instructions in "Connecting to a queue manager, using the `MQSERVER` environment variable on AIX" on page 245.
3. Test the communications between client and server, using the instructions in "Testing communication between a client and a server on AIX" on page 246.

Setting up the server using the command line on AIX: AIX

Follow these instructions to create a queue manager, queue, and channel on the server. You can then use these objects to verify the installation.

About this task

These instructions assume that no queue manager or other IBM MQ objects have been defined.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Create a user ID on the server that is not in the `mqm` group. This user ID must exist on the server and client. This is the user ID that the sample applications must be run as, otherwise a 2035 error is returned.

2. Log in as a user in the mqm group.
3. You must set various environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
4. Create a queue manager called QUEUE.MANAGER.1 by entering the following command:
   ```
   crtmqm QUEUE.MANAGER.1
   ```
   You see messages telling you that the queue manager has been created.
5. Start the queue manager by entering the following command:
   ```
   strmqm QUEUE.MANAGER.1
   ```
   A message tells you when the queue manager has started.
6. Start MQSC by entering the following command:
   ```
   runmqsc QUEUE.MANAGER.1
   ```
   A message tells you that an MQSC session has started. MQSC has no command prompt.
7. Define a local queue called QUEUE1 by entering the following command:
   ```
   DEFINE QLOCAL(QUEUE1)
   ```
   A message tells you when the queue has been created.
8. Allow the user ID that you created in step 1 to use QUEUE1 by entering the following command:
   ```
   SET AUTHREC PROFILE(QUEUE1) OBJTYPE(QUEUE) PRINCIPAL(' non_mqm_user ') AUTHADD(PUT,GET)
   ```
   where *non_mqm_user* is the user ID created in step 1. A message tells you when the authorization has been set. You must also run the following command to give the user ID authority to connect:
   ```
   SET AUTHREC OBJTYPE(QMGR) PRINCIPAL(' non_mqm_user ') AUTHADD(CONNECT)
   ```
   If this command is not run, a 2305 stop error is returned.
9. Define a server-connection channel by entering the following command:
   ```
   DEFINE CHANNEL (CHANNEL1) CHLTYPE (SVRCONN) TRPTYPE (TCP)
   ```
   A message tells you when the channel has been created.
10. Allow your client channel to connect to the queue manager and run under the user ID that you created in step 1, by entering the following MQSC command:
    ```
    SET CHLAUTH(CHANNEL1) TYPE(ADDRESSMAP) ADDRESS(' client_ipaddr ') MCAUSER(' non_mqm_user ')
    ```
    where *client_ipaddr* is the IP address of the client system, and *non_mqm_user* is the user ID created in step 1. A message tells you when the rule has been set.
11. Define a listener by entering the following command:
    ```
    DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT (port_number)
    ```
    where *port_number* is the number of the port the listener is to run on. This number must be the same as the number used when defining your client-connection channel in "Installing an IBM MQ client on AIX" on page 231.

    Note: If you omit the port parameter from the command, a default value of 1414 is used for the listener port. If you want to specify a port other than 1414, you must include the port parameter in the command, as shown.
12. Start the listener by entering the following command:
    ```
    START LISTENER (LISTENER1)
    ```

13. Stop MQSC by entering:
    ```
    end
    ```

    You see some messages, followed by the command prompt.

What to do next

Follow the instructions to set up the client. See "Connecting to a queue manager, using the MQSERVER environment variable on AIX."

Connecting to a queue manager, using the MQSERVER environment variable on AIX: AIX

When an IBM MQ application is run on the IBM MQ MQI client, it requires the name of the MQI channel, the communication type, and the address of the server to be used. Provide these parameters by defining the MQSERVER environment variable.

Before you begin

Before you start this task, you must complete the task, "Setting up the server using the command line on AIX" on page 243, and save the following information:
- The host name or IP address of the server and port number that you specified when creating the listener.
- The channel name of the server-connection channel.

About this task

This task describes how to connect an IBM MQ MQI client, by defining the MQSERVER environment variable on the client.

You can give the client access to the generated client channel definition table, amqclchl.tab instead; see Accessing client-connection channel definitions.

Procedure
1. Log in as the userid that you created in Step 1 of "Verifying a client installation using the command line on AIX" on page 243.
2. Check the TCP/IP connection. From the client, enter one of the following commands:
   - `ping server-hostname`
   - `ping n.n.n.n`

     `n.n.n.n` represents the network address. You can set the network address in IPv4 dotted decimal form, for example, `192.0.2.0`. Alternatively, set the address in IPv6 hexadecimal form, for example `2001:0DB8:0204:acff:fe97:2c34:fde0:3485`.

   If the **ping** command fails, correct your TCP/IP configuration.
3. Set the MQSERVER environment variable. From the client, enter the following command:
   ```
   export MQSERVER=CHANNEL1/TCP/'server-address (port)'
   ```

   Where:
   - *CHANNEL1* is the server-connection channel name.
   - *server-address* is the TCP/IP host name of the server.
   - *port* is the TCP/IP port number the server is listening on.

   If you do not give a port number, IBM MQ uses the one specified in the qm.ini file, or the client configuration file. If no value is specified in these files, IBM MQ uses the port number identified in the TCP/IP services file for the service name MQSeries. If an MQSeries entry in the services file does

not exist, a default value of 1414 is used. It is important that the port number used by the client and the port number used by the server listener program are the same.

What to do next

Use the sample programs to test communication between the client and server; see "Testing communication between a client and a server on AIX."

Testing communication between a client and a server on AIX: AIX

On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

Before you begin

Complete the previous topics in this section:
- Set up a queue manager, channels, and queue.
- Open a command window.
- Set system environment variables.

About this task

Note that IBM MQ object definitions are case-sensitive. Text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Change to the *MQ_INSTALLATION_PATH*/samp/bin directory, which contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
2. You must set certain environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
3. Start the PUT program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:
   ```
   ./amqsputc QUEUE1 QUEUE.MANAGER.1
   ```
   If the command is successful, the following messages are displayed:
   ```
   Sample AMQSPUT0 start target queue is QUEUE1
   ```
   Tip: You might get the error, MQRC_NOT_AUTHORIZED (2035). By default, channel authentication is enabled when a queue manager is created. Channel authentication prevents privileged users accessing a queue manager as an IBM MQ MQI client. For verifying the installation, you can either change the MCA user ID to a non-privileged user, or disable channel authentication. To disable channel authentication run the following MQSC command:
   ```
   ALTER QMGR CHLAUTH(DISABLED)
   ```
   When you finish the test, if you do not delete the queue manager, re-enable channel authentication:
   ```
   ALTER QMGR CHLAUTH(ENABLED)
   ```
4. Type some message text, then press **Enter** twice. The following message is displayed:
   ```
   Sample AMQSPUT0 end
   ```
   Your message is now on the queue that is on the server queue manager.

5. Start the GET program for `QUEUE1` on `QUEUE.MANAGER.1` by entering the following command:

   ```
   ./amqsgetc QUEUE1 QUEUE.MANAGER.1
   ```

   The sample program starts, and your message is displayed. After a short pause (approximately 30 seconds), the sample ends and the command prompt is displayed again.

Results

You have now successfully verified the client installation.

What to do next

1. You must set various environment variables on the server so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```

   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
2. On the server, stop the queue manager by entering the following command:

   ```
   endmqm QUEUE.MANAGER.1
   ```
3. On the server, delete the queue manager by entering the following command:

   ```
   dltmqm QUEUE.MANAGER.1
   ```

Uninstalling or modifying IBM MQ on AIX

AIX

On AIX, you can uninstall the IBM MQ server or client using the System Management Interface Tool (SMIT) or the **installp** command. You can also modify an installation by uninstalling a subset of the file sets.

Before you begin

If any updates have been applied, remove them before starting the uninstallation or modification procedure. For more information, see Reverting to the previous maintenance level on AIX.

Important: You must stop all IBM MQ queue managers, other objects, and applications, before you begin the process to uninstall or modify IBM MQ.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling or modifying, if you have not already done so.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling or modifying:
   a. Log in as a user in the group `mqm`.
   b. Set up your environment to work with the installation you want to uninstall or modify. Enter the following command:

      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv
      ```

      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:

      ```
      dspmq -o installation
      ```
   d. Stop all running queue managers associated with the installation you want to uninstall or modify. Enter the following command for each queue manager:

      ```
      endmqm QMgrName
      ```

   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:

      ```
      endmqlsr -m QMgrName
      ```
3. Log in as root.
4. Uninstall or modify IBM MQ using either **installp** or **smit**. If IBM MQ was installed in a non-default location, you must use **installp**.
   - To uninstall or modify IBM MQ by using **installp**, enter one of the following commands:
     - To uninstall an installation in the default location `/usr/mqm`:

       ```
       installp -u mqm
       ```
     - To uninstall an installation in a non-default location:

       ```
       installp -R usil -u mqm
       ```

       where *usil* is the path of the User Specified Installation Location (USIL) specified when the product was installed.
     - To modify an installation in a non-default location:

       ```
       installp -R usil -u list of file sets
       ```

       where *usil* is the path of the User Specified Installation Location (USIL) specified when the product was installed.
   - To uninstall or modify IBM MQ by using **smit**, complete the following steps:
     a. Select the required **smit** window using the following sequence:

        ```
        Software Installation and Maintenance
        Software Maintenance and Utilities
        Remove Installed Software
        ```
     b. List the software in the **SOFTWARE name** field:
        1) Enter **.**
        2) Press **F4**
     c. Select the file sets to uninstall from the list (those beginning with mqm):
        - For a complete uninstall, select all file sets.
        - To modify the installation, select a subset of the file sets.

        After selecting the file sets, press **Enter**. There is an option at this stage to do a preview. Leave the option set to the default value of **Yes** to preview the file sets you are uninstalling, or select **No** to not preview these file sets.
     d. Press **Enter** on the **Remove Installed Software** panel, it asks whether you are sure, press **Enter**.

Results

After uninstallation, certain files under the directory trees `/var/mqm` and `/etc/opt/mqm` are not removed. These files contain user data and remain so subsequent installations can reuse the data. Most of the remaining files contain text, such as INI files, error logs, and FDC files. The directory tree `/var/mqm/shared` contains files that are shared across installations, including the executable shared libraries `libmqzsd.a` and `libmqzsd_r.a`.

What to do next

- If the product successfully uninstalled, you can delete any files and directories contained in the `/usr/mqm` directory under the User Specified Installation Location (USIL) specified in the **installp** uninstallation command.
- Use the **lslpp** command to check for other products installed in the USIL. If there are no other products installed in the USIL and you do not intend to use it again, you can delete the USIL using the **rmusil** command.

- If there are no other IBM MQ installations on the system, and you are not planning to reinstall or migrate, you can delete the `/var/mqm` and `/etc/opt/mqm` directory trees, including the files `libmqzsd.a` and `libmqzsd_r.a`. Deleting these directories destroys all queue managers and their associated data.

Installing and uninstalling IBM MQ client for HP Integrity NonStop Server

NSS Client

Tasks that are associated with installing the IBM MQ client on HP Integrity NonStop Server systems are grouped in this section.

About this task

To prepare for installation and to install the IBM MQ client, complete the following tasks.

For information about how to uninstall the IBM MQ client, see “Uninstalling the IBM MQ client for HP Integrity NonStop Server” on page 263.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See “Hardware and software requirements on HP Integrity NonStop Server systems” on page 250.
2. Plan your installation. See “Planning your client installation on HP Integrity NonStop Server” on page 252.
3. Prepare your system for installation of the IBM MQ client for HP Integrity NonStop Server. See “Setting up the user and group on HP Integrity NonStop Server” on page 256.
4. Install an IBM MQ client. See “Installing the IBM MQ client on HP Integrity NonStop Server” on page 257.
5. Verify your installation. See “Verifying an IBM MQ installation on HP Integrity NonStop Server” on page 258.

IBM MQ client components for HP Integrity NonStop Server

NSS Client

There are no optional components within the client installer when you install the IBM MQ client for HP Integrity NonStop Server.

An installation of the IBM MQ client for HP Integrity NonStop Server contains product binary files, command utilities, and samples. There are no optional components.

Related concepts:

"Planning your client installation on HP Integrity NonStop Server" on page 252
This section describes what to do to prepare your HP Integrity NonStop Server system for installing the IBM MQ client for HP Integrity NonStop Server.

"Hardware and software requirements on HP Integrity NonStop Server systems"
Check that the server environment meets the prerequisites for installing the IBM MQ client for HP Integrity NonStop Server. Check the product readme files and install missing prerequisite software supplied on the server CD.

Related information:

Planning your IBM MQ client environment on HP Integrity NonStop Server

Hardware and software requirements on HP Integrity NonStop Server systems

NSS Client

Check that the server environment meets the prerequisites for installing the IBM MQ client for HP Integrity NonStop Server. Check the product readme files and install missing prerequisite software supplied on the server CD.

Hardware

The IBM MQ client for HP Integrity NonStop Server typically requires certain hardware specifications to run:

- HP Integrity NonStop Server H and J series
- Two or more processors
- At least 1 GB, and ideally 4 GB of memory per processor
- 500 MB of free disk space in the Guardian and OSS file systems

Operating system

Two operating systems are supported by the IBM MQ client for HP Integrity NonStop Server:

- HP Integrity NonStop Server running H06.24 or later NonStop OS
- HP Integrity NonStop BladeSystem running J06.13 or later NonStop OS

You must be running one of these operating systems to install the IBM MQ client for HP Integrity NonStop Server.

Other software requirements

IBM MQ client for HP Integrity NonStop Server has some additional software requirements:

- The operating system software, Open System Services (OSS), must be active, with file systems and a local sockets subsystem that is configured and running.
- Safeguard must be active.
- If two-phase commit transaction support is required, then TMF must be active and Pathway must be configured and available. The connected queue manager must be at IBM WebSphere MQ Version 7.1 or later.
- If the Java Message Service (JMS) API is required, then HP Integrity NonStop Server for Java V6 must be available.
- You might require compatible compilers, linkers, and maybe other tools for the C, C++, COBOL, JMS, or pTAL languages if you want to build and use applications.

File system requirements

In the selected installation root directory, in the OSS file system, an installation creates:

- `opt` - a directory tree that contains the "static" files for an installation in OSS.
- `var` - a directory tree that contains the "variable" files for an installation in OSS.

An installation also creates a single subvolume in the Guardian file system, which is selected during installation.

Related concepts:

"License requirements" on page 194
You must have purchased sufficient licenses for your installation. The details of the license agreement is stored on your system at installation time so that you can read it at any time. IBM MQ supports IBM License Metric Tool (ILMT).

Related tasks:

"Checking requirements on Windows" on page 444
Before you install IBM MQ on Windows, you must check for the latest information and system requirements.

UNIX Linux Disk space requirements

Verifying system software prerequisites on HP Integrity NonStop Server

NSS Client

Use the HP Integrity NonStop Server TACL utility, SYSINFO, to verify the base OS level of the HP Integrity NonStop Server.

Procedure

From a TACL command prompt, enter **SYSINFO**.

Results

The system information is displayed as shown in the following example:

```
SYSINFO - T9268H01 - (01 OCT 2004)  SYSTEM \NODE1  Date 05 Nov 2010, 11:56:51
Copyright 2003 Hewlett-Packard Development Company, L.P.

         System name    \NODE1
  EXPAND node number    025
       Current SYSnn    SYS00
       System number    nnnnnn
 Software release ID    J06.10.00
```

In this example, the base OS level is J06.10.00.

What to do next

Compare the base OS level with the "Hardware and software requirements on HP Integrity NonStop Server systems" on page 250. Verify any other HP Integrity NonStop Server software prerequisites or recommendations identified in the documentation or the product README; for example, SPRs to particular products.

Planning your client installation on HP Integrity NonStop Server

▶ NSS Client

This section describes what to do to prepare your HP Integrity NonStop Server system for installing the IBM MQ client for HP Integrity NonStop Server.

Understanding multiple installations

The IBM MQ client for HP Integrity NonStop Server can be installed more than once on an HP Integrity NonStop Server system. In addition, multiple different versions of the client can be installed on a single HP Integrity NonStop Server system, and be maintained independently.

To install IBM MQ client for HP Integrity NonStop Server, you must specify two locations; one in the OSS file system, and one in the Guardian file system, which is used by the installer to store the results of the installation. These locations must not contain or overlap with any other IBM MQ client for HP Integrity NonStop Server installation. The locations must also be free of other files.

Each installation is independent and self-contained, with all data, such as configuration logs, or trace and program files located within the installation directory hierarchy. All commands and libraries use an embedded runtime search path (RPath) to ensure that they load their dependencies from the same installation.

As several installations might be present, each application must locate and load the IBM MQ client libraries from the correct installation.

- For native applications, an application that is linked with the IBM MQ MQIC.LIB installation library inherits the IBM MQ installation RPATH, and can run without environment variables. Environment variables in OSS, for example, *_RLD_LIB_PATH* or DEFINEs in Guardian, are only required if you want to run the application using a different IBM MQ installation.
- For Java applications using the Java Messaging Service (JMS) API, the client Java archive (JAR) must be from the correct installation, and must be included on the class path. For more information, see Environment variables used by IBM MQ classes for JMS.

Product packaging and delivery

IBM MQ client for HP Integrity NonStop Server is downloaded to the OSS file system as a single file.

The IBM MQ client for HP Integrity NonStop Server package file is a self-extracting archive (SFX) that contains an installer and all files that are required to create installations.

The SFX for IBM MQ client for HP Integrity NonStop Server has a file extension of `.run`. There is no concept of placed files. When run, the SFX creates a single installation, directly from the archive, into the OSS and Guardian file systems.

The SFX can be used to create as many installations of the IBM MQ client for HP Integrity NonStop Server as you require. No information about installations is retained in the SFX, and no tools are provided for extracting individual files from the SFX.

File system on HP Integrity NonStop Server

NSS Client

Before you install the IBM MQ client for HP Integrity NonStop Server, make sure that the file system is set up correctly.

Review "Hardware and software requirements on HP Integrity NonStop Server systems" on page 250 to make sure that you understand the approximate amount of disk space in the OSS and Guardian file systems that is required for an installation. The OSS file set that is used for the installation requires enough free space for the installation files and the files you create in the installation. The Guardian volume that you use for installation does not require auditing.

Work with your systems administrator to verify the OSS file set and Guardian file system storage requirements, at least for an initial estimate of the storage. The best way to determine more precisely how much storage you would eventually need in production is to produce a prototype configuration and model the message storage requirements, scaling up as necessary for your production system.

OSS file system objects

For the OSS file system objects, this section concentrates on the differences between the HP Integrity NonStop Server installation, and the standard UNIX installation. Multiple independent installations are supported.

The `opt` and `var` trees must be present in a common root directory, which is selected at installation time. The opt tree contains files that do not change. For example, this tree contains program, library, dll, header files, and "static" data files. The `var` tree contains files that might change, and do hold status about the installation itself. Examples of files that this tree holds are configuration files, and log files.

Both the `opt` and `var` directories contain a single directory named `mqm`. The content of both trees is rooted in the `opt/mqm` and `var/mqm` directories.

Table 35. Summary of the contents at the top-level of `opt/mqm`

Directory	Purpose	Contents
`bin`	Contains the OSS programs and libraries for an installation	• `G` is a symbolic link file that locates the Guardian installation subvolume • `amq*` files, containing the product executables for the client • `lib*` files, containing product dll files • Files containing control commands, and other utilities and scripts
`inc`	Contains the header files for building IBM MQ applications	• `.h` files, which are C language header files • `.tal` files which are pTAL header files • `.cpy` files which are COBOL copy file • `cobcpy32` and `cobcpy64` directories for the individual COBOL copy files

Table 35. Summary of the contents at the top-level of `opt/mqm` (continued)

Directory	**Purpose**	**Contents**
`lib`	Contains the import libraries needed to link applications	• `G` is a symbolic link file that locates the Guardian installation subvolume • `amq*` files, containing product dll files • `iconv` is a directory that contains data conversion tables • `lib*` files, which are product dll files • `mqicb` used for supplying to a CONSULT directive for compiling COBOL programs
`license`	Contains text versions of the IBM License for the IBM MQ client for HP Integrity NonStop Server, which is translated into each supported national language	• `Lic_.txt` files, which are the individual national language translations of the license. • `notices.txt` is a file that contains any additional license terms from non-IBM software that is included with IBM MQ , if any.
`mq.id`	Single file that contains information about the build level and installation package	All contents in this directory might be used by IBM Support personnel.
`msg`	Contains globalization files for use by IBM MQ , in logging and displaying output in the supported national language translations	The contents include: • `amq.cat` globalization message catalog currently in use by the installation, created by the OSS utility "gencat" • `amq.msg` unprocessed globalization data that is used as input by `gencat` to create the catalog • Other minor files and directories that support the different translations

Table 35. Summary of the contents at the top-level of `opt/mqm` (continued)

Directory	Purpose	Contents
`samp`	Contains sample code and executables to illustrate the use of IBM MQ	• `*.cbl` sample COBOL language source files • `*.c` sample 'C' language source files • `*.tal` sample pTAL language source files • `ccsid.new` backup file of `ccsid.tbl` • `ccsid.tbl` file that contains a table of supported CCSIDs • `*.ini` sample configuration files • `java` directory that contains source for sample Java applications • `jms` directory that contains source for sample JMS applications • `bin` directory that contains executable versions of the samples • `dlq` directory that contains a source for the sample Dead Letter Queue Handler • `preconnect` directory that contains source for preconnect exit

For more information about the samples that are provided, see Samples for the IBM MQ client for HP Integrity NonStop Server.

Table 36. Summary of the contents at the top-level of `var/mqm`

Directory	Purpose	Contents
`conv`	Contains data conversion files	Binary data that supports the data conversion function for IBM MQ
`errors`	Contains installation-wide error logs and FDC files	Standard content, for example: • `AMQERR01.LOG` - current system-wide error log file • `AMQERR02.LOG` - previous system-wide error log file • `AMQERR03.LOG` - oldest system-wide error log file • `*.FDC` FFST files
`exits`	Stores DLLs containing exit code that is loaded by the queue managers in the installation	This file is empty at installation
`log`	Contains log files for recording and controlling units of work	Standard content
`mqs.ini`	The installation configuration file	Standard content
`qmgrs`	Directory beneath the location where all of the queue manager directories are created	Standard content
`sockets`	Directory tree that contains various queue manager control files	Standard content

Table 36. Summary of the contents at the top-level of `var/mqm` (continued)

Directory	Purpose	Contents
`trace`	Defined location to which trace data is written by IBM MQ	Standard content

Guardian installation subvolume

The Guardian single installation subvolume contains both the programs and libraries needed at runtime.

Table 37. Contents of the Guardian installation subvolume

File	Description
`AMQINST`	Internal file that describes installation configuration
`AMQS*`	Samples that are built for Guardian
`B*SAMP`	Sample build files for the various supported languages
`CMQ*`	Header files for the various supported languages, where files ending in: • `h` are C headers • `T` are pTAL headers • `L` are COBOL headers
`MQ*`	Product libraries
`MQS*C`	Sample C language source files
`MQS*T`	Sample pTAL language source files
`MQS*L`	Sample COBOL language source files

Control commands are also included, for a list, see IBM MQ client for HP Integrity NonStop Server client commands.

Setting up the user and group on HP Integrity NonStop Server

NSS Client

The administrator user ID must be used to administer the IBM MQ client for HP Integrity NonStop Server.

Ensure that you have access to an IBM MQ client for HP Integrity NonStop Server user ID in the user group called MQM. The MQM group must be created before the client can be installed. All user IDs that are used to install the client must have MQM as their primary group. If this user group does not exist, or you do not have access to such a user, contact your systems administrator.

Installing the IBM MQ client on HP Integrity NonStop Server

NSS Client

Installing the IBM MQ client on a HP Integrity NonStop Server system.

Before you begin

Before you start the installation procedure, make sure that you complete the necessary steps that are outlined in "Setting up the user and group on HP Integrity NonStop Server" on page 256.

About this task

After preparing your system for installation, install the IBM MQ client for HP Integrity NonStop Server by following the instructions. After installation, you might want to verify your installation to check that it installed successfully. There are three steps to the installation:

1. Downloading the installation package.
2. Running the installer.
3. Setting the environment.

Procedure

1. Log in to the OSS user ID that owns the installation. The OSS user ID must have MQM as its primary group.
2. Download the installation package file. Ensure that you use "binary mode" when you download the installation package file to OSS. Any corruption in the file causes the self-extracting archive to fail to run. After you have downloaded the package file, ensure that it has read and execute permissions for the user ID that is installing the package.
3. Set the *_RLD_FIRST_LIB_PATH* variable to `MQ_INSTALLATION_PATH/opt/mqm/bin`
4. Optional: Make your current directory the location of the installation file.
5. Type the following command to start the interactive installation procedure:

   `./name of package file -i OSS install_root -g Guardian install_root`

   where

   name of package file> is the name of the installation package.

   OSS install_root is the OSS root directory of the new installation.

   Guardian install_root is the Guardian subvolume for the new installation.

   Both `-i` and `-g` options are mandatory.

   - `-i` specifies the new or empty OSS directory that contains the `opt/mqm` and `var/mqm` directories of the installation.
   - `-g` specifies the subvolume into which the Guardian components of the IBM MQ client for HP Integrity NonStop Server are installed. The Guardian subvolume can be specified in either OSS-form or Guardian-form and can be abbreviated. The Guardian subvolume specification is not case sensitive. The following examples show valid Guardian subvolume specifications:
     - `/G/vol/subvol`
     - `vol/subvol`
     - `\$VOL.SUBVOL`
     - `vol.subvol`
6. Optional: For OSS, set your environment by installing the binary files into your path. To do this, type the following command:

   `export PATH=$PATH:OSS_install_root/opt/mqm/bin`

   where *OSS_install_root* is the OSS root directory of the new installation.

Example

To install the IBM MQ client for HP Integrity NonStop Server from package `mat1.run`, type the following command:

```
./mat1.run -i ~install/mq75client -g /G/data04/mqm
```

The command installs the OSS components into new `opt/mqm` and `var/mqm` directories in `~install/mq75client`. It installs the Guardian components into `/G/data04/mqm`.

What to do next

For instructions on how to verify your installation, see "Testing communication between a client and a server on HP Integrity NonStop Server" on page 261.

Verifying an IBM MQ installation on HP Integrity NonStop Server

NSS Client

The topics in this section provide instructions on how to verify a client installation of IBM MQ on HP Integrity NonStop Server systems.

Verifying a client installation using the command line on HP Integrity NonStop Server

NSS Client

You can verify a client installation using the command line. On the server you create a queue manager, a local queue, a listener, and a server-connection channel. You must also apply security rules to allow the client to connect and make use of the queue defined. On the client you create a client-connection channel, and then use the sample PUT and GET programs to complete the verification procedure.

The verification procedure shows how to create a queue manager called `queue.manager.1`, a local queue called `QUEUE1`, and a server-connection channel called `CHANNEL1` on the server.

It shows how to create the client-connection channel on the IBM MQ MQI client workstation. It then shows how to use the sample programs to put a message onto a queue, and get the message from the queue.

The example does not address any client security issues. See Setting up IBM MQ MQI client security for details if you are concerned with IBM MQ MQI client security issues.

The verification procedure assumes that:
- The server installation is accessible on your network.
- The IBM MQ MQI client software has been installed on a client system.
- The IBM MQ sample programs have been installed.
- TCP/IP has been configured on the server and client systems. For more information, see Configuring connections between the server and client.

First, set up the server using the command line, using the instructions in "Setting up the server using the command line on HP Integrity NonStop Server" on page 259.

Once you have set up the server, you must set up the client, using the instructions in "Connecting to a queue manager, using the `MQSERVER` environment variable on HP Integrity NonStop Server" on page 260.

Finally, you can test the communications between client and server, using the instructions in "Testing communication between a client and a server on HP Integrity NonStop Server" on page 261.

Setting up the server using the command line on HP Integrity NonStop Server: NSS Client

Follow these instructions to create a queue manager, queue, and channel on the server. You can then use these objects to verify the installation.

About this task

These instructions assume that no queue manager or other IBM MQ objects have been defined.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Create a user ID on the server that is not in the `mqm` group. This user ID must exist on the server and client. This is the user ID that the sample applications must be run as, otherwise a 2035 error is returned.
2. Log in as a user in the mqm group.
3. You must set various environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

   where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.
4. Create a queue manager called `QUEUE.MANAGER.1` by entering the following command:
   ```
   crtmqm QUEUE.MANAGER.1
   ```
   You see messages telling you that the queue manager has been created.
5. Start the queue manager by entering the following command:
   ```
   strmqm QUEUE.MANAGER.1
   ```
   A message tells you when the queue manager has started.
6. Start MQSC by entering the following command:
   ```
   runmqsc QUEUE.MANAGER.1
   ```
   A message tells you that an MQSC session has started. MQSC has no command prompt.
7. Define a local queue called `QUEUE1` by entering the following command:
   ```
   DEFINE QLOCAL(QUEUE1)
   ```
   A message tells you when the queue has been created.
8. Allow the user ID that you created in step 1 to use `QUEUE1` by entering the following command:
   ```
   SET AUTHREC PROFILE(QUEUE1) OBJTYPE(QUEUE) PRINCIPAL(' non_mqm_user ') AUTHADD(PUT,GET)
   ```
   where *non_mqm_user* is the user ID created in step 1. A message tells you when the authorization has been set. You must also run the following command to give the user ID authority to connect:
   ```
   SET AUTHREC OBJTYPE(QMGR) PRINCIPAL(' non_mqm_user ') AUTHADD(CONNECT)
   ```
   If this command is not run, a 2305 stop error is returned.
9. Define a server-connection channel by entering the following command:
   ```
   DEFINE CHANNEL (CHANNEL1) CHLTYPE (SVRCONN) TRPTYPE (TCP)
   ```
   A message tells you when the channel has been created.

10. Allow your client channel to connect to the queue manager and run under the user ID that you created in step 1, by entering the following MQSC command:
    ```
    SET CHLAUTH(CHANNEL1) TYPE(ADDRESSMAP) ADDRESS(' client_ipaddr ') MCAUSER(' non_mqm_user ')
    ```
    where *client_ipaddr* is the IP address of the client system, and *non_mqm_user* is the user ID created in step 1. A message tells you when the rule has been set.
11. Define a listener by entering the following command:
    ```
    DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT (port_number)
    ```
    where *port_number* is the number of the port the listener is to run on. This number must be the same as the number used when defining your client-connection channel in “Installing the IBM MQ client on HP Integrity NonStop Server” on page 257.

    Note: If you omit the port parameter from the command, a default value of `1414` is used for the listener port. If you want to specify a port other than `1414`, you must include the port parameter in the command, as shown.
12. Start the listener by entering the following command:
    ```
    START LISTENER (LISTENER1)
    ```
13. Stop MQSC by entering:
    ```
    end
    ```
    You see some messages, followed by the command prompt.

What to do next

Follow the instructions to set up the client. See “Connecting to a queue manager, using the `MQSERVER` environment variable on HP Integrity NonStop Server.”

Connecting to a queue manager, using the `MQSERVER` environment variable on HP Integrity NonStop Server: NSS Client

When an IBM MQ application is run on the IBM MQ MQI client, it requires the name of the MQI channel, the communication type, and the address of the server to be used. Provide these parameters by defining the `MQSERVER` environment variable.

Before you begin

Before you start this task, you must complete the task, “Setting up the server using the command line on HP Integrity NonStop Server” on page 259, and save the following information:
- The host name or IP address of the server and port number that you specified when creating the listener.
- The channel name of the server-connection channel.

About this task

This task describes how to connect an IBM MQ MQI client, by defining the `MQSERVER` environment variable on the client.

You can give the client access to the generated client channel definition table, `amqclchl.tab` instead; see Accessing client-connection channel definitions.

Procedure

1. Log in as the userid that you created in Step 1 of “Setting up the server using the command line on HP Integrity NonStop Server” on page 259.
2. Check the TCP/IP connection. From the client, enter one of the following commands:
   - `ping server-hostname`
   - `ping n.n.n.n`

     `n.n.n.n` represents the network address. You can set the network address in IPv4 dotted decimal form, for example, `192.0.2.0`. Alternatively, set the address in IPv6 hexadecimal form, for example `2001:0DB8:0204:acff:fe97:2c34:fde0:3485`.

   If the **`ping`** command fails, correct your TCP/IP configuration.
3. Set the `MQSERVER` environment variable. From the client, enter one of the following commands:
   a. On IBM MQ client for HP Integrity NonStop Server:
   ```
   export MQSERVER=CHANNEL1/TCP/' server-address (port)'
   ```
   b. On HP Integrity NonStop Server Guardian systems:
   ```
   param MQSERVER CHANNEL1/TCP/server-address (port)
   ```
   Where:
   - *CHANNEL1* is the server-connection channel name.
   - *server-address* is the TCP/IP host name of the server.
   - *port* is the TCP/IP port number the server is listening on.

   If you do not give a port number, IBM MQ uses the one specified in the `qm.ini` file, or the client configuration file. If no value is specified in these files, IBM MQ uses the port number identified in the TCP/IP services file for the service name `MQSeries`. If an `MQSeries` entry in the services file does not exist, a default value of `1414` is used. It is important that the port number used by the client and the port number used by the server listener program are the same.

What to do next

Use the sample programs to test communication between the client and server; see “Testing communication between a client and a server on HP Integrity NonStop Server.”

Testing communication between a client and a server on HP Integrity NonStop Server: NSS Client

On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

Before you begin

Complete the previous topics in this section:
- Set up a queue manager, channels, and queue.
- Open a command window.
- Set system environment variables.

About this task

Note that IBM MQ object definitions are case-sensitive. Text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Change into the *MQ_INSTALLATION_PATH*/opt/mqm/samp/bin directory, which contains the sample programs. . *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
2. Start the PUT program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:

   ```
   ./amqsputc QUEUE1 QUEUE.MANAGER.1
   ```

   If the command is successful, the following messages are displayed:

   ```
   Sample AMQSPUT0 start target queue is QUEUE1
   ```

   Tip: You might get the error, MQRC_NOT_AUTHORIZED (2035). By default, channel authentication is enabled when a queue manager is created. Channel authentication prevents privileged users accessing a queue manager as an IBM MQ MQI client. For verifying the installation, you can either change the MCA user ID to a non-privileged user, or disable channel authentication. To disable channel authentication run the following MQSC command:

   ```
   ALTER QMGR CHLAUTH(DISABLED)
   ```

   When you finish the test, if you do not delete the queue manager, re-enable channel authentication:

   ```
   ALTER QMGR CHLAUTH(ENABLED)
   ```
3. Type some message text, then press **Enter** twice. The following message is displayed:

   ```
   Sample AMQSPUT0 end
   ```

   Your message is now on the queue that is on the server queue manager.
4. Start the GET program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:

   ```
   ./amqsgetc QUEUE1 QUEUE.MANAGER.1
   ```

   The sample program starts, and your message is displayed. After a short pause (approximately 30 seconds), the sample ends and the command prompt is displayed again.

Results

You have now successfully verified the client installation.

What to do next

1. You must set various environment variables on the server so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```

   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
2. On the server, stop the queue manager by entering the following command:

   ```
   endmqm QUEUE.MANAGER.1
   ```
3. On the server, delete the queue manager by entering the following command:

   ```
   dltmqm QUEUE.MANAGER.1
   ```

Uninstalling the IBM MQ client for HP Integrity NonStop Server

NSS Client

On HP Integrity NonStop Server systems, you can uninstall the IBM MQ client by using the **rm** command.

Procedure

1. Stop all IBM MQ applications that are associated with the installation you are uninstalling.
2. Log in to the OSS as the user ID that owns the installation.
3. Use the OSS **rm** command to delete the files from the Guardian subvolume used by the installation. For example, use the following command:
   ```
   rm -rf MQ_INSTALLATION_PATH/opt/mqm/bin/G/*
   ```
4. Use the OSS **rm** command to delete the OSS directory trees for the installation. For example, use the following command:
   ```
   rm -rf MQ_INSTALLATION_PATH
   ```

Installing and uninstalling IBM MQ on HP-UX

HP-UX

Installation tasks that are associated with installing IBM MQ on HP-UX systems are grouped in this section.

About this task

To prepare for installation and to install the IBM MQ components, complete the following tasks.

For information about how to uninstall IBM MQ, see "Uninstalling or modifying IBM MQ on HP-UX" on page 296.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See "Checking requirements on HP-UX" on page 266.
2. Plan your installation.
   - As part of the planning process, you must choose which components to install and where to install them. See "IBM MQ components for HP-UX" on page 264.
   - You must also make some platform-specific choices. See "Planning to install IBM MQ on HP-UX" on page 267.
3. Prepare your system for installation of IBM MQ. See "Preparing the system on HP-UX" on page 268.
4. Install IBM MQ server. See "Installing IBM MQ server on HP-UX" on page 274.
5. Optional: Install an IBM MQ client. See "Installing an IBM MQ client on HP-UX" on page 280.
6. Verify your installation. See "Verifying an IBM MQ installation on HP-UX" on page 282.

IBM MQ components for HP-UX

HP-UX

You can select the components that you require when you install IBM MQ.

Important: See IBM MQ license information for details of what each purchase of IBM MQ entitles you to install.

Table 38 shows the components that are available when installing an IBM MQ server or client on an HP-UX system:

Table 38. IBM MQ components for HP-UX systems

Component	**Description**	**Server media**	**Client media**	**Component name**
Runtime	Contains files that are common to both server and client installations. **Note:** This component must be installed.	✓	✓	MQSERIES.MQM-RUNTIME
Server	You can use the server to run queue managers on your system and connect to other systems over a network. Provides messaging and queuing services to applications, and support for IBM MQ client connections.	✓		MQSERIES.MQM-SERVER
Standard Client	The IBM MQ MQI client is a small subset of IBM MQ, without a queue manager, that uses the queue manager and queues on other (server) systems. It can be used only when the system it is on is connected to another system that is running a full server version of IBM MQ. The client and the server can be on the same system if required.	✓	✓	MQSERIES.MQM-CL-HPUX
SDK	The SDK is required for compiling applications. It includes sample source files, and the bindings (files .H, .LIB, .DLL, and others), that you need to develop applications to run on IBM MQ.	✓	✓	MQSERIES.MQM-BASE
Sample programs	The sample application programs are needed if you want to check your IBM MQ installation using the verification procedures.	✓	✓	MQSERIES.MQM-SAMPLES
Java messaging	The files needed for messaging using Java (includes Java Message Service).	✓	✓	MQSERIES.MQM-JAVA
Man pages	UNIX man pages, in U.S. English, for: control commands MQI calls MQSC commands	✓	✓	MQSERIES.MQM-MAN
Java JRE	A Java Runtime Environment that is used by those parts of IBM MQ that are written in Java.	✓	✓	MQSERIES.MQM-JAVAJRE
Message Catalogs	For available languages, see the table of message catalogs that follows.	✓	✓	
IBM Global Security Kit	IBM Global Security Kit V8 Certificate and TLS, Base Runtime.	✓	✓	MQSERIES.MQM-GSKIT

Table 38. IBM MQ components for HP-UX systems (continued)

Component	Description	Server media	Client media	Component name
Managed File Transfer	MQ Managed File Transfer transfers files between systems in a managed and auditable way, regardless of file size or the operating systems used. For information about the function of each component, see Managed File Transfer product options.	✓		MQSERIES.MQM-FTAGENT MQSERIES.MQM-FTBASE MQSERIES.MQM-FTLOGGER MQSERIES.MQM-FTSERVICE MQSERIES.MQM-FTTOOLS
Advanced Message Security	Provides a high level of protection for sensitive data flowing through the IBM MQ network, while not impacting the end applications. You must install this component on all IBM MQ installations that host queues you want to protect. You must install the IBM Global Security Kit component on any IBM MQ installation that is used by a program that puts or gets messages to or from a protected queue, unless you are using only Java client connections. You must install the **Java JRE** component to install this component.	✓		MQSERIES.MQM-AMS
V 9.0.0 AMQP Service	Install this component to make AMQP channels available. AMQP channels support MQ Light APIs. You can use AMQP channels to give AMQP applications access to the enterprise-level messaging facilities provided by IBM MQ.	✓		MQSERIES.MQM-AMQP

Table 39. IBM MQ message catalogs for HP-UX systems

Message catalog language	Component name
Brazilian Portuguese	MQSERIES.MQM-MC-PORT
Czech	MQSERIES.MQM-MC-CZECH
French	MQSERIES.MQM-MC-FRENCH
German	MQSERIES.MQM-MC-GERMAN
Hungarian	MQSERIES.MQM-MC-HUNGARIAN
Italian	MQSERIES.MQM-MC-ITALIAN
Japanese	MQSERIES.MQM-MC-JAPAN
Korean	MQSERIES.MQM-MC-KOREAN
Polish	MQSERIES.MQM-MC-POLISH
Russian	MQSERIES.MQM-MC-RUSSIAN
Spanish	MQSERIES.MQM-MC-SPANISH
Simplified Chinese	MQSERIES.MQM-MC-CHINES
Traditional Chinese	MQSERIES.MQM-MC-CHINET
U.S. English	not applicable

Checking requirements on HP-UX

▶ HP-UX

Before you install IBM MQ on HP-UX, you must check for the latest information and system requirements.

About this task

A summary of the tasks that you must complete to check system requirements are listed here with links to further information.

Procedure

1. Check that you have the latest information, including information on hardware and software requirements. See "Where to find product requirements and support information" on page 195.
2. Check that your systems meet the initial hardware and software requirements for HP-UX. See "Hardware and software requirements on HP-UX systems."

   The supported hardware and software environments are occasionally updated. See System Requirements for IBM MQ for the latest information.
3. Check that your systems have sufficient disk space for the installation. See Disk space requirements.
4. Check that you have the correct licenses. See "License requirements" on page 194 and IBM MQ license information.

What to do next

When you have completed these tasks, you are ready to start preparing your system for installation. For the next steps in installing IBM MQ, see "Preparing the system on HP-UX" on page 268.

Related concepts:

"IBM MQ installation overview" on page 192

IBM MQ maintenance tasks

Hardware and software requirements on HP-UX systems

▶ HP-UX

Before you install IBM MQ , check that your system meets the hardware and operating system software requirements for the particular components you intend to install.

For hardware and software requirements, see System Requirements for IBM MQ.

IBM MQ does not support host names that contain spaces. If you install IBM MQ on a system with a host name that contains spaces, you are unable to create any queue managers.

Java Message Service and SOAP transport

If you want to use Java Message Service and SOAP support, you need an IBM Java 7 SDK and Runtime Environment Version 7.0 or later.

V 9.0.0 Java 8 is bundled with IBM MQ Version 9.0 but client components are built with Java 7 compatibility flags on.

For development, a JDK is required, and a JRE is required for running. The JRE does not need to be the JRE installed with IBM MQ, but has to be one from the supported list.

For a list of supported JDKs, see System Requirements for IBM MQ.

For further information about SOAP with IBM MQ , see IBM MQ transport for SOAP.

On HP-UX : To run a 64-bit or 32-bit JVM use the -d64 or -d32 parameters on the command line when running a Java application to ensure the correct JVM is used.

You can check the version installed using the following command:

```
java -version
```

Transport Layer Security (TLS)

If you want to use the TLS support, you need the IBM Global Security Kit (GSKit) V8 package. This package is supplied with IBM MQ as one of the components available for installation.

HP-UX
To use TLS, IBM MQ clients on HP-UX must be built using POSIX threads.

Before you install IBM MQ on Windows, you must check for the latest information and system requirements.

Planning to install IBM MQ on HP-UX

HP-UX

Before you install IBM MQ on HP-UX, you must choose which components to install and where to install them. You must also make some platform-specific choices.

About this task

The following steps provide links to additional information to help you with planning your installation of IBM MQ on HP-UX.

As part of your planning activities, make sure that you review the information on hardware and software requirements for the platform on which you are planning to install IBM MQ. For more information, see “Checking requirements on HP-UX” on page 266.

Procedure

1. Decide which IBM MQ components and features to install. See “IBM MQ components and features” on page 192.

   Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. For more information, see “License requirements” on page 194 and IBM MQ license information.
2. Review the options for naming your installation. In some cases, you can choose an installation name to use instead of the default name. See “Installation name on UNIX, Linux, and Windows” on page 197.
3. Review the options and restrictions for choosing an installation location for IBM MQ. For more information, see “Installation location on Multiplatforms” on page 198.
4. If you plan to install multiple copies of IBM MQ, see “Multiple installations on UNIX, Linux, and Windows” on page 200.
5. If you already have a primary installation, or plan to have one, see “Primary installation on UNIX, Linux, and Windows” on page 202.
6. Make sure that the communications protocol needed for server-to-server verification is installed and configured on both systems that you plan to use. For more information, see “Server-to-server links on UNIX, Linux, and Windows” on page 210.

Preparing the system on HP-UX

HP-UX

On HP-UX systems, you might have to complete several tasks before you install IBM MQ. You might also want to complete other tasks, depending on your installation intentions.

About this task

The tasks that you perform to prepare your systems for installation are listed here. Complete the appropriate tasks for your platform before installing.

Procedure

1. Set up a user ID of the name `mqm`, with a primary group of `mqm`. See “Setting up the user and group on HP-UX” on page 269.
2. Create file systems for both the product code and working data to be stored. See “Creating file systems on HP-UX” on page 270.
3. Configure any additional settings needed for your HP-UX system. See “Configuring and tuning the operating system on HP-UX” on page 271.

What to do next

When you have completed the tasks to prepare the system, you are ready to start installing IBM MQ. To install a server, see “Installing IBM MQ server on HP-UX” on page 274. To install a client, see “Installing an IBM MQ client on HP-UX” on page 280.

Related information:
Planning
Maintaining and migrating
IBM MQ maintenance tasks

Setting up the user and group on HP-UX

HP-UX

On HP-UX systems, IBM MQ requires a user ID of the name `mqm`, with a primary group of `mqm`. The `mqm` user ID owns the directories and files that contain the resources associated with the product.

Creating the user ID and groups

Set the primary group of the `mqm` user to the group `mqm`.

If you are installing IBM MQ on multiple systems you might want to ensure each UID and GID of `mqm` has the same value on all systems. If you are planning to configure multi-instance queue managers, it is essential the UID and GID are the same from system to system. It is also important to have the same UID and GID values in virtualization scenarios.

HP-UX
The user ID value for user `mqm` must be less than 60,000 to avoid problems with the maintenance update process.

You can use the System Management Homepage (SMH), or the **`groupadd`** and **`useradd`** commands to work with user IDs.

Adding existing user IDs to the group

If you want to run administration commands, for example **`crtmqm`** (create queue manager) or **`strmqm`** (start queue manager), your user ID must be a member of the `mqm` group. This user ID must not be longer than 12 characters.

Users do not need `mqm` group authority to run applications that use the queue manager; it is needed only for the administration commands.

Log files created by MQ Telemetry service

The **`umask`** setting of the user ID that creates a queue manager will determine the permissions of the Telemetry log files generated for that queue manager. Even though the ownership of the log files will be set to `mqm`.

Configure Solaris systems with the resource limits required by IBM MQ.

Creating file systems on HP-UX

HP-UX

Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

Determining the size of a server installations file system

To determine the size of the `/var/mqm` file system for a server installation, consider:

- The maximum number of messages in the system at one time.
- Contingency for message buildups, if there is a system problem.
- The average size of the message data, plus 500 bytes for the message header.
- The number of queues.
- The size of log files and error messages.
- The amount of trace that is written to the `/var/mqm/trace` directory.

Storage requirements for IBM MQ also depend on which components you install, and how much working space you need. For more details, see Disk space requirements.

Creating a file system for the working data

Before you install IBM MQ, create and mount a file system called `/var/mqm` which is owned by the user `mqm` in the group `mqm` ; see "Setting up the user and group on Linux" on page 334. This file system is used by all installations of IBM MQ on a system. If possible, use a partition strategy with a separate volume for the IBM MQ data. This means that other system activity is not affected if a large amount of IBM MQ work builds up. Configure the directory permissions to permit the `mqm` user to have full control, for example, file mode 755. These permissions will then be updated during the IBM MQ installation to match the permissions required by the queue manager.

Creating separate file systems for errors and logs

You can also create separate file systems for your log data (`/var/mqm/log`) and error files (`/var/mqm/errors`). If possible, place these directories on different physical disks from the queue manager data (`/var/mqm/qmgrs`) and from each other.

If you create separate file systems the `/var/mqm/errors` directory can be NFS mounted. However, if you choose to NFS-mount `/var/mqm/errors`, the error logs might be lost if the network fails.

You can protect the stability of your queue manager by having separate file systems for:
- `/var/mqm/errors`
- `/var/mqm/trace`
- `/var/mqm/qmgrs`
- `/var/mqm/log`

In the case of `/var/mqm/errors`, it is rare that this directory receives large quantities of data. But it is sometimes seen, particularly if there is a severe system problem leading to IBM MQ writing a lot of diagnostic information in to `.FDC` files. In the case of `/var/mqm/trace`, files are only written here when you use **`strmqtrc`** to start tracing IBM MQ.

You can obtain better performance of normal IBM MQ operations (for example, syncpoints, MQPUT, MQGET of persistent messages) by placing the following on separate disks:
- `/var/mqm/qmgrs`
- `/var/mqm/log`

In the rare event that you need to trace an IBM MQ system for problem determination, you can reduce performance impact by placing the `/var/mqm/trace` file system on a separate disk.

If you are creating separate file systems, allow a minimum of 30 MB of storage for `/var/mqm`, 100 MB of storage for `/var/mqm/log`, and 10 MB of storage for `/var/mqm/errors`. The 100 MB minimum allowance of storage for `/var/mqm/log` is the absolute minimum required for a single queue manager and is not a recommended value. The size of a file system must be scaled according to the number of queue managers that you intend to use, the number of pages per log file, and the number of log files per queue manager.

If you want to use individual queues that hold more than 2 GB of data, you must enable `/var/mqm` to use large files.

For more information about file systems, see File system support.

The size of the log file depends on the log settings that you use. The minimum sizes are for circular logging using the default settings. For more information about log sizes, see Calculating the size of the log.

Related concepts:

"Setting up the user and group on HP-UX" on page 269

"Configuring and tuning the operating system on HP-UX"
Before you install IBM MQ on an HP-UX system, you must check that the kernel is configured correctly.

Configuring and tuning the operating system on HP-UX

HP-UX

Before you install IBM MQ on an HP-UX system, you must check that the kernel is configured correctly.

Kernel configuration

It is possible that the default kernel configuration is not adequate because IBM MQ uses semaphores and shared memory.

Before installation, review the configuration of the machine and increase the values if necessary. Consider using the values of the tunable kernel parameters given in Table 40. These values might need to be increased if you obtain any First Failure Support Technology™ (FFST) records.

Note:
1. Semaphore and swap usage do not vary significantly with message rate or message persistence.
2. IBM MQ queue managers are independent of each other. Therefore system tunable kernel parameters, for example `shmmni`, `semmni`, `semmns`, and `semmnu` need to allow for the number of queue managers in the system.

See the HP-UX documentation for information about changing these values.

Table 40. Minimum tunable kernel parameters values

Name	**Value**	**Increase**	**Description**
`shmmax`	268435456	No	Maximum size of a shared-memory segment (bytes)
`shmseg`	1024	No	Maximum number of shared memory segments per process
`shmmni`	1024	Yes	Maximum number of shared memory segments
`semaem`	128	No	Maximum undo value for a semaphore for a single process
`semvmx`	32767	No	Maximum value of a semaphore
`semmns`	4096	Yes	Maximum number of semaphores
`semmni`	128	Yes	Maximum number of semaphore sets
`semmnu`	16384	Yes	Maximum number of process having semaphore operations that can be undone
`semume`	32	No	Maximum number of semaphore undo operations per process
`max_thread_proc`	66	No	Maximum number of threads in a process
`maxfiles`	10000	No	Maximum number of file handles per process (soft limit)
`maxfiles_lim`	10000	No	Maximum number of file handles per process (hard limit)

Notes:
- These values are sufficient to run two moderate sized queue managers on the system. If you intend to run more than two queue managers, or the queue managers are to process a significant workload, you might need to increase the values displayed as *Yes* in the *Increase* column.
- You must restart the system after you change any of the tunable kernel parameters.

System resource limits

You can set global limits for the size of process data segments and the size of process stack segments for the whole system. These limits are set by altering the tunable kernel parameters.

The tunable kernel parameters are:

Parameter	What it controls	Consider minimum value
maxdsiz	Maximum size of the data segment for 32-bit processes	1073741824
maxdsiz_64bit	Maximum size of the data segment for 64-bit processes	1073741824
maxssiz	Maximum size of the stack segment for 32-bit processes	8388608
maxssiz_64bit	Maximum size of the stack segment for 64-bit processes	8388608

If other software on the same machine needs higher values, then the operation of IBM MQ is not adversely affected if those higher values are used.

For the full documentation for these parameters see the HP-UX product documentation.

To apply the settings to an HP-UX 11i system which has the System Administration Manager (SAM) utility, you can use SAM to achieve the following steps:
- Select and alter the parameters
- Process the new kernel
- Apply the changes and restart the system

Other releases of HP-UX might provide different facilities to set the tunable kernel parameters. Consult your HP-UX product documentation for the relevant information.

The `ulimit` shell command

On a per-shell basis, the available limits can be tuned down from the values stored for the "System resource limits" on page 272 preceding parameters. Use the **`ulimit`** shell command to tune the values of the parameters with a combination of the following switches:

Switch	Meaning
-H	The hard limit
-S	The soft limit
-d	The data segments size
-s	The stack segment size

Verifying that the kernel settings are applied

You can verify that the resource limits have not been lowered by a **`ulimit`** command and that the queue manager has the correct limits. To verify the limits, go to the shell from which the queue manager is started and enter the following command:

```
ulimit -Ha
ulimit -Sa
```

Among the console output you see:

```
data(kbytes)  1048576
stack(kbytes) 8192
```

If the lowered numbers are returned, then a **`ulimit`** command has been issued in the current shell to reduce the limits. Consult with your system administrator to resolve the issue.

You can check your system configuration using the mqconfig command.

For more information on configuring your system, see How to configure UNIX and Linux systems for IBM MQ.

Related concepts:

"Setting up the user and group on HP-UX" on page 269

Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

Installing IBM MQ server on HP-UX

HP-UX

You can install an IBM MQ server on HP-UX either interactively or silently.

Before you begin

- Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on HP-UX" on page 268.
- If you install a copy of IBM MQ server for HP-UX using Electronic Software Download, obtained from Passport Advantage, you need to decompress the `tar.gz` file, and extract the installation files from the tar file, by using the following command:

  ```
  tar -xvf   WS_MQ_V8.0_TRIAL_FOR_HP-UX_ML.tar
  ```

  Important: You must use GNU tar (also known as `gtar`) to unpack any `tar` images.

About this task

This task describes the installation of a server, using the `swinstall` program to select which components you want to install. The components are listed in "IBM MQ components for HP-UX" on page 264.

Note: If you are using a screen reader, use the non-interactive installation option "Installing the IBM MQ server silently on HP-UX" on page 276, so that you can accept the license without viewing it.

If you are installing IBM MQ from a depot that contains service update packages, read Applying maintenance level updates on IBM MQ on HP-UX before installing the service update packages.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Set your current directory to the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Accept the license by running the `mqlicense` script:

   ```
   ./mqlicense.sh
   ```

   The license is displayed. If you accept the license, you can continue the installation.
4. Start the interactive installation procedure by typing the following command,

   ```
   swinstall -s /installation_file
   ```

   /installation_file is the absolute path to the installation file. The path must begin with a / and end with the name of the installation file. The installation file has a file name extension of `.v11`. In the resulting menu screen, select **MQSERIES**.
   a. If you do not want to install all IBM MQ components, open **MQSERIES**

   1) Mark the components you want to install. The installer resolves dependencies automatically.
   2) Review the information displayed by the installer.
5. Optional: To install IBM MQ to a non-default location, select **MQSERIES** from the lower part of the user interface, then select **Actions > Change Product Location**. The default installation location is `/opt/mqm`.

   For each installation, all of the IBM MQ components that you require must be installed in the same location.

   The installation path specified must either be an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.

   Note: Ensure that you do not select **Actions > Change Target** by accident, they are not the same.
6. If this installation is not the first installation on the system, select **Options > Allow creation of multiple versions**
7. Select **Actions > Install**. The log file tells you if there are any problems that need fixing.
8. Fix any problems, then click **OK** to install.

   The system tells you when the installation has finished.
9. If this installation is not the first installation on the system, you must enter the following command to configure IBM MQ.

   Note: *MQ_INSTALLATION_PATH* is the path where you have just installed IBM MQ and the character defining the path is a lower case L.

   ```
   swconfig -x allow_multiple_versions=true MQSERIES,l=MQ_INSTALLATION_PATH
   ```

   If you do not enter this command, the **swlist** command reports the installation as installed instead of configured. You must not use IBM MQ unless the installation is configured.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  where *MQ_INSTALLATION_PATH* represents the directory where IBM MQ is installed.

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ . For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. See "Verifying an IBM MQ installation on HP-UX" on page 282, for more information.

Changing the primary installation

Installing the IBM MQ server silently on HP-UX

▶ HP-UX

You can perform a non-interactive installation of the IBM MQ server using the **swinstall** command. A non-interactive installation is also known as a silent, or unattended installation.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on HP-UX" on page 268.

About this task

This topic describes the non-interactive installation of a server, using the **swinstall** program to select which components you want to install. The components and are listed in "IBM MQ components and features" on page 192.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Set your current directory to the location of the installation file. The location might be the mount point of the CD, a network location, or a local file system directory.
3. Accept the IBM MQ license agreement without an interactive prompt by entering the following command:
   ```
   ./mqlicense.sh -accept
   ```
4. Install IBM MQ using the **swinstall** command:
   a. If this installation is not the first installation on the system, you must add `-x allow_multiple_versions=true` to the **swinstall** command.
   b. Add the names of the components to install as parameters of the **swinstall** command. The installer automatically resolves any dependencies.
   c. Optional: Identify the installation location by adding **,l=** *MQ_INSTALLATION_PATH* as a parameter of the **swinstall** command. For each installation, all of the IBM MQ components that you require must be installed in the same location. The installation path specified must either be an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.

For example, to install all IBM MQ components, in a non-default location, as the first installation, enter the following command:

```
swinstall -s /installation_file.v11 MQSERIES,l=/opt/customLocation
```

To perform a partial installation, providing a list of components, in the default location, as the second installation, enter the following command:

```
swinstall -x allow_multiple_versions=true -s /installation_file.v11
MQSERIES.MQM-RUNTIME MQSERIES.MQM-BASE MQSERIES.MQM-SERVER
```

`/installation_file.v11` is the absolute path to the installation file. The path must begin with a `/` and end with the name of the installation file. The installation file has the extension `.v11`.

5. If this installation is not the first installation on the system, you must enter the following command to configure the installation:

   Note: *MQ_INSTALLATION_PATH* is the path where you have just installed IBM MQ and the character defining the path is a lower case `L`.

   ```
   swconfig -x allow_multiple_versions=true MQSERIES,l=MQ_INSTALLATION_PATH
   ```

   If you do not enter this command, the **swlist** command reports the installation as installed instead of configured. You must not use IBM MQ unless the installation is configured.

Example

The example shows the command to run a silent, full installation in the default location, using the alternative form of specifying the source depot using `-x source_directory=` instead of `-s`. Notice that all the language features are installed. Run a partial installation to install your chosen languages.

```
cd /downloads/WMQInstallFiles
swinstall -v -x source_directory=$PWD/hpUxxxxx.v11 MQSERIES
```

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  where *MQ_INSTALLATION_PATH* represents the directory where IBM MQ is installed.

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ . For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. See "Verifying an IBM MQ installation on HP-UX" on page 282, for more information.

Changing the primary installation

Converting a trial license on HP-UX

HP-UX

Convert a trial license to a full license without reinstalling IBM MQ.

When the trial license expires, the "count-down" displayed by the **strmqm** command informs you the license has expired, and the command does not run.

Before you begin

1. IBM MQ is installed with a trial license.
2. You have access to the installation media of a fully licensed copy of IBM MQ.

About this task

Run the **setmqprd** command to convert a trial license to a full license.

If you do not want to apply a full license to your trial copy of IBM MQ, you can uninstall it at any time.

Procedure

1. Obtain the full license from the fully licensed installation media.

   The full license file is `amqpcert.lic`. On HP-UX, it is in the */MediaRoot/*`licenses` directory on the installation media.
2. Run the **setmqprd** command from the installation that you are upgrading:
   ```
   MQ_INSTALLATION_PATH/bin/setmqprd /MediaRoot/licenses/amqpcert.lic
   ```

Related information:
setmqprd

Displaying messages in your national language on HP-UX

HP-UX

To display messages from a different national language message catalog, you must install the appropriate catalog and set the **LANG** environment variable.

About this task

Messages in U.S. English are automatically installed with IBM MQ

Message catalogs for all languages are installed in *MQ_INSTALLATION_PATH*/msg/*language identifier*, where *language identifier* is one of the identifiers in Table 41.

If you require messages in a different language, perform the following steps:

Procedure

1. Install the appropriate message catalog (see "IBM MQ components and features" on page 192).
2. To select messages in a different language, ensure the **LANG** environment variable is set to the identifier for the language you want to install:

Table 41. Language identifiers

Identifier	**Language**
cs_CZ	Czech
de_DE	German
es_ES	Spanish
fr_FR	French
hu_HU	Hungarian
it_IT	Italian
ja_JP	Japanese
ko_KR	Korean
pl_PL	Polish
pt_BR	Brazilian Portuguese
ru_RU	Russian
zh_CN	Simplified Chinese
zh_TW	Traditional Chinese

Installing an IBM MQ client on HP-UX

HP-UX

You can interactively install the IBM MQ client for HP-UX using `swinstall`.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in “Preparing the system on HP-UX” on page 268.

About this task

This topic describes the installation of a client, using the `swinstall` program to select which components you want to install. The components and are listed in “IBM MQ components for HP-UX” on page 264; you must install at least the Runtime and Client components.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Make your current directory the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Accept the license by running the `mqlicense` script:
   ```
   ./mqlicense.sh
   ```
   The license is displayed. If you accept the license, you can continue the installation.
4. Type the following command to start the interactive installation procedure:
   ```
   swinstall -s installation_file
   ```
   installation_file is the absolute path to the installation file. The path must begin with a / and end with the name of the installation file. The installation file has the extension `.v11`.

   If the files on your DVD are in uppercase with a ";1" suffix, use this name for the depot.
5. In the resulting menu screen, select **MQSERIES**.
   a. If you do not want to install all IBM MQ components, open **MQSERIES**
      1) Mark the components you want to install. The installer resolves dependencies automatically.
      2) Review the information displayed by the installer.
6. Optional: To install IBM MQ to a non-default location, select **Actions > Change Product Location**.

   For each installation, all of the IBM MQ components that you require must be installed in the same location.

   The installation path specified must either be an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.
7. Select **Actions > Install**. The log file tells you if there are any problems that need fixing.
8. Fix any problems, and click **OK** to install. You are informed when the installation has finished.
9. If this installation is not the first installation on the system, you must enter the following command:
   ```
   swconfig -x allow_multiple_versions=true MQSERIES,l= MQ_INSTALLATION_PATH
   ```
   where *MQ_INSTALLATION_PATH* is the path where you have just installed IBM MQ. If you do not enter this command, the **swlist** command reports the installation as installed instead of configured. You must not use IBM MQ unless the installation is configured.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

```
MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
```

You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.

- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see "Testing communication between a client and a server on HP-UX" on page 295.

Related tasks:

"Uninstalling or modifying IBM MQ on HP-UX" on page 296
On HP-UX, you can uninstall the IBM MQ server or client using the **swremove** command. You can also modify an IBM MQ installation by uninstalling selected IBM MQ components.

Installing an IBM MQ client silently on HP-UX

HP-UX

You can perform a non-interactive installation of the IBM MQ client using the **swinstall** command. A non-interactive installation is also known as a silent, or unattended installation.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on HP-UX" on page 268.

About this task

This topic describes the non-interactive installation of a client, using the **swinstall** program to select which components you want to install. The components and are listed in "IBM MQ components and features" on page 192 ; you must install at least the Runtime and client components.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Make your current directory the location of the installation file. The location might be the mount point of the CD, a network location, or a local file system directory.
3. Accept the IBM MQ license agreement without an interactive prompt by entering the following command:
   ```
   ./mqlicense.sh -accept
   ```
4. Install IBM MQ using the **swinstall** command:
   a. If this installation is not the first installation on the system, you must add `-x allow_multiple_versions=true` to the **swinstall** command.
   b. Add the names of the components to install as parameters of the **swinstall** command. The installer automatically resolves any dependencies.
   c. Optional: Identify the installation location by adding `,l=` *MQ_INSTALLATION_PATH* as a parameter of the **swinstall** command. For each installation, all of the IBM MQ components that you require must be installed in the same location. The installation path specified must either be an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.

   For example, to install all IBM MQ components, in a non-default location, as the first installation, enter the following command:
   ```
   swinstall -s /installation_file.v11 MQSERIES,l=/opt/customLocation
   ```

To perform a partial installation, providing a list of components, in the default location, as the second installation, enter the following command:

```
swinstall -s /installation_file.v11
MQSERIES.MQM-RUNTIME MQSERIES.MQM-BASE MQSERIES.MQM-CL-HPUX -x allow_multiple_versions=true
```

`/installation_file.v11` is the absolute path to the installation file. The path must begin with a `/` and end with the name of the installation file. The installation file has the extension `.v11`.

5. If this installation is not the first installation on the system, you must enter the following command:

```
swconfig -x allow_multiple_versions=true MQSERIES,l= MQ_INSTALLATION_PATH
```

where *MQ_INSTALLATION_PATH* is the path where you have just installed IBM MQ. If you do not enter this command, the **swlist** command reports the installation as installed instead of configured. You must not use IBM MQ unless the installation is configured.

What to do next

For instructions on how to verify your installation, see "Testing communication between a client and a server on HP-UX" on page 295.

Verifying an IBM MQ installation on HP-UX

HP-UX

The topics in this section provide instructions on how to verify a server or a client installation of IBM MQ on HP-UX systems.

About this task

You can verify a local (stand-alone) server installation or a server-to-server installation of the IBM MQ server:
- A local server installation has no communication links with other IBM MQ installations.
- A server-to-server installation does have links to other installations.

You can also verify that your IBM MQ MQI client installation completed successfully and that the communication link is working.

Procedure

- To verify a local server installation, see "Verifying a local server installation on HP-UX" on page 283.
- To verify a server-to-server installation, see "Verifying a server-to-server installation on HP-UX" on page 286.
- To verify a client installation, see "Verifying a client installation using the command line on HP-UX" on page 292.

Verifying a local server installation on HP-UX

HP-UX

You can use either the command line or the postcard application to verify a local (stand-alone) installation on HP-UX.

About this task

You can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a local server installation using the command line on HP-UX."
- To use the postcard application to verify an installation, see "Verifying a local server installation using the Postcard application on HP-UX" on page 285.

Verifying a local server installation using the command line on HP-UX: HP-UX

On HP-UX systems, you can verify a local installation by using the command line to create a simple configuration of one queue manager and one queue. You can also verify an installation using the postcard application.

Before you begin

To verify the installation, you must first install the samples package.

Before beginning the verification procedure, you might want to check that you have the latest fixes for your system. For more information about where to find the latest updates, see "Checking requirements on Windows" on page 444.

About this task

Use the following steps to configure your default queue manager from the command line. After the queue manager is configured, use the `amqsput` sample program to put a message on the queue. You then use the `amqsget` sample program to get the message back from the queue.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On an HP-UX system, log in as a user in the `mqm` group.
2. Set up your environment:
   a. Set up environment variables for use with a particular installation by entering one the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.
   b. Check that the environment is set up correctly by entering the following command:
   ```
   dspmqver
   ```

If the command completes successfully, and the expected version number and installation name are returned, the environment is set up correctly.

3. Create a queue manager called `QMA` by entering the following command:

   ```
   crtmqm QMA
   ```

   Messages indicate when the queue manager is created, and when the default IBM MQ objects are created.
4. Start the queue manager by entering the following command:

   ```
   strmqm QMA
   ```

   A message indicates when the queue manager starts.
5. Start MQSC by entering the following command:

   ```
   runmqsc QMA
   ```

   A message indicates when MQSC starts. MQSC has no command prompt.
6. Define a local queue called `QUEUE1` by entering the following command:

   ```
   DEFINE QLOCAL (QUEUE1)
   ```

   A message indicates when the queue is created.
7. Stop MQSC by entering the following command:

   ```
   end
   ```

   Messages are shown, followed by the command prompt.

Note: Subsequent steps require that the samples package is installed.

8. Change into the *`MQ_INSTALLATION_PATH`*`/samp/bin` directory, which contains the sample programs. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
9. Put a message on the queue by entering the following commands

   ```
   ./amqsput QUEUE1 QMA
   ```

   The following messages are shown:

   ```
   Sample AMQSPUT0 start
   target queue is QUEUE1
   ```
10. Type some message text on one or more lines, where each line is a different message. Enter a blank line to end the message input. The following message is shown:

    ```
    Sample AMQSPUT0 end
    ```

    Your messages are now on the queue and the command prompt is shown.
11. Get the messages from the queue, by entering the following command:

    ```
    ./amqsget QUEUE1 QMA
    ```

    The sample program starts, and your messages are displayed.

Results

You have successfully verified your local installation.

Verifying a local server installation using the Postcard application on HP-UX: HP-UX

Sending messages successfully between two Postcard applications verifies a local installation.

Before you begin

The postcard application is Java based and requires a system with the ability to view a graphical display.

You must ensure that you are a member of the IBM MQ administrators group (`mqm`).

Note: Using Postcard to verify an IBM MQ installation is only possible if there is one IBM MQ installation on that box. The Default Configuration wizard will not create a default configuration if a queue manager already exists on the box. The Default Configuration wizard will run on any installation on a box but only one default configuration can be created per box. Using Postcard to verify second and subsequent installations of IBM MQ on the same box is not possible.

To verify that the local installation is working, you can run two instances of the Postcard application on the same server. The postcard application can send messages to, and receive messages from, other postcard applications. Successful sending and receiving of messages verifies that IBM MQ is installed and working correctly on the server.

Procedure

1. Log on as a user in group `mqm`.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *`MQ_INSTALLATION_PATH`*`/java/bin`. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:
      ```
      ./postcard
      ```
   b. From the IBM MQ Explorer:
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.
3. At the Postcard - Sign On window, type in a nickname to use to send messages within the Postcard application (for example, `User1`).
4. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Launching the Default Configuration creates a default queue manager.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

When your selection is complete, click **OK** to display your first Postcard window.

5. Run a second instance of the Postcard application by following the steps used to open the first instance of the Postcard application.
6. The Postcard - Sign On panel is displayed again. Type in a second nickname to use to send messages within this second Postcard application (for example, `User2`).
7. Repeat the selection of the queue manager that you want to use as the mailbox (as described in step 4). The queue manager you select for this second Postcard must be the same queue manager as used for the first instance of the Postcard application.
8. In the first Postcard, (User1), enter the nickname (`User2`) for the second Postcard application in the **To:** field. Because the sender and receiver are on the same server, you can leave the **On:** field blank.
9. Type a message in the **Message:** field and click **Send**.
10. The **Postcards sent and received** area of the Postcard shows details of the message. In the sending Postcard, the message is displayed as sent. In the receiving Postcard, the message is displayed as received.
11. In the receiving Postcard, (User2), double-click the message in the **Postcards sent and received** area to view it. When this message arrives, it verifies that IBM MQ is correctly installed.

What to do next

Depending on your situation, you might want to do the following tasks:

- Install IBM MQ on other servers. Follow the installation procedure for the appropriate platform. Ensure that you use the **Join Default Cluster** window in the Default Configuration wizard to add the other servers to the cluster on your first server.
- Install the IBM MQ MQI client on other servers.
- Continue with further administration tasks, see Administering IBM MQ.

Verifying a server-to-server installation on HP-UX

HP-UX

You can use either the command line or the postcard application to verify a server-to-server installation on HP-UX.

Before you begin

For a server-to-server verification, the communication links between the two systems must be checked. Before you can do the verification, you must therefore ensure that the communications protocol is installed and configured on both systems.

On HP-UX, IBM MQ supports both TCP and SNA.

The examples in this task use TCP/IP. If you do not use TCP, see Setting up communication on UNIX and Linux.

About this task

For a server-to server installation, you can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a server-to-server installation using the command line on HP-UX."
- To use the postcard application to verify an installation, see "Verifying a server-to-server installation using the Postcard application on HP-UX" on page 290.

Verifying a server-to-server installation using the command line on HP-UX: HP-UX

You can verify a server-to-server installation using two servers, one as a sender and one as a receiver.

Before you begin

- Make sure that TCP/IP and IBM MQ are installed on both servers (see "Verifying a server-to-server installation on HP-UX" on page 286).
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Decide which installation is the sender server and which installation is the receiver server. The installations might be on the same system, or on different systems.

About this task

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On the **receiver** server:
   a. On HP-UX, log in as a user in the mqm group.
   b. Check which ports are free, for example by running **netstat**. For more information about this command, see the documentation of your operating system.

      If port 1414 is not in use, make a note of 1414 to use as the port number in step 2 h. Use the same number for the port for your listener later in the verification. If it is in use, note a port that is not in use; for example 1415.
   c. Set up the environment for the installation you are using by entering the following command at the command prompt:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   d. Create a queue manager called QMB by entering the following command at the command prompt:
      ```
      crtmqm QMB
      ```
      Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.
   e. Start the queue manager by entering the following command:
      ```
      strmqm QMB
      ```
      A message tells you when the queue manager has started.
   f. Start MQSC by entering the following command:
      ```
      runmqsc QMB
      ```
      A message tells you that MQSC has started. MQSC has no command prompt.
   g. Define a local queue called RECEIVER.Q by entering the following command:
      ```
      DEFINE QLOCAL (RECEIVER.Q)
      ```

A message tells you the queue has been created.

h. Define a listener by entering the following command:

```
DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT ( PORT_NUMBER )
```

Where *port_number* is the name of the port the listener runs on. This number must be the same as the number used when defining your sender channel.

i. Start the listener by entering the following command:

```
START LISTENER (LISTENER1)
```

Note: Do not start the listener in the background from any shell that automatically lowers the priority of background processes.

j. Define a receiver channel by entering the following command:

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (RCVR) TRPTYPE (TCP)
```

A message tells you when the channel has been created.

k. End MQSC by typing:

```
end
```

Some messages are displayed, followed by the command prompt.

2. On the **sender** server:

a. As the sender server is an AIX system, log in as a user in the mqm group.

b. Set up the environment for the installation you are using by entering the following command at the command prompt:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.

c. Create a queue manager called QMA by entering the following command at the command prompt:

```
crtmqm QMA
```

Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.

d. Start the queue manager, by entering the following command:

```
strmqm QMA
```

A message tells you when the queue manager has started.

e. Start MQSC by entering the following command:

```
runmqsc QMA
```

A message tells you that an MQSC session has started. MQSC had no command prompt.

f. Define a local queue called QMB (to be used as a transmission queue) by entering the following command:

```
DEFINE QLOCAL (QMB) USAGE (XMITQ)
```

A message tells you when the queue has been created.

g. Define a local definition of the remote queue with by entering the following command:

```
DEFINE QREMOTE (LOCAL.DEF.OF.REMOTE.QUEUE) RNAME (RECEIVER.Q) RQMNAME ('QMB') XMITQ (QMB)
```

h. Define a sender channel by entering one of the following commands:

con-name is the TCP/IP address of the receiver system. If both installations are on the same system, the *con-name* is localhost. *port* is the port you noted in 1 b. If you do not specify a port, the default value of 1414 is used.

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (SDR) CONNAME ('CON-NAME(PORT)') XMITQ (QMB) TRPTYPE (TCP)
```

i. Start the sender channel by entering the following command:

```
START CHANNEL(QMA.QMB)
```

The receiver channel on the receiver server starts automatically when the sender channel starts.

j. Stop MQSC by entering the following command:

```
end
```

Some messages are displayed, followed by the command prompt.

k. If the sender server is a UNIX or Linux system, change into the *MQ_INSTALLATION_PATH*/samp/bin directory. This directory contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.

l. If both the sender server and receiver server are installations on the same system, check that the queue managers have been created on different installations by entering the following command:

```
dspmq -o installation
```

If the queue managers are on the same installation, move either QMA to the sender installation or QMB to the receiver installation by using the **setmqm** command. For more information, see setmqm.

m. Put a message on the local definition of the remote queue, which in turn specifies the name of the remote queue. Enter one of the following commands:
   - On Windows:

     ```
     amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
     ```
   - On UNIX and Linux:

     ```
     ./amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
     ```

   A message tells you that amqsput has started.

n. Type some message text on one or more lines, followed by a blank line. A message tells you that amqsput has ended. Your message is now on the queue and the command prompt is displayed again.

3. On the **receiver** server:

   a. As your receiver server is an AIX system, change into the *MQ_INSTALLATION_PATH*/samp/bin directory. This directory contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.

   b. Get the message from the queue on the receiver by entering the following command:

   ```
   ./amqsget RECEIVER.Q QMB
   ```

   The sample program starts, and your message is displayed. After a pause, the sample ends. Then the command prompt is displayed.

Results

You have now successfully verified the server-to-server installation.

Verifying a server-to-server installation using the Postcard application on HP-UX: HP-UX

You can use two instances of the Postcard application to verify that a server-to-server installation is working.

Before you begin

You can use the Postcard application on two servers, one instance of the Postcard application on each server, to verify that a server-to-server installation is working. Successful sending and receiving of messages verifies that IBM MQ is successfully installed, and that communication between the two servers is working correctly.

Note:

- If the system has multiple IBM MQ installations, ensure that Postcard has not been run before on any installations on that server. As the default configuration can only exist on one IBM MQ installation per system, the Default Configuration wizard and Postcard can not be used for verification of a second or any subsequent installation.
- The two server installations must be on different systems to do a server-to-server verification using the postcard application. To verify a server-to-server installation on the same machine, you can use the command line.
- Make sure that TCP/IP and IBM MQ are installed on both servers.
- Make sure that your systems are able to view a graphical display.
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Check that one of the following scenarios applies:
  - Neither server has had any queue managers created.
  - Use the Default Configuration wizard to create default queue managers on each server and link them to the default cluster.

    Details on how to use the Default Configuration wizard are provided in this topic.
  - Both servers have existing queue managers and these queue managers are in the same cluster.

    If your queue managers are not in the same cluster, create new queue managers on both servers. Then create a cluster, and ensure that the queue managers that you create on each server belong to that cluster.
  - You have configured channels to communicate between the two servers.

    For instructions on how to set up the channels, see "Verifying a server-to-server installation using the command line on HP-UX" on page 287. After you have set up the channels, follow the instructions in this topic to verify your server-to-server installation.

Procedure

1. On the first server, log on as a user in group **mqm**.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *MQ_INSTALLATION_PATH*/java/bin. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:

```
./postcard
```

   b. From the IBM MQ Explorer:
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.

3. At the Postcard - Sign On window, type a nickname to use to send messages within the Postcard application. For example, `User1` for the first server, and `User2` for the second server.
4. When you have completed the wizard, you are taken back to the Postcard - Sign On window.
5. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Work through the Default Configuration wizard. When you get to the option to join the queue manager to the default cluster, tick the check box. On the next screen:
     – For the first server, select **yes, make it the repository for the cluster**.
     – For the second server, select **No another computer has already joined the cluster as a repository**. When requested, enter the location of the repository, by typing the name of the sender server.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK**.
6. Complete steps 1 - 5 for the second server.
7. In the Postcard on the first server:
   a. Enter the nickname (`user2`) for the Postcard application on the second server in the **To:** field.
   b. Enter the queue manager on the second server in the **On:** field.
   c. Type a message in the **Message:** field and click **Send**.
8. In the Postcard on the second server:
   a. In the **Postcards sent and received**, double-click the message marked as received to view the message from the first server.
   b. Optional: Send a postcard to the first server by adapting the instructions in step 7. You must enter details of the first server in the **To:** field and the **On:** field.

   The messages verify that IBM MQ is correctly installed and that your communication link between the two servers is working correctly.

Verifying a client installation using the command line on HP-UX

HP-UX

You can verify a client installation using the command line. On the server you create a queue manager, a local queue, a listener, and a server-connection channel. You must also apply security rules to allow the client to connect and make use of the queue defined. On the client you create a client-connection channel, and then use the sample PUT and GET programs to complete the verification procedure.

The verification procedure shows how to create a queue manager called `queue.manager.1`, a local queue called `QUEUE1`, and a server-connection channel called `CHANNEL1` on the server.

It shows how to create the client-connection channel on the IBM MQ MQI client workstation. It then shows how to use the sample programs to put a message onto a queue, and get the message from the queue.

The example does not address any client security issues. See Setting up IBM MQ MQI client security for details if you are concerned with IBM MQ MQI client security issues.

The verification procedure assumes that:
- The full IBM MQ server product has been installed on a server.
- The server installation is accessible on your network.
- The IBM MQ MQI client software has been installed on a client system.
- The IBM MQ sample programs have been installed.
- TCP/IP has been configured on the server and client systems. For more information, see Configuring connections between the server and client.

First, set up the server using the command line, using the instructions in “Setting up the server using the command line on HP-UX.”

Once you have set up the server, you must set up the client, using the instructions in “Connecting to a queue manager, using the `MQSERVER` environment variable on HP-UX” on page 294.

Finally, you can test the communications between client and server, using the instructions in “Testing communication between a client and a server on HP-UX” on page 295.

Setting up the server using the command line on HP-UX: HP-UX

Follow these instructions to create a queue manager, queue, and channel on the server. You can then use these objects to verify the installation.

About this task

These instructions assume that no queue manager or other IBM MQ objects have been defined.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Create a user ID on the server that is not in the `mqm` group. This user ID must exist on the server and client. This is the user ID that the sample applications must be run as, otherwise a 2035 error is returned.
2. Log in as a user in the mqm group.

3. You must set various environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

   where `MQ_INSTALLATION_PATH` refers to the location where IBM MQ is installed.
4. Create a queue manager called `QUEUE.MANAGER.1` by entering the following command:

   ```
   crtmqm QUEUE.MANAGER.1
   ```

   You see messages telling you that the queue manager has been created.
5. Start the queue manager by entering the following command:

   ```
   strmqm QUEUE.MANAGER.1
   ```

   A message tells you when the queue manager has started.
6. Start MQSC by entering the following command:

   ```
   runmqsc QUEUE.MANAGER.1
   ```

   A message tells you that an MQSC session has started. MQSC has no command prompt.
7. Define a local queue called `QUEUE1` by entering the following command:

   ```
   DEFINE QLOCAL(QUEUE1)
   ```

   A message tells you when the queue has been created.
8. Allow the user ID that you created in step 1 to use `QUEUE1` by entering the following command:

   ```
   SET AUTHREC PROFILE(QUEUE1) OBJTYPE(QUEUE) PRINCIPAL(' non_mqm_user ') AUTHADD(PUT,GET)
   ```

   where *non_mqm_user* is the user ID created in step 1. A message tells you when the authorization has been set. You must also run the following command to give the user ID authority to connect:

   ```
   SET AUTHREC OBJTYPE(QMGR) PRINCIPAL(' non_mqm_user ') AUTHADD(CONNECT)
   ```

   If this command is not run, a 2305 stop error is returned.
9. Define a server-connection channel by entering the following command:

   ```
   DEFINE CHANNEL (CHANNEL1) CHLTYPE (SVRCONN) TRPTYPE (TCP)
   ```

   A message tells you when the channel has been created.
10. Allow your client channel to connect to the queue manager and run under the user ID that you created in step 1, by entering the following MQSC command:

    ```
    SET CHLAUTH(CHANNEL1) TYPE(ADDRESSMAP) ADDRESS(' client_ipaddr ') MCAUSER(' non_mqm_user ')
    ```

    where *client_ipaddr* is the IP address of the client system, and *non_mqm_user* is the user ID created in step 1. A message tells you when the rule has been set.
11. Define a listener by entering the following command:

    ```
    DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT (port_number)
    ```

    where *port_number* is the number of the port the listener is to run on. This number must be the same as the number used when defining your client-connection channel in "Installing an IBM MQ client on HP-UX" on page 280.

    Note: If you omit the port parameter from the command, a default value of `1414` is used for the listener port. If you want to specify a port other than `1414`, you must include the port parameter in the command, as shown.
12. Start the listener by entering the following command:

    ```
    START LISTENER (LISTENER1)
    ```
13. Stop MQSC by entering:

```
end
```

You see some messages, followed by the command prompt.

What to do next

Follow the instructions to set up the client. See "Connecting to a queue manager, using the `MQSERVER` environment variable on HP-UX."

Connecting to a queue manager, using the `MQSERVER` environment variable on HP-UX: HP-UX

When an IBM MQ application is run on the IBM MQ MQI client, it requires the name of the MQI channel, the communication type, and the address of the server to be used. Provide these parameters by defining the `MQSERVER` environment variable.

Before you begin

Before you start this task, you must complete the task, "Setting up the server using the command line on HP-UX" on page 292, and save the following information:
- The host name or IP address of the server and port number that you specified when creating the listener.
- The channel name of the server-connection channel.

About this task

This task describes how to connect an IBM MQ MQI client, by defining the `MQSERVER` environment variable on the client.

You can give the client access to the generated client channel definition table, `amqclchl.tab` instead; see Accessing client-connection channel definitions.

Procedure
1. Log in as the userid that you created in Step 1 of "Setting up the server using the command line on HP-UX" on page 292.
2. Check the TCP/IP connection. From the client, enter one of the following commands:
   - `ping server-hostname`
   - `ping n.n.n.n`

     `n.n.n.n` represents the network address. You can set the network address in IPv4 dotted decimal form, for example, `192.0.2.0`. Alternatively, set the address in IPv6 hexadecimal form, for example `2001:0DB8:0204:acff:fe97:2c34:fde0:3485`.

   If the **`ping`** command fails, correct your TCP/IP configuration.
3. Set the `MQSERVER` environment variable. From the client, enter the following command:
   ```
   export MQSERVER=CHANNEL1/TCP/' server-address (port)'
   ```

   Where:
   - *CHANNEL1* is the server-connection channel name.
   - *server-address* is the TCP/IP host name of the server.
   - *port* is the TCP/IP port number the server is listening on.

   If you do not give a port number, IBM MQ uses the one specified in the `qm.ini` file, or the client configuration file. If no value is specified in these files, IBM MQ uses the port number identified in the TCP/IP services file for the service name `MQSeries`. If an `MQSeries` entry in the services file does

not exist, a default value of 1414 is used. It is important that the port number used by the client and the port number used by the server listener program are the same.

What to do next

Use the sample programs to test communication between the client and server; see "Testing communication between a client and a server on HP-UX."

Testing communication between a client and a server on HP-UX: HP-UX

On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

Before you begin

Complete the previous topics in this section:
- Set up a queue manager, channels, and queue.
- Open a command window.
- Set system environment variables.

About this task

Note that IBM MQ object definitions are case-sensitive. Text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Change to the *MQ_INSTALLATION_PATH*/samp/bin directory, which contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
2. You must set certain environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
3. Start the PUT program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:
   ```
   ./amqsputc QUEUE1 QUEUE.MANAGER.1
   ```
   If the command is successful, the following messages are displayed:
   ```
   Sample AMQSPUT0 start target queue is QUEUE1
   ```
   Tip: You might get the error, MQRC_NOT_AUTHORIZED (2035). By default, channel authentication is enabled when a queue manager is created. Channel authentication prevents privileged users accessing a queue manager as an IBM MQ MQI client. For verifying the installation, you can either change the MCA user ID to a non-privileged user, or disable channel authentication. To disable channel authentication run the following MQSC command:
   ```
   ALTER QMGR CHLAUTH(DISABLED)
   ```
   When you finish the test, if you do not delete the queue manager, re-enable channel authentication:
   ```
   ALTER QMGR CHLAUTH(ENABLED)
   ```
4. Type some message text, then press **Enter** twice. The following message is displayed:
   ```
   Sample AMQSPUT0 end
   ```
   Your message is now on the queue that is on the server queue manager.

5. Start the GET program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:
   ```
   ./amqsgetc QUEUE1 QUEUE.MANAGER.1
   ```
   The sample program starts, and your message is displayed. After a short pause (approximately 30 seconds), the sample ends and the command prompt is displayed again.

Results

You have now successfully verified the client installation.

What to do next

1. You must set various environment variables on the server so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
2. On the server, stop the queue manager by entering the following command:
   ```
   endmqm QUEUE.MANAGER.1
   ```
3. On the server, delete the queue manager by entering the following command:
   ```
   dltmqm QUEUE.MANAGER.1
   ```

Uninstalling or modifying IBM MQ on HP-UX

HP-UX

On HP-UX, you can uninstall the IBM MQ server or client using the **swremove** command. You can also modify an IBM MQ installation by uninstalling selected IBM MQ components.

Before you begin

If any updates have been applied, remove them before starting the uninstallation procedure. For more information, see Restoring the previous maintenance level on IBM MQ on HP-UX.

Important: You must stop all IBM MQ queue managers, other objects, and applications, before you begin the process to uninstall or modify IBM MQ.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling or modifying, if you have not already done so.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling or modifying:
   a. Log in as a user in the group mqm.
   b. Set up your environment to work with the installation you want to uninstall or modify. Enter the following command:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:
      ```
      dspmq -o installation
      ```
   d. Stop all running queue managers associated with the installation you want to uninstall or modify. Enter the following command for each queue manager:
      ```
      endmqm QMgrName
      ```

   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:
      ```
      endmqlsr -m QMgrName
      ```
3. Log in as root.
4. Uninstall IBM MQ using **swremove**:
   - To uninstall all IBM MQ components, enter the following command:
     ```
     swremove MQSERIES,l= MQ_INSTALLATION_PATH
     ```
     where *MQ_INSTALLATION_PATH* is the path where IBM MQ is installed.
   - To modify an IBM MQ installation and uninstall selected IBM MQ components, enter the following command:
     ```
     swremove componentname,l= MQ_INSTALLATION_PATH
     ```
     where *componentname* is the name of the component to uninstall, and *MQ_INSTALLATION_PATH* is the path where IBM MQ is installed.

     For example:
     – To uninstall the client component, from an installation in `/opt/myLocation`, enter the following command:
       ```
       swremove MQSERIES.MQM-CL-HPUX,l=/opt/myLocation
       ```
     – To uninstall the client and the telemetry client components, from an installation in `/opt/myLocation`, enter the following command:
       ```
       swremove MQSERIES.MQM-CL-HPUX,l=/opt/myLocation MQSERIES.MQM-TXCLIENT,l=/opt/myLocation
       ```

Results

After uninstallation, certain files under the directory trees `/var/mqm` and `/etc/opt/mqm` are not removed. These files contain user data and remain so subsequent installations can reuse the data. Most of the remaining files contain text, such as INI files, error logs, and FDC files. The directory tree `/var/mqm/shared` contains files that are shared across installations, including the executable shared libraries `libmqzsd.so` and `libmqzsd_r.so`.

What to do next

- If the product successfully uninstalled, you can delete any files and directories contained in the installation directory.
- If there are no other IBM MQ installations on the system, and you are not planning to reinstall or migrate, you can delete the `/var/mqm` and `/etc/opt/mqm` directory trees, including the files `libmqzsd.so` and `libmqzsd_r.so`. Deleting these directories destroys all queue managers and their associated data.

Installing and uninstalling IBM MQ on IBM i

IBM i

Installation tasks that are associated with installing IBM MQ on IBM i systems are grouped in this section.

About this task

To prepare for installation and to install the IBM MQ components, complete the following tasks.

For information about how to uninstall IBM MQ, see "Uninstalling IBM MQ for IBM i" on page 325.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See "Hardware and software requirements on IBM i systems" on page 299.
2. Plan your installation.
   - As part of the planning process, you must choose which components to install and where to install them. See "IBM MQ components for IBM i."
   - You must also make some platform-specific choices. See "Planning to install IBM MQ on IBM i" on page 301.
3. Prepare your system for installation of IBM MQ. See "Preparing the system on IBM i" on page 301.
4. Install IBM MQ server. See "Installing IBM MQ server on IBM i" on page 303.
5. Optional: Install an IBM MQ client. See "Installing an IBM MQ client on IBM i" on page 316.
6. Verify your installation. See "Verifying an IBM MQ installation on IBM i" on page 321.

IBM MQ components for IBM i

IBM i

The IBM MQ components that are available for IBM i.

Important: See IBM MQ license information for details of what each purchase of IBM MQ entitles you to install.

The components are as follows:

Server (Base)
Support to enable you to create and support your own applications. This includes the runtime component that provides support for external applications. It also includes support for client connections from IBM MQ installations on other computers.

Command Reference
Help for the CL commands is provided in HTML format and installed with the product in the /QIBM/ProdData/mqm/doc directory.

Samples (Option 1)
Sample application programs. The source is supplied in the QMQMSAMP library and executable files are supplied in the QMQM library.

AMS (Option 2)
The AMS component.

Documentation
The full product documentation is supplied on the IBM MQ Documentation CD.

Readme file
Latest information about the product that became available after publication of this product documentation or the full documentation. You can find the readme file in the root of the product or documentation CD. Review it before starting to install IBM MQ for IBM i.

Managed File Transfer (MFT) components

***BASE**
Support to enable you to create and support your own MFT applications. It also includes support for client connections from IBM MQ MFT installations on other computers.

2 Tools support

3 Agent

4 Services

You must install `*BASE` first because the other three options depend on `*BASE`. Note that option `4` requires that option 3 is installed.

Related concepts:
"IBM MQ components and features" on page 192
You can select the components or features that you require when you install IBM MQ.

Hardware and software requirements on IBM i systems

IBM i

Check that the server environment meets the prerequisites for installing IBM MQ for IBM i. Check the product readme files and install missing prerequisite software supplied on the server CD.

Before installation, you must check that your system meets the hardware and software requirements set out in the IBM MQ system requirements page. See System Requirements for IBM MQ. You must also review the release notes file, which are on the product CD in the `\Readmes` folder for each national language, and check the `READADD.txt` file for any changes made between translation and the manufacturing of the installation CD. `READADD.txt` is found in the root directory of the server installation CD.

During installation, the release notes file is copied to the IBM MQ program files folder (default `/QIBM/ProdData/mqm`).

Storage requirements for IBM MQ server

The storage requirements for IBM i depend on which components you install, and how much working space you need. The storage requirements also depend on the number of queues that you use, the number and size of the messages on the queues, and whether the messages are persistent. You also require archiving capacity on disk, tape, or other media. For more information, see System Requirements for IBM MQ.

Disk storage is also required:
- Prerequisite software
- Optional software
- Your application programs

Installing prerequisite software

To install the prerequisite software provided on the IBM MQ Server CD (which does not include service packs or web browsers), do one of the following:

- Use the IBM MQ installation procedure.

  When you install using the IBM MQ Server CD, there is a **Software Prerequisites** option in the IBM MQ Installation Launchpad window. You can use this option to check what prerequisite software is already installed and which is missing, and to install any missing software.

Using TLS Version 1.2

TLS version 1.2 is the latest version of the Transport Layer Security (TLS) protocol. The core System TLS v1.2 functionality is included in IBM i 7.1 Technology Refresh 6 (TR6). To enable and use the new protocols, program temporary fixes (PTFs) from multiple areas of the operating system are also required.

Provided DCM (5770SS1 option 34) is installed on your system, requesting and applying SI48659 obtains all of the enablement PTFs.

System value changes

The new support is installed, but dormant in System SSL after applying SI48659.

In order to activate the new protocols for System SSL, use Change System Value (CHGSYSVAL) to modify The QSSLPCL system value.

Change the default value of *OPSYS to:

*TLSV1.2

*TLSV1.1

*TLSV1

*SSLV3

If QSSLPCL is set to something other than *OPSYS, add *TLSV1.2 and *TLSV1.1 to the existing setting.

Prerequisite PTFs for multiple certificate support

You are not limited to a single certificate for TLS channels. To use multiple certificates on IBM i platforms, you must install the following program temporary fixes (PTFs):

MF57749

MF57889

SI52214

MF58003

See Digital certificate labels: understanding the requirements for details about how to select certificates by using certificate labels.

Related concepts:

"License requirements" on page 194
You must have purchased sufficient licenses for your installation. The details of the license agreement is stored on your system at installation time so that you can read it at any time. IBM MQ supports IBM License Metric Tool (ILMT).

"Where to find product requirements and support information" on page 195
Before you install IBM MQ, you must check for the latest information and system requirements.

Planning to install IBM MQ on IBM i

IBM i

Before you install IBM MQ on IBM i, you must choose which components to install and where to install them. You must also make some platform-specific choices.

About this task

The following steps provide links to additional information to help you with planning your installation of IBM MQ on IBM i.

Procedure

1. As part of your planning activities, make sure that you review the information on hardware and software requirements for the platform on which you are planning to install IBM MQ. For more information, see "Hardware and software requirements on IBM i systems" on page 299.
2. Decide which IBM MQ components and features to install. See "IBM MQ components and features" on page 192.

   Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. For more information, see "License requirements" on page 194 and IBM MQ license information.

Preparing the system on IBM i

IBM i

On IBM i systems, you might have to complete several tasks before you install IBM MQ. You might also want to complete other tasks, depending on your installation intentions.

About this task

The tasks that you perform to prepare your systems for installation are listed here. Complete the appropriate tasks for your platform before installing.

Procedure

Configure any additional settings needed for your IBM i system. See "Configuring and tuning the operating system on IBM i" on page 302.

What to do next

When you have completed the tasks to prepare the system, you are ready to start installing IBM MQ. To install a server, see "Installing IBM MQ server on IBM i" on page 303. To install a client, see "Installing an IBM MQ client on IBM i" on page 316.

IBM MQ maintenance tasks

Configuring and tuning the operating system on IBM i

IBM i

Before installing IBM MQ for IBM i, there are several system values which need to be checked using the DSPSYSVAL command. If necessary, reset the values using the CHGSYSVAL command.

Check the following values and change if required:

QCCSID
Every message has a coded-character set identifier (CCSID) in its header. The CCSID tag identifies the code page and character set of the source.

A queue manager obtains its CCSID from the job that created it. If the job CCSID is not a valid value in the range 1-65534, the queue manager uses the default CCSID value (65535) instead. You can change the CCSID used by the IBM MQ queue manager by using the CL command **CHGMQM**.

Note: The CCSID must be either single-byte character set (SBCS), or mixed, that is SBCS and DBCS. It must not be DBCS only.

QSYSLIBL
Ensure that QSYS2 is included in the list of libraries that make up the system part of the library list. IBM MQ uses programs in this library for data conversion and SNA LU 6.2 communication.

Note: Do not have QMQM as part of the system or user portion of the library list.

QALWOBJRST
Ensure that the QALWOBJRST system value is set to *ALL or *ALWPGMADP before you install MQ. If it is set to *NONE, installation fails.

After installation, reset QALWOBJRST to its original value to maintain system security.

QSHRMEMCTL
Ensure that the QSHRMEMCTL system value is set to 1 (Allowed).

A value of 1 is used in environments where pointers can be shared amongst programs between different jobs.

IBM MQ requires this setting to use the shared memory APIs shmat and shmget and to share its pointers across jobs.

If it is not set correctly, initialization of IBM MQ fails with system return code "3401" (Permission denied), and commands such as CRTMQM, STRMQM, ENDMQM, TRCMQM fail.

QFRCCVNRST
Ensure that the QFRCCVNRST system value is set to 0 (Restore all objects without conversion), or 1 (Objects with validation errors are converted), before you install MQ. If it is not set, installation fails.

QMLTTHDACN
Optionally set this to control the generation of messages into joblogs. Set QMLTTHDACN to 2 to get messages generated in a joblog; set it to 1 to avoid the messages. For example, the message CPD000D is an informational message that is generated when a command that is not thread-safe is issued from a multi-threaded application. Setting QMLTTHDACN to 1 avoids the message.

Related concepts:

"Hardware and software requirements on IBM i systems" on page 299
Check that the server environment meets the prerequisites for installing IBM MQ for IBM i. Check the product readme files and install missing prerequisite software supplied on the server CD.

"License requirements" on page 194
You must have purchased sufficient licenses for your installation. The details of the license agreement is stored on your system at installation time so that you can read it at any time. IBM MQ supports IBM License Metric Tool (ILMT).

"Installing IBM MQ server on IBM i"
Install IBM MQ for IBM i by installing the IBM MQ server in its primary language, installing samples and installing additional languages.

Installing IBM MQ server on IBM i

IBM i

Install IBM MQ for IBM i by installing the IBM MQ server in its primary language, installing samples and installing additional languages.

Before you begin

Note: Installing the latest version of the IBM MQ server includes client capabilities. Only install the stand-alone client if you do not need the server capabilities.

You have completed planning the installation, obtained the installation CDs and set the system values, see "Configuring and tuning the operating system on IBM i" on page 302. For a complete list of IBM MQ installable services and components for IBM i systems, see Installable services and components for IBM i

About this task

How to install the base IBM MQ server in its primary language, install samples, and install translated versions from a choice of national-languages.

You can install only one instance of IBM MQ for IBM i in each partition of your server.

Procedure

1. Sign on to the system with a user profile that has `*ALLOBJ` special authority, for example `QSECOFR`.
2. Install IBM MQ for IBM i, V9.0 base product, and primary language.

   ```
   RSTLICPGM LICPGM (5724H72) DEV (installation device) OPTION (*BASE) OUTPUT (*PRINT)
   ```

   where the parameters of RSTLICPGM are,

   `LICPGM(5724H72)`
   The product identifier for IBM i.

   `DEV(`*`installation device`*`)`
   The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`.

   `OPTION (*BASE)`
   Install the base IBM MQ for IBM i product.

   `Unspecified parameters`
   Unspecified parameters, such as **`RSTOBJ`** `(*ALL)`, revert to defaults. The command installs both IBM MQ and the language files for the primary language of your system. For installing additional languages, see step 4.

3. Optional: Install the samples using the command:

   ```
   RSTLICPGM LICPGM (5724H72) DEV (installation device) OPTION (1) OUTPUT (*PRINT)
   ```

   Where the parameters of RSTLICPGM are,

   LICPGM (5724H72)
      The product identifier for IBM i.

   DEV (*installation device*)
      The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`.

   OPTION (1)
      Install the samples for IBM i.

   OUTPUT (*PRINT)
      The output is printed with the spooled output of the job.
4. Optional: To install additional languages, sign on to the system with a user profile that has *ALLOBJ special authority. Choose a language code from the table.

Table 42. Globalizations of IBM MQ for IBM i.

Language ID	Language
2909	Belgian English
2966	Belgian French MNCS (Multi-National Character Set)
2980	Brazilian Portuguese
2981	Canadian French MNCS
2975	Czech
2924	English uppercase and lowercase
2984	English US DBCS
2938	English US uppercase DBCS
2928	French
2940	French MNCS
2929	German
2939	German MNCS
2976	Hungarian
2932	Italian
2942	Italian MNCS
2962	Japanese
2930	Japanese Universal
2986	Korean
2978	Polish
2979	Russian
2989	Simplified Chinese
2931	Spanish

- If installing Japanese language feature code 2962, ensure the CCSID of the job installing the product is set to 939 and not 930. Do this to avoid problems with invariant lowercase characters in CCSID 930

  ```
  CHGJOB CCSID(939)
  ```

- If the language feature code is not in the table then the product has not been translated into your language. You must choose one of the available language feature codes and install that version instead. You must manually change the system library list to use IBM MQ in that language load.

  ```
  CHGSYSLIBL LIB(QSYS2924)
  ```
- If you are using Korean DBCS and you configure your terminal emulators to 24*80 sessions you might find that EDTF incorrectly displays DBCS characters in MQ error log messages that extend beyond 80 columns. To avoid this, configure your terminal emulators to use sessions capable of displaying 132 columns, for example 27*132.
- Issue the following command specifying the appropriate language ID:

  ```
  RSTLICPGM LICPGM(5724H72) DEV( installation device ) RSTOBJ(*LNG) LNG( language ID )
  ```

  This installs the commands, message file, and panel groups into the relevant QSYS library for the language. For example, library QSYS2928 is used for French. If this QSYS29nn library does not exist, it is created by the RSTLICPGM command.

5. To ensure that the product has loaded correctly, issue the Display Software Resources (DSPSFWRSC) command and check that the licensed program 5724H72 is listed. If you have installed the base and the optional samples, you see:

   ```
   Resource
   ID    Option Feature Description
   5724H72  *BASE  5050  IBM MQ for IBM i
   5724H72  *BASE  2924  IBM MQ for IBM i
   5724H72  1    5050  IBM MQ for IBM i - Samples
   ```

6. Press F11, while viewing the Display Software Resources screen, and you see the library and version number of the products installed:

   ```
   Resource          Feature
   ID    Option Feature  Type  Library  Release
   5724H72  *BASE  5050   *CODE  QMQM   V9R0M0
   5724H72  *BASE  2924   *LNG   QMQM   V9R0M0
   5724H72  1    5050   *CODE  QMQMSAMP V9R0M0
   ```

7. If you have installed additional language versions, you also see entries for these versions. For example, if you have installed the French version, for which the language ID is 2928, you see:

   a.

   ```
   Resource
   ID    Option Feature Description
   5724H72  *BASE  2928  IBM MQ for IBM i
   ```

   b. and when you press F11:

   ```
   Resource          Feature
   ID    Option Feature  Type  Library   Release
   5724H72  *BASE  2928  *LNG  QSYS2928  V9R0M0
   ```

8. Use the command DSPMQMVER to check exactly what version you have installed. For V9R0M0, it reports:

   ```
   Version: 9.0.0.0
   ```

9. Do the post installation tasks of checking for updates, checking program authorities and starting the IBM MQ subsystem, see "Performing post installation tasks for IBM MQ on IBM i" on page 314.

What to do next

If you want to see how the installation went in more detail, perform one or more of the following tasks:
- View the log file using the `DSPJOBLOG` command.
- View the spoolfile generated from the `RSTLICPGM` command.

If the installation of IBM MQ fails, see "Handling installation failures for IBM i" on page 315.

Related concepts:
"Uninstalling IBM MQ for IBM i" on page 325
There are two ways of uninstalling IBM MQ for IBM i.

Installing IBM MQ server silently on IBM i

IBM i

You can perform a non-interactive installation of IBM MQ using the `CALL PGM(QSYS/QLPACAGR)` command. A non-interactive installation is also known as a silent, or unattended installation.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on IBM i" on page 301.

About this task

This topic describes the non-interactive installation of a server.

Procedure

1. Pre-agree the license terms and conditions for the base by running the command,
   ```
   CALL PGM  ( QSYS/QLPACAGR) PARM ('5724H72' 'V8R0M0' '0000' 0)
   ```
   Where the parameters of **PARM** are,

   5724H72
   The product identifier for IBM i.

   V9R0M0
   The version, release, and modification level.

   0000
   The option number for the IBM MQ product.

   0 Unused error structure.
2. Optionally pre-agree the license terms and conditions for the samples by running the command,
   ```
   CALL PGM (QSYS/QLPACAGR) PARM ('5724H72' 'V8R0M0' '0001' 0)
   ```
   Where the parameters of **PARM** are,

   5724H72
   The product identifier for IBM i.

   V9R0M0
   The version, release, and modification level.

   0001
   The option number for the IBM MQ product.

   0 Unused error structure.
3. Install IBM MQ for IBM i, V9.0 base product, and primary language.

```
RSTLICPGM LICPGM (5724H72) DEV (installation device) OPTION (*BASE) OUTPUT (*PRINT)
```

where the parameters of RSTLICPGM are,

LICPGM(5724H72)
The product identifier for IBM i.

DEV(*installation device*)
The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`.

OPTION (*BASE)
Install the base IBM MQ for IBM i product.

Unspecified parameters
Unspecified parameters, such as **RSTOBJ** (`*ALL`), revert to defaults. The command installs both IBM MQ and the language files for the primary language of your system. For installing additional languages, see step 4.

4. Optional: Install the samples using the command:

```
RSTLICPGM LICPGM (5724H72) DEV (installation device) OPTION (1) OUTPUT (*PRINT)
```

Where the parameters of RSTLICPGM are,

LICPGM (5724H72)
The product identifier for IBM i.

DEV (*installation device*)
The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`.

OPTION (1)
Install the samples for IBM i.

OUTPUT (*PRINT)
The output is printed with the spooled output of the job.

5. Optional: To install additional languages, sign on to the system with a user profile that has *ALLOBJ special authority. Choose a language code from the table.

Table 43. Globalizations of IBM MQ for IBM i.

Language ID	Language
2909	Belgian English
2966	Belgian French MNCS (Multi-National Character Set)
2980	Brazilian Portuguese
2981	Canadian French MNCS
2975	Czech
2924	English uppercase and lowercase
2984	English US DBCS
2938	English US uppercase DBCS
2928	French
2940	French MNCS
2929	German
2939	German MNCS
2976	Hungarian
2932	Italian

Table 43. Globalizations of IBM MQ for IBM i. (continued)

Language ID	Language
2942	Italian MNCS
2962	Japanese
2930	Japanese Universal
2986	Korean
2978	Polish
2979	Russian
2989	Simplified Chinese
2931	Spanish

- If installing Japanese language feature code 2962, ensure the CCSID of the job installing the product is set to 939 and not 930. Do this to avoid problems with invariant lowercase characters in CCSID 930

  ```
  CHGJOB CCSID(939)
  ```
- If the language feature code is not in the table then the product has not been translated into your language. You must choose one of the available language feature codes and install that version instead. You must manually change the system library list to use IBM MQ in that language load.

  ```
  CHGSYSLIBL LIB(QSYS2924)
  ```
- If you are using Korean DBCS and you configure your terminal emulators to 24*80 sessions you might find that EDTF incorrectly displays DBCS characters in MQ error log messages that extend beyond 80 columns. To avoid this, configure your terminal emulators to use sessions capable of displaying 132 columns, for example 27*132.
- Issue the following command specifying the appropriate language ID:

  ```
  RSTLICPGM LICPGM(5724H72) DEV( installation device ) RSTOBJ(*LNG) LNG( language ID )
  ```

  This installs the commands, message file, and panel groups into the relevant QSYS library for the language. For example, library QSYS2928 is used for French. If this QSYS29nn library does not exist, it is created by the RSTLICPGM command.

6. To ensure that the product has loaded correctly, issue the Display Software Resources (DSPSFWRSC) command and check that the licensed program 5724H72 is listed. If you have installed the base and the optional samples, you see:

```
Resource
ID    Option Feature Description
5724H72  *BASE  5050  IBM MQ for IBM i
5724H72  *BASE  2924  IBM MQ for IBM i
5724H72  1    5050  IBM MQ for IBM i - Samples
```

7. Press F11, while viewing the Display Software Resources screen, and you see the library and version number of the products installed:

```
Resource          Feature
ID    Option Feature  Type  Library  Release
5724H72  *BASE  5050   *CODE  QMQM   V9R0M0
5724H72  *BASE  2924   *LNG   QMQM   V9R0M0
5724H72  1    5050   *CODE  QMQMSAMP V9R0M0
```

8. If you have installed additional language versions, you also see entries for these versions. For example, if you have installed the French version, for which the language ID is 2928, you see:

   a.

```
Resource
ID    Option Feature Description
5724H72  *BASE  2928  IBM MQ for IBM i
```

b. and when you press F11:

```
Resource          Feature
ID    Option Feature  Type  Library   Release
5724H72  *BASE  2928  *LNG  QSYS2928  V9R0M0
```

9. Use the command DSPMQMVER to check exactly what version you have installed. For V9R0M0, it reports:

```
Version: 9.0.0.0
```

10. Do the post installation tasks of checking for updates, checking program authorities and starting the IBM MQ subsystem, see "Performing post installation tasks for IBM MQ on IBM i" on page 314.

What to do next

If you want to see how the installation went in more detail, perform one or more of the following tasks:

- View the log file using the `DSPJOBLOG` command.
- View the spoolfile generated from the `RSTLICPGM` command.

If the installation of IBM MQ fails, see "Handling installation failures for IBM i" on page 315.

Installing Managed File Transfer on IBM i

IBM i

Install IBM MQ Managed File Transfer for IBM i by installing IBM MQ Java Messaging and Web Services server in its primary language, and installing additional options.

Before you begin

Note: Installing the latest version of IBM MQ Managed File Transfer includes client capabilities.

You have completed planning the installation, obtained the installation CDs and set the system values, see "Configuring and tuning the operating system on IBM i" on page 302.

You have installed the following components:

Table 44. Software requirements for IBM MQ Managed File Transfer

Program	Option	Description
5761JV1	14 or 15	Java SE 7 32 bit or Java SE 7 64 bit
5770SS1	39	International Components for Unicode
5724L26	*BASE	IBM MQ Java Messaging and Web Services

About this task

How to install base Managed File Transfer in its primary language, and install the other options.

You can install only one instance of Managed File Transfer for IBM i in each partition of your server.

Procedure

1. Sign on to the system with a user profile that has *ALLOBJ special authority, for example QSECOFR.
2. Install Managed File Transfer for IBM i, V9.0 base product.

   ```
   RSTLICPGM LICPGM (5725M50) DEV (installation device) OPTION (*BASE) OUTPUT (*PRINT)
   ```

   where the parameters of RSTLICPGM are,

   LICPGM (5725M50)
   The product identifier for Managed File Transfer for IBM i.

   DEV (*installation device*)
   The device from which the product is to be loaded, typically an optical drive, for example, OPT01.

   OPTION (*BASE)
   Install Managed File Transfer for IBM i for the IBM MQ base product.

   Unspecified parameters
   Unspecified parameters such as **RSTOBJ** (*ALL), revert to defaults. The command installs both IBM MQ and the language files for the primary language of your system.
3. Optional: Install the tools using the command:

   ```
   RSTLICPGM LICPGM(5725M50) DEV(installation device) OPTION(2) OUTPUT(*PRINT)
   ```

   Where the parameters of RSTLICPGM are,

   LICPGM (5725M50)
   The product identifier for Managed File Transfer for IBM i.

   DEV (*installation device*)
   The device from which the product is to be loaded, typically an optical drive, for example, OPT01.

   OPTION (2)
   Install the tools for Managed File Transfer for IBM i.

   OUTPUT (*PRINT)
   The output is printed with the spooled output of the job.

   Repeat step 3 for options 3 (agent) and 4 (services)
4. To ensure that the product has loaded correctly, issue the Display Software Resources (DSPSFWRSC) command and check that the licensed program 5725M50 is listed. If you have installed the base and the optional tools, you see:

   ```
   Resource
   ID       Option  Feature  Description
   5725M50  *BASE   5050     Managed File Transfer for IBM i
   5725M50  *BASE   2924     Managed File Transfer for IBM i
   5725M50  2       5050     Managed File Transfer for IBM i - Tools
   ```

5. Press F11, while viewing the Display Software Resources screen, and you see the library and version number of the products installed:

   ```
   Resource
   ID       Option  Feature  Type   Library  Release
   5725M50  *BASE   5050     *CODE  QMQMMFT  V9R0M0
   5725M50  *BASE   2924     *LNG   QMQMMFT  V9R0M0
   5725M50  2       5050     *CODE  MFTTOOL  V9R0M0
   ```

6. Do the post installation tasks of checking for updates, checking program authorities, and starting the Managed File Transfer subsystem.

What to do next

If you want to see how the installation went in more detail, perform one or more of the following tasks:
- View the log file using the `DSPJOBLOG` command.
- View the spoolfile generated from the `RSTLICPGM` command.

If the installation of IBM MQ fails, see "Handling installation failures for IBM i" on page 315.

Installing IBM MQ for IBM i from an Electronic Software Download

IBM i

You can perform an installation of IBM MQ for IBM i Version 9.0 from an installation image downloaded from IBM.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on IBM i" on page 301.

About this task

Two installation images are provided as zip files, a client and server image. These images contain all the licensed programs, and a client only image for the clients only.

The client and server image contains all seven compressed IBM i save files (**`SAVF`**), while the client image contains four save files. The save files are:
- MQ90BASE - IBM MQ client and server base program objects
- MQ90SAMP - IBM MQ client & server samples
- MQ90EN24 - IBM MQ client and server English US (2924) language objects

plus the client only images:
- MQ90CBASE - IBM MQ client
- MQ90CSAMP - IBM MQ client samples
- MQ90JBASE - IBM MQ Java
- MQ90JSAMP - IBM MQ Java samples

Procedure

1. Download one of the installation images and extract it to a temporary directory.
2. On IBM i, create a library containing sufficient empty save files to hold the uploaded files by using the commands:

   ```
   CRTLIB LIB(MQ90PROD)
   CRTSAVF FILE(MQ90PROD/MQ90BASE) /* Server and Client */
   CRTSAVF FILE(MQ90PROD/MQ90SAMP) /* Server and Client Samples */
   CRTSAVF FILE(MQ90PROD/MQ90EN24) /* 2924 English */
   CRTSAVF FILE(MQ90PROD/MQ90CBASE) /* Standalone Client */
   CRTSAVF FILE(MQ90PROD/MQ90CSAMP) /* Standalone Client Samples */
   CRTSAVF FILE(MQ90PROD/MQ90JBASE) /* Java and JMS Classes */
   CRTSAVF FILE(MQ90PROD/MQ90JSAMP) /* Java and JMS Samples */
   ```

   For additional languages

```
CRTSAVF FILE(MQ90PROD/MQ90EN09) /* 2909 Belgian English */
CRTSAVF FILE(MQ90PROD/MQ90FR28) /* 2928 French */
CRTSAVF FILE(MQ90PROD/MQ90JA30) /* 2930 Japanese */
CRTSAVF FILE(MQ90PROD/MQ90ES31) /* 2931 Spanish */
CRTSAVF FILE(MQ90PROD/MQ90IT32) /* 2932 Italian */
CRTSAVF FILE(MQ90PROD/MQ90EN38) /* 2938 English DBCS UPPERCASE */
CRTSAVF FILE(MQ90PROD/MQ90FR40) /* 2940 French MNCS */
CRTSAVF FILE(MQ90PROD/MQ90IT42) /* 2942 Italian MNCS */
CRTSAVF FILE(MQ90PROD/MQ90FR66) /* 2966 French MNCS */
CRTSAVF FILE(MQ90PROD/MQ90FR81) /* 2981 French MNCS */
CRTSAVF FILE(MQ90PROD/MQ90EN84) /* 2984 English DBCS */
CRTSAVF FILE(MQ90PROD/MQ90CZ75) /* 2975 Czech */
CRTSAVF FILE(MQ90PROD/MQ90HU76) /* 2976 Hungarian */
CRTSAVF FILE(MQ90PROD/MQ90PL78) /* 2978 Polish */
CRTSAVF FILE(MQ90PROD/MQ90RU79) /* 2979 Russian */
CRTSAVF FILE(MQ90PROD/MQ90PT80) /* 2980 Portugese/Brazilian */
CRTSAVF FILE(MQ90PROD/MQ90JA62) /* 2962 Japanese */
CRTSAVF FILE(MQ90PROD/MQ90KO86) /* 2986 Korean */
CRTSAVF FILE(MQ90PROD/MQ90ZH89) /* 2989 Chinese */
CRTSAVF FILE(MQ90PROD/MQ90DE29) /* 2929 German */
CRTSAVF FILE(MQ90PROD/MQ90DE39) /* 2939 German */
```

3. Start an ftp session to your IBM i machine and upload the required save files with the commands:

```
ftp (your_ibmi_hostname)
bin
put MQ90BASE MQ90PROD/MQ90BASE
put MQ90SAMP MQ90PROD/MQ90SAMP
put MQ90EN24 MQ90PROD/MQ90EN24
put MQ90CBASE MQ90PROD/MQ90CBASE
put MQ90CSAMP MQ90PROD/MQ90CSAMP
put MQ90JBASE MQ90PROD/MQ90JBASE
put MQ90JSAMP MQ90PROD/MQ90JSAMP
```

For additional language loads:

```
put MQ90EN09 MQ90PROD/MQ90EN09
put MQ90FR28 MQ90PROD/MQ90FR28
put MQ90JA30 MQ90PROD/MQ90JA30
put MQ90ES31 MQ90PROD/MQ90ES31
put MQ90IT32 MQ90PROD/MQ90IT32
put MQ90EN38 MQ90PROD/MQ90EN38
put MQ90FR40 MQ90PROD/MQ90FR40
put MQ90IT42 MQ90PROD/MQ90IT42
put MQ90FR66 MQ90PROD/MQ90FR66
put MQ90FR81 MQ90PROD/MQ90FR81
put MQ90EN84 MQ90PROD/MQ90EN84
put MQ90CZ75 MQ90PROD/MQ90CZ75
put MQ90HU76 MQ90PROD/MQ90HU76
put MQ90PL78 MQ90PROD/MQ90PL78
put MQ90RU79 MQ90PROD/MQ90RU79
put MQ90PT80 MQ90PROD/MQ90PT80
put MQ90JA62 MQ90PROD/MQ90JA62
put MQ90KO86 MQ90PROD/MQ90KO86
put MQ90ZH89 MQ90PROD/MQ90ZH89
put MQ90DE29 MQ90PROD/MQ90DE29
put MQ90DE39 MQ90PROD/MQ90DE39
```

4. To prepare for installation of IBM MQ for IBM i, sign on to your IBM i machine and ensure that you have followed the instructions detailed in "Preparing the system on IBM i" on page 301.
5. Enter the **RSTLICPGM** commands, specifying the installation device as *SAVF and naming the save file containing the options that you want to install. The IBM MQ Java licensed program can be installed stand-alone or can coexist with any of the other licensed programs.

   The IBM MQ client can be installed standalone, but it can only coexist with the IBM MQ Java on the same system.

Attempting to install the IBM MQ server on a system where the IBM MQ client is already installed performs a slip installation upgrade, replacing the client with the server licensed program.

Attempting to install the IBM MQ client stand-alone over the top of an existing server licensed program is not possible, and the installation fails.

For example:

```
/* IBM MQ Client and Server program objects */
RSTLICPGM LICPGM(5724H72) DEV(*SAVF) SAVF(MQ90PROD/MQ90BASE) +
RSTOBJ(*PGM) OPTION(*BASE) OUTPUT(*PRINT)

/* IBM MQ Client & Server English 2924 Language Load */
RSTLICPGM LICPGM(5724H72) DEV(*SAVF) SAVF(MQ90PROD/MQ90EN24) +
RSTOBJ(*LNG) LNG(2924) OUTPUT(*PRINT)

/* Additional languages - alter SAVF and LNG parameters... */
/* IBM MQ Client & Server Japanese 2930 Language Load */
RSTLICPGM LICPGM(5724H72) DEV(*SAVF) SAVF(MQ90PROD/MQ90JA30) +
RSTOBJ(*LNG) LNG(2930) OUTPUT(*PRINT)

/* IBM MQ Client & Server Samples */
RSTLICPGM LICPGM(5724H72) DEV(*SAVF) SAVF(MQ90PROD/MQ90SAMP) +
OPTION(1) OUTPUT(*PRINT)

/* IBM MQ Java */
RSTLICPGM LICPGM(5724L26) DEV(*SAVF) SAVF(MQ90PROD/MQ90JBASE) +
OPTION(*BASE) OUTPUT(*PRINT)

/* IBM MQ Java Samples */
RSTLICPGM LICPGM(5724L26) DEV(*SAVF) SAVF(MQ90PROD/MQ90JSAMP) +
OPTION(1) OUTPUT(*PRINT)

/* IBM MQ Client */
RSTLICPGM LICPGM(5725A49) DEV(*SAVF) SAVF(MQ90PROD/MQ90CBASE) +
OPTION(*BASE) OUTPUT(*PRINT)

/* IBM MQ Client Samples */
RSTLICPGM LICPGM(5725A49) DEV(*SAVF) SAVF(MQ90PROD/MQ90CSAMP) +
OPTION(1) OUTPUT(*PRINT)
```

6. Do the post installation tasks of checking for updates, checking program authorities and starting the IBM MQ subsystem, see "Performing post installation tasks for IBM MQ on IBM i" on page 314.

What to do next

If you want to see how the installation went in more detail, perform one or more of the following tasks:

- View the log file using the `DSPJOBLOG` command.
- View the spoolfile generated from the `RSTLICPGM` command.

If the installation of IBM MQ fails, see "Handling installation failures for IBM i" on page 315.

Performing post installation tasks for IBM MQ on IBM i

IBM i

Tasks to perform after you have installed IBM MQ for IBM i, and before using it.

About this task

When you have correctly installed IBM MQ for IBM i on your system:

Procedure

1. See the IBM MQ website at: http://www.ibm.com/software/products/ibm-mq for the latest product information.
2. Install and apply all fix packs.
3. Where you have more than one system and a mixture of releases of OS/400 or IBM i, and IBM MQ, you must take care when compiling CL programs. You must compile CL programs either on the system they are to run on, or on one with an identical combination of releases of OS/400 or IBM i, and IBM MQ. When you install later versions of IBM MQ, delete all IBM MQ commands from previous releases in any QSYSVvRrMm libraries using the QSYS/DLTCMD command.
4. If you have not installed IBM MQ on your system before, you must add user profiles to the `QMQMADM` group profile. Make all user profiles that are to be used for creating and administering queue managers members of the `QMQMADM` group profile, using the command `CHGUSRPRF`.
   a. Start the IBM MQ subsystem, by issuing the command:
      ```
      STRSBS SBSD(QMQM/QMQM)
      ```
      Note: The subsystem must be started after each IPL of the system, so you might choose to start it as part of your system startup process.
5. Create the system-default objects. The system-default objects are created automatically when you issue the CRTMQM command to create a queue manager. For example: `CRTMQM MQMNAME(QMGRNAME) ASP(*SYSTEM)`. You can refresh them using the STRMQM command (Warning: this command will replace any existing default objects). For example: `STRMQM MQMNAME(QMGRNAME) RDEFSYS(*YES)`. Refer to the onscreen help for information about using this command.

   Note: on the command `STRMQM MQMNAME(QMGRNAME) RDEFSYS(*YES)`:
   - The command does not re-create the objects, it performs a CRTxxxx REPLACE(*YES) for all of the SYSTEM.* objects.
   - This means that it refreshes the parameters on the objects back to their defaults. So if, for example, on the SYSTEM.DEFAULT.LOCAL.QUEUE object, TRGENBL had previously been changed to *YES, then, when the command is run, it is changed back to TRGENBL(*NO).
   - If any messages exist on a queue, they are not removed, because the queues are not physically deleted.
   - The contents of the SYSTEM.AUTH.DATA.QUEUE are untouched when this command is run.
   - So, if the contents of this (or any other significant queue) become corrupt, it must be physically deleted and re-created either from scratch, or from a backup.

Results

You are now ready to start using IBM MQ for IBM i.

Note: When you install IBM MQ for IBM i, two user profiles are created:
- QMQM
- QMQMADM

These two objects are central to the correct running of IBM MQ for IBM i. Do not alter or delete them. If you do, IBM cannot guarantee correct behavior of your product.

If you uninstall IBM MQ and data, these profiles are deleted. If you uninstall IBM MQ only, these profiles are retained.

Handling installation failures for IBM i

IBM i

If the installation of IBM MQ Server or Client for IBM i fails, you must remove the installed and partially installed objects before attempting reinstallation.

Procedure

1. Delete installed options using `DLTLICPGM LICPGM(5725A49)OPTION(*ALL)`.
2. Delete partially installed options by deleting the `QMQM` library (and the `QMQMSAMP` libraries if necessary).
3. Delete the IFS directory `/QIBM/ProdData/mqm` and its subdirectories using the `EDTF` command, for example: `EDTF STMF('/QIBM/ProdData')` and select **option 9** for the `mqm` directory.

   If the installation of IBM MQ Java fails, remove the partly installed objects before attempting reinstallation:

   a. Delete the `QMQMJAVA` library.
   b. Delete the IFS directory `/QIBM/ProdData/mqm/java` and its subdirectories using the **`EDTF`** command, for example:

      ```
      EDTF STMF ('/QIBM/ProdData/mqm')
      ```

      Select option 9 against the Java directory.

Converting a trial license on IBM i

IBM i

Convert a trial license to a full license without reinstalling IBM MQ.

When the trial license expires, the “count-down” displayed by the **`strmqm`** command informs you the license has expired, and the command does not run.

Before you begin

1. IBM MQ is installed with a trial license.
2. You have access to the installation media of a fully licensed copy of IBM MQ.

About this task

Run the **`setmqprd`** command to convert a trial license to a full license.

If you do not want to apply a full license to your trial copy of IBM MQ, you can uninstall it at any time.

Procedure

1. Obtain the full license from the fully licensed installation media.

   The full license file is `amqpcert.lic`. On IBM i, issue the command

   ```
   CALL PGM(QMQM/SETMQPRD) PARM('/QOPT/OPT01/amqpcert.lic')
   ```
2. Run the **`setmqprd`** command from the installation that you are upgrading:

   ```
   MQ_INSTALLATION_PATH/bin/setmqprd /MediaRoot/licenses/amqpcert.lic
   ```

Related information:
setmqprd

Installing an IBM MQ client on IBM i

IBM i

The IBM MQ client for IBM i is a part of the IBM MQ product.

Before you begin

Attention: If you have already installed the IBM MQ server, you already have a client and must not attempt to install the stand-alone client.

You can install only one instance of IBM MQ client for IBM i in each partition of your server.

When you install IBM MQ client for IBM i two user profiles are created:
- QMQM
- QMQMADM

These two objects are central to the correct running of IBM MQ for IBM i. Do not alter or delete them. If you do, IBM cannot guarantee correct behavior of your product. These profiles are retained when the product is deleted.

About this task

This procedure covers the installation of both the client and the client samples. If you do not want to install the client samples, then do not complete the steps specific to the samples.

After following the optional step to pre-agree the license, and then issuing the **RSTLICPGM** command, the installation runs without requiring any interactive input.

Procedure

1. Sign on to the system with a user profile that has `*ALLOBJ` special authority, for example `QSECOFR`.
2. Optional: Pre-agree the license terms and conditions. If you do not choose to pre-agree the license, the license agreement is displayed for you to accept. Run the following commands to pre-agree the license terms and conditions:
   a. For the client:
   ```
   CALL PGM (QSYS/QLPACAGR) PARM ('5725A49' 'V8R0M0' '0000' 0)
   ```
   The parameters of **PARM** are:

   5725A49
   The product identifier for IBM MQ client for IBM i

   V8R0M0
   The version, release, and modification level

   0000
   The option number for the base IBM MQ client for IBM i product

   0 Unused error structure

   b. For the client samples:
   ```
   CALL PGM (QSYS/QLPACAGR) PARM ('5725A49' 'V8R0M0' '0001' 0)
   ```
   The parameters of **PARM** are:

5725A49
The product identifier for IBM MQ client for IBM i

V8R0M0
The version, release, and modification level

0001
The option number for the samples

0 Unused error structure

3. Issue the installation command to run the installation without requiring any interactive input:
   a. Install the client by issuing the following command:
      ```
      RSTLICPGM LICPGM (5725A49) DEV (installation device) OPTION (*BASE) OUTPUT (*PRINT)
      ```
      The parameters of RSTLICPGM are:

      LICPGM (5725A49)
      The product identifier for IBM MQ client for IBM i

      DEV (*installation device*)
      The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`

      OPTION (*BASE)
      The level of IBM MQ client for IBM i product installed

      OUTPUT (*PRINT)
      Whether the spooled output of the job is printed
   b. Install the samples by issuing the following command:
      ```
      RSTLICPGM LICPGM (5725A49) DEV (installation device) OPTION (1) OUTPUT (*PRINT)
      ```
      The parameters of RSTLICPGM are:

      LICPGM (5725A49)
      The product identifier for IBM MQ client for IBM i

      DEV (*installation device*)
      The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`

      OPTION (1)
      The samples option

      OUTPUT (*PRINT)
      Whether the spooled output of the job is printed
4. To ensure that the product has loaded correctly, issue the Display Software Resources (**DSPSFWRSC**) command and check that the licensed program 5725A49 is listed. If you have installed the base and the optional samples, you see:
   ```
   Resource
   ID    Option Feature Description
   5725A49  *BASE  5050   IBM MQ client for IBM i
   5725A49  1    5050   IBM MQ client for IBM i -Samples
   ```
5. To see the library and version number of the products installed, press **F11**, while viewing the Display Software Resources screen. The following screen is displayed:
   ```
   Resource          Feature
   ID    Option Feature  Type  Library  Release
   5725A49  *BASE  5050   *CODE  QMQM    V8R0M0
   5725A49  1    5050   *CODE  QMQMSAMP  V8R0M0
   ```

6. To check exactly what version you have installed, use the **DSPMQMVER** program. For example, `CALL PGM(QMQM/DSPMQVER)` from the command line or `/QSYS.LIB/QMQM.LIB/DSPMQVER.PGM -a` in a qshell.

What to do next

If you want to see how the installation went in more detail, perform one or more of the following tasks:
- View the log file using the `DSPJOBLOG` command.
- View the spoolfile generated from the `RSTLICPGM` command.

If the installation of IBM MQ client for IBM i failed, see "Handling installation failures for IBM i" on page 315

Related concepts:

"Uninstalling IBM MQ for IBM i" on page 325
There are two ways of uninstalling IBM MQ for IBM i.

Installation of IBM MQ client and IBM MQ server for IBM i

When you install an IBM MQ server on an IBM i system, the client is also automatically installed.

The installed version of the IBM MQ client for IBM i can be refreshed by using a "slip installation" which replaces an existing installation with a fresh image.

Installing a client over an existing client results in a successful installation.

Installing a client over an existing server results in a failure with a CPDB6A4 error.

Installing a server over an existing client results in a successful upgrade of the client to both server and client capabilities.

Installing IBM MQ Java messaging and web services for IBM i

Install IBM MQ Java messaging and web services for IBM i from either product CD, using the **RSTLICPGM** command.

Before you begin

You can install only one instance of IBM MQ Client for IBM i in each partition of your server.

If you have Java messaging and web services v7.0 or v7.1 installed and want to install v8.0, you can install the new version without uninstalling the old one.

If you have MA88 installed, and try to install anyway, the installation fails with a warning requesting you to uninstall the old client. To uninstall MA88, issue the following command:

```
DLTLICPGM LICPGM(5648C60) OPTION(*ALL)
```

If this command fails to delete the IFS directory `/QIBM/ProdData/mqm/java` and its subdirectories, use the EDTF command and select option 9 against the Java directory. For example:

```
EDTF STMF('/QIBM/ProdData/mqm')
```

About this task

This procedure covers the installation of both the Java messaging and web services, and the Java messaging and web services samples. If you do not want to install the samples, then do not complete the steps specific to the samples.

After following the optional step to pre-agree the license, and then issuing the **RSTLICPGM** command, the installation runs without requiring any interactive input.

Procedure

1. Sign on to the system with a user profile that has `*ALLOBJ` special authority, for example `QSECOFR`.
2. Optional: Pre-agree the license terms and conditions. If you do not choose to pre-agree the license, the license agreement is displayed for you to accept. Run the following commands to pre-agree the license terms and conditions:
   a. For Java messaging and web services:
      ```
      CALL PGM (QSYS/QLPACAGR) PARM ('5724L26' 'V8R0M0' '0000' 0)
      ```

      The parameters of **PARM** are:

      5724L26
      The product identifier for IBM MQ Java messaging and web services for IBM i

      V8R0M0
      The version, release, and modification level

      0000
      The option number for the base IBM MQ Java messaging and web services product.

      0 Unused error structure
   b. For the samples:
      ```
      CALL PGM (QSYS/QLPACAGR) PARM ('5724L26' 'V8R0M0' '0001' 0)
      ```

      The parameters of **PARM** are:

      5724L26
      The product identifier for IBM MQ Java messaging and web services for IBM i

      V8R0M0
      The version, release, and modification level

      0001
      The option number for the samples.

      0 Unused error structure
3. Issue the installation command to run the installation without requiring any interactive input:
   a. Install the IBM MQ Java messaging and web services by issuing the following command:
      ```
      RSTLICPGM LICPGM (5724L26) DEV (installation device) OPTION (*BASE) OUTPUT (*PRINT)
      ```

      The parameters of RSTLICPGM are:

      LICPGM (5724L26)
      The product identifier for IBM MQ Java messaging and web services for IBM i

      DEV (*installation device*)
      The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`

      OPTION (*BASE)
      Install the base IBM MQ Java messaging and web services for IBM i

OUTPUT (*PRINT)
Whether the spooled output of the job is printed

b. Install the samples by issuing the following command:

```
RSTLICPGM LICPGM (5724L26) DEV (installation device) OPTION (1) OUTPUT (*PRINT)
```

The parameters of RSTLICPGM are:

LICPGM (5724L26)
The product identifier for IBM MQ Java messaging and web services for IBM i

DEV (*installation device*)
The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`

OPTION (1)
Install the samples

OUTPUT (*PRINT)
Whether the spooled output of the job is printed

4. To ensure that the product has loaded correctly, issue the Display Software Resources (DSPSFWRSC) command and check that the licensed program `5724L26` is listed. If you have installed the base and the optional samples, you see:

```
Resource
ID    Option Feature Description
5724L26  *BASE  5050  IBM MQ Java Messaging and Web Services
5724L26  1    5050  IBM MQ Java Messaging and Web Services - Samp
```

5. Press **F11** while viewing the Display Software Resources screen, and you see the library and version number of the products installed:

```
Resource          Feature
ID    Option Feature  Type  Library  Release
5724L26  *BASE  5050   *CODE  QMQMJAVA V8R0V0
5724L26  1    5050   *CODE  QMQMJAVA V8R0V0
```

6. Check what versions you have installed by using the following commands:
IBM MQ Classes for Java:

```
java com.ibm.mq.MQJavaLevel
```

Note: For this command to work, you might have to set your environment classpath to:
• `/QIBM/ProdData/mqm/java/lib/com.ibm.mq.jar`

IBM MQ Classes for Java Message Service:

```
java com.ibm.mq.jms.MQJMSLevel
```

Note: For this command to work, you might need to set your environment classpath to:
• `/QIBM/ProdData/mqm/java/lib/com.ibm.mqjms.jar`

See Environment variables relevant to IBM MQ classes for Java and Environment variables used by IBM MQ classes for JMS.

For v8.0, both report:

```
Version: 8.0.0.0
```

Note: The command uses the Java classes, and so it reports the version and also performs some verification that the classes are installed and working.

7. See the following topics for full details of verification of both:

- Using IBM MQ classes for Java
- Using IBM MQ classes for JMS

Verifying an IBM MQ installation on IBM i

IBM i

The topics in this section provide instructions on how to verify a client installation of IBM MQ on IBM i systems.

Verifying a client installation using the command line on IBM i

IBM i

You can verify a client installation using the command line. On the server you create a queue manager, a local queue, a listener, and a server-connection channel. You must also apply security rules to allow the client to connect and make use of the queue defined. On the client you create a client-connection channel, and then use the sample PUT and GET programs to complete the verification procedure.

The verification procedure shows how to create a queue manager called `queue.manager.1`, a local queue called `QUEUE1`, and a server-connection channel called `CHANNEL1` on the server.

It shows how to create the client-connection channel on the IBM MQ MQI client workstation. It then shows how to use the sample programs to put a message onto a queue, and get the message from the queue.

The example does not address any client security issues. See Setting up IBM MQ MQI client security for details if you are concerned with IBM MQ MQI client security issues.

The verification procedure assumes that:
- The full IBM MQ server product has been installed on a server.
- The server installation is accessible on your network.
- The IBM MQ MQI client software has been installed on a client system.
- The IBM MQ sample programs have been installed.
- TCP/IP has been configured on the server and client systems. For more information, see Configuring connections between the server and client.

First, set up the server using the command line, using the instructions in "Setting up the server using the command line IBM i" on page 322.

Once you have set up the server, you must set up the client, using the instructions in "Connecting to a queue manager, using the `MQSERVER` environment variable on IBM i" on page 323.

Finally, you can test the communications between client and server, using the instructions in "Testing communication between a client and a server on IBM i" on page 324.

Setting up the server using the command line IBM i: IBM i

Follow these instructions to create a queue manager, queue, and channel on the server. You can then use these objects to verify the installation.

About this task

These instructions assume that no queue manager or other IBM MQ objects have been defined.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Create a user ID on the server that is not in the `mqm` group. This user ID must exist on the server and client. This is the user ID that the sample applications must be run as, otherwise a 2035 error is returned.
2. Log in as a user in the MQM group.
3. Create a queue manager called `QUEUE.MANAGER.1` by entering the following command:
   ```
   crtmqm QUEUE.MANAGER.1
   ```
   You see messages telling you that the queue manager has been created.
4. Start the queue manager by entering the following command:
   ```
   strmqm QUEUE.MANAGER.1
   ```
   A message tells you when the queue manager has started.
5. Define a local queue called `QUEUE1` by entering the following command:
   ```
   CRTMQMQ QNAME(QUEUE1) QTYPE(*LCL)
   ```
   A message tells you when the queue has been created.
6. Allow the user ID that you created in step 1 to use `QUEUE1` by entering the following command:
   ```
   SET AUTHREC PROFILE(QUEUE1) OBJTYPE(QUEUE) PRINCIPAL(' non_mqm_user ') AUTHADD(PUT,GET)
   ```
   where *non_mqm_user* is the user ID created in step 1. A message tells you when the authorization has been set. You must also run the following command to give the user ID authority to connect:
   ```
   SET AUTHREC OBJTYPE(QMGR) PRINCIPAL(' non_mqm_user ') AUTHADD(CONNECT)
   ```
   If this command is not run, a 2305 stop error is returned.
7. Define a server-connection channel by entering the following command:
   ```
   CRTMQMCHL CHLNAME(CHANNEL1) CHLTYPE(*SVRCN) TRPTYPE(*TCP)
   MCAUSRID('QMQM')
   ```
   A message tells you when the channel has been created.
8. Allow your client channel to connect to the queue manager and run under the user ID that you created in step 1, by entering the following MQSC command:
   ```
   SET CHLAUTH(CHANNEL1) TYPE(ADDRESSMAP) ADDRESS(' client_ipaddr ') MCAUSER(' non_mqm_user ')
   ```
   where *client_ipaddr* is the IP address of the client system, and *non_mqm_user* is the user ID created in step 1. A message tells you when the rule has been set.
9. Define a listener by entering the following command:
   ```
   DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT (port_number)
   ```

where *port_number* is the number of the port the listener is to run on. This number must be the same as the number used when defining your client-connection channel in "Installing an IBM MQ client on IBM i" on page 316.

Note: If you omit the port parameter from the command, a default value of `1414` is used for the listener port. If you want to specify a port other than `1414`, you must include the port parameter in the command, as shown.

10. Start the listener by entering the following command:
    ```
    STRMQMLSR MQMNAME('QUEUE.MANAGER.1') PORT(1414)
    ```
11. Stop MQSC by entering:
    ```
    end
    ```

    You see some messages, followed by the command prompt.

What to do next

Follow the instructions to set up the client. See "Connecting to a queue manager, using the `MQSERVER` environment variable on IBM i."

Connecting to a queue manager, using the `MQSERVER` environment variable on IBM i: IBM i

When an IBM MQ application is run on the IBM MQ MQI client, it requires the name of the MQI channel, the communication type, and the address of the server to be used. Provide these parameters by defining the `MQSERVER` environment variable.

Before you begin

Before you start this task, you must complete the task, "Setting up the server using the command line IBM i" on page 322, and save the following information:
- The host name or IP address of the server and port number that you specified when creating the listener.
- The channel name of the server-connection channel.

About this task

This task describes how to connect an IBM MQ MQI client, by defining the `MQSERVER` environment variable on the client.

Procedure

1. Log in as the userid that you created in Step 1 of "Setting up the server using the command line IBM i" on page 322.
2. Check the TCP/IP connection. From the client, enter one of the following commands:
   - `ping server-hostname`
   - `ping n.n.n.n`

     `n.n.n.n` represents the network address. You can set the network address in IPv4 dotted decimal form, for example, `192.0.2.0`. Alternatively, set the address in IPv6 hexadecimal form, for example `2001:0DB8:0204:acff:fe97:2c34:fde0:3485`.

   If the **`ping`** command fails, correct your TCP/IP configuration.
3. Set the `MQSERVER` environment variable. From the client, enter one the following command:
   ```
   ADDENVVAR ENVVAR(MQSERVER) VALUE('CHANNEL1/TCP/server-address (port)')
   ```

   Where:

- *CHANNEL1* is the server-connection channel name.
- *server-address* is the TCP/IP host name of the server.
- *port* is the TCP/IP port number the server is listening on.

If you do not give a port number, IBM MQ uses the one specified in the `qm.ini` file, or the client configuration file. If no value is specified in these files, IBM MQ uses the port number identified in the TCP/IP services file for the service name `MQSeries`. If an `MQSeries` entry in the services file does not exist, a default value of `1414` is used. It is important that the port number used by the client and the port number used by the server listener program are the same.

What to do next

Use the sample programs to test communication between the client and server; see "Testing communication between a client and a server on IBM i."

Testing communication between a client and a server on IBM i: IBM i

On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

Before you begin

Complete the previous topics in this section:
- Set up a queue manager, channels, and queue.
- Open a command window.
- Set system environment variables.

About this task

Note that IBM MQ object definitions are case-sensitive. Text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Start the PUT program for `QUEUE1` on `QUEUE.MANAGER.1` by entering the following command:
   ```
   CALL PGM(QMQM/AMQSPUTC) PARM(QUEUE1 QUEUE.MANAGER.1)
   ```
   If the command is successful, the following messages are displayed:
   ```
   Sample AMQSPUT0 start target queue is QUEUE1
   ```
   Tip: You might get the error, `MQRC_NOT_AUTHORIZED` (2035). By default, channel authentication is enabled when a queue manager is created. Channel authentication prevents privileged users accessing a queue manager as an IBM MQ MQI client. For verifying the installation, you can either change the MCA user ID to a non-privileged user, or disable channel authentication. To disable channel authentication run the following MQSC command:
   ```
   ALTER QMGR CHLAUTH(DISABLED)
   ```
   When you finish the test, if you do not delete the queue manager, re-enable channel authentication:
   ```
   ALTER QMGR CHLAUTH(ENABLED)
   ```
2. Type some message text, then press **Enter** twice. The following message is displayed:
   ```
   Sample AMQSPUT0 end
   ```

Your message is now on the queue that is on the server queue manager.

3. Start the GET program for `QUEUE1` on `QUEUE.MANAGER.1` by entering the following command:

   ```
   CALL PGM(QMQM/AMQSGETC) PARM(QUEUE1 QUEUE.MANAGER.1)
   ```

   The sample program starts, and your message is displayed. After a short pause (approximately 30 seconds), the sample ends and the command prompt is displayed again.

Results

You have now successfully verified the client installation.

What to do next

1. On the server, stop the queue manager by entering the following command:

   ```
   ENDMQM MQMNAME(QUEUE.MANAGER.1)
   ```

2. On the server, delete the queue manager by entering the following command:

   ```
   DLTMQM MQMNAME(QUEUE.MANAGER.1)
   ```

Uninstalling IBM MQ for IBM i

IBM i

There are two ways of uninstalling IBM MQ for IBM i.

To uninstall IBM MQ for IBM i, perform one of the following tasks:

- A *standard* deletion removes IBM MQ product code but preserves user data.
- An *entire* deletion removes both IBM MQ product code and user data.

Both types of deletion require you to be signed on to the system with a user profile that has *ALLOBJ special authority, for example, QSECOFR. Security administrator (*SECADM) special authority is also required to delete the QMQM and QMQMADM user profiles.

Related concepts:

"Reinstalling IBM MQ for IBM i" on page 329
You can reinstall IBM MQ for IBM i without losing any of your data.

Related tasks:

If you want to retain your user data, for example, because you intend to reinstall IBM MQ for IBM i at a later date, you must perform a standard deletion of the product.

"Uninstalling IBM MQ and data on IBM i" on page 327
You can delete IBM MQ entirely, including all user data.

"Uninstalling IBM MQ Java Messaging and Web Services on IBM i" on page 328
Follow these instructions to uninstall IBM MQ Java.

"Uninstalling IBM MQ MQI client for IBM i" on page 328
If the IBM MQ MQI client for IBM i must be uninstalled, follow the correct procedure to ensure that all the relevant directories and files are removed.

Uninstalling IBM MQ but retaining data on IBM i

IBM i

If you want to retain your user data, for example, because you intend to reinstall IBM MQ for IBM i at a later date, you must perform a standard deletion of the product.

About this task

To perform a standard deletion of IBM MQ for IBM i, so that your user data is retained, complete the following steps:

Procedure

1. Quiesce IBM MQ for IBM i. For more information, see Quiescing IBM MQ for IBM i.
2. End the IBM MQ subsystem, by issuing the command:
   ```
   ENDSBS SBS(QMQM)
   ```
3. Ensure that no locks are held on the library QMQM, by issuing the command:
   ```
   WRKOBJLCK OBJ(QMQM) OBJTYPE(*LIB)
   ```
4. Use the Delete Licensed Program (DLTLICPGM) command to delete the base product (and also the samples if you chose to install them).

   To delete only the samples, issue the command:
   ```
   DLTLICPGM LICPGM( 5724H72 ) OPTION(1)
   ```
   To delete only extra language versions installed, issue the command:
   ```
   DLTLICPGM LICPGM(5724H72) LNG(nnnn)
   ```

   where *nnnn* is the language number, as in the list here:

Table 45. Globalizations of IBM MQ for IBM i.

Language ID	Language
2909	Belgian English
2966	Belgian French MNCS (Multi-National Character Set)
2981	Canadian French MNCS
2975	Czech
2950	English uppercase
2924	English uppercase and lowercase
2984	English US DBCS
2938	English US uppercase DBCS
2928	French
2940	French MNCS
2929	German
2939	German MNCS
2976	Hungarian
2932	Italian
2942	Italian MNCS
2962	Japanese
2986	Korean
2978	Polish
2979	Russian
2989	Simplified Chinese
2931	Spanish

   To delete the base product and the samples, issue the command:
   ```
   DLTLICPGM LICPGM( 5724H72 ) OPTION(*ALL)
   ```

Results

Deleting IBM MQ for IBM i in this way deletes only the objects that belong to IBM MQ: the QMQM library, the QMQM samp library, and the subdirectories that belong to IBM MQ server within the `/QIBM/ProdData/mqm` directory.

If that leaves no other subdirectories (for example, if IBM MQ Java is installed it uses subdirectories there) then the `/QIBM/ProdData/mqm` directory itself is deleted.

None of the queue manager journal libraries, or IFS directories based upon `/QIBM/UserData` are removed.

Uninstalling IBM MQ and data on IBM i

IBM i

You can delete IBM MQ entirely, including all user data.

About this task

Important: If you are going to delete IBM MQ entirely, including all user data, save your user data first. It cannot be recovered.

To delete IBM MQ for IBM i entirely, complete the following steps:

Procedure

1. Quiesce IBM MQ for IBM i. For more information, see Quiescing IBM MQ for IBM i.
2. Delete each queue manager in turn by using the command `WRKMQM` and selecting option `4`.
3. End the IBM MQ subsystem, by issuing the command:
   ```
   ENDSBS SBS(QMQM)
   ```
4. Ensure that no locks are held on the library QMQM, by issuing the command:
   ```
   WRKOBJLCK OBJ(QMQM) OBJTYPE(*LIB)
   ```
5. Optional: If you want to also uninstall IBM MQ Java, you can do it now, using the command:
   ```
   DLTLICPGM LICPGM( 5724L26 ) OPTION(*ALL)
   ```
   This will also uninstall the Java Samples, if they were installed.
6. Use the Delete Licensed Program (DLTLICPGM) command to delete the base product (and also the samples if you chose to install them). To delete the base product and the samples issue the command:
   ```
   DLTLICPGM LICPGM( 5724H72 ) OPTION(*ALL)
   ```
7. Delete the directory /QIBM/UserData/mqm and its subdirectories. Do this using the EDTF command and selecting option 9 (recursive delete) for the mqm directory, as follows,

   Note: If you do this, you no longer have any information regarding your installation. Use this command with extreme caution.

   The format of the command is:
   ```
   EDTF STMF('/QIBM/UserData')
   ```
   Alternatively, you can delete the /QIBM/UserData/mqm directory and its subdirectories by repeated use of the RMVLNK and RMVDIR commands.
8. Identify all the users who belong to the QMQMADM group. Use the DSPUSRPRF command to display a list of them. You must remove the QMQMADM group profile from their user profiles before you can delete the QMQMADM user profile. The format of the command is:
   ```
   DSPUSRPRF USRPRF(QMQMADM) TYPE(*GRPMBR)
   ```

9. You must alter the ownership or delete the objects. For each of the user profiles QMQM and QMQMADM, use the WRKOBJOWN command to list all the objects owned by the profile. The format of the command is:

   ```
   WRKOBJOWN USRPRF( PROFILE )
   ```

10. Delete the two user profiles. The format of the command is:

    ```
    DLTUSRPRF USRPRF(QMQM) OWNOBJOPT(*DLT)
    DLTUSRPRF USRPRF(QMQMADM) OWNOBJOPT(*DLT)
    ```

Uninstalling IBM MQ Java Messaging and Web Services on IBM i

IBM i

Follow these instructions to uninstall IBM MQ Java.

About this task

To uninstall the IBM MQ Java product.

Procedure

1. Make sure you are signed on to the system with a user profile that has *ALLOBJ special authority, for example QSECOFR.
2. Issue the command:

   ```
   DLTLICPGM LICPGM(5724L26) OPTION(*ALL)
   ```

Results

Deleting IBM MQ Java for IBM i deletes the objects that belong to it: the QMQMJAVA library, and the subdirectories that belong to IBM MQ Java within the `/QIBM/ProdData/mqm` directory.

If that leaves no other subdirectories (for example if the IBM MQ Server is installed it uses subdirectories there) then the `/QIBM/ProdData/mqm` directory itself is deleted.

Uninstalling IBM MQ MQI client for IBM i

IBM i

If the IBM MQ MQI client for IBM i must be uninstalled, follow the correct procedure to ensure that all the relevant directories and files are removed.

Procedure

1. Make sure you are signed on to the system with a user profile that has *ALLOBJ special authority, for example QSECOFR.
2. Use the Delete Licensed Program (**DLTLICPGM**) command to delete the IBM MQ MQI client for IBM i product (and also the samples if you chose to install them):

   To delete only the samples, issue the command

   ```
   DLTLICPGM LICPGM(5725A49) OPTION(1)
   ```

   To delete IBM MQ MQI client and the samples, issue the command:

   ```
   DLTLICPGM LICPGM(5725A49) OPTION(*ALL)
   ```

Results

Deleting IBM MQ MQI client for IBM i deletes the objects that belong to it - the QMQM library, and the subdirectories that belong to IBM MQ MQI client for IBM i within the `/QIBM/ProdData/mqm` directory. If that leaves no other subdirectories (for example if the IBM MQ Java Client for IBM i is installed it uses subdirectories there) then the `/QIBM/ProdData/mqm` directory itself is deleted.

Uninstalling Managed File Transfer on IBM i

Follow these instructions to uninstall Managed File Transfer on IBM i.

Before you begin

To uninstall IBM MQ Managed File Transfer for IBM i, perform one of the following tasks:

- A *standard* deletion removes Managed File Transfer product code but preserves user data.
- An *entire* deletion removes both Managed File Transfer product code and user data.

  Note that an entire deletion requires that you manually remove the configuration data in the `/QIBM/UserData/mqm/mqft` directory.

Both types of deletion require you to be signed on to the system with a user profile that has *ALLOBJ special authority, for example, QSECOFR.

About this task

To uninstall the Managed File Transfer product.

Procedure

1. Make sure you are signed on to the system with a user profile that has *ALLOBJ special authority, for example QSECOFR.
2. Issue the command:

   ```
   DLTLICPGM LICPGM(5725M50) OPTION(*ALL)
   ```

Results

Deleting Managed File Transfer for IBM i deletes the objects that belong to it: the QMQMMFT library, and the subdirectories that belong to Managed File Transfer within the `/QIBM/ProdData/mqm` directory.

Note that licence files are copied to `/QIBM/ProdData/mqm/properties/version`, and an uninstallation will delete files in this directory. However, files are left in `/QIBM/ProdData/mqm/properties/5725M50` as trash. For a clean uninstallation, you must delete the files in this directory.

Reinstalling IBM MQ for IBM i

You can reinstall IBM MQ for IBM i without losing any of your data.

When you reinstall IBM MQ for IBM i, the system checks whether the IBM MQ configuration file (mqs.ini) exists. If the file exists, it is kept and used with the newly installed system. If the file does not exist, an empty mqs.ini file is placed in the directory `/QIBM/UserData/mqm`.

All data that you have in the UserData directory is referenced by the newly installed system. In addition, all the queue manager-associated libraries containing journal and receiver information are referenced by the new system.

Installing and uninstalling IBM MQ on Linux

Linux

Installation tasks that are associated with installing IBM MQ on Linux are grouped in this section.

About this task

To prepare for installation and to install IBM MQ, complete the following tasks.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

- To install IBM MQ on Linux using rpm, see "Installing IBM MQ on Linux using rpm" on page 340.
- V 9.0.2 To install IBM MQ on Linux Ubuntu using a Debian installer , see "Installing IBM MQ on Linux Ubuntu using Debian" on page 363.

Checking requirements on Linux

Linux

Before you install IBM MQ on Linux, you must check for the latest information and system requirements.

About this task

A summary of the tasks that you must complete to check system requirements are listed here with links to further information.

Procedure

1. Check that you have the latest information, including information on hardware and software requirements. See "Where to find product requirements and support information" on page 195.
2. Check that your systems meet the initial hardware and software requirements for Linux. See "Hardware and software requirements on Linux systems" on page 331.

   The supported hardware and software environments are occasionally updated. See System Requirements for IBM MQ for the latest information.
3. Check that your systems have sufficient disk space for the installation. See Disk space requirements.
4. Check that you have the correct licenses. See "License requirements" on page 194 and IBM MQ license information.

What to do next

When you have completed these tasks, you are ready to start preparing your system for installation. For the next steps in installing IBM MQ, see "Preparing the system on Linux" on page 333.

Related concepts:

"IBM MQ installation overview" on page 192

IBM MQ maintenance tasks

Hardware and software requirements on Linux systems

Linux

Before you install IBM MQ , check that your system meets the hardware and operating system software requirements for the particular components you intend to install.

For hardware and software requirements, see System Requirements for IBM MQ.

IBM MQ does not support host names that contain spaces. If you install IBM MQ on a system with a host name that contains spaces, you are unable to create any queue managers.

Java Message Service and SOAP transport

If you want to use Java Message Service and SOAP support, you need an IBM Java 7 SDK and Runtime Environment Version 7.0 or later.

V 9.0.0 Java 8 is bundled with IBM MQ Version 9.0 but client components are built with Java 7 compatibility flags on.

For development, a JDK is required, and a JRE is required for running. The JRE does not need to be the JRE installed with IBM MQ, but has to be one from the supported list.

For a list of supported JDKs, see System Requirements for IBM MQ.

On Linux : Apache Axis V1.4 provides support for SOAP and is shipped on the server DVD, but not installed.

For further information about SOAP with IBM MQ , see IBM MQ transport for SOAP.

On Linux: On the Power platform, the 32-bit and 64-bit JDKs are typically installed to different locations, for example, the 32-bit JDK is located in `/opt/IBMJava2-ppc-50` and the 64-bit JDK is located in `/opt/IBMJava2-ppc64-50`. Ensure that the PATH variable is correctly set for your applications that use Java. To use the Postcard application described in "Verifying a local server installation using the Postcard application on Linux" on page 380, you must use a 32-bit JDK.

You can check the version installed using the following command:

```
java -version
```

Transport Layer Security (TLS)

If you want to use the TLS support, you need the IBM Global Security Kit (GSKit) V8 package. This package is supplied with IBM MQ as one of the components available for installation.

Linux

Installing the g++ version runtime support
If you intend to run TLS channels then you must have the g++ runtime libraries installed.

The GNU g++ libraries are called `libgcc_s.so` and `libstdc++.so.6`. On RPM based systems these are installed as part of the `libgcc` and `libstdc++` software packages.

The version of these libraries installed must be compatible with g++ version 3.4.

See System Requirements for IBM MQ for further details on the required packages for TLS support.

On 64 bit platforms, install both the 32 bit and the 64 bit versions of the package so that 32 bit and 64 bit processes can both use TLS functions.

IBM MQ Explorer requirements

Linux IBM MQ Explorer can be installed either as part of the product installation, or from the stand-alone IBM MQ Explorer support pack MS0T. See IBM MQ Explorer Requirements for the minimum requirements that your system needs, if you want to use the IBM MQ Explorer .

Note that IBM MQ Explorer is available for use only with IBM MQ for Linux, x86 and x86-64 platforms.

V 9.0.4

RDQM (replicated data queue manager)

Pacemaker is one of the prerequisites for RDQM. Pacemaker requires that the following Linux packages are installed on the system:

- OpenIPMI-libs.x86_64
- OpenIPMI-modalias.x86_64
- PyYAML.x86_64
- libesmtp.x86_64
- libyaml.x86_64
- net-snmp-agent-libs.x86_64
- openhpi-libs.x86_64

Related concepts:

Check that the server environment meets the prerequisites for installing IBM MQ for Windows and install any prerequisite software that is missing from your system from the server DVD.

Related tasks:

“Checking requirements on Windows” on page 444
Before you install IBM MQ on Windows, you must check for the latest information and system requirements.

Planning to install IBM MQ on Linux

Linux

Before you install IBM MQ on Linux, you must choose which components to install and where to install them. You must also make some platform-specific choices.

About this task

The following steps provide links to additional information to help you with planning your installation of IBM MQ on Linux.

As part of your planning activities, make sure that you review the information on hardware and software requirements for the platform on which you are planning to install IBM MQ. For more information, see "Checking requirements on Linux" on page 330.

Procedure

1. Decide which IBM MQ components and features to install. See "IBM MQ components and features" on page 192.

   Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. For more information, see "License requirements" on page 194 and IBM MQ license information.
2. Review the options for naming your installation. In some cases, you can choose an installation name to use instead of the default name. See "Installation name on UNIX, Linux, and Windows" on page 197.
3. Review the options and restrictions for choosing an installation location for IBM MQ. For more information, see "Installation location on Multiplatforms" on page 198.
4. If you plan to install multiple copies of IBM MQ, see "Multiple installations on UNIX, Linux, and Windows" on page 200.
5. If you already have a primary installation, or plan to have one, see "Primary installation on UNIX, Linux, and Windows" on page 202.
6. Make sure that the communications protocol needed for server-to-server verification is installed and configured on both systems that you plan to use. For more information, see "Server-to-server links on UNIX, Linux, and Windows" on page 210.

Preparing the system on Linux

Linux

On Linux systems, you might have to complete several tasks before you install IBM MQ. You might also want to complete other tasks, depending on your installation intentions.

About this task

The tasks that you perform to prepare your systems for installation are listed here. Complete the appropriate tasks for your platform before installing.

Procedure

1. Set up a user ID of the name `mqm`, with a primary group of `mqm`. See "Setting up the user and group on Linux" on page 334.
2. Create file systems for both the product code and working data to be stored. See "Creating file systems on Linux" on page 335.
3. Configure any additional settings needed for your Linux system. See "Configuring and tuning the operating system on Linux" on page 337.

What to do next

When you have completed the tasks to prepare the system, you are ready to start installing IBM MQ. To install a server using rpm , see "Installing IBM MQ server on Linux" on page 344. To install a client using rpm, see "Installing an IBM MQ client on Linux" on page 355.

V 9.0.2 To install a server using a Debian installer, see "Installing an IBM MQ server on Linux Ubuntu using Debian packages" on page 368. To install a client using a Debian installer, see "Installing an IBM MQ client on Linux Ubuntu using Debian packages" on page 372

V 9.0.2

Important: Having both Debian and rpm installed versions of IBM MQ on the same system is not supported.

Related information:

Planning

Maintaining and migrating

IBM MQ maintenance tasks

Setting up the user and group on Linux

Linux

On Linux systems, IBM MQ requires a user ID of the name `mqm`, with a primary group of `mqm`. The `mqm` user ID owns the directories and files that contain the resources associated with the product.

Creating the user ID and group on UNIX and Linux systems

Set the primary group of the `mqm` user to the group `mqm`.

If you are installing IBM MQ on multiple systems you might want to ensure each UID and GID of `mqm` has the same value on all systems. If you are planning to configure multi-instance queue managers, it is essential the UID and GID are the same from system to system. It is also important to have the same UID and GID values in virtualization scenarios.

Linux RPM creates the `mqm` user ID and group ID as part of the installation procedure if they do not exist.

If you have special requirements for these IDs (for example they need to have the same values as other machines you are using, or your users and group ID are centrally managed) you should create the IDs before running the installation procedure, using the **`groupadd`** and **`useradd`** commands to set the UID and GID the same on each machine.

Note: The only IBM MQ requirement, is that the `mqm` user should have the `mqm` group as its primary group.

Adding existing user IDs to the group on Linux systems

If you want to run administration commands, for example **`crtmqm`** (create queue manager) or **`strmqm`** (start queue manager), your user ID must be a member of the `mqm` group. This user ID must not be longer than 12 characters.

Users do not need `mqm` group authority to run applications that use the queue manager; it is needed only for the administration commands.

Log files created by MQ Telemetry service

The **`umask`** setting of the user ID that creates a queue manager will determine the permissions of the Telemetry log files generated for that queue manager. Even though the ownership of the log files will be set to `mqm`.

Related concepts:

"Creating file systems on AIX" on page 223
Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

When installing IBM MQ on AIX systems, there are some additional settings that must be configured.

Related information:

"Configuring and tuning the operating system on Solaris" on page 409
Configure Solaris systems with the resource limits required by IBM MQ.

Creating file systems on Linux

Linux

Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

Determining the size of a server installations file system

To determine the size of the `/var/mqm` file system for a server installation, consider:

- The maximum number of messages in the system at one time.
- Contingency for message buildups, if there is a system problem.
- The average size of the message data, plus 500 bytes for the message header.
- The number of queues.
- The size of log files and error messages.
- The amount of trace that is written to the `/var/mqm/trace` directory.

Storage requirements for IBM MQ also depend on which components you install, and how much working space you need. For more details, see Disk space requirements.

Creating a file system for the working data

Before you install IBM MQ, create and mount a file system called `/var/mqm` which is owned by the user `mqm` in the group `mqm` ; see "Setting up the user and group on Linux" on page 334. This file system is used by all installations of IBM MQ on a system. If possible, use a partition strategy with a separate volume for the IBM MQ data. This means that other system activity is not affected if a large amount of IBM MQ work builds up. Configure the directory permissions to permit the `mqm` user to have full control, for example, file mode 755. These permissions will then be updated during the IBM MQ installation to match the permissions required by the queue manager.

Creating separate file systems for errors and logs

You can also create separate file systems for your log data (`/var/mqm/log`) and error files (`/var/mqm/errors`). If possible, place these directories on different physical disks from the queue manager data (`/var/mqm/qmgrs`) and from each other.

If you create separate file systems the `/var/mqm/errors` directory can be NFS mounted. However, if you choose to NFS-mount `/var/mqm/errors`, the error logs might be lost if the network fails.

You can protect the stability of your queue manager by having separate file systems for:
- `/var/mqm/errors`
- `/var/mqm/trace`
- `/var/mqm/qmgrs`
- `/var/mqm/log`

In the case of `/var/mqm/errors`, it is rare that this directory receives large quantities of data. But it is sometimes seen, particularly if there is a severe system problem leading to IBM MQ writing a lot of diagnostic information in to `.FDC` files. In the case of `/var/mqm/trace`, files are only written here when you use **`strmqtrc`** to start tracing IBM MQ.

You can obtain better performance of normal IBM MQ operations (for example, syncpoints, MQPUT, MQGET of persistent messages) by placing the following on separate disks:
- `/var/mqm/qmgrs`
- `/var/mqm/log`

In the rare event that you need to trace an IBM MQ system for problem determination, you can reduce performance impact by placing the `/var/mqm/trace` file system on a separate disk.

If you are creating separate file systems, allow a minimum of 30 MB of storage for `/var/mqm`, 100 MB of storage for `/var/mqm/log`, and 10 MB of storage for `/var/mqm/errors`. The 100 MB minimum allowance of storage for `/var/mqm/log` is the absolute minimum required for a single queue manager and is not a recommended value. The size of a file system must be scaled according to the number of queue managers that you intend to use, the number of pages per log file, and the number of log files per queue manager.

If you want to use individual queues that hold more than 2 GB of data, you must enable `/var/mqm` to use large files.

For more information about file systems, see File system support.

The size of the log file depends on the log settings that you use. The minimum sizes are for circular logging using the default settings. For more information about log sizes, see Calculating the size of the log.

Linux For a client installation, the file system can be mounted on a remote network device, for example NFS.

If you are performing both a client and a server installation, the requirements of the server installation take precedence over the requirements of the client installation.

Allow 15 MB as a minimum for an IBM MQ client.

A new sample IBM MQ MQI client configuration file is created in the `var/mqm` directory, by the client package, during installation, but only if this file does not exist. This file contains the `ClientExitPath` stanza. An example `mqclient.ini` file is shown in Configuring a client using a configuration file.

If you are using a common configuration file for multiple clients, either in the IBM MQ installation directory or in another location using the MQCLNTCF environment variable, you must grant read access to all user identifiers under which the IBM MQ client applications run. If, for any reason, the file cannot be read the failure is traced, and the search logic continues as if the file had not existed.

Related concepts:

"Setting up the user and group on Linux" on page 334
On Linux systems, IBM MQ requires a user ID of the name `mqm`, with a primary group of `mqm`. The `mqm` user ID owns the directories and files that contain the resources associated with the product.

"Configuring and tuning the operating system on Linux"
Use this topic when you are configuring IBM MQ on Linux systems.

Configuring and tuning the operating system on Linux

Linux

Use this topic when you are configuring IBM MQ on Linux systems.

Attention: The information in this topic applies only if the queue manager is started by the `mqm` user ID.

If any other user ID starts the queue manager, ensure that the **`NOFILE`** and **`NPROC`** entries, shown for `mqm`, are duplicated for that user ID.

Shell interpreter

Ensure that `/bin/sh` shell is a valid shell interpreter compatible with the Bourne shell, otherwise the post-installation configuration of IBM MQ does not complete successfully. If the shell was not installed using RPM, you might see a prerequisites failure of `/bin/sh` shell when you try to install IBM MQ . The failure is because the RPM tables do not recognize that a valid shell interpreter is installed. If the failure occurs, you can reinstall the `/bin/sh` shell by using RPM, or specify the RPM option `--nodeps` to disable dependency checking during installation of IBM MQ .

Note: The **`--dbpath`** option is not supported when installing IBM MQ on Linux.

System V IPC kernel configuration

IBM MQ uses System V IPC resources, in particular shared memory. However, a limited number of semaphores are also used.

The minimum configuration for IBM MQ for these resources is as follows:

Table 46. Minimum tunable kernel parameters values

Name	Kernel-name	Value	Increase	Description
`shmmni`	`kernel.shmmni`	4096	Yes	Maximum number of shared memory segments
`shmmax`	`kernel.shmmax`	268435456	No	Maximum size of a shared-memory segment (bytes)
`shmall`	`kernel.shmall`	2097152	Yes	Maximum amount of shared memory (pages)
`semmsl`	`kernel.sem`	32	No	Maximum amount of semaphores permitted per set
`semmns`	`kernel.sem`	4096	Yes	Maximum number of semaphores
`semopm`	`kernel.sem`	32	No	Maximum number of operations in single operations
`semmni`	`kernel.sem`	128	Yes	Maximum number of semaphore sets
`thrmax`	`kernel.threads-max`	32768	Yes	Maximum number of threads
`pidmax`	`kernel.pid_max`	32768	Yes	Maximum number of process identifiers

Notes:

1. These values are sufficient to run two moderate sized queue managers on the system. If you intend to run more than two queue managers, or the queue managers are to process a significant workload, you might need to increase the values displayed as Yes in the Increase column.
2. The `kernel.sem` values are contained within a single kernel parameter containing the four values in order.

To view the current value of the parameter log on, as a user with root authority, and type:

```
sysctl Kernel-name
```

To add or alter these values, log on as a user with root authority. Open the file `/etc/sysctl.conf` with a text editor, then add or change the following entries to your chosen values:

```
kernel.shmmni = 4096
kernel.shmall = 2097152
kernel.shmmax = 268435456
kernel.sem = 32 4096 32 128
```

Then save and close the file.

To load these **`sysctl`** values immediately, enter the following command `sysctl -p`.

If you do not issue the `sysctl -p` command, the new values are loaded when the system is rebooted.

By default the Linux kernel has a maximum process identifier, that can also be used with threads, and might limit the allowed number of threads.

The operating system reports when the system lacks the necessary resources to create another thread, or the system-imposed limit on the total number of threads in a process {PTHREAD_THREADS_MAX} would be exceeded.

For more information on `kernel.threads-max` and `kernel.pid-max`, see Resource shortage in IBM MQ queue manager when running a large number of clients

TCP/IP configuration

If you want to use **`keepalive`** for IBM MQ channels, you can configure the operation of the KEEPALIVE using the kernel parameters:

```
net.ipv4.tcp_keepalive_intvl
net.ipv4.tcp_keepalive_probes
net.ipv4.tcp_keepalive_time
```

See Using the TCP/IP SO_KEEPALIVE option for further information.

To view the current value of the parameter log on, as a user with root authority, and type `sysctl` *`Kernel-name`*.

To add or alter these values, log on as a user with root authority. Open the file `/etc/sysctl.conf` with a text editor, then add or change the following entries to your chosen values.

To load these **`sysctl`** values immediately, enter the following command `sysctl -p`.

If you do not issue the `sysctl -p` command, the new values are loaded when the system is rebooted.

Maximum open files

The maximum number of open file-handles in the system is controlled by the parameter **`fs.file-max`**

The minimum value for this parameter for a system with two moderate sized queue managers is 524288.

If you intend to run more than two queue managers, or the queue managers are to process a significant workload, you might need to increase this value.

To view the current value of a parameter, log on as a user with root authority, and type `sysctl fs.file-max`.

To add or alter these values, log on as a user with root authority. Open the file `/etc/sysctl.conf` with a text editor, then add or change the following entry to your chosen value:

```
fs.file-max = 524288
```

Then save and close the file.

To load these **`sysctl`** values immediately, enter the following command `sysctl -p`.

If you do not issue the `sysctl -p` command, the new values are loaded when the system is rebooted.

If you are using a pluggable security module such as PAM (Pluggable Authentication Module), ensure that this module does not unduly restrict the number of open files for the `mqm` user. To report the maximum number of open file descriptors per process for the `mqm` user, login as the `mqm` user and enter the following values:

```
ulimit -n
```

For a standard IBM MQ queue manager, set the *nofile* value for the `mqm` user to 10240 or more. To set the maximum number of open file descriptors for processes running under the `mqm` user, add the following information to the `/etc/security/limits.conf` file:

```
mqm       hard  nofile     10240
mqm       soft  nofile     10240
```

Maximum processes

A running IBM MQ queue manager consists of a number of thread programs. Each connected application increases the number of threads running in the queue manager processes. It is normal for an operating system to limit the maximum number of processes that a user runs. The limit prevents operating system failures due to an individual user or subsystem creating too many processes. You must ensure that the maximum number of processes that the `mqm` user is allowed to run is sufficient. The number of processes must include the number of channels and applications that connect to the queue manager.

The following calculation is useful when determining the number of processes for the `mqm` user:

```
nproc = 2048 + clientConnections * 4 + qmgrChannels * 4 +
    localBindingConnections
```

where:
- *clientConnections* is the maximum number of connections from clients on other machines connecting to queue managers on this machine.
- *qmgrChannels* is the maximum number of running channels (as opposed to channel definitions) to other queue managers. This includes cluster channels, sender/receiver channels, and so on.
- *localBindingConnections* does not include application threads.

The following assumptions are made in this algorithm:

- 2048 is a large enough contingency to cover the queue manager threads. This might need to be increased if a lot of other applications are running.
- When settting nproc, take into account the maximum number of applications, connections, channels and queue managers that might be run on the machine in the future.
- This algorithm takes a pessimistic view and the actual nproc needed might be slightly lower for later versions of IBM MQ and fastpath channels.
- V 8.0.0.1 V 8.0.2 In Linux, each thread is implemented as a light-weight process (LWP) and each LWP is counted as one process against nproc.

You can use the `PAM_limits` security module to control the number of processes that users run. You can configure the maximum number of processes for the `mqm` user as follows:

```
mqm       hard  nproc      4096
mqm       soft  nproc      4096
```

For more details on how to configure the `PAM_limits` security module type, enter the following command:

```
man limits.conf
```

You can check your system configuration using the mqconfig command.

For more information on configuring your system, see How to configure UNIX and Linux systems for IBM MQ.

Related concepts:

"Setting up the user and group on Linux" on page 334
On Linux systems, IBM MQ requires a user ID of the name `mqm`, with a primary group of `mqm`. The `mqm` user ID owns the directories and files that contain the resources associated with the product.

"Creating file systems on Linux" on page 335
Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

mqconfig

Installing IBM MQ on Linux using rpm

Linux

Installation tasks that are associated with installing IBM MQ on Linux systems using rpm are grouped in this section.

About this task

To install IBM MQ using rpm, complete the following tasks.

For information about how to uninstall IBM MQ, see "Uninstalling or modifying IBM MQ on Linux using rpm" on page 395.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See "Checking requirements on Linux" on page 330.
2. Plan your installation.
   - As part of the planning process, you must choose which components to install and where to install them. See "IBM MQ rpm components for Linux systems."
   - You must also make some platform-specific choices. See "Planning to install IBM MQ on Linux" on page 332.
3. Prepare your system for installation of IBM MQ. See "Preparing the system on Linux" on page 333.
4. Install IBM MQ server. See "Installing IBM MQ server on Linux" on page 344.
5. Optional: Install an IBM MQ client. See "Installing an IBM MQ client on Linux" on page 355.
6. Verify your installation. See "Verifying an IBM MQ installation on Linux" on page 377.

IBM MQ rpm components for Linux systems

Linux

You can select the components that you require when you install IBM MQ.

Important: See IBM MQ license information for details of what each purchase of IBM MQ entitles you to install.

To display these components you can use, for example, the following command:

```
rpm -qa | grep MQ | xargs rpm -q --info
```

Table 47 shows the components that are available when installing an IBM MQ server or client on a Linux system:

Table 47. IBM MQ components for Linux systems

Component	Description	Server media	Client media	RPM package name
Runtime	Contains files that are common to both server and client installations. **Note:** MQSeriesRuntime component must be installed.	✓	✓	MQSeriesRuntime
Server	You can use the server to run queue managers on your system and connect to other systems over a network. Provides messaging and queuing services to applications, and support for IBM MQ client connections.	✓		MQSeriesServer
Standard Client	The IBM MQ MQI client is a small subset of IBM MQ, without a queue manager, that uses the queue manager and queues on other (server) systems. It can be used only when the system it is on is connected to another system that is running a full server version of IBM MQ. The client and the server can be on the same system if required.	✓	✓	MQSeriesClient
SDK	The SDK is required for compiling applications. It includes sample source files, and the bindings (files .H, .LIB, .DLL, and others), that you need to develop applications to run on IBM MQ.	✓	✓	MQSeriesSDK

Table 47. IBM MQ components for Linux systems (continued)

Component	Description	Server media	Client media	RPM package name
Sample programs	The sample application programs are needed if you want to check your IBM MQ installation using the verification procedures.	✓	✓	MQSeriesSamples
Java messaging	The files needed for messaging using Java (includes Java Message Service).	✓	✓	MQSeriesJava
Man pages	UNIX man pages, in U.S. English, for: control commands MQI calls MQSC commands	✓	✓	MQSeriesMan
Java JRE	A Java Runtime Environment that is used by those parts of IBM MQ that are written in Java.	✓	✓	MQSeriesJRE
Message Catalogs	For available languages, see the table of message catalogs that follows.	✓	✓	
IBM Global Security Kit	IBM Global Security Kit V8 Certificate and TLS, Base Runtime.	✓	✓	MQSeriesGSKit
Telemetry Service	MQ Telemetry supports the connection of Internet Of Things (IOT) devices (that is, remote sensors, actuators and telemetry devices) that use the IBM MQ Telemetry Transport (MQTT) protocol. The telemetry service, which is also know as the MQXR service, enables a queue manager to act as an MQTT server, and communicate with MQTT client apps. The telemetry service is only available on Linux for System x (64 bit) and Linux for IBM Z . A set of MQTT client libraries is also available in the IBM Messaging Telemetry Clients SupportPac. These libraries help you write the MQTT client apps that IOT devices use to communicate with MQTT servers. See also "Installation considerations for MQ Telemetry" on page 538.	✓		MQSeriesXRService
IBM MQ Explorer	Use IBM MQ Explorer to administer and monitor resources on Linux x86-64 systems. Also available using a stand-alone installer from MS0T.	✓		MQSeriesExplorer
Managed File Transfer	MQ Managed File Transfer transfers files between systems in a managed and auditable way, regardless of file size or the operating systems used. For information about the function of each component, see Managed File Transfer product options.	✓		MQSeriesFTAgent MQSeriesFTBase MQSeriesFTLogger MQSeriesFTService MQSeriesFTTools

Table 47. IBM MQ components for Linux systems (continued)

Component	Description	Server media	Client media	RPM package name
Advanced Message Security	Provides a high level of protection for sensitive data flowing through the IBM MQ network, while not impacting the end applications. You must install this component on all IBM MQ installations that host queues you want to protect. You must install the IBM Global Security Kit component on any IBM MQ installation that is used by a program that puts or gets messages to or from a protected queue, unless you are using only Java client connections. You must install the **Java JRE** component to install this component.	✓		MQSeriesAMS
V 9.0.0 AMQP Service	Install this component to make AMQP channels available. AMQP channels support MQ Light APIs. You can use AMQP channels to give AMQP applications access to the enterprise-level messaging facilities provided by IBM MQ.	✓		MQSeriesAMQP
V 9.0.1 REST API and Console	Adds HTTP based administration for IBM MQ through the REST API and IBM MQ Console.	✓		MQSeriesWeb
V 9.0.2 IBM MQ Bridge to Salesforce	Install this component to configure the connections to Salesforce and IBM MQ, then run the **runmqsfb** command to subscribe to events from Salesforce and publish them to an IBM MQ network. **Note:** The IBM MQ Bridge to Salesforce is available only on Linux for System x (64 bit).	✓	✓	MQSeriesSFBridge
V 9.0.4 IBM MQ Bridge to blockchain	Install this component to configure the connections to your blockchain network and IBM MQ. You can then run the **runmqbcb** command to start the bridge and send queries and updates to, and receive responses from your blockchain network. The queue manager that the bridge connects to must be an IBM MQ Advanced queue manager. For more information, see What is IBM MQ Advanced?. **Note:** The IBM MQ Bridge to blockchain is available only on Linux for System x (64 bit). This component is not supported for use with Docker.	✓	✓	MQSeriesBCBridge

Table 47. IBM MQ components for Linux systems (continued)

Component	Description	Server media	Client media	RPM package name
V 9.0.4 RDQM (replicated data queue manager)	Install this component to make the replicated data queue manager high availability configuration available. See "Installing RDQM (replicated data queue managers)" on page 545 for more information. This component is available only on Linux for System x (64 bit), on RHEL 7.3 or later. **Note:** This component is not supported for use with Docker.	✓		MQSeriesRDQM

Table 48. IBM MQ message catalogs for Linux systems

Message catalog language	RPM package name
Brazilian Portuguese	MQSeriesMsg_pt
Czech	MQSeriesMsg_cs
French	MQSeriesMsg_fr
German	MQSeriesMsg_de
Hungarian	MQSeriesMsg_hu
Italian	MQSeriesMsg_it
Japanese	MQSeriesMsg_ja
Korean	MQSeriesMsg_ko
Polish	MQSeriesMsg_pl
Russian	MQSeriesMsg_ru
Spanish	MQSeriesMsg_es
Simplified Chinese	MQSeriesMsg_Zh_CN
Traditional Chinese	MQSeriesMsg_Zh_TW
U.S. English	not applicable

Related concepts:

"IBM MQ components and features" on page 192
You can select the components or features that you require when you install IBM MQ.

"Planning considerations for installation on Multiplatforms" on page 196
Before you install IBM MQ, you must choose which components to install and where to install them. You must also make some platform-specific choices.

Installing IBM MQ server on Linux

Linux

You can install an IBM MQ server on a 64-bit Linux system.

Before you begin

- **CAUTION:**
  The instructions in this topic do not apply to Linux Ubuntu or Linux on POWER Systems - Little Endian. For information about these platforms, see "Installing IBM MQ server on Linux Ubuntu or Linux on POWER Systems - Little Endian" on page 350.

- If you install a copy of IBM MQ server for Linux using Electronic Software Download, obtained from Passport Advantage, you need to decompress the `tar.gz` file by using the **`gunzip`** command:

  ```
  gunzip IBM_MQ_V9.0_TRIAL_FOR_LINUX_ML.tar.gz
  ```

  and extract the installation files from the tar file, by using the following command:

  ```
  tar -xvf IBM_MQ_V9.0_TRIAL_FOR_LINUX_ML.tar
  ```

  Important: You must use GNU tar (also known as `gtar`) to unpack any `tar` images.
- Before you start the installation procedure, ensure that you have completed the necessary steps outlined in "Preparing the system on Linux" on page 333.
- If this installation is not the first installation on the system, you must ensure that the **`crtmqpkg`** command can write to a temporary location. By default, the **`crtmqpkg`** command will write to the `/var/tmp` directory. To use a different location, you can set the *TMPDIR* environment variable before you run the **`crtmqpkg`** command.
- To run the **`crtmqpkg`** command used in this task, you must have the **`pax`** command or **`rpmbuild`** installed.

  Attention: **`pax`** and **`rpmbuild`** are not supplied as part of the product. You must obtain these from your Linux distribution supplier.

About this task

Install the server by using the RPM Package Manager installer to select the components you want to install. The components and package names are listed in "Installing IBM MQ server on Linux Ubuntu or Linux on POWER Systems - Little Endian" on page 350.

Attention: If you install the packages using the wildcard character, that is, using the command `rpm -ivh MQ*.rpm`, you should install the packages in the following order:

- MQSeriesRuntime
- MQSeriesJRE
- MQSeriesJava
- MQSeriesServer
- MQSeriesWeb
- MQSeriesFTBase
- MQSeriesFTAgent
- MQSeriesFTService
- MQSeriesFTLogger
- MQSeriesFTTools
- V 9.0.0 MQSeriesAMQP
- MQSeriesAMS
- MQSeriesXRService
- MQSeriesExplorer
- MQSeriesGSKit
- MQSeriesClient
- MQSeriesMan
- MQSeriesMsg
- MQSeriesSamples
- MQSeriesSDK
- V 9.0.2 MQSeriesSFBridge
- V 9.0.4 MQSeriesBCBridge

Procedure

1. Log in as `root`, or switch to the superuser by using the **su** command.
2. Set your current directory to the location of the installation file. The location might be the mount point of the server DVD, a network location, or a local file system directory.
3. You must accept the terms of the license agreement before you can proceed with the installation. To do this run the `mqlicense.sh` script:

   ```
   ./mqlicense.sh
   ```

   The license agreement is displayed in a language appropriate to your environment and you are prompted to accept or decline the terms of the license.

   If possible, `mqlicense.sh` opens an X-window to display the license.

   If you need the license to be presented as text in the current shell, which can be read by a screen reader, type the following command, `./mqlicense.sh -text_only`
4. If this installation is not the only installation of IBM MQ on the system, you must run the **crtmqpkg** command to create a unique set of packages to install on the system. To run the **crtmqpkg** command to run on Linux, you must install the **pax** command and **rpmbuild**, which is located in the rpm-build package.

   Note: The **crtmqpkg** command is required only if this is not the first installation of IBM MQ on the system. If you have earlier versions of IBM MQ installed on your system, then installing the latest version works correctly if you install it in a different location.

   To run the **crtmqpkg** command on a Linux system:

   a. Enter the following command:

```
./crtmqpkg suffix
```

where *suffix* is a name of your choosing that uniquely identifies the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.

Note: This command creates a full copy of the installation packages in a temporary directory. By default, the temporary directory is located at /var/tmp. You must ensure that the system has enough free space before you run this command. To use a different location, you can set the *TMPDIR* environment variable before you run the **crtmqpkg** command. For example:

```
$ TMPDIR=/test ./crtmqpkg suffix
```

b. Set your current directory to the location specified when the **crtmqpkg** command operation completes successfully. This directory is a subdirectory of the /var/tmp/mq_rpms directory, in which the unique set of packages is created. The packages have the *suffix* value contained within the file name. For example, using a suffix of "1":

```
./crtmqpkg 1
```

means there is a subdirectory named /var/tmp/mq_rpms/1/x86_64.

The packages are renamed according to the subdirectory, for example:

```
From: MQSeriesRuntime-8.0.0-0.x86_64.rpm
To: MQSeriesRuntime-1-8.0.0-0.x86_64.rpm
```

5. Install IBM MQ. To support the running of a queue manager, you must install at least the the MQSeriesRuntime and the MQSeriesServer components.
   - To install to the default location, /opt/mqm, use the **rpm -ivh** command to install each component that you require.

     For example, to install the runtime and server components to the default location, use the following command:

     ```
     rpm -ivh MQSeriesRuntime-*.rpm MQSeriesServer-*.rpm
     ```

     To install all components that are available in your current location on the installation media to the default location, use the following command:

     ```
     rpm -ivh MQSeries*.rpm
     ```

     Important: The components that you need to install might not all be in the same folder on the installation media. Some components might be under the /Advanced folder. For more information about installing IBM MQ Advanced components, see "Installing IBM MQ Advanced for Multiplatforms" on page 519.
   - To install to a non-default location, use the **rpm --prefix** option. For each installation, all of the IBM MQ components that you require must be installed in the same location.

     The installation path specified must be either an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.

     For example, enter the following installation path to install the runtime and server components to the /opt/customLocation directory on a 64-bit Linux system:

     ```
     rpm --prefix /opt/customLocation -ivh MQSeriesRuntime-*.rpm
     MQSeriesServer-*.rpm
     ```

Results

You installed IBM MQ on your Linux system.

What to do next

- If required, you can now set this installation to be the primary installation. Enter the following command at the command prompt:

```
MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
```

where *MQ_INSTALLATION_PATH* represents the directory where IBM MQ is installed.

You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.

- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ . For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. See "Verifying an IBM MQ installation on Linux" on page 377, for more information.
- Only a user with a UID that is a member of the **mqm** group can issue administration commands. If you want to enable users to issue administration commands, they must be added to the **mqm** group. For more information, see "Setting up the user and group on Linux" on page 334 and Authority to administer IBM MQ on UNIX, Linux, and Windows systems.

Changing the primary installation

Installing the IBM MQ server silently on Linux: Linux

You can carry out a non-interactive installation of the IBM MQ server. A non-interactive installation is also known as a silent, or unattended installation.

About this task

To install IBM MQ silently, accept the IBM MQ license in non-interactive mode and then follow the interactive installation procedure.

Procedure

1. Log in as `root`, or switch to the superuser by using the **su** command.
2. You must accept the terms of the license agreement before you can proceed with the installation. To do this run the `mqlicense.sh` script.

   The license agreement will be displayed in a language appropriate to your environment and you will be prompted to accept or decline the terms of the license.

   If possible, `mqlicense.sh` opens an X-window to display the license.

   If you need the license to be presented as text in the current shell, which can be read by a screen reader, type the following command, `mqlicense.sh -text_only`
3. Follow the procedure detailed in "Installing IBM MQ server on Linux" on page 344 or "Installing IBM MQ server on Linux Ubuntu or Linux on POWER Systems - Little Endian" on page 350 as appropriate.

Related concepts:

Changing the primary installation

Checking the availability of rpm on your Linux Ubuntu machine: Linux

If you are using an rpm installer, you must ensure that rpm is installed on your Linux Ubuntu machine before installing IBM MQ. V 9.0.2 From IBM MQ Version 9.0.2 you can use a Debian installer as an alternative to rpm.

Before you begin

V 9.0.2 If you choose to use the Debian installer, see "Installing IBM MQ on Linux Ubuntu using Debian" on page 363.

About this task

Important: The installation procedure uses the same rpm packages that are used by the other rpm based distributions. Technologies that convert these rpm packages into other forms, such as alien to convert rpms to Debian packages, are not compatible with the IBM MQ rpm packages and must not be used.

Procedure

1. To determine if the correct rpm package is installed on you system use the following command:
   ```
   dpkg-query -W --showformat '${Status}\n' rpm
   ```
   If you receive a response that is of the form:
   ```
   install ok installed
   ```
   rpm is installed on your system and no further action is required.

   If you receive a response that is of the form:
   ```
   unknown ok not-installed
   ```
   rpm is not installed on your system and you must install the rpm package before attempting to install IBM MQ, using the command described in step 2.
2. Run the following command, using root authority. In the example, you obtain root authority using the `sudo` command:
   ```
   sudo apt-get install rpm
   ```
   Attention: If this command does not complete successfully, consult your system administrator for instructions specific to your system on how to install the rpm package.

What to do next

You are now ready to install IBM MQ.

Related concepts:

"Multiple installations on UNIX, Linux, and Windows" on page 200
On UNIX, Linux, and Windows, it is possible to have more than one copy of IBM MQ on a system.

"Primary installation on UNIX, Linux, and Windows" on page 202
On systems that support multiple installations of IBM MQ (UNIX, Linux, and Windows), the primary installation is the one to which IBM MQ system-wide locations refer. Having a primary installation is optional, but convenient.

Related tasks:

"Uninstalling or modifying IBM MQ on Linux using rpm" on page 395
On Linux, you can uninstall the IBM MQ server or client using the **rpm** command. You can also modify an installation by removing selected packages (components) currently installed on your system.

Related information:

setmqinst

Changing the primary installation

Installing IBM MQ server on Linux Ubuntu or Linux on POWER Systems - Little Endian:

Linux

You can install an IBM MQ server on a Linux Ubuntu system, or Linux on POWER Systems - Little Endian system, in accordance with the system requirements web page.

Before you begin

You can install IBM MQ on a Linux Ubuntu system by using the RPM installer or by using the Debian installer. For more information about using the Debian installer, see "Installing IBM MQ on Linux Ubuntu using Debian" on page 363.

See System Requirements for IBM MQ for details of the supported software levels.

- Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on Linux" on page 333.
- If you install a copy of IBM MQ server for Linux Ubuntu using Electronic Software Download, obtained from Passport Advantage, you need to decompress the `tar.gz` file, and extract the installation files from the tar file, by using the following command:

  ```
  tar -xvf   WS_MQ_V9.0_TRIAL_FOR_LINUXUbuntu_ML.tar
  ```

  Important: You must use GNU tar (also known as `gtar`) to unpack any `tar` images.
- Ensure that RPM is installed on your system, as RPM is not installed by default on this platform.

  To determine if the correct RPM package is installed on you system, see "Checking the availability of rpm on your Linux Ubuntu machine" on page 349.
- Once RPM is installed on your system, carry out the following procedure, as root:
  1. Create directory `/etc/rpm`
  2. Add file `/macros`, containing the following code, `%_dbpath /var/lib/rpm`, to the `/etc/rpm` directory.

  Attention: You should only set up a `/macros` file if you are not already using RPM, as the previous instruction changes the default system-wide RPM database.

About this task

Install the server by using the RPM Package Manager installer to select the components that you want to install. The components and package names are listed in “IBM MQ components and features” on page 192.

Procedure

1. Open a shell terminal and set your current directory to the location of the installation packages. The location might be the mount point of the server DVD, a network location, or a local file system directory. You must have root authority to run the following commands. You can do so by adding **sudo** before the following commands, or by changing to the root user in the shell with the **su** command.
2. Run the `mqlicense.sh` script. If you want to view a text-only version of the license, which can be read by a screen reader, type the following message:

   ```
   ./mqlicense.sh -text_only
   ```

   The license is displayed.

   You must accept the license agreement before you can proceed with the installation.
3. If this installation is not the first installation of IBM MQ on the system, you must run the **crtmqpkg** command to create a unique set of packages to install on the system. For the **crtmqpkg** command to run on Linux, you must install the **pax** command and **rpmbuild**, which is located in the rpm package.
   a. Enter the following command:

      ```
      ./crtmqpkg suffix
      ```

      where *suffix* is a name of your choosing, that uniquely identifies the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.

      Note: This command creates a full copy of the installation packages in a temporary directory. By default, the temporary directory is located at `/var/tmp`. You must ensure that the system has enough free space before you run this command. To use a different location, you can set the *TMPDIR* environment variable before you run the **crtmqpkg** command. For example:

      ```
      TMPDIR=/test ./crtmqpkg
      ```
   b. Set your current directory to the location specified when the **crtmqpkg** command completes. This directory is a subdirectory of the `/var/tmp/mq_rpms` directory, in which the unique set of packages is created. The packages have the *suffix* value contained within the file name. In the following example, the suffix of "1" `./crtmqpkg 1` means that there is a subdirectory named `/var/tmp/mq_rpms/1/i386`.

      The packages are renamed according to the subdirectory, for example, on Linux for System x (64-bit):

      ```
      From: MQSeriesRuntime-8.0.0-0.x86_64.rpm
      To: MQSeriesRuntime_1-8.0.0-0.x86_64.rpm
      ```
4. Install IBM MQ. At a minimum, you must install the `MQSeriesRuntime` and the `MQSeriesServer` components.

   If you are installing a subset of components, you must ensure that any dependencies are first installed, as listed in Table 49 on page 352.

   An additional flag is required when installing on Ubuntu 14.04 on Linux on POWER Systems - Little Endian:

   - **--ignorearch**: You must include this option to prevent problems with some levels of rpm not recognizing the Linux on POWER Systems - Little Endian architecture

   An additional flag is required when installing on Linux Ubuntu:

- **--force-debian**: You must include this option to prevent warning messages from the version of RPM for your platform, which indicates that the RPM packages are not intended to be directly installed using RPM.

To install the IBM MQ Explorer on Linux Ubuntu (x86-64 only):

a. Install all the components that you want, except for the IBM MQ Explorer component.
b. Install the IBM MQ Explorer component with the **--nodeps** flag. If you do not include the **--nodeps** flag, the installation fails with a dependency error. The dependency error occurs because the GTK2 packages are not installed by RPM and therefore cannot be found as package dependencies.

Notes:

- To install to the default location, `/opt/mqm`, use the rpm **-ivh** command to install each component that you require.

  To install the runtime and server components to the default location on Ubuntu Linux for System x (64-bit), use the following command:

  ```
  rpm -ivh --force-debian MQSeriesRuntime-*.rpm MQSeriesServer-*.rpm
  ```

  To install the runtime and server components to the default location on Linux on POWER Systems - Little Endian, use the following command:

  ```
  rpm -ivh --ignorearch MQSeriesRuntime-*.rpm MQSeriesServer-*.rpm
  ```

  To install all components to the default location on Linux on POWER Systems - Little Endian use the following command:

  ```
  rpm -ivh --ignorearch MQSeries*.rpm
  ```

- To install to a nondefault location, use the **rpm --prefix** option. For each installation, all of the IBM MQ components that you require must be installed in the same location.

  The installation path specified must be, either an empty directory, the root of an unused file system, or a path that does not exist.

  Attention: The length of the path is limited to 256 bytes and must not contain spaces.

  For example, enter the following installation path to install the runtime and server components to the `/opt/customLocation` directory on Linux on POWER Systems - Little Endian:

  ```
  rpm --prefix /opt/customLocation -ivh --ignorearch
  MQSeriesRuntime-*.rpm MQSeriesServer-*.rpm
  ```

Table 49 lists all available packages on Ubuntu, together with all the associated dependencies.

To install and use the package listed in the *Package Name* column, you must also install the components listed in the *Package Dependencies* column.

Table 49. Package component dependencies

Package Name	Component Function	Dependencies
MQSeriesRuntime	Common function for all other components	None
MQSeriesServer	Queue Manager	MQSeriesRuntime
MQSeriesClient	C IBM MQ client libraries	MQSeriesRuntime
MQSeriesJava	Java and JMS IBM MQ APIs	MQSeriesRuntime
MQSeriesJRE	Java Runtime Environment	MQSeriesRuntime

Table 49. Package component dependencies (continued)

Package Name	Component Function	Dependencies
MQSeriesExplorer	IBM MQ Explorer IBM MQ Explorer is only available on Linux for System x (64-bit). There is no IBM support for this component on Ubuntu, unless you are running on Ubuntu Version 14.04 (or later) and have installed IBM MQ Version 8.0.0, Fix Pack 2 (or later).	MQSeriesRuntime MQSeriesJRE GTK2 version 2.2.4-0 or later, including the GTK2 engines that contain the GTK2 themes Bitstream-vera-fonts
MQSeriesGSKit	IBM Global Security Kit **Note:** There is no IBM support for this component on Ubuntu, unless you are running on Ubuntu Version 14.04 (or later) and have installed IBM MQ Version 8.0.0, Fix Pack 2 (or later).	MQSeriesRuntime MQSeriesJRE
MQSeriesWeb	REST API and IBM MQ Console.	MQSeriesRuntime MQSeriesServer MQSeriesJava MQSeriesJRE
MQSeriesSDK	Header files and libraries for non-Java APIs	MQSeriesRuntime
MQSeriesMan	UNIX man pages for IBM MQ	MQSeriesRuntime
MQSeriesSamples	IBM MQ application samples	MQSeriesRuntime
MQSeriesMsg_cz MQSeriesMsg_de MQSeriesMsg_es MQSeriesMsg_fr MQSeriesMsg_hu MQSeriesMsg_it MQSeriesMsg_ja MQSeriesMsg_ko MQSeriesMsg_pl MQSeriesMsg_pt MQSeriesMsg_ru MQSeriesMsg_Zh_CN MQSeriesMsg_Zh_TW	Additional language message catalog files. English message catalog files are installed by default. For more information about these message catalogs, see “Displaying messages in your national language on Linux” on page 376	MQSeriesRuntime
MQSeriesFTBase	Managed File Transfer component	MQSeriesRuntime MQSeriesJava MQSeriesJRE

Table 49. Package component dependencies (continued)

Package Name	Component Function	Dependencies
MQSeriesFTLogger	Managed File Transfer component	MQSeriesRuntime MQSeriesServer MQSeriesFTBase MQSeriesJava MQSeriesJRE
MQSeriesFTTools MQSeriesFTAgent	Managed File Transfer components	MQSeriesRuntime MQSeriesFTBase MQSeriesJava MQSeriesJRE
MQSeriesFTService	Managed File Transfer component	MQSeriesRuntime MQSeriesServer MQSeriesFTAgent MQSeriesFTBase MQSeriesJava MQSeriesJRE
MQSeriesAMS	Advanced Message Security component **Note:** There is no IBM support for this component on Ubuntu, unless you are running on Ubuntu Version 14.04 (or later) and have installed IBM MQ Version 8.0.0, Fix Pack 2 (or later).	MQSeriesRuntime MQSeriesServer
V 9.0.2 MQSeriesSFBridge	Install the IBM MQ Bridge to Salesforce to subscribe to Salesforce push topics and platform events. V 9.0.4 From IBM MQ Version 9.0.4 you can also use the bridge to create event messages for Salesforce platform events. **Note:** The IBM MQ Bridge to Salesforce is available only on Linux for System x (64 bit).	ibmmq-runtime ibmmq-java ibmmq-jre
MQSeriesBCBridge	Install the IBM MQ Bridge to blockchain to send queries and updates to, and receive responses from your blockchain network. **Note:** The IBM MQ Bridge to blockchain is available only on Linux for System x (64 bit).	ibmmq-runtime ibmmq-java ibmmq-jre

Results

You have installed the packages you require.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  where *MQ_INSTALLATION_PATH* represents the directory where IBM MQ is installed.

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ . For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. See "Verifying an IBM MQ installation on Linux" on page 377, for more information.

setmqinst

Changing the primary installation

Installing an IBM MQ client on Linux

Linux

Installing an IBM MQ client on a 32 bit or 64 bit Linux system.

Before you begin

- Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on Linux" on page 333.
- If this installation is not the only installation on the system, you must ensure that you have write access to `/var/tmp`.

About this task

This task describes the installation of the client, using the RPM Package Manager installer to select which components you want to install. You must install at least the Runtime and Client components. The components are listed in "IBM MQ rpm components for Linux systems" on page 341.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Make your current directory the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Run the `mqlicense.sh` script. If you want to view a text-only version of license, which can be read by a screen-reader, type:

   ```
   ./mqlicense.sh -text_only
   ```

   The license is displayed.

   If want to accept the license without it being displayed, you can run the `mqlicense.sh` script with the `-accept` option.

   ```
   ./mqlicense.sh -accept
   ```

   You must accept the license agreement before you can proceed with the installation.
4. If you have multiple installations on this system, you must run **crtmqpkg** to create a unique set of packages to install on the system:
   a. Enter the following command:

      ```
      ./crtmqpkg suffix
      ```

      where *suffix* is a name of your choosing, that will uniquely identify the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.
   b. Set your current directory to the location specified when the **crtmqpkg** command completes. This directory is a sub-directory of `/var/tmp/mq_rpms`, in which the unique set of packages is created. The packages have the *suffix* value contained within the filename.
5. Install IBM MQ. The minimum components you must install are the MQSeriesRuntime and the MQSeriesClient.
   - To install to the default location, `/opt/mqm`, use the **rpm -ivh** command to install each component that you require.

     For example, to install all components to the default location use the following command:

     ```
     rpm -ivh MQSeries*.rpm
     ```

     If you are using Ubuntu, add the **--force-debian** attribute. For example, to install all components to the default location use the following command:

     ```
     rpm --force-debian -ivh MQSeries*.rpm
     ```

     You must include this option to prevent seeing warning messages from the version of RPM for your platform, which indicates that the RPM packages are not intended to be directly installed using RPM.
   - To install to a non-default location use the **rpm --prefix** option. For each installation, all of the IBM MQ components that you require must be installed in the same location.

     The installation path specified must either be an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.

     For example, to install the runtime and server components to `/opt/customLocation` on a 64-bit Linux system:

```
rpm --prefix /opt/customLocation -ivh MQSeriesRuntime-V.R.M-F.x86_64.rpm
MQSeriesClient-V.R.M-F.x86_64.rpm
```

     where:

     V Represents the version of the product that you are installing

     R Represents the release of the product that you are installing

M Represents the modification of the product that you are installing

F Represents the fix pack level of the product that you are installing

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see “Testing communication between a client and a server on Linux” on page 393

Related tasks:

“Uninstalling or modifying IBM MQ on Linux using rpm” on page 395
On Linux, you can uninstall the IBM MQ server or client using the **rpm** command. You can also modify an installation by removing selected packages (components) currently installed on your system.

Checking the availability of RPM on your machine: Linux

You must ensure that RPM is installed on your Linux machine before installing IBM MQ.

V 9.0.2 From IBM MQ Version 9.0.2 you can use a Debian installer as an alternative to rpm.

Before you begin

V 9.0.2 If you choose to use the Debian installer, see “Installing IBM MQ on Linux Ubuntu using Debian” on page 363.

About this task

Important: The installation procedure uses the same rpm packages that are used by the other rpm based distributions. Technologies that convert these rpm packages into other forms, such as alien to convert rpms to Debian packages, are not compatible with the IBM MQ rpm packages and must not be used.

Procedure

1. To determine if the correct rpm package is installed on you system use the following command:

   ```
   dpkg-query -W --showformat '${Status}\n' rpm
   ```

   If you receive a response that is of the form:

   ```
   install ok installed
   ```

   rpm is installed on your system and no further action is required.

   If you receive a response that is of the form:

   ```
   unknown ok not-installed
   ```

   rpm is not installed on your system and you must install the rpm package before attempting to install IBM MQ, using the command described in step 2 on page 349.
2. Run the following command, using root authority. In the example, you obtain root authority using the `sudo` command:

```
sudo apt-get install rpm
```

Attention: If this command does not complete successfully, consult your system administrator for instructions specific to your system on how to install the rpm package.

What to do next

You are now ready to install IBM MQ.

Related concepts:

"Multiple installations on UNIX, Linux, and Windows" on page 200
On UNIX, Linux, and Windows, it is possible to have more than one copy of IBM MQ on a system.

Related information:

setmqinst

Changing the primary installation

Installing IBM MQ client on Linux Ubuntu or Linux on POWER Systems - Little Endian:

Linux

You can install an IBM MQ client on a Linux Ubuntu , or Linux on POWER Systems - Little Endian, system in accordance with the system requirements web page.

Before you begin

See System Requirements for IBM MQ for details of the supported software levels.

- Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on Linux" on page 333.
- Ensure that RPM is installed on your system, as RPM is not installed by default on this platform.

  To determine if the correct RPM package is installed on you system, see "Checking the availability of RPM on your machine" on page 357.
- Once RPM is installed on your system, carry out the following procedure, as root:
  1. Create directory `/etc/rpm`
  2. Add file `/macros`, containing the following code, `%_dbpath /var/lib/rpm`, to the `/etc/rpm` directory.

Attention: You should only set up a `/macros` file if you are not already using RPM, as the previous instruction changes the default system-wide RPM database.

About this task

Install the client by using the RPM Package Manager installer to select the components that you want to install. The components and package names are listed in "IBM MQ components and features" on page 192.

Procedure

1. Open a shell terminal and set your current directory to the location of the installation packages. The location might be the mount point of the client DVD, a network location, or a local file system directory. You must have root authority to run the following commands. You can do so by adding **sudo** before the following commands, or by changing to the root user in the shell with the **su** command.
2. Run the `mqlicense.sh` script. If you want to view a text-only version of the license, which can be read by a screen reader, type the following message:
   ```
   ./mqlicense.sh -text_only
   ```
   The license is displayed.

   You must accept the license agreement before you can proceed with the installation.
3. If this installation is not the first installation of IBM MQ on the system, you must run the **crtmqpkg** command to create a unique set of packages to install on the system. For the **crtmqpkg** command to run on Linux, you must install the **pax** command and **rpmbuild**, which is located in the rpm package.
   a. Enter the following command:
      ```
      ./crtmqpkg suffix
      ```
      where *suffix* is a name of your choosing, that uniquely identifies the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.

      Note: This command creates a full copy of the installation packages in a temporary directory. By default, the temporary directory is located at `/var/tmp`. You must ensure that the system has enough free space before you run this command. To use a different location, you can set the *TMPDIR* environment variable before you run the **crtmqpkg** command. For example:
      ```
      TMPDIR=/test ./crtmqpkg
      ```
   b. Set your current directory to the location specified when the **crtmqpkg** command completes. This directory is a subdirectory of the `/var/tmp/mq_rpms` directory, in which the unique set of packages is created. The packages have the *suffix* value contained within the file name. In the following example, the suffix of "1" `./crtmqpkg 1` means that there is a subdirectory named `/var/tmp/mq_rpms/1/i386`.

      The packages are renamed according to the subdirectory, for example, on Linux for System x (64-bit):
      ```
      From: MQSeriesRuntime-8.0.0-0.x86_64.rpm
      To: MQSeriesRuntime_1-8.0.0-0.x86_64.rpm
      ```
4. Install IBM MQ. At a minimum, you must install the `MQSeriesRuntime` component.

   An additional flag is required when installing on Linux Ubuntu:
   - **--force-debian**: You must include this option to prevent warning messages from the version of RPM for your platform, which indicates that the RPM packages are not intended to be directly installed using RPM.

   An additional flag is required when installing on Ubuntu 14.04 on Linux on POWER Systems - Little Endian:
   - **--ignorearch**: You must include this option to prevent problems with some levels of rpm not recognizing the Linux on POWER Systems - Little Endian architecture

   If you are installing a subset of components, you must ensure that any dependencies are first installed, as listed in Table 50 on page 360.

   Notes:
   - To install to the default location, `/opt/mqm`, use the rpm **-ivh** command to install each component that you require.

To install the runtime component to the default location on Ubuntu Linux for System x (64-bit), use the following command:

```
rpm -ivh --force-debian MQSeriesRuntime-*.rpm
```

To install the runtime component to the default location on Ubuntu Linux on POWER Systems - Little Endian, use the following command:

```
rpm -ivh --force-debian --ignorearch MQSeriesRuntime-*.rpm
```

To install all components to the default location on Ubuntu Linux on POWER Systems - Little Endian use the following command:

```
rpm -ivh --force-debian --ignorearch MQSeries*.rpm
```

- To install to a nondefault location, use the **`rpm --prefix`** option. For each installation, all of the IBM MQ components that you require must be installed in the same location.

  The installation path specified must be, either an empty directory, the root of an unused file system, or a path that does not exist.

  Attention: The length of the path is limited to 256 bytes and must not contain spaces.

  For example, enter the following installation path to install the runtime component to the `/opt/customLocation` directory on Ubuntu Linux on POWER Systems - Little Endian:

  ```
  rpm --prefix /opt/customLocation -ivh --force-debian --ignorearch
  MQSeriesRuntime-*.rpm
  ```

Table 50 lists all available packages on Ubuntu, together with all the associated dependencies.

To install and use the package listed in the *Package Name* column, you must also install the components listed in the *Package Dependencies* column.

Table 50. Package component dependencies

Package Name	Component Function	Package Dependencies
MQSeriesRuntime	Common function for all other components	None
MQSeriesClient	C IBM MQ client libraries	MQSeriesRuntime
MQSeriesJava	Java and JMS IBM MQ APIs	MQSeriesRuntime
MQSeriesJRE	Java Runtime Environment	MQSeriesRuntime
MQSeriesExplorer	IBM MQ Explorer IBM MQ Explorer is only available on Linux for System x (64-bit). **Note:** There is no IBM support for this component on Ubuntu, unless you are running on Ubuntu Version 14.04 (or later) and have installed IBM MQ Version 8.0.0.2. Results

You have installed the packages you require.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see "Testing communication between a client and a server on Linux" on page 393

Related concepts:

"Multiple installations on UNIX, Linux, and Windows" on page 200
On UNIX, Linux, and Windows, it is possible to have more than one copy of IBM MQ on a system.

"Primary installation on UNIX, Linux, and Windows" on page 202
On systems that support multiple installations of IBM MQ (UNIX, Linux, and Windows), the primary installation is the one to which IBM MQ system-wide locations refer. Having a primary installation is optional, but convenient.

Related tasks:

"Uninstalling or modifying IBM MQ on Linux using rpm" on page 395
On Linux, you can uninstall the IBM MQ server or client using the **rpm** command. You can also modify an installation by removing selected packages (components) currently installed on your system.

Changing the primary installation

Installing IBM MQ on Linux Ubuntu using Debian

Linux V 9.0.2

Installation tasks that are associated with installing IBM MQ on Linux systems using a Debian installer are grouped in this section.

Before you begin

Important: Using both Debian and rpm to install IBM MQ on the same system is not supported.

About this task

To install IBM MQ using a Debian installer, complete the following tasks.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See "Checking requirements on Linux" on page 330.
2. Plan your installation. As part of the planning process, you must choose which components to install and where to install them. See "IBM MQ Debian components for Linux Ubuntu systems" on page 364.
3. Prepare your system for installation of IBM MQ. See "Preparing the system on Linux" on page 333.
4. Install IBM MQ server. See "Installing an IBM MQ server on Linux Ubuntu using Debian packages" on page 368.
5. Optional: Install an IBM MQ client. See "Installing an IBM MQ client on Linux Ubuntu using Debian packages" on page 372.
6. Verify your installation. See "Verifying an IBM MQ installation on Linux" on page 377.

Overview of the Debian installer for IBM MQ on Linux Ubuntu

▶ Linux ▶ V 9.0.2

An overview of the concepts and considerations for installing IBM MQ, on Linux Ubuntu, using the Debian installer.

Installation tools

Use **dpkg**, or a higher level installation tool, to install and uninstall the product. The installed product on disk appears identical to an rpm-installed copy.

Attention: The Debian installation tools have no provision for overriding the installation directory. This means that there is *no relocatable or multi-version support*. Therefore the product will be installed to `/opt/mqm`, but this can be set as the primary installation if you require.

Package names

The package names have been changed to use an IBM MQ derived name.

For example, the Debian equivalent of the existing rpm server component, `MQSeriesServer`, is `ibmmq-server`.

Coexistence

Having both Debian and rpm installed versions of IBM MQ on the same system is not supported.

Therefore, on a single system, you can have a single version of IBM MQ installed by Debian, or multiple versions of IBM MQ installed by rpm.

However, you can achieve multi-version installation with Debian through the use of container based technologies, such as Docker.

Related tasks:

"Installing IBM MQ server on Linux Ubuntu or Linux on POWER Systems - Little Endian" on page 350
You can install an IBM MQ server on a Linux Ubuntu system, or Linux on POWER Systems - Little Endian system, in accordance with the system requirements web page.

IBM MQ Debian components for Linux Ubuntu systems

▶ Linux ▶ V 9.0.2

You can select the components that you require when you install IBM MQ.

Table 51 shows the components that are available when installing an IBM MQ server or client on a Linux Ubuntu system using the Debian installer:

Table 51. IBM MQ Debian components for Linux Ubuntu systems

Component	Description	Server media	Client media	Debian package name
Runtime	Contains files that are common to both server and client installations. **Note:** ibmmq-runtime component must be installed.	✓	✓	ibmmq-runtime

Table 51. IBM MQ Debian components for Linux Ubuntu systems (continued)

Component	Description	Server media	Client media	Debian package name
Server	You can use the server to run queue managers on your system and connect to other systems over a network. Provides messaging and queuing services to applications, and support for IBM MQ client connections.	✓		ibmmq-server
Standard Client	The IBM MQ MQI client is a small subset of IBM MQ, without a queue manager, that uses the queue manager and queues on other (server) systems. It can be used only when the system it is on is connected to another system that is running a full server version of IBM MQ. The client and the server can be on the same system if required.	✓	✓	ibmmq-client
SDK	The SDK is required for compiling applications. It includes sample source files, and the bindings (files .H, .LIB, .DLL, and others), that you need to develop applications to run on IBM MQ.	✓	✓	ibmmq-sdk
Sample programs	The sample application programs are needed if you want to check your IBM MQ installation using the verification procedures.	✓	✓	ibmmq-samples
Java messaging	The files needed for messaging using Java (includes Java Message Service).	✓	✓	ibmmq-java
Man pages	UNIX man pages, in U.S. English, for: control commands MQI calls MQSC commands	✓	✓	ibmmq-man
Java JRE	A Java Runtime Environment that is used by those parts of IBM MQ that are written in Java.	✓	✓	ibmmq-jre
Message Catalogs	For available languages, see the table of message catalogs that follows.	✓	✓	
IBM Global Security Kit	IBM Global Security Kit V8 Certificate and TLS, Base Runtime.	✓	✓	ibmmq-gskit

Table 51. IBM MQ Debian components for Linux Ubuntu systems (continued)

Component	Description	Server media	Client media	Debian package name
Telemetry Service	MQ Telemetry supports the connection of Internet Of Things (IOT) devices (that is, remote sensors, actuators and telemetry devices) that use the IBM MQ Telemetry Transport (MQTT) protocol. The telemetry service, which is also know as the MQXR service, enables a queue manager to act as an MQTT server, and communicate with MQTT client apps. The telemetry service is only available on Linux for System x (64 bit) and Linux for IBM Z . A set of MQTT client libraries is also available in the IBM Messaging Telemetry Clients SupportPac. These libraries help you write the MQTT client apps that IOT devices use to communicate with MQTT servers. See also "Installation considerations for MQ Telemetry" on page 538.	✓		ibmmq-xrservice
IBM MQ Explorer	Use IBM MQ Explorer to administer and monitor resources on Linux x86-64 systems. Also available using a stand-alone installer from MS0T.	✓		ibmmq-explorer
Managed File Transfer	MQ Managed File Transfer transfers files between systems in a managed and auditable way, regardless of file size or the operating systems used. For information about the function of each component, see Managed File Transfer product options.	✓		ibmmq-ftagent ibmmq-ftbase ibmmq-ftlogger ibmmq-ftservice ibmmq-fttools
Advanced Message Security	Provides a high level of protection for sensitive data flowing through the IBM MQ network, while not impacting the end applications. You must install this component on all IBM MQ installations that host queues you want to protect. You must install the IBM Global Security Kit component on any IBM MQ installation that is used by a program that puts or gets messages to or from a protected queue, unless you are using only Java client connections. You must install the **Java JRE** component to install this component.	✓		ibmmq-ams
V 9.0.0 AMQP Service	Install this component to make AMQP channels available. AMQP channels support MQ Light APIs. You can use AMQP channels to give AMQP applications access to the enterprise-level messaging facilities provided by IBM MQ.	✓		ibmmq-amqp

Table 51. IBM MQ Debian components for Linux Ubuntu systems (continued)

Component	Description	Server media	Client media	Debian package name
REST API and Console	Adds HTTP based administration for IBM MQ through the REST API and IBM MQ Console.	✓		ibmmq-web
V 9.0.2 IBM MQ Bridge to Salesforce	Install the IBM MQ Bridge to Salesforce to configure the connections to Salesforce and IBM MQ, then run the command **runmqsfb** to subscribe to events from Salesforce and publish them to an IBM MQ network. **Note:** The IBM MQ Bridge to Salesforce is available only on Linux for System x (64 bit).	✓	✓	ibmmq-sfbridge
V 9.0.4 IBM MQ Bridge to blockchain	Install the IBM MQ Bridge to blockchain to send queries and updates to, and receive responses from your blockchain network. **Note:** The IBM MQ Bridge to blockchain is available only on Linux for System x (64 bit).	✓	✓	ibmmq-bcbridge

Table 52. IBM MQ message catalogs for Linux systems

Message catalog language	Component name
Brazilian Portuguese	ibmmq-msg-pt
Czech	ibmmq-msg-cs
French	ibmmq-msg-fr
German	ibmmq-msg-de
Hungarian	ibmmq-msg-hu
Italian	ibmmq-msg-it
Japanese	ibmmq-msg-ja
Korean	ibmmq-msg-ko
Polish	ibmmq-msg-pl
Russian	ibmmq-msg-ru

Installing an IBM MQ server on Linux Ubuntu using Debian packages

Linux V 9.0.2

You can install an IBM MQ server on a Linux Ubuntu system, using a Debian installer, in accordance with the system requirements web page.

Before you begin

See System Requirements for IBM MQ for details of the supported software levels.

Before you start the installation procedure, make sure that you first complete the necessary steps that are outlined in "Preparing the system on Linux" on page 333.

If you have installed IBM MQ Version 9.0.2, or earlier, on Ubuntu using rpm, you must uninstall all rpm versions of the product before installing the Debian version of the product.

About this task

Install the server by using a Debian installer to select the components that you want to install. The components and package names are listed in "IBM MQ Debian components for Linux Ubuntu systems" on page 364.

You can use various installers. This topic describes the use of the **dpkg** and **apt** installers.

dpkg Install the packages that you need by following instructions in step 3. You can install multiple packages with the same command but take care to place the packages in the correct order as **dpkg** does not sort them according to dependency.

apt Install the packages that you need by following instructions in step 4 on page 369. The **apt** tool installs dependency packages for the package that you require. The **apt** management tool orders the **dpkg** commands.

Procedure

1. Open a shell terminal and set your current directory to the location of the installation packages. The location might be the mount point of the server DVD, a network location, or a local file system directory. You must have root authority to run the following commands. You can do so by adding **sudo** before the following commands, or by changing to the root user in the shell with the **su** command.
2. Run the `mqlicense.sh` script. If you want to view a text-only version of the license, which can be read by a screen reader, type the following message:
   ```
   ./mqlicense.sh -text_only
   ```
   The license is displayed.

   You must accept the license agreement before you can proceed with the installation.
3. Complete this step if you want to use the **dpkg** command and install packages individually. Issue the **dpkg** command for each IBM MQ package. For example, issue the following command:
   ```
   dpkg -i ibmmq-runtime_9.0.2.0_amd64.deb
   ```
   To support the running of a queue manager, you must install at least the `ibmmq-runtime` and the `ibmmq-server` components.

Important: You can specify multiple package files in the same command but unlike rpm, **dpkg** does not sort the package files into dependency order.

You must place the package file names in the following order when you issue your command:
- ibmmq-runtime
- ibmmq-jre
- ibmmq-java
- ibmmq-server
- ibmmq-web
- ibmmq-ftbase
- ibmmq-ftagent
- ibmmq-ftservice
- ibmmq-ftlogger
- ibmmq-fttools
- ibmmq-amqp
- ibmmq-ams
- ibmmq-xrservice
- ibmmq-explorer
- ibmmq-gskit
- ibmmq-client
- ibmmq-man
- ibmmq-msg_*language*
- ibmmq-samples
- ibmmq-sdk
- ibmmq-sfbridge
- ibmmq-bcbridge

If you are installing a subset of components by using **dpkg**, you must ensure that any dependencies are first installed, as listed in Table 53 on page 370.

4. Complete this step if you want to use the **apt** management tool to install the IBM MQ packages that you want along with their dependency packages. **apt** is a higher-level package management tool that is a front end to **dpkg**.

   Important: **apt** operations, unlike **dpkg**, are dependency aware, and automatically select and install the required packages. Therefore, the **apt** management tool orders the **dpkg** commands appropriately.

   apt is configured with a list of repositories that can include local directories. To add a local, or nfs-mounted, directory that contains the IBM MQ packages:

   a. Create a file with the suffix `.list`, for example, `IBM_MQ.list`, in the `/etc/apt/sources.list.d` directory. This file should contain a `deb` entry for the location of the directory that contains the IBM MQ packages.

      For example:

      ```
      # Local directory containing IBM MQ packages
      deb [trusted=yes] file:/var/tmp/mq ./
      ```

      Note: The inclusion of the `[trusted=yes]` statement (including the brackets) is optional and suppresses warnings and prompts during subsequent operations.

   b. Run the command **apt update** to add this directory, and the list of packages the directory contains, to the apt cache. You can now carry out various operations. For example, issuing the command:

      ```
      apt install "ibmmq-*"
      ```

installs the complete product, and issuing the command:

```
apt install ibmmq-server
```

selects and installs the server package and all its dependencies.

Attention: Do not run the `apt install ibmmq-*` command in the directory which holds the `.deb` files, unless you are using quotation characters in the shell.

If you are using tools such as aptitude or synaptic, the install packages can be found in the `misc\non-free` category.

To support the running of a queue manager, you must install at least the `ibmmq-runtime` and the `ibmmq-server` components.

If you are installing a subset of components, you must ensure that any dependencies are first installed, as listed in Table 53. To install and use a package listed in the *Package Name* column, you must also install the corresponding components that are listed in the *Package Dependencies* column.

Table 53. Package component dependencies

Package Name	Component Function	Package Dependencies
ibmmq-runtime	Common function for all other components	None
ibmmq-server	Queue Manager	ibmmq-runtime
ibmmq-client	C IBM MQ client libraries	ibmmq-runtime
ibmmq-java	Java and JMS IBM MQ APIs	ibmmq-runtime
ibmmq-jre	Java Runtime Environment	ibmmq-runtime
ibmmq-sdk	Header files and libraries for non-Java APIs	ibmmq-runtime
ibmmq-man	UNIX man pages for IBM MQ	ibmmq-runtime
ibmmq-samples	IBM MQ application samples	ibmmq-runtime
ibmmq-msg-cz ibmmq-msg-de ibmmq-msg-es ibmmq-msg-fr ibmmq-msg-hu ibmmq-msg-it ibmmq-msg-ja ibmmq-msg-ko ibmmq-msg-pl ibmmq-msg-pt ibmmq-msg-ru ibmmq-msg-zh-cn ibmmq-msg-zh-tw	Additional language message catalog files. English message catalog files are installed by default. For more information about these message catalogs, see "Displaying messages in your national language on Linux" on page 376	ibmmq-runtime
ibmmq-mqexplorer	IBM MQ Explorer. Only on Linux x86-64 systems.	ibmmq-runtime ibmmq-jre

Table 53. Package component dependencies (continued)

Package Name	**Component Function**	**Package Dependencies**
ibmmq-gskit	IBM Global Security Kit	ibmmq-runtime ibmmq-jre
ibmmq-web	REST API and IBM MQ Console.	ibmmq-runtime ibmmq-server ibmmq-java ibmmq-jre
ibmmq-ftbase	Managed File Transfer component	ibmmq-runtime ibmmq-java ibmmq-jre
ibmmq-ftlogger	Managed File Transfer component	ibmmq-runtime ibmmq-server ibmmq-ftbase ibmmq-java ibmmq-jre
ibmmq-fttools ibmmq-ftagent	Managed File Transfer components	ibmmq-runtime ibmmq-ftbase ibmmq-java ibmmq-jre
ibmmq-ftservice	Managed File Transfer component	ibmmq-runtime ibmmq-server ibmmq-ftagent ibmmq-ftbase ibmmq-java ibmmq-jre
ibmmq-ams	Advanced Message Security component	ibmmq-runtime ibmmq-server
V 9.0.2 ibmmq-sfb	Install the IBM MQ Bridge to Salesforce to configure the connections to Salesforce and IBM MQ, then run the command **`runmqsfb`** to subscribe to events from Salesforce and publish them to an IBM MQ network. **Note:** The IBM MQ Bridge to Salesforce is available only on Linux for System x (64 bit).	ibmmq-runtime ibmmq-java ibmmq-jre

Table 53. Package component dependencies (continued)

Package Name	Component Function	Package Dependencies
V 9.0.4 ibmmq-bcb	Install the IBM MQ Bridge to blockchain to send queries and updates to, and receive responses from your blockchain network. **Note:** The IBM MQ Bridge to blockchain is available only on Linux for System x (64 bit).	ibmmq-runtime ibmmq-java ibmmq-jre

Results

You have installed the packages you require.

What to do next

- If required, you can now set this installation to be the primary installation. Enter the following command at the command prompt:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  where *MQ_INSTALLATION_PATH* represents the directory where IBM MQ is installed.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ . For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. See "Verifying an IBM MQ installation on Linux" on page 377, for more information.

Related tasks:

"Uninstalling or modifying IBM MQ on Linux using rpm" on page 395
On Linux, you can uninstall the IBM MQ server or client using the **rpm** command. You can also modify an installation by removing selected packages (components) currently installed on your system.

Installing an IBM MQ client on Linux Ubuntu using Debian packages

Linux V 9.0.2

You can install an IBM MQ client on a Linux Ubuntu system, using a Debian package, in accordance with the system requirements web page.

Before you begin

See System Requirements for IBM MQ for details of the supported software levels.

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on Linux" on page 333.

About this task

Install the client by using a Debian installer to select the components that you want to install. The components and package names are listed in "IBM MQ Debian components for Linux Ubuntu systems" on page 364.

Procedure

1. Open a shell terminal and set your current directory to the location of the installation packages. The location might be the mount point of the client DVD, a network location, or a local file system

directory. You must have root authority to run the following commands. You can do so by adding **sudo** before the following commands, or by changing to the root user in the shell with the **su** command.

2. Run the `mqlicense.sh` script. If you want to view a text-only version of the license, which can be read by a screen reader, type the following message:

   ```
   ./mqlicense.sh -text_only
   ```

   The license is displayed.

   You must accept the license agreement before you can proceed with the installation.

3. Install the IBM MQ client. You can use any Debian installer. "Installing an IBM MQ server on Linux Ubuntu using Debian packages" on page 368 describes the use of the **dpkg** and **apt** packages to install a server. At a minimum, you must install the `ibmmq-runtime` component.

   If you are installing a subset of components, you must ensure that any dependencies are first installed, as listed in Table 54.

   To install and use the package listed in the *Package Name* column, you must also install the components listed in the *Package Dependencies* column.

Table 54. Package component dependencies

Package Name	Component Function	Package Dependencies
ibmmq-runtime	Common function for all other components	None
ibmmq-client	C IBM MQ client libraries	ibmmq-runtime
ibmmq-java	Java and JMS IBM MQ APIs	ibmmq-runtime
ibmmq-jre	Java Runtime Environment	ibmmq-runtime
ibmmq-sdk	Header files and libraries for non-Java APIs	ibmmq-runtime
ibmmq-man	UNIX man pages for IBM MQ	ibmmq-runtime

setmqinst
Changing the primary installation

Redistributable clients on Linux

Linux

The Linux x86-64 image is shipped in a `LinuxX64.tar.gz` file.

File names

The archive or .zip file names describe the file contents and equivalent maintenance levels. For example, in IBM MQ Version 8.0.0, Fix Pack 4 the client images are available under the following file names:

Linux x86-64
`8.0.0.4-WS-MQC-Redist-LinuxX64.tar.gz`

Java - all platforms
`8.0.0.4-WS-MQC-Redist-Java.zip`

Choosing the runtime files to distribute with an application

A script file named **genmqpkg** is provided by the redistributable client under the `bin` directory.

You can use the **genmqpkg** script to generate a smaller subset of files that are tailored to the needs of the application, for which the files are intended to be distributed.

You are asked a series of interactive `Yes` or `No` questions to determine the runtime requirements for an IBM MQ application.

Finally, **genmqpkg** asks you to supply a new target directory, where the script duplicates the required directories and files.

Important: A fully qualified path should be supplied to **genmqpkg**, as **genmqpkg** will not expand or evaluate shell variables.

Important: IBM support is only able to provide assistance with the full, unmodified set of files contained within the redistributable client packages.

Other considerations

There is a minor change to the default data path of a non-installed client, and now the path is, on:

Linux x86-64
`$HOME/IBM/MQ/data`

A redistributable client runtime co-exists with a full IBM MQ client or server installation, provided that they are installed in different locations.

Important: Unpacking a redistributable image into the same location as a full IBM MQ installation is not supported.

On Linux the `ccsid.tbl` used to define the supported CCSID conversions is traditionally expected to be found in the `UserData` directory structure, along with error logs, trace files, and so on.

The `UserData` directory structure is populated by unpacking the redistributable client, and so, if the file is not found in its usual location, the redistributable client falls back to locate the file in the `/lib` subdirectory of the installation.

Classpath changes

The classpath used by **dspmqver**, **setmqenv**, and **crtmqenv** commands, add the `com.ibm.mq.allclient.jar` to the environment, immediately following the `com.ibm.mq.jar` and `com.ibm.mqjms.jar`.

An example of **dspmqver** output from the redistributable client on Linux:

```
Name:        IBM MQ
Version:     8.0.0.4
Level:       p800-804-L150909
BuildType:   IKAP - (Production)
Platform:    IBM MQ for Linux (x86-64 platform)
Mode:        64-bit
O/S:         Linux 2.6.32.59-0.7-default
InstName:    MQNI08000004
```

```
InstDesc:    IBM MQ V8.0.0.4 (Redistributable)
Primary:     No
InstPath:    /Development/johndoe/unzip/unpack
DataPath:    /u/johndoe/IBM/MQ/data
MaxCmdLevel: 802
```

Related concepts:

The Linux x86-64 image is shipped in a `LinuxX64.tar.gz` file.

Converting a trial license on Linux

Linux

Convert a trial license to a full license without reinstalling IBM MQ.

When the trial license expires, the "count-down" displayed by the **strmqm** command informs you the license has expired, and the command does not run.

Before you begin

1. IBM MQ is installed with a trial license.
2. You have access to the installation media of a fully licensed copy of IBM MQ.

About this task

Run the **setmqprd** command to convert a trial license to a full license.

If you do not want to apply a full license to your trial copy of IBM MQ, you can uninstall it at any time.

Procedure

1. Obtain the full license from the fully licensed installation media.

   The full license file is `amqpcert.lic`. On Linux, it is in the *`/MediaRoot/`*`licenses` directory on the installation media.
2. Run the **setmqprd** command from the installation that you are upgrading:
   ```
   MQ_INSTALLATION_PATH/bin/setmqprd /MediaRoot/licenses/amqpcert.lic
   ```

Related information:

setmqprd

Displaying messages in your national language on Linux

Linux

To display messages from a different national language message catalog, you must install the appropriate catalog and set the **LANG** environment variable.

About this task

Messages in U.S. English are automatically installed with IBM MQ

Message catalogs for all languages are installed in *`MQ_INSTALLATION_PATH`*`/msg/`*`language identifier`*, where *language identifier* is one of the identifiers in Table 55 on page 377.

If you require messages in a different language, perform the following steps:

Procedure

1. Install the appropriate message catalog (see "IBM MQ components and features" on page 192).

2. To select messages in a different language, ensure the **LANG** environment variable is set to the identifier for the language you want to install:

Table 55. Language identifiers

Identifier	Language
cs_CZ	Czech
de_DE	German
es_ES	Spanish
fr_FR	French
hu_HU	Hungarian
it_IT	Italian
ja_JP	Japanese
ko_KR	Korean
pl_PL	Polish
pt_BR	Brazilian Portuguese
ru_RU	Russian
zh_CN	Simplified Chinese
zh_TW	Traditional Chinese

Verifying an IBM MQ installation on Linux

Linux

The topics in this section provide instructions on how to verify a server or a client installation of IBM MQ on Linux systems.

About this task

You can verify a local (stand-alone) server installation or a server-to-server installation of the IBM MQ server:
- A local server installation has no communication links with other IBM MQ installations.
- A server-to-server installation does have links to other installations.

You can also verify that your IBM MQ MQI client installation completed successfully and that the communication link is working.

Procedure

- To verify a local server installation, see “Verifying a local server installation on Linux” on page 378.
- To verify a server-to-server installation, see “Verifying a server-to-server installation on Linux” on page 381.
- To verify a client installation, see “Verifying a client installation on Linux” on page 387.

Verifying a local server installation on Linux

You can use either the command line or the postcard application to verify a local (stand-alone) installation on Linux.

About this task

You can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a local server installation using the command line on Linux."
- To use the postcard application to verify an installation, see "Verifying a local server installation using the Postcard application on Linux" on page 380.

Verifying a local server installation using the command line on Linux:

On Linux systems, you can verify a local installation by using the command line to create a simple configuration of one queue manager and one queue. You can also verify an installation using the postcard application.

Before you begin

To verify the installation, you must first install the samples package.

Before beginning the verification procedure, you might want to check that you have the latest fixes for your system. For more information about where to find the latest updates, see "Checking requirements on Linux" on page 330.

About this task

Use the following steps to configure your default queue manager from the command line. After the queue manager is configured, use the `amqsput` sample program to put a message on the queue. You then use the `amqsget` sample program to get the message back from the queue.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On a Linux system, log in as a user in the `mqm` group.
2. Set up your environment:
   a. Set up environment variables for use with a particular installation by entering one the following command:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```
      where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.
   b. Check that the environment is set up correctly by entering the following command:

```
dspmqver
```

If the command completes successfully, and the expected version number and installation name are returned, the environment is set up correctly.

3. Create a queue manager called `QMA` by entering the following command:
   ```
   crtmqm QMA
   ```
   Messages indicate when the queue manager is created, and when the default IBM MQ objects are created.
4. Start the queue manager by entering the following command:
   ```
   strmqm QMA
   ```
   A message indicates when the queue manager starts.
5. Start MQSC by entering the following command:
   ```
   runmqsc QMA
   ```
   A message indicates when MQSC starts. MQSC has no command prompt.
6. Define a local queue called `QUEUE1` by entering the following command:
   ```
   DEFINE QLOCAL (QUEUE1)
   ```
   A message indicates when the queue is created.
7. Stop MQSC by entering the following command:
   ```
   end
   ```
   Messages are shown, followed by the command prompt.

Note: Subsequent steps require that the samples package is installed.

8. Change into the *`MQ_INSTALLATION_PATH`*`/samp/bin` directory, which contains the sample programs. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
9. Put a message on the queue by entering the following commands
   ```
   ./amqsput QUEUE1 QMA
   ```
   The following messages are shown:
   ```
   Sample AMQSPUT0 start
   target queue is QUEUE1
   ```
10. Type some message text on one or more lines, where each line is a different message. Enter a blank line to end the message input. The following message is shown:
    ```
    Sample AMQSPUT0 end
    ```
    Your messages are now on the queue and the command prompt is shown.
11. Get the messages from the queue, by entering the following command:
    ```
    ./amqsget QUEUE1 QMA
    ```
    The sample program starts, and your messages are displayed.

Results

You have successfully verified your local installation.

Verifying a local server installation using the Postcard application on Linux: Linux

Sending messages successfully between two Postcard applications verifies a local installation.

Before you begin

The postcard application is Java based and requires a system with the ability to view a graphical display.

You must ensure that you are a member of the IBM MQ administrators group (**mqm**).

Note: Using Postcard to verify an IBM MQ installation is only possible if there is one IBM MQ installation on that box. The Default Configuration wizard will not create a default configuration if a queue manager already exists on the box. The Default Configuration wizard will run on any installation on a box but only one default configuration can be created per box. Using Postcard to verify second and subsequent installations of IBM MQ on the same box is not possible.

To verify that the local installation is working, you can run two instances of the Postcard application on the same server. The postcard application can send messages to, and receive messages from, other postcard applications. Successful sending and receiving of messages verifies that IBM MQ is installed and working correctly on the server.

Procedure

1. Log on as a user in group **mqm**.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *MQ_INSTALLATION_PATH*/java/bin. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:
         ```
         ./postcard
         ```
   b. From the IBM MQ Explorer: On Linux (x86-64 platforms), you can start IBM MQ Explorer by using the system menu, the **MQExplorer** command (preferred command), or the MQExplorer executable file. The **strmqcfg** command is still usable.
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.
3. At the Postcard - Sign On window, type in a nickname to use to send messages within the Postcard application (for example, User1).
4. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Launching the Default Configuration creates a default queue manager.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.

- If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK** to display your first Postcard window.

5. Run a second instance of the Postcard application by following the steps used to open the first instance of the Postcard application.
6. The Postcard - Sign On panel is displayed again. Type in a second nickname to use to send messages within this second Postcard application (for example, `User2`).
7. Repeat the selection of the queue manager that you want to use as the mailbox (as described in step 4). The queue manager you select for this second Postcard must be the same queue manager as used for the first instance of the Postcard application.
8. In the first Postcard, (User1), enter the nickname (`User2`) for the second Postcard application in the **To:** field. Because the sender and receiver are on the same server, you can leave the **On:** field blank.
9. Type a message in the **Message:** field and click **Send**.
10. The **Postcards sent and received** area of the Postcard shows details of the message. In the sending Postcard, the message is displayed as sent. In the receiving Postcard, the message is displayed as received.
11. In the receiving Postcard, (User2), double-click the message in the **Postcards sent and received** area to view it. When this message arrives, it verifies that IBM MQ is correctly installed.

What to do next

Depending on your situation, you might want to do the following tasks:
- Install IBM MQ on other servers. Follow the installation procedure for the appropriate platform. Ensure that you use the **Join Default Cluster** window in the Default Configuration wizard to add the other servers to the cluster on your first server.
- Install the IBM MQ MQI client on other servers.
- Continue with further administration tasks, see Administering IBM MQ.

Verifying a server-to-server installation on Linux

Linux

You can use either the command line or the postcard application to verify a server-to-server installation on Linux.

Before you begin

For a server-to-server verification, the communication links between the two systems must be checked. Before you can do the verification, you must therefore ensure that the communications protocol is installed and configured on both systems.

On Linux, IBM MQ supports TCP on all Linux platforms. On x86 platforms and Power platforms, SNA is also supported. If you want to use the SNA LU6.2 support on these platforms, you need the IBM Communications Server for Linux Version 6.2. The Communications Server is available as a PRPQ product from IBM. For more details, see Communications Server.

The examples in this task use TCP/IP. If you do not use TCP, see Setting up communication on UNIX and Linux.

About this task

For a server-to server installation, you can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a server-to-server installation using the command line on Linux."
- To use the postcard application to verify an installation, see "Verifying a server-to-server installation using the Postcard application on Linux" on page 385.

Verifying a server-to-server installation using the command line on Linux: Linux

You can verify a server-to-server installation using two servers, one as a sender and one as a receiver.

Before you begin

- Make sure that TCP/IP and IBM MQ are installed on both servers (see "Verifying a server-to-server installation on Linux" on page 381).
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Decide which installation is the sender server and which installation is the receiver server. The installations might be on the same system, or on different systems.

About this task

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On the **receiver** server:
   a. On Linux, log in as a user in the mqm group.
   b. Check which ports are free, for example by running **netstat**. For more information about this command, see the documentation of your operating system.

      If port 1414 is not in use, make a note of 1414 to use as the port number in step 2 h. Use the same number for the port for your listener later in the verification. If it is in use, note a port that is not in use; for example 1415.
   c. Set up the environment for the installation you are using by entering the following command at the command prompt:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   d. Create a queue manager called QMB by entering the following command at the command prompt:
      ```
      crtmqm QMB
      ```
      Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.
   e. Start the queue manager by entering the following command:
      ```
      strmqm QMB
      ```

A message tells you when the queue manager has started.

f. Start MQSC by entering the following command:

```
runmqsc QMB
```

A message tells you that MQSC has started. MQSC has no command prompt.

g. Define a local queue called `RECEIVER.Q` by entering the following command:

```
DEFINE QLOCAL (RECEIVER.Q)
```

A message tells you the queue has been created.

h. Define a listener by entering the following command:

```
DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT ( PORT_NUMBER )
```

Where *port_number* is the name of the port the listener runs on. This number must be the same as the number used when defining your sender channel.

i. Start the listener by entering the following command:

```
START LISTENER (LISTENER1)
```

Note: Do not start the listener in the background from any shell that automatically lowers the priority of background processes.

j. Define a receiver channel by entering the following command:

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (RCVR) TRPTYPE (TCP)
```

A message tells you when the channel has been created.

k. End MQSC by typing:

```
end
```

Some messages are displayed, followed by the command prompt.

2. On the **`sender`** server:

a. As the sender server is an AIX system, log in as a user in the `mqm` group.

b. Set up the environment for the installation you are using by entering the following command at the command prompt:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.

c. Create a queue manager called `QMA` by entering the following command at the command prompt:

```
crtmqm QMA
```

Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.

d. Start the queue manager, by entering the following command:

```
strmqm QMA
```

A message tells you when the queue manager has started.

e. Start MQSC by entering the following command:

```
runmqsc QMA
```

A message tells you that an MQSC session has started. MQSC had no command prompt.

f. Define a local queue called `QMB` (to be used as a transmission queue) by entering the following command:

```
DEFINE QLOCAL (QMB) USAGE (XMITQ)
```

A message tells you when the queue has been created.

g. Define a local definition of the remote queue with by entering the following command:

```
DEFINE QREMOTE (LOCAL.DEF.OF.REMOTE.QUEUE) RNAME (RECEIVER.Q) RQMNAME ('QMB') XMITQ (QMB)
```

h. Define a sender channel by entering one of the following commands:

con-name is the TCP/IP address of the receiver system. If both installations are on the same system, the *con-name* is `localhost`. *port* is the port you noted in 1 b. If you do not specify a port, the default value of 1414 is used.

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (SDR) CONNAME ('CON-NAME(PORT)') XMITQ (QMB) TRPTYPE (TCP)
```

i. Start the sender channel by entering the following command:

```
START CHANNEL(QMA.QMB)
```

The receiver channel on the receiver server starts automatically when the sender channel starts.

j. Stop MQSC by entering the following command:

```
end
```

Some messages are displayed, followed by the command prompt.

k. Change into the `MQ_INSTALLATION_PATH/samp/bin` directory. This directory contains the sample programs. `MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

l. If both the sender server and receiver server are installations on the same system, check that the queue managers have been created on different installations by entering the following command:

```
dspmq -o installation
```

If the queue managers are on the same installation, move either QMA to the sender installation or QMB to the receiver installation by using the **`setmqm`** command. For more information, see setmqm.

m. Put a message on the local definition of the remote queue, which in turn specifies the name of the remote queue. Enter the following command:

```
./amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
```

A message tells you that `amqsput` has started.

n. Type some message text on one or more lines, followed by a blank line. A message tells you that `amqsput` has ended. Your message is now on the queue and the command prompt is displayed again.

3. On the **receiver** server:

a. As your receiver server is an AIX system, change into the `MQ_INSTALLATION_PATH/samp/bin` directory. This directory contains the sample programs. `MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

b. Get the message from the queue on the receiver by entering the following command:

```
./amqsget RECEIVER.Q QMB
```

The sample program starts, and your message is displayed. After a pause, the sample ends. Then the command prompt is displayed.

Results

You have now successfully verified the server-to-server installation.

Verifying a server-to-server installation using the Postcard application on Linux: Linux

You can use two instances of the Postcard application to verify that a server-to-server installation is working.

Before you begin

You can use the Postcard application on two servers, one instance of the Postcard application on each server, to verify that a server-to-server installation is working. Successful sending and receiving of messages verifies that IBM MQ is successfully installed, and that communication between the two servers is working correctly.

Note:
- If the system has multiple IBM MQ installations, ensure that Postcard has not been run before on any installations on that server. As the default configuration can only exist on one IBM MQ installation per system, the Default Configuration wizard and Postcard can not be used for verification of a second or any subsequent installation.
- The two server installations must be on different systems to do a server-to-server verification using the postcard application. To verify a server-to-server installation on the same machine, you can use the command line.
- Make sure that TCP/IP and IBM MQ are installed on both servers.
- Make sure that your systems are able to view a graphical display.
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Check that one of the following scenarios applies:
  - Neither server has had any queue managers created.
  - Use the Default Configuration wizard to create default queue managers on each server and link them to the default cluster.

    Details on how to use the Default Configuration wizard are provided in this topic.
  - Both servers have existing queue managers and these queue managers are in the same cluster.

    If your queue managers are not in the same cluster, create new queue managers on both servers. Then create a cluster, and ensure that the queue managers that you create on each server belong to that cluster.
  - You have configured channels to communicate between the two servers.

    For instructions on how to set up the channels, see “Verifying a server-to-server installation using the command line on Linux” on page 382. After you have set up the channels, follow the instructions in this topic to verify your server-to-server installation.

Procedure
1. On the first server, log on as a user in group **mqm**.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *MQ_INSTALLATION_PATH*/java/bin. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:
      ```
      ./postcard
      ```
   b. From the IBM MQ Explorer: On Linux systems (x86-64 platforms), you can start IBM MQ Explorer by using the system menu, the MQExplorer executable file, or the **strmqcfg** command.
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.

3. At the Postcard - Sign On window, type a nickname to use to send messages within the Postcard application. For example, `User1` for the first server, and `User2` for the second server.
4. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Work through the Default Configuration wizard. When you get to the option to join the queue manager to the default cluster, tick the check box. On the next screen:
     - For the first server, select **yes, make it the repository for the cluster**.
     - For the second server, select **No another computer has already joined the cluster as a repository**. When requested, enter the location of the repository, by typing the name of the sender server.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK**.
5. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Work through the Default Configuration wizard. When you get to the option to join the queue manager to the default cluster, tick the check box. On the next screen:
     - For the first server, select **yes, make it the repository for the cluster**.
     - For the second server, select **No another computer has already joined the cluster as a repository**. When requested, enter the location of the repository, by typing the name of the sender server.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK**.
6. Complete steps 1 - 5 for the second server.
7. In the Postcard on the first server:
   a. Enter the nickname (`user2`) for the Postcard application on the second server in the **To:** field.
   b. Enter the queue manager on the second server in the **On:** field.
   c. Type a message in the **Message:** field and click **Send**.

8. In the Postcard on the second server:
   a. In the **Postcards sent and received**, double-click the message marked as received to view the message from the first server.
   b. Optional: Send a postcard to the first server by adapting the instructions in step 7. You must enter details of the first server in the **To:** field and the **On:** field.

   The messages verify that IBM MQ is correctly installed and that your communication link between the two servers is working correctly.

Verifying a client installation on Linux

▶ Linux

You can verify that your IBM MQ MQI client installation completed successfully and that the communication link is working.

About this task

The verification procedure shows how to create a queue manager called `queue.manager.1`, a local queue called `QUEUE1`, and a server-connection channel called `CHANNEL1` on the server.

It shows how to create the client-connection channel on the IBM MQ MQI client workstation. It then shows how to use the sample programs to put a message onto a queue, and get the message from the queue.

The example does not address any client security issues. See Setting up IBM MQ MQI client security for details if you are concerned with IBM MQ MQI client security issues.

The verification procedure assumes that:
- The full IBM MQ server product has been installed on a server.
- The server installation is accessible on your network.
- The IBM MQ MQI client software has been installed on a client system.
- The IBM MQ sample programs have been installed.
- TCP/IP has been configured on the server and client systems. For more information, see Configuring connections between the server and client.

Procedure

1. Set up the server and client:
   - To set up the server and client by using the command line, follow the instructions in "Setting up the server and client using the command line on Linux" on page 388.
   - To set up the server and client by using IBM MQ Explorer, follow the instructions in "Setting up the server and client using IBM MQ Explorer on Linux" on page 391.
2. Test the communications between client and server, using the instructions in "Testing communication between a client and a server on Linux" on page 393.

Related tasks:

"Installing an IBM MQ client on Linux" on page 355
Installing an IBM MQ client on a 32 bit or 64 bit Linux system.

Setting up the server and client using the command line on Linux: Linux

You can use the command line to create the objects that you need to use to verify a client installation on Linux. On the server you create a queue manager, a local queue, a listener, and a server-connection channel. You must also apply security rules to allow the client to connect and make use of the queue defined. On the client you create a client-connection channel. After setting up the server and client, you can then use the sample programs to complete the verification procedure.

Before you begin

Before starting this task, review the information in "Verifying a client installation on Linux" on page 387.

About this task

This task explains how to use the command line to set up the server and client so that you can verify your client installation.

If you prefer to use IBM MQ Explorer, see "Setting up the server and client using IBM MQ Explorer on Linux" on page 391.

Procedure

1. Set up the server by following the instructions in "Setting up the server using the command line on Linux."
2. Set up the client by following instructions in "Connecting to a queue manager, using the `MQSERVER` environment variable on Linux" on page 390.

What to do next

Test the communications between client and server by following the instructions in "Testing communication between a client and a server on Linux" on page 393.

Setting up the server using the command line on Linux: Linux

Follow these instructions to create a queue manager, queue, and channel on the server. You can then use these objects to verify the installation.

About this task

These instructions assume that no queue manager or other IBM MQ objects have been defined.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Create a user ID on the server that is not in the `mqm` group. This user ID must exist on the server and client. This is the user ID that the sample applications must be run as, otherwise a 2035 error is returned.
2. Log in as a user in the mqm group.

3. You must set various environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

   where `MQ_INSTALLATION_PATH` refers to the location where IBM MQ is installed.
4. Create a queue manager called `QUEUE.MANAGER.1` by entering the following command:

```
crtmqm QUEUE.MANAGER.1
```

   You see messages telling you that the queue manager has been created.
5. Start the queue manager by entering the following command:

```
strmqm QUEUE.MANAGER.1
```

   A message tells you when the queue manager has started.
6. Start MQSC by entering the following command:

```
runmqsc QUEUE.MANAGER.1
```

   A message tells you that an MQSC session has started. MQSC has no command prompt.
7. Define a local queue called `QUEUE1` by entering the following command:

```
DEFINE QLOCAL(QUEUE1)
```

   A message tells you when the queue has been created.
8. Allow the user ID that you created in step 1 to use `QUEUE1` by entering the following command:

```
SET AUTHREC PROFILE(QUEUE1) OBJTYPE(QUEUE) PRINCIPAL(' non_mqm_user ') AUTHADD(PUT,GET)
```

   where *non_mqm_user* is the user ID created in step 1. A message tells you when the authorization has been set. You must also run the following command to give the user ID authority to connect:

```
SET AUTHREC OBJTYPE(QMGR) PRINCIPAL(' non_mqm_user ') AUTHADD(CONNECT)
```

   If this command is not run, a 2305 stop error is returned.
9. Define a server-connection channel by entering the following command:

```
DEFINE CHANNEL (CHANNEL1) CHLTYPE (SVRCONN) TRPTYPE (TCP)
```

   A message tells you when the channel has been created.
10. Allow your client channel to connect to the queue manager and run under the user ID that you created in step 1, by entering the following MQSC command:

```
SET CHLAUTH(CHANNEL1) TYPE(ADDRESSMAP) ADDRESS(' client_ipaddr ') MCAUSER(' non_mqm_user ')
```

   where *client_ipaddr* is the IP address of the client system, and *non_mqm_user* is the user ID created in step 1. A message tells you when the rule has been set.
11. Define a listener by entering the following command:

```
DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT (port_number)
```

   where *port_number* is the number of the port the listener is to run on. This number must be the same as the number used when defining your client-connection channel in "Installing an IBM MQ client on Linux" on page 355.

   Note: If you omit the port parameter from the command, a default value of `1414` is used for the listener port. If you want to specify a port other than `1414`, you must include the port parameter in the command, as shown.
12. Start the listener by entering the following command:

```
START LISTENER (LISTENER1)
```

13. Stop MQSC by entering:

```
end
```

You see some messages, followed by the command prompt.

What to do next

Follow the instructions to set up the client. See "Connecting to a queue manager, using the `MQSERVER` environment variable on Linux."

Connecting to a queue manager, using the `MQSERVER` environment variable on Linux: Linux

When an IBM MQ application is run on the IBM MQ MQI client, it requires the name of the MQI channel, the communication type, and the address of the server to be used. Provide these parameters by defining the `MQSERVER` environment variable.

Before you begin

Before you start this task, you must complete the task, "Setting up the server using the command line on Linux" on page 388, and save the following information:
- The host name or IP address of the server and port number that you specified when creating the listener.
- The channel name of the server-connection channel.

About this task

This task describes how to connect an IBM MQ MQI client, by defining the `MQSERVER` environment variable on the client.

You can give the client access to the generated client channel definition table, `amqclchl.tab` instead; see Accessing client-connection channel definitions.

Procedure
1. Log in as the userid that you created in Step 1 of "Setting up the server using the command line on Linux" on page 388.
2. Check the TCP/IP connection. From the client, enter one of the following commands:
   - `ping server-hostname`
   - `ping n.n.n.n`

     `n.n.n.n` represents the network address. You can set the network address in IPv4 dotted decimal form, for example, `192.0.2.0`. Alternatively, set the address in IPv6 hexadecimal form, for example `2001:0DB8:0204:acff:fe97:2c34:fde0:3485`.

   If the **`ping`** command fails, correct your TCP/IP configuration.
3. Set the `MQSERVER` environment variable. From the client, enter the following command:
   ```
   export MQSERVER=CHANNEL1/TCP/'server-address (port)'
   ```

   Where:
   - *CHANNEL1* is the server-connection channel name.
   - *server-address* is the TCP/IP host name of the server.
   - *port* is the TCP/IP port number the server is listening on.

   If you do not give a port number, IBM MQ uses the one specified in the `qm.ini` file, or the client configuration file. If no value is specified in these files, IBM MQ uses the port number identified in the TCP/IP services file for the service name `MQSeries`. If an `MQSeries` entry in the services file does

not exist, a default value of 1414 is used. It is important that the port number used by the client and the port number used by the server listener program are the same.

What to do next

Use the sample programs to test communication between the client and server; see "Testing communication between a client and a server on Linux" on page 393.

Setting up the server and client using IBM MQ Explorer on Linux: Linux

You can use IBM MQ Explorer to create the objects that you need to use to verify a client installation on Linux. On the server, you create a queue manager, a local queue, a listener and a server-connection channel. On the client system you create a client-connection channel. Then from the command line you use the sample PUT and GET programs to complete the verification procedure.

Before you begin

Before starting this task, review the information in "Verifying a client installation on Linux" on page 387.

About this task

This task explains how to use IBM MQ Explorer to set up the server and client so that you can verify your client installation.

If you prefer to use the command line, see "Setting up the server and client using the command line on Linux" on page 388.

Procedure
1. Set up the server by following the instructions in "Setting up the server using IBM MQ Explorer on Linux."
2. Set up the client by following instructions in "Setting up the client using IBM MQ Explorer on Linux" on page 392.

What to do next

Test the communications between client and server by following the instructions in "Testing communication between a client and a server on Linux" on page 393.

Related tasks:

"Installing an IBM MQ client on Linux" on page 355

Installing an IBM MQ client on a 32 bit or 64 bit Linux system.

Setting up the server using IBM MQ Explorer on Linux: Linux

You can use the IBM MQ Explorer to create the server objects that you need to verify your client installation.

About this task

To verify your installation, you must first create a queue manager, a local queue, a listener and a server-connection channel on the server.

Procedure
1. Create a queue manager:
   a. Open IBM MQ Explorer.

   b. Right-click the folder called **Queue Managers**, select **New** > **Queue Manager**.
   c. In the first entry field, type the queue manager name, *QUEUE.MANAGER.1*, and click **Finish**.
2. Create a local queue:
   a. Expand the queue manager you have just created and right-click **queues**.
   b. Select **New** > **Local Queue**.
   c. Enter the queue name, *QUEUE1*, and click **Finish**.
3. Define the server-connection channel:
   a. Right-click **Channels**.
   b. Select **New** > **Server Connection Channel**.
   c. Enter the channel name, *CHANNEL1*, and click **Next**.
   d. In the dialog navigation pane, click **MCA** to open the MCA page.
   e. In the MCA User ID field, enter a userid that is a member of the mqm group, typically your own.
   f. Click **Finish**.
4. Run the listener.

   The listener is automatically started when the queue manager is configured. To check that the listener is running, open **Listeners** and look for `LISTENER.TCP`.

What to do next

Set up the client. See "Setting up the client using IBM MQ Explorer on Linux."

Related tasks:

"Installing an IBM MQ client on Linux" on page 355
Installing an IBM MQ client on a 32 bit or 64 bit Linux system.

Setting up the client using IBM MQ Explorer on Linux: Linux

You can use IBM MQ Explorer to define the client-connection if you are setting up the client and server on the same workstation on a Linux system.

Procedure

1. Select the queue manager, *QUEUE.MANAGER.1*
2. Open the **Channels** folder, then right-click **Client Connections** > **New** > **Client-connection Channel...**
3. Enter the channel name, *CHANNEL1*, for the client connection, and click **Next**.
4. Enter the queue manager name, *QUEUE.MANAGER.1*
5. Enter the following string as the connection name:
   ```
    server-address (port)
   ```
   Where:
   - `server-address` is the TCP/IP host name of the server
   - `port` is the TCP/IP port number the server is listening on
6. Click Finish.
7. From the command line, set the `MQCHLLIB` environment variable: Enter the following command:
   ```
   export MQCHLLIB=var/mqm/qmgrs/QUEUE!MANAGER!1/@ipcc
   ```
   Note: The queue manager name contains "**.**". IBM MQ creates the queue manager directory with the name, `QUEUE!MANAGER!1`

What to do next

Use the sample programs to test communication between the client and server. See "Testing communication between a client and a server on Linux."

Related tasks:

"Installing an IBM MQ client on Linux" on page 355

Installing an IBM MQ client on a 32 bit or 64 bit Linux system.

Testing communication between a client and a server on Linux: Linux

On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

Before you begin

Complete the previous topics in this section:
- Set up a queue manager, channels, and queue.
- Open a command window.
- Set system environment variables.

About this task

Note that IBM MQ object definitions are case-sensitive. Text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

You must be logged in with the appropriate authority. For example, user `ivtid` in the `mqm` group.

Procedure

1. Change to the `*MQ_INSTALLATION_PATH*/samp/bin directory`, which contains the sample programs. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
2. You must set certain environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.
3. Start the PUT program for `QUEUE1` on `QUEUE.MANAGER.1` by entering the following command:
   ```
   ./amqsputc QUEUE1 QUEUE.MANAGER.1
   ```
   If the command is successful, the following messages are displayed:
   ```
   Sample AMQSPUT0 start
   target queue is QUEUE1
   ```
   Tip: You might get the error, `MQRC_NOT_AUTHORIZED` (2035). By default, channel authentication is enabled when a queue manager is created. Channel authentication prevents privileged users accessing a queue manager as an IBM MQ MQI client. For verifying the installation, you can either change the MCA user ID to a non-privileged user, or disable channel authentication. To disable channel authentication run the following MQSC command:
   ```
   ALTER QMGR CHLAUTH(DISABLED)
   ```
   When you finish the test, if you do not delete the queue manager, re-enable channel authentication:
   ```
   ALTER QMGR CHLAUTH(ENABLED)
   ```

4. Type some message text, then press **Enter** twice. The following message is displayed:
   ```
   Sample AMQSPUT0 end
   ```
   Your message is now on the queue that is on the server queue manager.
5. Start the GET program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:
   ```
   ./amqsgetc QUEUE1 QUEUE.MANAGER.1
   ```
   The sample program starts, and your message is displayed. After a short pause (approximately 30 seconds), the sample ends and the command prompt is displayed again.

Results

You have now successfully verified the client installation.

What to do next

1. You must set various environment variables on the server so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
2. On the server, stop the queue manager by entering the following command:
   ```
   endmqm QUEUE.MANAGER.1
   ```
3. On the server, delete the queue manager by entering the following command:
   ```
   dltmqm QUEUE.MANAGER.1
   ```

Uninstalling or modifying IBM MQ on Linux

▶ Linux

You can uninstall an IBM MQ server or client. You can also modify an installation by removing selected packages (components) currently installed on your system.

Procedure

For information on how to uninstall or modify IBM MQ on Linux, see the following subtopics:
- "Uninstalling or modifying IBM MQ on Linux using rpm" on page 395
- "Uninstalling or modifying IBM MQ on Linux Ubuntu using Debian packages" on page 396

Uninstalling or modifying IBM MQ on Linux using rpm

Linux

On Linux, you can uninstall the IBM MQ server or client using the **rpm** command. You can also modify an installation by removing selected packages (components) currently installed on your system.

Before you begin

If you have applied one or more fix packs to the version of IBM MQ that you want to uninstall, you need to remove the fix packs in reverse chronological installation order before you remove the base packages.

You must remove any updates before starting the uninstallation procedure. For more information, see Restoring the previous maintenance level on IBM MQ on Linux.

Important: You must stop all IBM MQ queue managers, other objects, and applications, before you begin the process to uninstall or modify IBM MQ.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling or modifying, if you have not already done so.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling or modifying:
   a. Log in as a user in the group `mqm`.
   b. Set up your environment to work with the installation you want to uninstall or modify. Enter the following command:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:
      ```
      dspmq -o installation
      ```
   d. Stop all running queue managers associated with the installation you want to uninstall or modify. Enter the following command for each queue manager:
      ```
      endmqm QMgrName
      ```
   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:
      ```
      endmqlsr -m QMgrName
      ```
3. Log in as root.
4. Uninstall or modify IBM MQ using the **rpm** command:
   a. On a system with a single installation:
      - Find out the names of the packages (components) currently installed on your system, by entering the following command:
        ```
        rpm -qa | grep MQSeries
        ```
      - Remove all components by appending all the package names to the **rpm** command arguments. For example:
        ```
        rpm -qa | grep MQSeries | xargs rpm -ev
        ```
      - Modify your installation by appending individual package names to the rpm command arguments. For example, to remove the runtime, Server and SDK components enter the following command:
        ```
        rpm -ev MQSeriesRuntime MQSeriesServer MQSeriesSDK
        ```
      - If you are using Ubuntu, add the **--force-debian** attribute. For example, to remove the runtime, Server and SDK components enter the following command:

```
rpm --force-debian -ev MQSeriesRuntime MQSeriesServer MQSeriesSDK
```

b. On a system with multiple installations:
   - Find out the names of the packages (components) currently installed on your system, by entering the following command:

     ```
     rpm -qa | grep suffix
     ```

     where *suffix* is the unique name given to the packages when **crtmqpkg** was run at installation time. *suffix* is included in each of the package names that belong to a particular installation.
   - Remove all components by appending all the package names to the **rpm** command arguments. For example, to remove all components from an installation with the suffix MQ80 enter the following command:

     ```
     rpm -qa | grep '\<MQSeries.*MQ80\>' | xargs rpm -ev
     ```
   - Modify your installation by appending individual package names to the **rpm** command arguments. For example, to remove the runtime, Server and SDK components from an installation with the suffix MQ80 enter the following command:

     ```
     rpm -ev MQSeriesRuntime-MQ80 MQSeriesServer-MQ80 MQSeriesSDK-MQ80
     ```
   - If you are using Ubuntu, add the **--force-debian** attribute. For example, to remove the runtime, Server and SDK components for an installation with the *suffix* MQ80, enter the following command:

     ```
     rpm --force-debian -ev MQSeriesRuntime-MQ80 MQSeriesServer-MQ80 MQSeriesSDK-MQ80
     ```

Results

After uninstallation, certain files under the directory trees `/var/mqm` and `/etc/opt/mqm` are not removed. These files contain user data and remain so subsequent installations can reuse the data. Most of the remaining files contain text, such as INI files, error logs, and FDC files. The directory tree `/var/mqm/shared` contains files that are shared across installations, including the executable shared libraries `libmqzsd.so` and `libmqzsd_r.so`.

What to do next

- If the product successfully uninstalled, you can delete any files and directories contained in the installation directory.
- If there are no other IBM MQ installations on the system, and you are not planning to reinstall or migrate, you can delete the `/var/mqm` and `/etc/opt/mqm` directory trees, including the files `libmqzsd.so` and `libmqzsd_r.so`. Deleting these directories destroys all queue managers and their associated data.

Uninstalling or modifying IBM MQ on Linux Ubuntu using Debian packages

Linux

You can uninstall an IBM MQ server or client that was installed using the Debian package manager. You can also modify an installation by removing selected packages (components) currently installed on your system.

Before you begin

If you have applied one or more fix packs to the version of IBM MQ that you want to uninstall, you need to remove the fix packs in reverse chronological installation order before you remove the base packages.

You must remove any updates before starting the uninstallation procedure. For more information, see Restoring the previous maintenance level on IBM MQ on Linux.

Important: You must stop all IBM MQ queue managers, other objects, and applications, before you begin the process to uninstall or modify IBM MQ.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling or modifying, if you have not already done so.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling or modifying:
   a. Log in as a user in the group `mqm`.
   b. Set up your environment to work with the installation you want to uninstall or modify. Enter the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:
   ```
   dspmq -o installation
   ```
   d. Stop all running queue managers associated with the installation you want to uninstall or modify. Enter the following command for each queue manager:
   ```
   endmqm QMgrName
   ```
   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:
   ```
   endmqlsr -m QMgrName
   ```
3. Log in as root.
4. Uninstall or modify IBM MQ using a Debian installation command:
   - Using **dpkg**.
     Issuing the command:
     ```
     dpkg -r packagename
     ```
     removes the product but leaves the package definition cached.
     Issuing the command:
     ```
     dpkg -P packagename
     ```
     purges the cached definition of the product.
   - Using **apt**.
     Issuing the command:
     ```
     apt remove "ibmmq-*"
     ```
     removes the product but leaves the package definition cached.
     Issuing the command:
     ```
     apt purge "ibmmq-*"
     ```
     purges the cached definition of the product.

Results

After uninstallation, certain files under the directory trees `/var/mqm` and `/etc/opt/mqm` are not removed. These files contain user data and remain so subsequent installations can reuse the data. Most of the remaining files contain text, such as INI files, error logs, and FDC files. The directory tree `/var/mqm/shared` contains files that are shared across installations, including the executable shared libraries `libmqzsd.so` and `libmqzsd_r.so`.

What to do next

- If the product successfully uninstalled, you can delete any files and directories contained in the installation directory.

- If there are no other IBM MQ installations on the system, and you are not planning to reinstall or migrate, you can delete the `/var/mqm` and `/etc/opt/mqm` directory trees, including the files `libmqzsd.so` and `libmqzsd_r.so`. Deleting these directories destroys all queue managers and their associated data.

Installing and uninstalling IBM MQ on Solaris

Solaris

Installation tasks that are associated with installing IBM MQ on Solaris systems are grouped in this section.

About this task

To prepare for installation and to install the IBM MQ components, complete the following tasks.

For information about how to uninstall IBM MQ, see “Uninstalling IBM MQ on Solaris” on page 434.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See “Checking requirements on Solaris” on page 403.
2. Plan your installation.
   - As part of the planning process, you must choose which components to install and where to install them. See “IBM MQ components for Solaris systems.”
   - You must also make some platform-specific choices. See “Planning to install IBM MQ on Solaris” on page 404.
3. Prepare your system for installation of IBM MQ. See “Preparing the system on Solaris” on page 405.
4. Install IBM MQ server. See “Installing IBM MQ server on Solaris” on page 410.
5. Optional: Install an IBM MQ client. See “Installing an IBM MQ client on Solaris” on page 416.
6. Verify your installation. See “Verifying an IBM MQ installation on Solaris” on page 420.

IBM MQ components for Solaris systems

Solaris

You can select the components that you require when you install IBM MQ.

Important: See IBM MQ license information for details of what each purchase of IBM MQ entitles you to install.

Table 56 on page 399 shows the components that are available when installing an IBM MQ server or client on a Solaris system.

Note: When you install interactively on Solaris systems, the options that are available install various combinations of the components listed in this table. Details are given in the “Interactive installation” on page 400 section.

Table 56. IBM MQ components for Solaris systems

Component	Description	Server media	Client media	Component name
Runtime	Contains files that are common to both server and client installations. **Note:** This component must be installed.	✓	✓	runtime
Server	You can use the server to run queue managers on your system and connect to other systems over a network. Provides messaging and queuing services to applications, and support for IBM MQ client connections.	✓		server
Standard Client	The IBM MQ MQI client is a small subset of IBM MQ, without a queue manager, that uses the queue manager and queues on other (server) systems. It can be used only when the system it is on is connected to another system that is running a full server version of IBM MQ. The client and the server can be on the same system if required.	✓	✓	sol_client
SDK	The SDK is required for compiling applications. It includes sample source files, and the bindings (files .H, .LIB, .DLL, and others), that you need to develop applications to run on IBM MQ.	✓	✓	base
Sample programs	The sample application programs are needed if you want to check your IBM MQ installation using the verification procedures.	✓	✓	samples
Java messaging	The files needed for messaging using Java (includes Java Message Service).	✓	✓	java
Man pages	UNIX man pages, in U.S. English, for: control commands MQI calls MQSC commands	✓	✓	man
Java JRE	A Java Runtime Environment that is used by those parts of IBM MQ that are written in Java.	✓	✓	jre
Message Catalogs	For available languages, see the table of message catalogs that follows.	✓	✓	
IBM Global Security Kit	IBM Global Security Kit V8 Certificate and TLS, Base Runtime.	✓	✓	gskit
Managed File Transfer	MQ Managed File Transfer transfers files between systems in a managed and auditable way, regardless of file size or the operating systems used. For information about the function of each component, see Managed File Transfer product options.	✓		ftagent ftbase ftlogger ftservice fttools

Table 56. IBM MQ components for Solaris systems (continued)

Component	Description	Server media	Client media	Component name
Advanced Message Security	Provides a high level of protection for sensitive data flowing through the IBM MQ network, while not impacting the end applications. You must install this component on all IBM MQ installations that host queues you want to protect. You must install the IBM Global Security Kit component on any IBM MQ installation that is used by a program that puts or gets messages to or from a protected queue, unless you are using only Java client connections. You must install the **Java JRE** component to install this component.	✓		mqams
V 9.0.0 AMQP Service	Install this component to make AMQP channels available. AMQP channels support MQ Light APIs. You can use AMQP channels to give AMQP applications access to the enterprise-level messaging facilities provided by IBM MQ.	✓		amqp

Table 57. IBM MQ message catalogs for Solaris systems.

A two-column table listing the available message catalogs.

Message catalog language	Component name
Brazilian Portuguese	Pt_BR
Czech	Cs_CZ
French	Fr_FR
German	De_DE
Hungarian	Hu_HU
Italian	It_IT
Japanese	Ja_JP
Korean	Ko_KR
Polish	Pl_PL
Russian	Ru_RU
Spanish	Es_ES
Simplified Chinese	Zh_CN
Traditional Chinese	Zh_TW
U.S. English	not applicable

Interactive installation

The options available with interactive installation install various combinations of the product components described in the previous tables. The following table shows you what will be installed for each option, together with the option number on the server and client DVDs:

Table 58. IBM MQ interactive installation options for Solaris systems.

A four-column table listing interactive installation options and the components installed with each one. Server and client option numbers are also listed.

Interactive installation option	**Components installed**
IBM MQ Server	base runtime server java gskit
Man pages	runtime man
Sample programs	base runtime samples
IBM MQ MQI client libraries (including Java, JMS, and Web Services support)	base runtime sol_client java gskit
IBM Java runtime for Solaris, Java 2 Technology Edition, Version 6	jre runtime
IBM Global Security Kit for IBM MQ	gskit jre runtime
Managed File Transfer Service	ftservice ftbase jre java runtime ftagent
Managed File Transfer Tools	fttools ftbase jre java runtime
Managed File Transfer Agent	ftagent ftbase jre java runtime
Managed File Transfer Logger	ftlogger ftbase jre java runtime server
Advanced Message Security	runtime mqams
V 9.0.0 AMQP Service	runtime jre java amqp

Table 58. IBM MQ interactive installation options for Solaris systems (continued).

A four-column table listing interactive installation options and the components installed with each one. Server and client option numbers are also listed.

Interactive installation option	**Components installed**
V 9.0.1 REST API and Console	runtime jre java web
Spanish message catalog	runtime Es_ES
French message catalog	runtime Fr_FR
German message catalog	runtime De_DE
Japanese message catalog	runtime Ja_JP
Italian message catalog	runtime It_IT
Brazilian Portuguese message catalog	runtime Pt_BR
Traditional Chinese message catalog	runtime Zh_TW
Simplified Chinese message catalog	runtime Zh_CN

Before you install IBM MQ, you must choose which components to install and where to install them. You must also make some platform-specific choices.

Checking requirements on Solaris

Solaris

Before you install IBM MQ on Solaris, you must check for the latest information and system requirements.

About this task

A summary of the tasks that you must complete to check system requirements are listed here with links to further information.

Procedure

1. Check that you have the latest information, including information on hardware and software requirements. See "Where to find product requirements and support information" on page 195.
2. Check that your systems meet the initial hardware and software requirements for Solaris. See "Hardware and software requirements on Solaris systems."

   The supported hardware and software environments are occasionally updated. See System Requirements for IBM MQ for the latest information.
3. Check that your systems have sufficient disk space for the installation. See Disk space requirements.
4. Check that you have the correct licenses. See "License requirements" on page 194 and IBM MQ license information.

What to do next

When you have completed these tasks, you are ready to start preparing your system for installation. For the next steps in installing IBM MQ, see "Preparing the system on Solaris" on page 405.

Related concepts:

"IBM MQ installation overview" on page 192
An overview of concepts and considerations for installing IBM MQ, with links to instructions on how to install, verify, and uninstall IBM MQ on each of the supported platforms.

Related information:

IBM MQ maintenance tasks

Hardware and software requirements on Solaris systems

Solaris

Before you install IBM MQ , check that your system meets the hardware and operating system software requirements for the particular components you intend to install.

For hardware and software requirements, see System Requirements for IBM MQ.

IBM MQ does not support host names that contain spaces. If you install IBM MQ on a system with a host name that contains spaces, you are unable to create any queue managers.

Java Message Service and SOAP transport

If you want to use Java Message Service and SOAP support, you need an IBM Java 7 SDK and Runtime Environment Version 7.0 or later.

V 9.0.0 Java 8 is bundled with IBM MQ Version 9.0 but client components are built with Java 7 compatibility flags on.

For development, a JDK is required, and a JRE is required for running. The JRE does not need to be the JRE installed with IBM MQ, but has to be one from the supported list.

For a list of supported JDKs, see System Requirements for IBM MQ.

For further information about SOAP with IBM MQ , see IBM MQ transport for SOAP.

On Solaris : The 32-bit and 64-bit JDKs are typically installed to the same directory. To run a 64-bit JVM use the -d64 or -d32 parameters on the command line when running a Java application to ensure the correct JVM is used.

You can check the version installed using the following command:

```
java -version
```

Transport Layer Security (TLS)

If you want to use the TLS support, you need the IBM Global Security Kit (GSKit) V8 package. This package is supplied with IBM MQ as one of the components available for installation.

Solaris 11 operating system

If you are installing on the Solaris 11 operating system, ensure that the IPS package (package/svr4) that supports `pkgadd` and equivalent utilities is installed.

Related concepts:

“Hardware and software requirements on Windows systems” on page 445
Check that the server environment meets the prerequisites for installing IBM MQ for Windows and install any prerequisite software that is missing from your system from the server DVD.

Related tasks:

“Checking requirements on Windows” on page 444
Before you install IBM MQ on Windows, you must check for the latest information and system requirements.

Planning to install IBM MQ on Solaris

Solaris

Before you install IBM MQ on Solaris, you must choose which components to install and where to install them. You must also make some platform-specific choices.

About this task

The following steps provide links to additional information to help you with planning your installation of IBM MQ on Solaris.

As part of your planning activities, make sure that you review the information on hardware and software requirements for the platform on which you are planning to install IBM MQ. For more information, see "Checking requirements on Solaris" on page 403.

Procedure

1. Decide which IBM MQ components and features to install. See "IBM MQ components and features" on page 192.

   Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. For more information, see "License requirements" on page 194 and IBM MQ license information.
2. Review the options for naming your installation. In some cases, you can choose an installation name to use instead of the default name. See "Installation name on UNIX, Linux, and Windows" on page 197.
3. Review the options and restrictions for choosing an installation location for IBM MQ. For more information, see "Installation location on Multiplatforms" on page 198.
4. If you plan to install multiple copies of IBM MQ, see "Multiple installations on UNIX, Linux, and Windows" on page 200.
5. If you already have a primary installation, or plan to have one, see "Primary installation on UNIX, Linux, and Windows" on page 202.
6. Make sure that the communications protocol needed for server-to-server verification is installed and configured on both systems that you plan to use. For more information, see "Server-to-server links on UNIX, Linux, and Windows" on page 210.

Preparing the system on Solaris

Solaris

On Solaris systems, you might have to complete several tasks before you install IBM MQ. You might also want to complete other tasks, depending on your installation intentions.

About this task

The tasks that you perform to prepare your systems for installation are listed here. Complete the appropriate tasks for your platform before installing.

Procedure

1. Set up a user ID of the name `mqm`, with a primary group of `mqm`. See "Setting up the user and group on Solaris" on page 406.
2. Create file systems for both the product code and working data to be stored. See "Creating file systems on Linux" on page 335.
3. Configure any additional settings needed for your Solaris system. See "Configuring and tuning the operating system on Solaris" on page 409.

What to do next

When you have completed the tasks to prepare the system, you are ready to start installing IBM MQ. To install a server, see "Installing IBM MQ server on Solaris" on page 410. To install a client, see "Installing an IBM MQ client on Solaris" on page 416.

IBM MQ maintenance tasks

Setting up the user and group on Solaris

Solaris

On Solaris systems, IBM MQ requires a user ID of the name `mqm`, with a primary group of `mqm`. The `mqm` user ID owns the directories and files that contain the resources associated with the product.

Creating the user ID and group

Set the primary group of the `mqm` user to the group `mqm`.

If you are installing IBM MQ on multiple systems you might want to ensure each UID and GID of `mqm` has the same value on all systems. If you are planning to configure multi-instance queue managers, it is essential the UID and GID are the same from system to system. It is also important to have the same UID and GID values in virtualization scenarios.

Solaris

The user ID value for user `mqm` must be less than 262,143 to avoid problems with the maintenance update process.

Create the IDs using the **`groupadd`** and **`useradd`** commands to set the UID and GID the same on each machine.

Adding existing user IDs to the group on Solaris systems

If you want to run administration commands, for example **`crtmqm`** (create queue manager) or **`strmqm`** (start queue manager), your user ID must be a member of the `mqm` group. This user ID must not be longer than 12 characters.

Users do not need `mqm` group authority to run applications that use the queue manager; it is needed only for the administration commands.

Log files created by MQ Telemetry service

The **`umask`** setting of the user ID that creates a queue manager will determine the permissions of the Telemetry log files generated for that queue manager. Even though the ownership of the log files will be set to `mqm`.

Creating file systems on Solaris

▶ Solaris

Before installing IBM MQ, you might need to create file systems for both the product code and working data to be stored. There are minimum storage requirements for these file systems. The default installation directory for the product code can be changed at installation time, but the working data location cannot be changed.

Determining the size of a server installations file system

To determine the size of the `/var/mqm` file system for a server installation, consider:

- The maximum number of messages in the system at one time.
- Contingency for message buildups, if there is a system problem.
- The average size of the message data, plus 500 bytes for the message header.
- The number of queues.
- The size of log files and error messages.
- The amount of trace that is written to the `/var/mqm/trace` directory.

Storage requirements for IBM MQ also depend on which components you install, and how much working space you need. For more details, see Disk space requirements.

Creating a file system for the working data

Before you install IBM MQ, create and mount a file system called `/var/mqm` which is owned by the user `mqm` in the group `mqm` ; see "Setting up the user and group on Linux" on page 334. This file system is used by all installations of IBM MQ on a system. If possible, use a partition strategy with a separate volume for the IBM MQ data. This means that other system activity is not affected if a large amount of IBM MQ work builds up. Configure the directory permissions to permit the `mqm` user to have full control, for example, file mode 755. These permissions will then be updated during the IBM MQ installation to match the permissions required by the queue manager.

Creating separate file systems for errors and logs

You can also create separate file systems for your log data (`/var/mqm/log`) and error files (`/var/mqm/errors`). If possible, place these directories on different physical disks from the queue manager data (`/var/mqm/qmgrs`) and from each other.

If you create separate file systems the /var/mqm/errors directory can be NFS mounted. However, if you choose to NFS-mount /var/mqm/errors, the error logs might be lost if the network fails.

You can protect the stability of your queue manager by having separate file systems for:
- /var/mqm/errors
- /var/mqm/trace
- /var/mqm/qmgrs
- /var/mqm/log

In the case of /var/mqm/errors, it is rare that this directory receives large quantities of data. But it is sometimes seen, particularly if there is a severe system problem leading to IBM MQ writing a lot of diagnostic information in to .FDC files. In the case of /var/mqm/trace, files are only written here when you use **strmqtrc** to start tracing IBM MQ.

You can obtain better performance of normal IBM MQ operations (for example, syncpoints, MQPUT, MQGET of persistent messages) by placing the following on separate disks:
- /var/mqm/qmgrs
- /var/mqm/log

In the rare event that you need to trace an IBM MQ system for problem determination, you can reduce performance impact by placing the /var/mqm/trace file system on a separate disk.

If you are creating separate file systems, allow a minimum of 30 MB of storage for /var/mqm, 100 MB of storage for /var/mqm/log, and 10 MB of storage for /var/mqm/errors. The 100 MB minimum allowance of storage for /var/mqm/log is the absolute minimum required for a single queue manager and is not a recommended value. The size of a file system must be scaled according to the number of queue managers that you intend to use, the number of pages per log file, and the number of log files per queue manager.

If you want to use individual queues that hold more than 2 GB of data, you must enable /var/mqm to use large files.

For more information about file systems, see File system support.

The size of the log file depends on the log settings that you use. The minimum sizes are for circular logging using the default settings. For more information about log sizes, see Calculating the size of the log.

Solaris

For a client installation, the file system can be mounted on a remote network device, for example NFS.

If you are performing both a client and a server installation, the requirements of the server installation take precedence over the requirements of the client installation.

Allow 15 MB as a minimum for an IBM MQ client.

A new sample IBM MQ MQI client configuration file is created in the var/mqm directory, by the client package, during installation, but only if this file does not exist. This file contains the ClientExitPath stanza. An example mqclient.ini file is shown in Configuring a client using a configuration file.

If you are using a common configuration file for multiple clients, either in the IBM MQ installation directory or in another location using the MQCLNTCF environment variable, you must grant read access to all user identifiers under which the IBM MQ client applications run. If, for any reason, the file cannot be read the failure is traced, and the search logic continues as if the file had not existed.

"Configuring and tuning the operating system on Solaris"
Configure Solaris systems with the resource limits required by IBM MQ.

Configuring and tuning the operating system on Solaris

Solaris

Configure Solaris systems with the resource limits required by IBM MQ.

IBM MQ uses semaphores, shared memory, and file descriptors, and it is probable that the default resource limits are not adequate.

For further information on **maxusers**, and other process-sizing parameters, see Process sizing parameters.

To set new default limits for all users in the *mqm* group, set up a project for the *mqm* group in each zone.

To find out if you already have a project for the *mqm* group, log in as root and enter the following command:

```
projects -l
```

If you do not already have a *group.mqm* project defined, enter the following command:

```
projadd -c "IBM MQ default settings"
        -K "process.max-file-descriptor=(basic,10000,deny)"
        -K "project.max-shm-memory=(priv,4GB,deny)"
        -K "project.max-shm-ids=(priv,1024,deny)"
        -K "project.max-sem-ids=(priv,128,deny)" group.mqm
```

If a project called *group.mqm* is listed, review the attributes for that project. The attributes must include the following minimum values:

```
process.max-file-descriptor=(basic,10000,deny)
project.max-sem-ids=(priv,128,deny)
project.max-shm-ids=(priv,1024,deny)
project.max-shm-memory=(priv,4294967296,deny)
```

If you need to change any of these values, enter the following command:

```
projmod -s -K "process.max-file-descriptor=(basic,10000,deny)"
           -K "project.max-shm-memory=(priv,4GB,deny)"
           -K "project.max-shm-ids=(priv,1024,deny)"
           -K "project.max-sem-ids=(priv,128,deny)" group.mqm
```

Note that you can omit any attributes from this command that are already correct.

For example, to change only the number of file descriptors, enter the following command:

```
projmod -s -K "process.max-file-descriptor=(basic,10000,deny)" group.mqm
```

(To set only the limits for starting the queue manager under the mqm user, login as mqm and enter the command `projects`. The first listed project is likely to be `default`, and so you can use `default` instead of `group.mqm`, with the `projmod` command.)

To ensure that the attributes for the project `group.mqm` are used by a user session when running IBM MQ, make sure that the primary group of that user ID is mqm. In the examples in this topic, the `group.mqm` project ID will be used.

For further information on how projects are associated with user sessions, see System Administration Guide: Oracle Solaris Containers-Resource Management and Oracle Solaris Zones for your release of Solaris.

You can check your system configuration using the mqconfig command.

For more information on configuring your system, see How to configure UNIX and Linux systems for IBM MQ.

Installing IBM MQ server on Solaris

Solaris

You can install an IBM MQ server on Solaris either interactively or silently.

Before you begin

- Before you start the installation procedure, make sure that you complete the necessary steps that are outlined in "Preparing the system on Solaris" on page 405.
- If you install a copy of IBM MQ server for Solaris by using Electronic Software Download, obtained from Passport Advantage, you need to decompress the `tar.gz` file, and extract the installation files from the tar file, by using the following command:

  ```
  tar -xvf   WS_MQ_V8.0_TRIAL_FOR_SOLARIS_ML.tar
  ```

  Important: You must use GNU tar (also known as `gtar`) to unpack the `tar` images.
- If you are using Solaris zones, you have a choice between installing IBM MQ into the global zone, or installing IBM MQ into a non-global zone.

  For more information on how to install IBM MQ into Solaris zones, see the following technote: WebSphere MQ support position regarding Solaris zones. The technote is applicable to IBM WebSphere MQ Version 7.1 or later with the following changes:
  - You do not need the `-G` option on the **`pkgadd`** command as GSKit is now installed as part of the IBM MQ installation.
  - If you install IBM MQ into the global zone for use in sparse zones, you must copy the `/var/mqm` file system into the sparse zone. You must also copy the `/etc/opt/mqm/mqinst.ini` installation entry into the sparse zone.
  - Limitations for shared `/usr` file systems: the **`dspmqinst`** and **`dspmqver`** commands might report the primary installation incorrectly when compared with the symbolic links in `/usr/bin`. To synchronize the reporting of the primary installation in a Solaris zone and the global zone, run **`setmqinst`** with the **`-i`** or **`-x`** parameter, on the individual zones.
  - You cannot change the primary installation within a non-global zone. You must change the primary installation through the global zone, which has the appropriate write access to `/usr/bin`.

About this task

This task describes the installation of the IBM MQ for Solaris server, by using the `pkgadd` program. You can choose which components you want to install. The components are listed in “IBM MQ components for Solaris systems” on page 398.

Note: If you are installing on the Solaris 11 operating system, ensure that the IPS package (package/svr4) that supports `pkgadd` and equivalent utilities is installed.

Procedure

1. Log in as root, or switch to the superuser by using the **su** command.
2. Set your current directory to the location of the installation file. The location might be the mount point of the server DVD, a network location, or a local file system directory.
3. Run the `mqlicense.sh` script to accept the license:

   ```
   ./mqlicense.sh
   ```

   If you want to view a text-only version of the license, which can be read by a screen reader, type:

   ```
   ./mqlicense.sh -text_only
   ```

   The license is displayed. Follow the instructions to accept the license. If you accept the license, the installation continues. If you do not accept the license, you cannot continue the installation process.
4. If this installation is not the first installation on the system, run **crtmqpkg** to create a unique set of packages to install on the system:
   a. Enter the following command:

      ```
      ./crtmqpkg suffix
      ```

      where *suffix* is a name of your choosing that uniquely identifies the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.

      The **crtmqpkg** script can use two environment variables that are useful when you are installing from a non-disk media location:
      - *CDROOT*, the root of the installation media or downloaded installation files.
      - *TMPDIR*, the output location of the modified installation files.

      No environment variables are required if you are running the image as `./crtmqpkg`.
   b. Set your current directory to the location specified when the **crtmqpkg** command completes. This directory is a subdirectory of `/var/spool`, in which the unique set of packages is created. The packages have the *suffix* value contained within the file name.
5. Start the installation process:
   - If the installation is the first installation on the system, enter the following command to start the installation process:

     ```
     pkgadd -d.
     ```

     where " . " means use the current directory.
   - If the installation is not the first installation on the system, enter the following command to start the installation process:

     ```
     pkgadd mqm-suffix
     ```

     where *suffix* is the suffix that is chosen in the previous step.
6. When prompted, choose a location for installation.
   - To install to the default location, `/opt/mqm`, enter `y`.

- To install to a non-default directory, enter `n` then enter the required installation path, and confirm your choice.

7. When the list of components is displayed, enter the numbers of the components that you require, separated by spaces or commas. If you are installing (adding) an IBM MQ component to an existing installation, choose option `yes` when you are asked whether to overwrite.

   Note: During the IBM MQ base version installation, you can choose to install all components or a subset of the components. When you install a fix pack, only the currently installed components are upgraded. If, at a later stage, you want to add further IBM MQ components that are not already installed, these components can be installed (added) to the IBM MQ base version only. If your current version of IBM MQ is not the base version, you must first uninstall all the fix packs before you add the required components to the existing installation, and then install the required fix packs. Also, when you are adding IBM MQ components to an existing installation, you must choose option `yes` when you are asked whether to overwrite by the installation process.
8. If the path chosen in step 6 does not exist, and you are asked if you want to create it, enter `y` to proceed.
9. Answer any questions appropriately for your system. If you are prompted to choose whether to install certain IBM MQ files as `setuid/setgid` files, you must enter `y`.
10. When a message informing you that the installation is complete appears, enter `q` to exit the `pkgadd` program.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation by entering the following command at the command line:
  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```
  where *`MQ_INSTALLATION_PATH`* represents the directory where IBM MQ is installed.

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **`setmqenv`** or **`crtmqenv`** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. For more information, see "Verifying an IBM MQ installation on Solaris" on page 420.

Changing the primary installation

Installing the server silently on Solaris

Solaris

You can perform a non-interactive installation of the IBM MQ server using the installation script `silent.sh`. A non-interactive installation is also known as a silent, or unattended installation.

Before you begin

Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on Solaris" on page 405.

About this task

You can perform a silent installation of IBM MQ. A sample script file called `silent.sh` is supplied in the `silent` directory on the DVD. You can use this script to perform a non-interactive installation that requires no input and shows nothing on the screen. It must be run as root.

The installation script `silent.sh` uses an `admin` file and a `response` file, both of which are supplied in the `silent` directory. You can use these files as supplied to perform a silent installation of all the components, including all the national language features, to the default location.

Note: If you are installing on the Solaris 11 operating system, ensure that the IPS package (package/svr4) that supports `pkgadd` and equivalent utilities is installed.

Procedure

1. Copy the `silent.sh` script into a writeable directory.
2. If this installation is not the first installation on the system, run **`crtmqpkg`** to create a unique set of packages to install on the system:
   a. Enter the following command:
   ```
   ./crtmqpkg suffix
   ```
   where *suffix* is a name of your choosing, that will uniquely identify the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.
   b. Set your current directory to the location specified when the **`crtmqpkg`** command completes. This directory is a sub-directory of `/var/spool`, in which the unique set of packages is created. The packages have the *suffix* value contained within the filename.

   Once a new package has been generated for the second installation the `silent.sh` script needs to have its MQ_PACKAGE_NAME variable modified so that its value is not `mqm` but the new package name.

   Also the MQ_PACKAGE_LOCATION variable needs to be modified so that its value is not $MQ_MEDIA_LOCATION but the location of the new package (which by default is `/var/spool/pkg`).
3. Optional: If you want to change where the IBM MQ server DVD is mounted, update the values in the `silent.sh` script. By default, the script assumes that the server DVD has been mounted at `/CD7FVML`.
4. Optional: If you want to change where the output and logs are written to, update the values in the `silent.sh` script. By default, output and logs are written to the file `/var/tmp/mq.install`.
5. Optional: If you want to install to a non-default location, update the *`MQ_INSTALLATION_PATH`* variable in the `silent.sh` script.

   Note:
   - The installation path specified must either be an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.

- If the directory you specified does not exist, the installation script creates that directory.

6. Optional: If you want to change the components that are installed, edit the `response` file. A list of all the installable IBM MQ components can be found at: "IBM MQ components and features" on page 192.

   Solaris does not check, during a silent installation, that prerequisite components are installed. You can use the following procedure to create a response file interactively, before using it to install the product. **`pkgask`** prompts you for the names of the components to install.

   a. Run the **`mqlicense.sh`** command to accept the license agreement for the product.
   b. **`pkgask`** -d *path_to_install_image* -r *response_file* `mqm`

   The inputs to **`pkgask`** are the same as those inputs documented for **`pkgadd`**, but instead of the product being installed a response file is created.
7. Optional: If you have edited the `response` file, you must then edit the `silent.sh` to use your custom response file.
8. To start the installation, run `silent.sh`.
9. Check the log file for any errors.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation by entering the following command at the command line:

  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```

  where *`MQ_INSTALLATION_PATH`* represents the directory where IBM MQ is installed.

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **`setmqenv`** or **`crtmqenv`** command to set various environment variables for a particular installation of IBM MQ . For more information, see setmqenv and crtmqenv.
- If you want to confirm that the installation was successful, you can verify your installation. See "Verifying an IBM MQ installation on Solaris" on page 420, for more information.

Changing the primary installation

Converting a trial license on Solaris

▶ Solaris

Convert a trial license to a full license without reinstalling IBM MQ.

When the trial license expires, the "count-down" displayed by the **strmqm** command informs you the license has expired, and the command does not run.

Before you begin

1. IBM MQ is installed with a trial license.
2. You have access to the installation media of a fully licensed copy of IBM MQ.

About this task

Run the **setmqprd** command to convert a trial license to a full license.

If you do not want to apply a full license to your trial copy of IBM MQ, you can uninstall it at any time.

Procedure

1. Obtain the full license from the fully licensed installation media.

   The full license file is `amqpcert.lic`. On Solaris, it is in the */MediaRoot/*`licenses` directory on the installation media.
2. Run the **setmqprd** command from the installation that you are upgrading:

   ```
   MQ_INSTALLATION_PATH/bin/setmqprd /MediaRoot/licenses/amqpcert.lic
   ```

Related information:
setmqprd

Displaying messages in your national language on Solaris systems

Solaris

To display messages from a different national language message catalog, you must install the appropriate catalog and set the **LANG** environment variable.

About this task

Messages in U.S. English are automatically installed with IBM MQ

Message catalogs for all languages are installed in *MQ_INSTALLATION_PATH*`/msg/`*language identifier*, where *language identifier* is one of the identifiers in Table 59.

If you require messages in a different language, perform the following steps:

Procedure

1. Install the appropriate message catalog (see "IBM MQ components and features" on page 192).
2. To select messages in a different language, ensure the **LANG** environment variable is set to the identifier for the language you want to install:

Table 59. Language identifiers

Identifier	Language
cs_CZ	Czech
de_DE	German
es_ES	Spanish
fr_FR	French
hu_HU	Hungarian
it_IT	Italian

Table 59. Language identifiers (continued)

Identifier	Language
ja_JP	Japanese
ko_KR	Korean
pl_PL	Polish
pt_BR	Brazilian Portuguese
ru_RU	Russian
zh_CN	Simplified Chinese
zh_TW	Traditional Chinese

Installing an IBM MQ client on Solaris

Solaris

You can interactively install the IBM MQ client for Solaris using `pkgadd`.

Before you begin

- Before you start the installation procedure, make sure that you have completed the necessary steps outlined in “Preparing the system on Solaris” on page 405.
- This procedure is for the installation of a standard IBM MQ client, from the client DVD. If you are installing an IBM MQ client on a system that is already running an IBM MQ server, are therefore using a server DVD to install the client, follow the steps in “Installing IBM MQ server on Solaris” on page 410, and select the appropriate client components in step 8.

About this task

This task describes the installation of the IBM MQ for Solaris client, using the **pkgadd** program. You can choose which components you want to install. The components (or file sets) are listed in “IBM MQ components for Solaris systems” on page 398; you must install at least the Client component.

Note: If you are installing on the Solaris 11 operating system, ensure that the IPS package (package/svr4) that supports `pkgadd` and equivalent utilities is installed.

Procedure

1. Log in as root, or switch to the superuser using the **su** command.
2. Make your current directory the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Run the `mqlicense.sh` script to accept the license:
   ```
   ./mqlicense.sh
   ```
   If you want to view a text-only version of the license, which can be read by a screen-reader, type:
   ```
   ./mqlicense.sh -text_only
   ```
   The license is displayed. Follow the instructions to accept the license. If you accept the license, the installation continues. If you do not accept the license, you cannot continue the installation process.
4. If this installation is not the first installation on the system, you must run **crtmqpkg** to create a unique set of packages to install on the system:
   a. Enter the following command:
      ```
      ./crtmqpkg suffix
      ```

where *suffix* is a name of your choosing, that will uniquely identify the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.

   b. Set your current directory to the location specified when the **crtmqpkg** command completes. This directory is a sub-directory of `/var/spool`, in which the unique set of packages is created. The packages have the *suffix* value contained within the filename.

5. Start the installation process:
   - If the installation is the first installation on the system, enter the following command to start the installation process:
     ```
     pkgadd -d.
     ```
     where " **.** " means use the current directory.
   - If the installation is not the first installation on the system, enter the following command to start the installation process:
     ```
     pkgadd mqm-suffix
     ```
     where *suffix* is the suffix chosen in the previous step.
6. You are presented with a list of the packages that are available. Enter the number of the `mqm` package.
7. You are prompted to choose a location for installation.
   - To install to the default location, enter `y`.
   - To install to a non-default directory, enter `n`. Then enter the required installation path, and confirm your choice.
8. You receive a number of messages, after which a list of components is displayed. Enter the numbers of the components that you require separated by spaces or commas.
9. If the path chosen in step 7 does not exist, you are asked if you want to create it. You must enter `y` to proceed.
10. Answer any questions appropriately for your system.
11. A message tells you when installation is complete. Enter `q` to exit the `pkgadd` program.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:
  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```
  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see “Testing communication between a client and a server on Solaris” on page 432.

Related tasks:
"Uninstalling IBM MQ on Solaris" on page 434
On Solaris, you can uninstall the IBM MQ server or client using the **pkgrm** command.

Installing a client silently on Solaris

Solaris

You can perform a non-interactive installation of the IBM MQ client using the installation script `silent.sh`. A non-interactive installation is also known as a silent, or unattended installation.

Before you begin

- Before you start the installation procedure, make sure that you have completed the necessary steps outlined in "Preparing the system on Solaris" on page 405.
- This procedure is for the installation of a standard IBM MQ client, from the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
- This procedure is for the installation of a standard IBM MQ client, from the client DVD. If you are installing an IBM MQ client on a system that is already running an IBM MQ server, are therefore using a server DVD to install the client, follow the steps in "Installing IBM MQ server on Solaris" on page 410, and select the appropriate client components in step 8.

About this task

You can perform a silent installation of IBM MQ. A sample script file called `silent.sh` is supplied in the `silent` directory on the DVD. You can use this script to perform a non-interactive installation that requires no input and shows nothing on the screen. It must be run as root.

The installation script `silent.sh` uses an `admin` file and a `response` file, both of which are supplied in the `silent` directory. You can use these files as supplied to perform a silent installation of all the components, including all the national language features, to the default location.

Note: If you are installing on the Solaris 11 operating system, ensure that the IPS package (package/svr4) that supports `pkgadd` and equivalent utilities is installed.

Procedure

1. Copy the `silent.sh` script into a writeable directory.
2. If this installation is not the first installation on the system, run **crtmqpkg** to create a unique set of packages to install on the system:
   a. Enter the following command:
      ```
      ./crtmqpkg suffix
      ```
      where *suffix* is a name of your choosing, that will uniquely identify the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.
   b. Set your current directory to the location specified when the **crtmqpkg** command completes. This directory is a sub-directory of `/var/spool`, in which the unique set of packages is created. The packages have the *suffix* value contained within the filename.

   Once a new package has been generated for the second installation the `silent.sh` script needs to have its MQ_PACKAGE_NAME variable modified so that its value is not `mqm` but the new package name.

   Also the MQ_PACKAGE_LOCATION variable needs to be modified so that its value is not $MQ_MEDIA_LOCATION but the location of the new package (which by default is `/var/spool/pkg`).

3. Optional: If you want to change where the IBM MQ client DVD is mounted, you must update the values in the `silent.sh` script. By default, the script assumes that the DVD has been mounted at `/CD7FVML`.
4. Optional: If you want to change where the output and logs are written to, update the values in the `silent.sh` script. By default, output and logs are written to the file `/var/tmp/mq.install`.
5. Optional: If you want to install to a non-default location, update the *`MQ_INSTALLATION_PATH`* variable in the `silent.sh` script.

   Note:
   - The installation path specified must either be an empty directory, the root of an unused file system, or a path that does not exist. The length of the path is limited to 256 bytes and must not contain spaces.
   - If the directory you specified does not exist, the installation script creates that directory.
6. Optional: If you want to change the components that are installed, edit the `response` file. A list of all the installable IBM MQ components can be found at: "IBM MQ components and features" on page 192.

   Solaris does not check, during a silent installation, that prerequisite components are installed. You can use the following procedure to create a response file interactively, before using it to install the product. **`pkgask`** prompts you for the names of the components to install.
   a. Run the **`mqlicense.sh`** command to accept the license agreement for the product.
   b. **`pkgask`** -d *path_to_install_image* -r *response_file* `mqm`

   The inputs to **`pkgask`** are the same as those inputs documented for **`pkgadd`**, but instead of the product being installed a response file is created.
7. Optional: If you have edited the `response` file, you must then edit the `silent.sh` to use your custom response file.
8. To start the installation, run `silent.sh`.
9. Check the log file for any errors.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:
  ```
  MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
  ```
  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **`setmqenv`** or **`crtmqenv`** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see "Testing communication between a client and a server on Solaris" on page 432.

Verifying an IBM MQ installation on Solaris

Solaris

The topics in this section provide instructions on how to verify a server or a client installation of IBM MQ on Solaris systems.

About this task

You can verify a local (stand-alone) server installation or a server-to-server installation of the IBM MQ server:
- A local server installation has no communication links with other IBM MQ installations.
- A server-to-server installation does have links to other installations.

You can also verify that your IBM MQ MQI client installation completed successfully and that the communication link is working.

Procedure

- To verify a local server installation, see "Verifying a local server installation on Solaris."
- To verify a server-to-server installation, see "Verifying a server-to-server installation on Solaris" on page 424.
- To verify a client installation, see "Verifying a client installation using the command line on Solaris" on page 429.

Verifying a local server installation on Solaris

Solaris

You can use either the command line or the postcard application to verify a local (stand-alone) installation on Solaris.

About this task

You can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a local server installation using the command line on Solaris" on page 421.
- To use the postcard application to verify an installation, see "Verifying a local server installation using the Postcard application on Solaris" on page 422.

Verifying a local server installation using the command line on Solaris: ▶ Solaris

On Solaris systems, you can verify a local installation by using the command line to create a simple configuration of one queue manager and one queue. You can also verify an installation using the postcard application.

Before you begin

To verify the installation, you must first install the samples package.

Before beginning the verification procedure, you might want to check that you have the latest fixes for your system. For more information about where to find the latest updates, see “Checking requirements on Windows” on page 444.

About this task

Use the following steps to configure your default queue manager from the command line. After the queue manager is configured, use the `amqsput` sample program to put a message on the queue. You then use the `amqsget` sample program to get the message back from the queue.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. If you are verifying an installation on a Solaris system, log in as a user in the `mqm` group.
2. Set up your environment:
   a. Set up environment variables for use with a particular installation by entering one the following command:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   b. Check that the environment is set up correctly by entering the following command:
      ```
      dspmqver
      ```
      If the command completes successfully, and the expected version number and installation name are returned, the environment is set up correctly.
3. Create a queue manager called `QMA` by entering the following command:
   ```
   crtmqm QMA
   ```
   Messages indicate when the queue manager is created, and when the default IBM MQ objects are created.
4. Start the queue manager by entering the following command:
   ```
   strmqm QMA
   ```
   A message indicates when the queue manager starts.
5. Start MQSC by entering the following command:
   ```
   runmqsc QMA
   ```
   A message indicates when MQSC starts. MQSC has no command prompt.
6. Define a local queue called `QUEUE1` by entering the following command:
   ```
   DEFINE QLOCAL (QUEUE1)
   ```

A message indicates when the queue is created.

7. Stop MQSC by entering the following command:

```
end
```

Messages are shown, followed by the command prompt.

Note: Subsequent steps require that the samples package is installed.

8. Change into the *MQ_INSTALLATION_PATH*/samp/bin directory, which contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
9. Put a message on the queue by entering the following commands

```
./amqsput QUEUE1 QMA
```

The following messages are shown:

```
Sample AMQSPUT0 start
target queue is QUEUE1
```

10. Type some message text on one or more lines, where each line is a different message. Enter a blank line to end the message input. The following message is shown:

```
Sample AMQSPUT0 end
```

Your messages are now on the queue and the command prompt is shown.

11. Get the messages from the queue, by entering the following command:

```
./amqsget QUEUE1 QMA
```

The sample program starts, and your messages are displayed.

Results

You have successfully verified your local installation.

Verifying a local server installation using the Postcard application on Solaris: ▶ Solaris

Sending messages successfully between two Postcard applications verifies a local installation.

Before you begin

The postcard application is Java based and requires a system with the ability to view a graphical display.

You must ensure that you are a member of the IBM MQ administrators group (**mqm**).

Note: Using Postcard to verify an IBM MQ installation is only possible if there is one IBM MQ installation on that box. The Default Configuration wizard will not create a default configuration if a queue manager already exists on the box. The Default Configuration wizard will run on any installation on a box but only one default configuration can be created per box. Using Postcard to verify second and subsequent installations of IBM MQ on the same box is not possible.

To verify that the local installation is working, you can run two instances of the Postcard application on the same server. The postcard application can send messages to, and receive messages from, other postcard applications. Successful sending and receiving of messages verifies that IBM MQ is installed and working correctly on the server.

Procedure

1. Log on as a user in group **mqm**.
2. Start the postcard application in one of the following ways:

a. From the command line:
   1) Change the directory to `MQ_INSTALLATION_PATH/java/bin`. `MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.
   2) Run the postcard application by entering the following command:
      ```
      ./postcard
      ```
b. From the IBM MQ Explorer:
   1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
   2) Click **Launch Postcard** to start the Postcard.

3. At the Postcard - Sign On window, type in a nickname to use to send messages within the Postcard application (for example, `User1`).
4. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Launching the Default Configuration creates a default queue manager.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK** to display your first Postcard window.
5. Run a second instance of the Postcard application by following the steps used to open the first instance of the Postcard application.
6. The Postcard - Sign On panel is displayed again. Type in a second nickname to use to send messages within this second Postcard application (for example, `User2`).
7. Repeat the selection of the queue manager that you want to use as the mailbox (as described in step 4). The queue manager you select for this second Postcard must be the same queue manager as used for the first instance of the Postcard application.
8. In the first Postcard, (User1), enter the nickname (`User2`) for the second Postcard application in the **To:** field. Because the sender and receiver are on the same server, you can leave the **On:** field blank.
9. Type a message in the **Message:** field and click **Send**.
10. The **Postcards sent and received** area of the Postcard shows details of the message. In the sending Postcard, the message is displayed as sent. In the receiving Postcard, the message is displayed as received.
11. In the receiving Postcard, (User2), double-click the message in the **Postcards sent and received** area to view it. When this message arrives, it verifies that IBM MQ is correctly installed.

What to do next

Depending on your situation, you might want to do the following tasks:
- Install IBM MQ on other servers. Follow the installation procedure for the appropriate platform. Ensure that you use the **Join Default Cluster** window in the Default Configuration wizard to add the other servers to the cluster on your first server.

- Install the IBM MQ MQI client on other servers.
- Continue with further administration tasks, see Administering IBM MQ.

Verifying a server-to-server installation on Solaris

Solaris

You can use either the command line or the postcard application to verify a server-to-server installation on Solaris.

Before you begin

For a server-to-server verification, the communication links between the two systems must be checked. Before you can do the verification, you must therefore ensure that the communications protocol is installed and configured on both systems.

On Solaris, IBM MQ supports both TCP and SNA.

The examples in this task use TCP/IP. If you do not use TCP, see Setting up communication on UNIX and Linux.

About this task

For a server-to server installation, you can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a server-to-server installation using the command line on Solaris."
- To use the postcard application to verify an installation, see "Verifying a server-to-server installation using the Postcard application on Solaris" on page 427.

Verifying a server-to-server installation using the command line on Solaris: Solaris

You can verify a server-to-server installation using two servers, one as a sender and one as a receiver.

Before you begin

- Make sure that TCP/IP and IBM MQ are installed on both servers (see "Verifying a server-to-server installation on Solaris").
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Decide which installation is the sender server and which installation is the receiver server. The installations might be on the same system, or on different systems.

About this task

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On the **receiver** server:
   a. On AIX, log in as a user in the mqm group.
   b. Check which ports are free, for example by running **netstat**. For more information about this command, see the documentation of your operating system.

      If port 1414 is not in use, make a note of 1414 to use as the port number in step 2 h. Use the same number for the port for your listener later in the verification. If it is in use, note a port that is not in use; for example 1415.
   c. Set up the environment for the installation you are using by entering the following command at the command prompt:

      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv -s
      ```

      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   d. Create a queue manager called QMB by entering the following command at the command prompt:

      ```
      crtmqm QMB
      ```

      Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.
   e. Start the queue manager by entering the following command:

      ```
      strmqm QMB
      ```

      A message tells you when the queue manager has started.
   f. Start MQSC by entering the following command:

      ```
      runmqsc QMB
      ```

      A message tells you that MQSC has started. MQSC has no command prompt.
   g. Define a local queue called RECEIVER.Q by entering the following command:

      ```
      DEFINE QLOCAL (RECEIVER.Q)
      ```

      A message tells you the queue has been created.
   h. Define a listener by entering the following command:

```
DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT ( PORT_NUMBER )
```

      Where *port_number* is the name of the port the listener runs on. This number must be the same as the number used when defining your sender channel.
   i. Start the listener by entering the following command:

      ```
      START LISTENER (LISTENER1)
      ```

      Note: Do not start the listener in the background from any shell that automatically lowers the priority of background processes.
   j. Define a receiver channel by entering the following command:

      ```
      DEFINE CHANNEL (QMA.QMB) CHLTYPE (RCVR) TRPTYPE (TCP)
      ```

      A message tells you when the channel has been created.
   k. End MQSC by typing:

      ```
      end
      ```

      Some messages are displayed, followed by the command prompt.
2. On the **sender** server:
   a. As the sender server is an AIX system, log in as a user in the mqm group.

b. Set up the environment for the installation you are using by entering the following command at the command prompt:

```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```

where `MQ_INSTALLATION_PATH` refers to the location where IBM MQ is installed.

c. Create a queue manager called QMA by entering the following command at the command prompt:

```
crtmqm QMA
```

Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.

d. Start the queue manager, by entering the following command:

```
strmqm QMA
```

A message tells you when the queue manager has started.

e. Start MQSC by entering the following command:

```
runmqsc QMA
```

A message tells you that an MQSC session has started. MQSC had no command prompt.

f. Define a local queue called QMB (to be used as a transmission queue) by entering the following command:

```
DEFINE QLOCAL (QMB) USAGE (XMITQ)
```

A message tells you when the queue has been created.

g. Define a local definition of the remote queue with by entering the following command:

```
DEFINE QREMOTE (LOCAL.DEF.OF.REMOTE.QUEUE) RNAME (RECEIVER.Q) RQMNAME ('QMB') XMITQ (QMB)
```

h. Define a sender channel by entering one of the following commands:

con-name is the TCP/IP address of the receiver system. If both installations are on the same system, the *con-name* is `localhost`. *port* is the port you noted in 1 b. If you do not specify a port, the default value of 1414 is used.

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (SDR) CONNAME ('CON-NAME(PORT)') XMITQ (QMB) TRPTYPE (TCP)
```

i. Start the sender channel by entering the following command:

```
START CHANNEL(QMA.QMB)
```

The receiver channel on the receiver server starts automatically when the sender channel starts.

j. Stop MQSC by entering the following command:

```
end
```

Some messages are displayed, followed by the command prompt.

k. If the sender server is a UNIX or Linux system, change into the `MQ_INSTALLATION_PATH/samp/bin` directory. This directory contains the sample programs. `MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

l. If both the sender server and receiver server are installations on the same system, check that the queue managers have been created on different installations by entering the following command:

```
dspmq -o installation
```

If the queue managers are on the same installation, move either QMA to the sender installation or QMB to the receiver installation by using the **setmqm** command. For more information, see setmqm.

m. Put a message on the local definition of the remote queue, which in turn specifies the name of the remote queue. Enter one of the following commands:

- On Windows:

```
amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
```

- On UNIX and Linux:

  ```
  ./amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
  ```

  A message tells you that `amqsput` has started.

n. Type some message text on one or more lines, followed by a blank line. A message tells you that `amqsput` has ended. Your message is now on the queue and the command prompt is displayed again.

3. On the **receiver** server:

   a. As your receiver server is an AIX system, change into the *MQ_INSTALLATION_PATH*/samp/bin directory. This directory contains the sample programs. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.

   b. Get the message from the queue on the receiver by entering the following command:

   ```
   ./amqsget RECEIVER.Q QMB
   ```

   The sample program starts, and your message is displayed. After a pause, the sample ends. Then the command prompt is displayed.

Results

You have now successfully verified the server-to-server installation.

Verifying a server-to-server installation using the Postcard application on Solaris: Solaris

You can use two instances of the Postcard application to verify that a server-to-server installation is working.

Before you begin

You can use the Postcard application on two servers, one instance of the Postcard application on each server, to verify that a server-to-server installation is working. Successful sending and receiving of messages verifies that IBM MQ is successfully installed, and that communication between the two servers is working correctly.

Note:
- If the system has multiple IBM MQ installations, ensure that Postcard has not been run before on any installations on that server. As the default configuration can only exist on one IBM MQ installation per system, the Default Configuration wizard and Postcard can not be used for verification of a second or any subsequent installation.
- The two server installations must be on different systems to do a server-to-server verification using the postcard application. To verify a server-to-server installation on the same machine, you can use the command line.
- Make sure that TCP/IP and IBM MQ are installed on both servers.
- Make sure that your systems are able to view a graphical display.
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Check that one of the following scenarios applies:
  - Neither server has had any queue managers created.
  - Use the Default Configuration wizard to create default queue managers on each server and link them to the default cluster.

    Details on how to use the Default Configuration wizard are provided in this topic.
  - Both servers have existing queue managers and these queue managers are in the same cluster.

If your queue managers are not in the same cluster, create new queue managers on both servers. Then create a cluster, and ensure that the queue managers that you create on each server belong to that cluster.

– You have configured channels to communicate between the two servers.

  For instructions on how to set up the channels, see “Verifying a server-to-server installation using the command line on Solaris” on page 424. After you have set up the channels, follow the instructions in this topic to verify your server-to-server installation.

Procedure

1. On the first server, log on as a user in group **`mqm`**.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *`MQ_INSTALLATION_PATH`*`/java/bin`. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:
         ```
         ./postcard
         ```
   b. From the IBM MQ Explorer:
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.
3. At the Postcard - Sign On window, type a nickname to use to send messages within the Postcard application. For example, `User1` for the first server, and `User2` for the second server.
4. When you have completed the wizard, you are taken back to the Postcard - Sign On window.
5. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Work through the Default Configuration wizard. When you get to the option to join the queue manager to the default cluster, tick the check box. On the next screen:
     – For the first server, select **yes, make it the repository for the cluster**.
     – For the second server, select **No another computer has already joined the cluster as a repository**. When requested, enter the location of the repository, by typing the name of the sender server.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK**.
6. Complete steps 1 - 5 for the second server.
7. In the Postcard on the first server:
   a. Enter the nickname (`user2`) for the Postcard application on the second server in the **To:** field.
   b. Enter the queue manager on the second server in the **On:** field.
   c. Type a message in the **Message:** field and click **Send**.

8. In the Postcard on the second server:
   a. In the **Postcards sent and received**, double-click the message marked as received to view the message from the first server.
   b. Optional: Send a postcard to the first server by adapting the instructions in step 7. You must enter details of the first server in the **To:** field and the **On:** field.

   The messages verify that IBM MQ is correctly installed and that your communication link between the two servers is working correctly.

Verifying a client installation using the command line on Solaris

Solaris

You can verify a client installation using the command line. On the server you create a queue manager, a local queue, a listener, and a server-connection channel. You must also apply security rules to allow the client to connect and make use of the queue defined. On the client you create a client-connection channel, and then use the sample PUT and GET programs to complete the verification procedure.

The verification procedure shows how to create a queue manager called `queue.manager.1`, a local queue called `QUEUE1`, and a server-connection channel called `CHANNEL1` on the server.

It shows how to create the client-connection channel on the IBM MQ MQI client workstation. It then shows how to use the sample programs to put a message onto a queue, and get the message from the queue.

The example does not address any client security issues. See Setting up IBM MQ MQI client security for details if you are concerned with IBM MQ MQI client security issues.

The verification procedure assumes that:
- The full IBM MQ server product has been installed on a server.
- The server installation is accessible on your network.
- The IBM MQ MQI client software has been installed on a client system.
- The IBM MQ sample programs have been installed.
- TCP/IP has been configured on the server and client systems. For more information, see Configuring connections between the server and client.

First, set up the server using the command line, using the instructions in "Setting up the server using the command line on Solaris" on page 430.

Once you have set up the server, you must set up the client, using the instructions in "Connecting to a queue manager, using the `MQSERVER` environment variable on Solaris" on page 431.

Finally, you can test the communications between client and server, using the instructions in "Testing communication between a client and a server on Solaris" on page 432.

Setting up the server using the command line on Solaris: ▶ Solaris

Follow these instructions to create a queue manager, queue, and channel on the server. You can then use these objects to verify the installation.

About this task

These instructions assume that no queue manager or other IBM MQ objects have been defined.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Create a user ID on the server that is not in the `mqm` group. This user ID must exist on the server and client. This is the user ID that the sample applications must be run as, otherwise a 2035 error is returned.
2. Log in as a user in the mqm group.
3. You must set various environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
```
. MQ_INSTALLATION_PATH/bin/setmqenv -s
```
   where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.
4. Create a queue manager called `QUEUE.MANAGER.1` by entering the following command:
```
crtmqm QUEUE.MANAGER.1
```
   You see messages telling you that the queue manager has been created.
5. Start the queue manager by entering the following command:
```
strmqm QUEUE.MANAGER.1
```
   A message tells you when the queue manager has started.
6. Start MQSC by entering the following command:
```
runmqsc QUEUE.MANAGER.1
```
   A message tells you that an MQSC session has started. MQSC has no command prompt.
7. Define a local queue called `QUEUE1` by entering the following command:
```
DEFINE QLOCAL(QUEUE1)
```
   A message tells you when the queue has been created.
8. Allow the user ID that you created in step 1 to use `QUEUE1` by entering the following command:
```
SET AUTHREC PROFILE(QUEUE1) OBJTYPE(QUEUE) PRINCIPAL(' non_mqm_user ') AUTHADD(PUT,GET)
```
   where *non_mqm_user* is the user ID created in step 1. A message tells you when the authorization has been set. You must also run the following command to give the user ID authority to connect:
```
SET AUTHREC OBJTYPE(QMGR) PRINCIPAL(' non_mqm_user ') AUTHADD(CONNECT)
```
   If this command is not run, a 2305 stop error is returned.
9. Define a server-connection channel by entering the following command:
```
DEFINE CHANNEL (CHANNEL1) CHLTYPE (SVRCONN) TRPTYPE (TCP)
```
   A message tells you when the channel has been created.

10. Allow your client channel to connect to the queue manager and run under the user ID that you created in step 1, by entering the following MQSC command:
    ```
    SET CHLAUTH(CHANNEL1) TYPE(ADDRESSMAP) ADDRESS(' client_ipaddr ') MCAUSER(' non_mqm_user ')
    ```
    where *client_ipaddr* is the IP address of the client system, and *non_mqm_user* is the user ID created in step 1. A message tells you when the rule has been set.
11. Define a listener by entering the following command:
    ```
    DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT (port_number)
    ```
    where *port_number* is the number of the port the listener is to run on. This number must be the same as the number used when defining your client-connection channel in "Installing an IBM MQ client on Solaris" on page 416.

    Note: If you omit the port parameter from the command, a default value of 1414 is used for the listener port. If you want to specify a port other than 1414, you must include the port parameter in the command, as shown.
12. Start the listener by entering the following command:
    ```
    START LISTENER (LISTENER1)
    ```
13. Stop MQSC by entering:
    ```
    end
    ```
    You see some messages, followed by the command prompt.

What to do next

Follow the instructions to set up the client. See "Connecting to a queue manager, using the MQSERVER environment variable on Solaris."

Connecting to a queue manager, using the MQSERVER environment variable on Solaris: Solaris

When an IBM MQ application is run on the IBM MQ MQI client, it requires the name of the MQI channel, the communication type, and the address of the server to be used. Provide these parameters by defining the MQSERVER environment variable.

Before you begin

Before you start this task, you must complete the task, "Setting up the server using the command line on Solaris" on page 430, and save the following information:
- The host name or IP address of the server and port number that you specified when creating the listener.
- The channel name of the server-connection channel.

About this task

This task describes how to connect an IBM MQ MQI client, by defining the MQSERVER environment variable on the client.

You can give the client access to the generated client channel definition table, amqclchl.tab instead; see Accessing client-connection channel definitions.

Procedure
1. Log in as the userid that you created in Step 1 of "Setting up the server using the command line on Solaris" on page 430.

2. Check the TCP/IP connection. From the client, enter one of the following commands:
   - `ping server-hostname`
   - `ping n.n.n.n`

     `n.n.n.n` represents the network address. You can set the network address in IPv4 dotted decimal form, for example, `192.0.2.0`. Alternatively, set the address in IPv6 hexadecimal form, for example `2001:0DB8:0204:acff:fe97:2c34:fde0:3485`.

   If the **`ping`** command fails, correct your TCP/IP configuration.
3. Set the `MQSERVER` environment variable. From the client, enter the following command:
   ```
   export MQSERVER=CHANNEL1/TCP/' server-address (port)'
   ```
   Where:
   - *CHANNEL1* is the server-connection channel name.
   - *server-address* is the TCP/IP host name of the server.
   - *port* is the TCP/IP port number the server is listening on.

   If you do not give a port number, IBM MQ uses the one specified in the `qm.ini` file, or the client configuration file. If no value is specified in these files, IBM MQ uses the port number identified in the TCP/IP services file for the service name `MQSeries`. If an `MQSeries` entry in the services file does not exist, a default value of `1414` is used. It is important that the port number used by the client and the port number used by the server listener program are the same.

What to do next

Use the sample programs to test communication between the client and server; see "Testing communication between a client and a server on Solaris."

Testing communication between a client and a server on Solaris: Solaris

On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

Before you begin

Complete the previous topics in this section:
- Set up a queue manager, channels, and queue.
- Open a command window.
- Set system environment variables.

About this task

Note that IBM MQ object definitions are case-sensitive. Text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure
1. Change to the `MQ_INSTALLATION_PATH/samp/bin directory`, which contains the sample programs. *`MQ_INSTALLATION_PATH`* represents the high-level directory in which IBM MQ is installed.
2. You must set certain environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```
   where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.

3. Start the PUT program for `QUEUE1` on `QUEUE.MANAGER.1` by entering the following command:

   ```
   ./amqsputc QUEUE1 QUEUE.MANAGER.1
   ```

   If the command is successful, the following messages are displayed:

   ```
   Sample AMQSPUT0 start target queue is QUEUE1
   ```

   Tip: You might get the error, `MQRC_NOT_AUTHORIZED` (2035). By default, channel authentication is enabled when a queue manager is created. Channel authentication prevents privileged users accessing a queue manager as an IBM MQ MQI client. For verifying the installation, you can either change the MCA user ID to a non-privileged user, or disable channel authentication. To disable channel authentication run the following MQSC command:

   ```
   ALTER QMGR CHLAUTH(DISABLED)
   ```

   When you finish the test, if you do not delete the queue manager, re-enable channel authentication:

   ```
   ALTER QMGR CHLAUTH(ENABLED)
   ```
4. Type some message text, then press **Enter** twice. The following message is displayed:

   ```
   Sample AMQSPUT0 end
   ```

   Your message is now on the queue that is on the server queue manager.
5. Start the GET program for `QUEUE1` on `QUEUE.MANAGER.1` by entering the following command:

   ```
   ./amqsgetc QUEUE1 QUEUE.MANAGER.1
   ```

   The sample program starts, and your message is displayed. After a short pause (approximately 30 seconds), the sample ends and the command prompt is displayed again.

Results

You have now successfully verified the client installation.

What to do next

1. You must set various environment variables on the server so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv -s
   ```

   where *`MQ_INSTALLATION_PATH`* refers to the location where IBM MQ is installed.
2. On the server, stop the queue manager by entering the following command:

   ```
   endmqm QUEUE.MANAGER.1
   ```
3. On the server, delete the queue manager by entering the following command:

   ```
   dltmqm QUEUE.MANAGER.1
   ```

Uninstalling IBM MQ on Solaris

▶ Solaris

On Solaris, you can uninstall the IBM MQ server or client using the **pkgrm** command.

Before you begin

If any updates have been applied, remove them before starting this uninstallation procedure. For more information, see Restoring the previous maintenance level on IBM MQ on Solaris.

Restriction: On Solaris, you cannot remove components from an installation. There is no supported method of doing this.

Important: You must stop all IBM MQ queue managers, other objects, and applications, before you begin the process to uninstall or modify IBM MQ.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling or modifying, if you have not already done so.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling:
   a. Log in as a user in the group `mqm`.
   b. Set up your environment to work with the installation you want to uninstall. Enter the following command:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:
      ```
      dspmq
      ```
   d. Stop all running queue managers associated with the installation you want to uninstall. Enter the following command for each queue manager:
      ```
      endmqm QMgrName
      ```
   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:
      ```
      endmqlsr -m QMgrName
      ```
3. Log in as root.
4. Uninstall IBM MQ using **pkgrm**:
   a. On a system with a single installation, enter the following command:
      ```
      pkgrm mqm
      ```
   b. On a system with multiple installations:
      ```
      pkgrm mqm-suffix
      ```
      where *suffix* is the unique name given to the packages when **crtmqpkg** was run at installation time. *suffix* is included in each of the package names that belong to a particular installation. The first installation on the system does not have a *suffix*, and is uninstalled using the same method as for a single installation.

   If a package has a dependency on `mqm`, **pkgrm** returns the name of the package. Uninstall the dependent packages first.

Results

After uninstallation, certain files under the directory trees `/var/mqm` and `/etc/opt/mqm` are not removed. These files contain user data and remain so subsequent installations can reuse the data. Most of the remaining files contain text, such as INI files, error logs, and FDC files. The directory tree `/var/mqm/shared` contains files that are shared across installations, including the executable shared library `libmqzsd.so`.

What to do next

- If the product successfully uninstalled, you can delete any files and directories contained in the installation directory.
- If there are no other IBM MQ installations on the system, and you are not planning to reinstall or migrate, you can delete the `/var/mqm` and `/etc/opt/mqm` directory trees, including the file `libmqzsd.so`. Deleting these directories destroys all queue managers and their associated data.

Installing and uninstalling IBM MQ on Windows

Windows

Installation tasks that are associated with installing IBM MQ on Windows systems are grouped in this section.

About this task

To prepare for installation and to install the IBM MQ components, complete the following tasks.

For information about how to uninstall IBM MQ, see “Uninstalling IBM MQ on Windows” on page 514.

If product fixes or updates are made available, see IBM MQ maintenance tasks for information about how to apply these changes.

Procedure

1. Check the system requirements. See “Checking requirements on Windows” on page 444.
2. Plan your installation.
   - As part of the planning process, you must choose which components to install and where to install them. See “IBM MQ features for Windows systems” on page 436.
   - You must also make some platform-specific choices. See “Planning to install IBM MQ on Windows” on page 446.
3. Install IBM MQ server. See “Installing IBM MQ server on Windows” on page 453.
4. Optional: Install an IBM MQ client. See “Installing an IBM MQ client on Windows” on page 481.
5. Verify your installation. See “Verifying an IBM MQ installation on Windows” on page 496.

Related information:

Video: Installing and verifying IBM MQ V9.0 (YouTube)

IBM MQ features for Windows systems

Windows

You can select the features that you require when you install IBM MQ.

Important: See IBM MQ license information for details of what each purchase of IBM MQ entitles you to install.

If you choose an interactive installation, before you install, you must decide what type of installation you require. For more information about the available types of installation and the features that are installed with each option, see "Installation methods for Windows" on page 448.

The following table shows the features that are available when installing an IBM MQ server or client on a Windows system.

Interactive displayed name	Non-interactive displayed name	Description	Server media	Client media
Server	Server	You can use the server to run queue managers on your system and connect to other systems over a network. Provides messaging and queuing services to applications, and support for IBM MQ client connections. V 9.0.2 From IBM MQ Version 9.0.2, additional prerequisite checking is performed on this	✓	
IBM MQ Explorer	Explorer	IBM MQ Explorer allows you to administer and monitor resources in IBM MQ.	✓	

Interactive displayed name	Non-interactive displayed name	Description	Server media	Client media
Managed File Transfer Service	MFT Service	The Managed File Transfer Service install option installs a file transfer agent that has additional capabilities beyond those provided by the file transfer agent installed using the Managed File Transfer Agent install option. These additional capabilities are:- • Create protocol bridge agents which are used to send and receive files with legacy FTP, FTPS or SFTP servers The Managed File Transfer Service install option must be installed on systems where the IBM MQ Server install option is already installed.	✓	
Managed File Transfer Logger	MFT Logger	The Managed File Transfer Logger install option installs a file transfer logger which connects to an IBM MQ queue manager, often the queue manager designated as the coordination queue manager. It logs file transfer audit related data to either a database or a file. It must be installed on systems where the IBM MQ Server install option is already installed.	✓	

Interactive displayed name	Non-interactive displayed name	Description	Server media	Client media
Managed File Transfer Agent	MFT Agent	The Managed File Transfer Agent install option installs a file transfer agent which connects to an IBM MQ queue manager and transfers file data, as messages, to other file transfer agents. These must be installed either as part of the Managed File Transfer Agent or Managed File Transfer Service install options.	✓	
Managed File Transfer Tools	MFT Tools	The Managed File Transfer Tools install option installs command line tools that are used to interact with file transfer agents. You can use these tools to start file transfers, schedule file transfers and create resource monitors from the command line. The Managed File Transfer Tools can be installed and used on either a system where file transfer agents are installed, or on a system where no file transfer agents are installed.	✓	

Interactive displayed name	Non-interactive displayed name	Description	Server media	Client media
LTS Windows Client V 9.0.1 MQI Client	Client	The Windows client is a small subset of IBM MQ, without a queue manager, that uses the queue manager and queues on other (server) systems. It can be used only when the system it is on is connected to another system that is running a full server version of IBM MQ. The client and server can be on the same system if required. V 9.0.1 From Version 9.0.1, this feature is named MQI Client.	✓	✓
LTS Java and .NET Messaging and Web Services V 9.0.1 Extended Messaging APIs	JavaMsg	The files needed for messaging using Java. This feature includes support for JMS, XMS, .NET, and IBM MQ web services. V 9.0.1 From Version 9.0.1, this feature is named Extended Messaging APIs.	✓	✓
V 9.0.1 Web Administration	V 9.0.1 Web	V 9.0.1 Adds HTTP based administration for IBM MQ through the REST API and IBM M If you want to install the Web Administration feature you must also install the I	✓	

Interactive displayed name	**Non-interactive displayed name**	**Description**	**Server media**	**Client media**
Development Toolkit	Toolkit	This feature includes sample source files, and the bindings (files .H, .LIB, .DLL, and others), that you need to develop applications to run on IBM MQ. Bindings and samples are provided for the following languages: C, C++, Visual Basic, ActiveX, Cobol, and .NET (including C#). Java and Java Message Service support is included and samples are provided for MTS (COM+), and MQSC.	✓	✓

Interactive displayed name	Non-interactive displayed name	Description	Server media	Client media
Telemetry Service	XR Service	MQ Telemetry supports the connection of Internet Of Things (IOT) devices (that is, remote sensors, actuators and telemetry devices) that use the IBM MQ Telemetry Transport (MQTT) protocol. The telemetry service, which is also know as the MQXR service, enables a queue manager to act as an MQTT server, and communicate with MQTT client apps. A set of MQTT client libraries is also available in the IBM Messaging Telemetry Clients SupportPac. These libraries help you write the MQTT client apps that IOT devices use to communicate with MQTT servers.The XR Service install option must be installed on systems where the IBM MQ Server install option is already installed. See also "Installation considerations for MQ Telemetry" on page 538.	✓	

Interactive displayed name	Non-interactive displayed name	Description	Server media	Client media
Advanced Message Security	AMS	Provides a high level of protection for sensitive data flowing through the IBM MQ network, while not impacting the end applications. You must install this component on all IBM MQ installations that host queues you want to protect. You must install the IBM Global Security Kit component on any IBM MQ installation that is used by a program that puts or gets messages to or from a protected queue, unless you are using only Java client connections.The AMS install option must be installed on systems where the IBM MQ Server install option is already installed.	✓	
AMQP Service	AMQP	Install this component to make AMQP channels available. AMQP channels support MQ Light APIs. You can use AMQP channels to give AMQP applications access to the enterprise-level messaging facilities provided by IBM MQ. The AMQP Service install option must be installed on systems where the IBM MQ Server install option is already installed.	✓	

Interactive displayed name	Non-interactive displayed name	Description	Server media	Client media
V 9.0.2 Java Runtime Environment	JRE	The Java Runtime Environment (JRE) has become a separate feature at IBM MQ Version 9.0.2. The JRE feature installs a JRE that has been tailored for IBM MQ use, and is a required feature for all other features that use Java. That is: • IBM MQExplorer • Web Administration • Telemetry Service • AMQP Service • Managed File Transfer Additional prerequisite checking is performed on this option. See Prerequisite checking for more information.	✓	✓

V 9.0.2

Windows standard installation features

The following features are part of the Windows standard installation feature set. They are the features installed by the GUI installer for a "*typical installation*".

Interactive displayed name	Non-interactive displayed name	Notes
Server	Server	
MQ Explorer	Explorer	
Java and .NET messaging and Web Services (Version 9.0.0) Extended Messaging APIs (Version 9.0.1)	JavaMsg	Feature renamed at Version 9.0.1
Web Administration (Version 9.0.1)	Web	Feature added at Version 9.0.1
Development Toolkit	Toolkit	
V 9.0.2 Java Runtime Environment	JRE	Feature added at Version 9.0.2. Prior to Version 9.0.2 JRE was always installed.

When you install an IBM MQ server, using **msiexec**, the features that are included in a *typical installation* are added to the list of features you specify in the **ADDLOCAL** directive.

If you specify **ADDLOCAL**="" all these features will be installed.

If you do not want specific features added, you must add those specific features to the **REMOVE** directive.

For example, suppose that you specify the following settings for an **msiexec** installation:

```
ADDLOCAL="Client"
REMOVE="Web,Toolkit"
```

This results in the following features being installed:

```
Server,Explorer,JavaMsg,JRE,Client
```

Related concepts:

"IBM MQ components and features" on page 192
You can select the components or features that you require when you install IBM MQ.

Before you install IBM MQ, you must choose which components to install and where to install them. You must also make some platform-specific choices.

Checking requirements on Windows

▶ Windows

Before you install IBM MQ on Windows, you must check for the latest information and system requirements.

About this task

A summary of the tasks that you must complete to check system requirements are listed here with links to further information.

Procedure

1. Check that you have the latest information, including information on hardware and software requirements. See "Where to find product requirements and support information" on page 195.
2. Check that your systems meet the initial hardware and software requirements for Windows. See "Hardware and software requirements on Windows systems" on page 445.

   The supported hardware and software environments are occasionally updated. See System Requirements for IBM MQ for the latest information.
3. Check that your systems have sufficient disk space for the installation. See Disk space requirements.
4. Check that you have the correct licenses. See "License requirements" on page 194 and IBM MQ license information.

Related concepts:

"IBM MQ installation overview" on page 192
An overview of concepts and considerations for installing IBM MQ, with links to instructions on how to install, verify, and uninstall IBM MQ on each of the supported platforms.

Related information:

IBM MQ maintenance tasks

Hardware and software requirements on Windows systems

Windows

Check that the server environment meets the prerequisites for installing IBM MQ for Windows and install any prerequisite software that is missing from your system from the server DVD.

Before you install IBM MQ, you must check that your system meets the hardware and software requirements. For the latest details of hardware and software requirements on all supported platforms, see System Requirements for IBM MQ.

You must also review the product readme file, which includes information about last-minute changes and known problems and workarounds. For the latest version of the product readme file, see the IBM MQ, WebSphere MQ, and MQSeries product readmes web page.

Storage requirements for IBM MQ server

The storage requirements depend on which components you install, and how much working space you need. The storage requirements also depend on the number of queues that you use, the number and size of the messages on the queues, and whether the messages are persistent. You also require archiving capacity on disk, tape, or other media. For more information, see System Requirements for IBM MQ.

Disk storage is also required:

- Prerequisite software
- Optional software
- Your application programs

Requirements for IBM MQ Explorer

IBM MQ Explorer can be installed either as part of the product installation, or from the stand-alone IBM MQ Explorer support pack MS0T.

- The product version is available for Windows x86_64.
- The support pack version is available for Windows x86 and x86_64.

The requirements for installing IBM MQ Explorer as part of the product installation, and not as the stand-alone IBM MQ Explorer support pack MS0T, include:

- A 64-bit (x86_64) processor
- 64-bit Windows operating system

Attention: V 9.0.0 The 32-bit version of IBM MQ Explorer is no longer supported.

For further information about Windows requirements, see IBM MQ Explorer Requirements and the following web pages:

- Windows 7 system requirements
- Windows 8 system requirements

Installation directories used for Windows operating systems

The 64-bit IBM MQ server or client, by default, installs its program directories into the 64-bit installation location: `C:\Program Files\IBM\MQ`.

Attention: ▶ V 9.0.0 The 32-bit client version of IBM MQ is no longer supported.

The default data directory that is used by IBM MQ changed in Version 8.0 to `C:\ProgramData\IBM\MQ`. This change affects both servers, in 32 and 64 bits and clients in 64 bits. However, if there has been a previous installation of IBM MQ on the machine on which you are installing, the new installation continues to use the existing data directory location. For more information, see Program and data directory locations.

Installing prerequisite software

To install the prerequisite software that is provided on the IBM MQ Server DVD (which does not include service packs or web browsers), choose one of the following options:

- Use the IBM MQ installation procedure.

  When you install using the IBM MQ Server DVD, there is a **Software Prerequisites** option in the IBM MQ Installation Launchpad window. You can use this option to check what prerequisite software is already installed and what is missing, and then install any missing software.
- Use Windows Explorer:
  1. Use Windows Explorer to select the `Prereqs` folder on the IBM MQ Server DVD.
  2. Select the folder for the software item to be installed.
  3. Start the installation program.

IBM MQ Explorer Requirements

Planning to install IBM MQ on Windows

▶ Windows

Before you install IBM MQ on Windows, you must choose which components to install and where to install them. You must also make some platform-specific choices.

About this task

The following steps provide links to additional information to help you with planning your installation of IBM MQ on Windows.

As part of your planning activities, make sure that you review the information on hardware and software requirements for the platform on which you are planning to install IBM MQ. For more information, see "Checking requirements on Windows" on page 444.

Procedure

1. Decide which IBM MQ components and features to install. See "IBM MQ components and features" on page 192.

   Important: Ensure that your enterprise has the correct license, or licenses, for the components that you are going to install. For more information, see "License requirements" on page 194 and IBM MQ license information.
2. Review the options for naming your installation. In some cases, you can choose an installation name to use instead of the default name. See "Installation name on UNIX, Linux, and Windows" on page 197.
3. Review the options and restrictions for choosing an installation location for IBM MQ. For more information, see "Installation location on Multiplatforms" on page 198.
4. If you plan to install multiple copies of IBM MQ, see "Multiple installations on UNIX, Linux, and Windows" on page 200.
5. If you already have a primary installation, or plan to have one, see "Primary installation on UNIX, Linux, and Windows" on page 202.
6. Make sure that the communications protocol needed for server-to-server verification is installed and configured on both systems that you plan to use. For more information, see "Server-to-server links on UNIX, Linux, and Windows" on page 210.

Additional Windows features prerequisite checking

Windows V 9.0.2

There are two Windows installation features that have additional prerequisite checking enabled in the Windows IBM MQ installer from IBM MQ Version 9.0.2. These are the `Server` feature and the `Java Runtime Environment` (JRE) feature. These features are required by other features and installing those features, without these prerequisite checks, would cause those features to be unusable.

If you perform a Graphical User Interface installation, and select the **custom install** option, you can deselect the `JRE` or `Server` features.

Attention: Dialog panels prevent you from completing the installation, until you have resolved any issues.

If you perform a silent installation, and you elect to **`REMOVE`** the `Server` or `JRE` features while installing any other features that require those features, the `Server` and `JRE` features, as appropriate, will be added to your selected installation features.

Table Table 60 on page 448 describes how the selection of certain installation features requires the `Server` or `JRE` to be added automatically.

Table 60. Installation features requiring either the Server or JRE feature

	Required by	Non-interactive name
Server	Web Administration	Web
JRE	IBM MQ Explorer Telemetry Service Managed File Transfer Service Managed File Transfer Agent Managed File Transfer Logger Managed File Transfer Tools AMQP Service Web Administration	Explorer XR Service MFT Service MFT Agent MFT Logger MFT Tools AMQP Service Web

To check whether the `JRE` or `Server` features have been installed, look in the `[INSTALLDIR]\swidtag` directory. If the:
- `ibm.com_IBM_MQ-9.0.`**`x`**`.swidtag` file is present, the `Server` has been installed
- `IBM_MQ_JRE-1.8.0.mqtag` file is present, the `JRE` has been installed.

If this is not what you require, consult the installation log.

Important: Each of the `JRE` and `Server` features are part of the set of Windows standard IBM MQ installation features. To remove the `JRE` (or the `Server`) when installing silently, add the feature to the **`REMOVE`** directive, do not merely omit it from the **`ADDLOCAL`** directive. See "Windows standard installation features" on page 443 for further details.

Installation methods for Windows

▶ Windows

If you install IBM MQ on Windows, there are several different installation types to choose from.

If you are migrating from an earlier version of IBM MQ, see Migration planning before moving to the latest version of IBM MQ. To modify an existing installation, see "Modifying a server installation" on page 469.

Interactive or Non-Interactive installation

IBM MQ for Windows is installed using the Microsoft Installer (MSI). You can use the Installation Launchpad to invoke MSI, this process is called an attended or interactive installation. Or, you can invoke MSI directly for a silent installation, without using the IBM MQ Installation Launchpad. This means that you can install IBM MQ on a system without interaction. This process is called unattended, silent, or non-interactive installation, and is useful for installing IBM MQ over a network on a remote system.

For a list of interactive and non-interactive features, see "IBM MQ features for Windows systems" on page 436.

Interactive installation

If you choose an interactive installation, before you install, you must decide what type of installation you require. Table 61 shows the installation types available, and the features that are installed with each option. For the prerequisites required for each feature, see System Requirements for IBM MQ.

The installation types are:
- Typical installation
- Compact installation
- Custom Installation

You can also:
- Specify the installation location, name, and description.
- Have multiple installations on the same computer.

See "Primary installation on UNIX, Linux, and Windows" on page 202 for important information about these features, including whether to designate your installation as the *primary installation*.

Table 61. Features installed with each type of interactive installation

Installation type	Server Features installed	Client Features installed	Comments
Typical	• Server • IBM MQ Explorer • Development Toolkit • LTS Java and .NET Messaging and Web Services V 9.0.1 Extended Messaging APIs • V 9.0.1 Web Administration	• LTS Windows Client V 9.0.1 MQI Client • Development Toolkit • LTS Java and .NET Messaging and Web Services V 9.0.1 Extended Messaging APIs	The default option. Features are installed to default locations with a default installation name. Java and .NET Messaging and Web Services (known as Extended Messaging APIs from Version 9.0.1) includes IBM MQ classes for .NET, support for the Microsoft Windows Communication Foundation (WCF) for use with Microsoft.NET 3.
Compact	• Server only	• LTS Windows Client V 9.0.1 MQI Clientonly	The feature is installed to the default location with a default installation name.

Table 61. Features installed with each type of interactive installation (continued)

Installation type	**Server Features installed**	**Client Features installed**	**Comments**
Custom	By default, the following features are preselected: • Server • IBM MQ Explorer • Development Toolkit • LTS Java and .NET Messaging and Web Services V 9.0.1 Extended Messaging APIs • V 9.0.1 Web Administration A custom installation can also install: • Telemetry Service • Advanced Message Security • Managed File Transfer Service • Managed File Transfer Logger • Managed File Transfer Agent • Managed File Transfer Tools • LTS Windows Client V 9.0.1 MQI Client	By default, the following features are preselected: • LTS Windows Client V 9.0.1 MQI Client • Development Toolkit • LTS Java and .NET Messaging and Web Services V 9.0.1 Extended Messaging APIs	A server custom installation can be used if you want to install the Windows client from within the server image. All the available features are listed and you can select which ones to install, and where to install them. You can also name and provide a description for the installation. Use a custom installation when you want to specify that the installation is primary. Java and .NET Messaging and Web Services (known as Extended Messaging APIs from Version 9.0.1) includes IBM MQ classes for .NET, support for the Microsoft Windows Communication Foundation (WCF) for use with Microsoft.NET 3 or later.

If Microsoft.NET is not installed before IBM MQ and you add it, rerun **`setmqinst -i -n Installationname`** if this is a primary installation.

The following table describes which level of .NET is required for which function:

Table 62. Required levels of Microsoft.NET

IBM MQ function	**.NET version required**
IBM MQ classes for .NET. For more information, see: Getting started with IBM MQ classes for .NET 2	.NET 2
The IBM MQ custom channel for WCF. For more information, see Developing WCF applications with IBM MQ. To build the sample solution files, either the Microsoft.NET 3.5 SDK, or Microsoft Visual Studio 2008 is needed. For more information, see: Software requirements for the WCF custom channel for IBM MQ	.NET framework 3.5 or later

For instructions on how to install IBM MQ on Windows systems, see Installing IBM MQ Server on Windows systems and “Installing an IBM MQ client on Windows” on page 481.

Non-interactive installation

If you choose a non-interactive installation the system on which you want to install must be able to access the IBM MQ image, or a copy of the files, and you must be able to access the system.

If you are running IBM WebSphere MQ Version 7.5 or later, with User Account Control (UAC) enabled, you must invoke the non-interactive installation from an elevated command prompt. Elevate a command prompt by using a right-click to start the command prompt and choose **Run as administrator**. If you try to silently install from a non-elevated command prompt, the installation fails with an error of AMQ4353 in the installation log.

There are several ways to invoke MSI:
- Using the `msiexec` command with command-line parameters.
- Using the `msiexec` command with a parameter that specifies a response file. The response file contains the parameters that you normally supply during an interactive installation. See "Installing the server using msiexec" on page 455.
- Use the `MQParms` command with command-line parameters, a parameter file, or both. The parameter file can contain many more parameters than a response file. See "Installing the server using the MQParms command" on page 463.

If the system belongs to a Windows domain you may need a special domain ID for the IBM MQ service, see "Considerations when installing IBM MQ server on Windows" on page 452 for more information.

Clearing IBM MQ installation settings

When you install IBM MQ on Windows, various values, such as the location of the data directory for IBM MQ, are stored in the registry.

In addition, the data directory contains configuration files that are read at installation time. To provide a trouble free re-installation experience, these values and files persist even after the last IBM MQ installation has been removed from the machine.

This is designed to assist you, and
- Allows you to easily uninstall and reinstall
- Ensures that you do not lose any previously defined queue managers in the process.

However in some cases this feature can be an annoyance. For example, if you want to:
- Move the data directory
- Pick up the default data directory for IBM MQ Version 9.0. See Windows: changes from IBM MQ Version 8.0 for further information.
- Install as if installing on a new machine, for example, for test purposes.
- Remove IBM MQ permanently.

To assist you in these situations, IBM MQ Version 8.0 onwards supplies a Windows command file, on the root directory of the installation media, called **`ResetMQ.cmd`**.

To run the command, enter the following:

```
ResetMQ.cmd [LOSEDATA] [NOPROMPT]
```

Attention: The parameters **`LOSEDATA`** and **`NOPROMPT`** are optional. If you supply either, or both, of these parameters, the following action results:

`LOSEDATA`
Existing queue managers become unusable. However, the data remains on disk.

NOPROMPT
Configuration information is permanently removed without further prompting.

You can run this command only after the last IBM MQ installation has been removed.

Important: You should use this script with caution. The command, even without specifying the optional parameter **LOSEDATA**, can irrecoverably remove queue manager configuration.

"Considerations when installing IBM MQ server on Windows"
There are some considerations relating to security that you should take into account when installing an IBM MQ server on Windows. There are some additional considerations relating to the object naming rules and logging.

Considerations when installing IBM MQ server on Windows

▶ Windows

There are some considerations relating to security that you should take into account when installing an IBM MQ server on Windows. There are some additional considerations relating to the object naming rules and logging.

Security considerations when installing IBM MQ server on a Windows system

- If you are installing IBM MQ on a Windows domain network running Active Directory Server, you probably need to obtain a special domain account from your domain administrator. For further information, and the details that the domain administrator needs to set up this special account, see Configuring IBM MQ accounts.
- When you are installing IBM MQ server on a Windows system you must have local administrator authority .
- In order to administer any queue manager on that system, or to run any of the IBM MQ control commands your user ID must belong to the *local* `mqm` or `Administrators` group . If the local `mqm` group does not exist on the local system, it is created automatically when IBM MQ is installed. A user ID can either belong to the local `mqm` group directly, or belong indirectly through the inclusion of global groups in the local `mqm` group.
- Windows versions with a User Account Control (UAC) feature restricts the actions users can perform on certain operating system facilities, even if they are members of the Administrators group. If your user ID is in the Administrators group but not the mqm group you must use an elevated command prompt to issue IBM MQ admin commands such as crtmqm, otherwise the error AMQ7077 is generated. To open an elevated command prompt, right-click the start menu item, or icon, for the command prompt, and select **Run as administrator**
- Some commands can be run without being a member of the mqm group (see Authority to administer IBM MQ).
- If you intend to administer queue managers on a remote system, your user ID must be authorized on the target system.
- As with other versions of Windows, the object authority manager (OAM) gives members of the Administrators group the authority to access all IBM MQ objects even when UAC is enabled.

Naming considerations

Windows has some rules regarding the naming of objects created and used by IBM MQ. These naming considerations apply to IBM WebSphere MQ Version 7.5 or later.

- Ensure that the machine name does not contain any spaces. IBM MQ does not support machine names that include spaces. If you install IBM MQ on such a machine, you cannot create any queue managers.
- For IBM MQ authorizations, names of user IDs and groups must be no longer than 64 characters (spaces are not allowed).

- An IBM MQ for Windows server does not support the connection of a Windows client if the client is running under a user ID that contains the @ character, for example, abc@d. Similarly, the client user ID should not be the same as local group.
- A user account that is used to run the IBM MQ Windows service is set up by default during the installation process; the default user ID is MUSR_MQADMIN. This account is reserved for use by IBM MQ. Refer to Configuring IBM MQ accounts.
- When an IBM MQ client connects to a queue manager on the server, the username under which the client runs must not be same as the domain or machine name. If the user has the same name as the domain or machine, the connection fails with return code 2035(MQRC_NOT_AUTHORIZED).

Logging

You can set up logging during installation which assists you in troubleshooting any problems you might have with the installation.

From Version 7.5, logging is enabled by default from the Launchpad. You can also enable complete logging, for more information, see How to enable Windows Installer logging.

Digital signatures

The IBM MQ programs and installation image are digitally signed on Windows to confirm that they are genuine and unmodified. From IBM MQ Version 8.0 the SHA-256 with RSA algorithm is used to sign the IBM MQ product.

Installing IBM MQ server on Windows

Windows

This topic describes how to install IBM MQ server on Windows systems either by using the Launchpad, or by using the MSI technology.

About this task

To install IBM MQ server on Windows systems, you can choose either to install with the Launchpad or to install using MSI technology. MSI provides both an interactive installation and a non interactive installation.

Procedure

- To install IBM MQ server by using the Launchpad, see “Installing the server using the Launchpad” on page 454.
- To install IBM MQ server on by using the MSI technology, see “Installing the server using msiexec” on page 455.

Related concepts:

"Modifying a server installation" on page 469
You can modify an IBM MQ server installation interactively using the launchpad or non-interactively using msiexec.

"Configuring an IBM MQ server" on page 470
After installing IBM MQ server, it is necessary to configure it.

Related tasks:

"Uninstalling IBM MQ on Windows" on page 514
You can uninstall the IBM MQ MQI clients and servers on Windows systems by using the control panel, the command line (`msiexec`), `MQParms`, or by using the installation media, in which case you can optionally remove queue managers as well.

Installing the server using the Launchpad

Windows

This topic describes how to install IBM MQ server on Windows systems by using the Launchpad. This procedure can be used for installing a first or a subsequent installation.

About this task

These instructions cover how to display the installation Launchpad window. You can use the launchpad to make a compact, typical, or custom installation of IBM MQ. You can reuse the launchpad multiple times to install further installations. It automatically selects the next available installation name, instance, and location to use. To view all the installation types and the features that are installed with each option, see "Installation methods for Windows" on page 448.

Note that if you have previously uninstalled IBM MQ from your system (see "Uninstalling IBM MQ on Windows" on page 514), some configuration information might remain, and some default values might be changed.

Procedure

1. Access the IBM MQ installation image. The location might be the mount point of the DVD, a network location, or a local file system directory.
2. Locate `setup.exe` in the base directory of the IBM MQ installation image.
   - From a DVD, this location might be `E:\setup.exe`
   - From a network location, this location might be `m:\instmqs\setup.exe`
   - From a local file system directory, this location might be `C:\instmqs\setup.exe`
3. Double-click the **Setup** icon to start the installation process. It is possible to run either by:
   - Running `setup.exe` from the command prompt. Or
   - Double-clicking `setup.exe` from Windows Explorer.

   If you are installing on a Windows system with UAC enabled, accept the Windows prompt to allow the launchpad to run as elevated. During installation, you might also see Open File - Security Warning dialog boxes that list International Business Machines Limited as the publisher. Click **Run** to allow the installation to continue.

   The IBM MQ Installation Launchpad window is displayed.
4. Continue to follow the Launchpad instructions as shown on screen.

What to do next

- If you have chosen this installation to be the primary installation on the system, you must now set it as the primary installation. Enter the following command at the command prompt:

```
MQ_INSTALLATION_PATH\bin\setmqinst -i -p MQ_INSTALLATION_PATH
```

You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.

- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see "Verifying an IBM MQ installation on Windows" on page 496.

Related concepts:

You can uninstall the IBM MQ MQI clients and servers on Windows systems by using the control panel, the command line (**msiexec**), **MQParms**, or by using the installation media, in which case you can optionally remove queue managers as well.

Installing the server using msiexec

Windows

IBM MQ on Windows uses the MSI technology to install software. MSI provides both an interactive installation and a non interactive installation.

Before you begin

If you are running IBM MQ on Windows systems with User Account Control (UAC) enabled, you must invoke the installation with elevated privileges. If you are using the Command prompt or IBM MQ Explorer elevate privileges by using a right-click to start the program and selecting Run as administrator. If you try to run **msiexec** without using elevated privileges, the installation fails with an error of AMQ4353 in the installation log.

About this task

IBM MQ on Windows uses the MSI technology to install software. MSI provides both an interactive installation and a non interactive installation. An interactive installation displays panels and ask questions.

The **msiexec** command uses parameters to give MSI some or all of the information that can also be specified through panels during an interactive installation. This means that a user can create a reusable automated or semi-automated installation configuration. Parameters can be given through the command line, a transform file, a response file, or a combination of the three.

Procedure

To install using msiexec, at the command line, enter the **msiexec** command in the following format:

```
msiexec parameters [USEINI="response-file"] [TRANSFORMS="transform_file"]
```

Where:

parameters
: are either command-line parameters preceded by a `/` character, or property=value pairs (if using both forms of parameter always put the command-line parameters first). For further information, see "Specifying command line parameters with msiexec," which contains a link to the web site that lists all the command line parameters that are available.

  For an unattended installation, you must include the /q or /qn parameter in the command line. Without this parameter, the installation is interactive.

  Note: You must include the **`/i`** parameter and the file location of the IBM MQ installer package.

response-file
: is the full path and file name of the file that contains the [Response] stanza and the required property=value pairs, for example `C:\MyResponseFile.ini`. An example response file, `Response.ini`, is supplied with IBM MQ. This file contains default installation parameters. For further information, see "Using a response file with msiexec" on page 457.

transform_file
: is the full path and file name of a transform file. For further information, see "Using transforms with msiexec for server installation" on page 462 and "Choosing MSI Instance IDs for multiple server installations" on page 461.

Note: For a silent installation to succeed, the AGREETOLICENSE="yes" property must be defined either on the command line or in the response file.

Results

After the command has been entered, the command prompt immediately reappears. IBM MQ is installing as a background process. If you have entered parameters to produce a log, check this file to see how the installation is progressing. If the installation completes successfully, you see the message `Installation operation completed successfully` in the log file.

Specifying command line parameters with msiexec:
About this task

The **`msiexec`** command can accept two types of parameters on the command line, as follows:

- Standard command line parameters, preceded by a `/` character.

  For a table of the **`msiexec`** command line parameters, see the MSDN Command-Line Options web page.
- Property=value pair parameters on the command line. All the parameters available for use in a response file can be used on the command line, for a list of these, see Table 64 on page 458. In addition there are some extra property=value pair parameters that are only for use on the command line, for details see Table 63 on page 457.

  When using the property=value pair parameters note that:
  - Property strings must be in uppercase.
  - Value strings are not case-sensitive, except for feature names. You can enclose value strings in double quotation marks. If a value string includes a blank, enclose the blank value string in double quotation marks.
  - For a property that can take more than one value, use the format:

    ```
    ADDLOCAL="Server,Client"
    ```
  - For properties taking paths and filenames, for example PGMFOLDER, you must supply the paths as absolute paths and not relative; that is, `C:\folder\file` and not `".\folder\file"`.

  When using property=value pair and command line parameters with the **`msiexec`** command, enter command line parameters first.

If a parameter is specified both on the command line and in a response file, the setting on the command line takes precedence.

Example

Here is an example of a typical **msiexec** command. All parameters, separated by one or more spaces, must be typed on the same line as the **msiexec** call.

```
msiexec
/i "path\MSI\IBM MQ.msi"
/l*v c:\install.log
/q
TRANSFORMS="1033.mst"
AGREETOLICENSE="yes"
ADDLOCAL="Server"
```

Here is an example of a typical **msiexec** command when you are installing a second copy of IBM WebSphere MQ Version 7.5, or later. All parameters, separated by one or more spaces, must be typed on the same line as the **msiexec** call.

```
msiexec
/i "path\MSI\IBM MQ.msi"
/l*v c:\install.log
/q
TRANSFORMS=":InstanceId2.mst;1033.mst"
AGREETOLICENSE="yes"
ADDLOCAL="Server"
MSINEWINSTANCE=1
```

Where `/l*v c:\install.log` writes installation log to file `c:\install.log`.

The following table shows the parameters which can only be provided on the command line and not in a response file.

Table 63. msiexec property=value parameters

Property	Values	Meaning
USEINI	*path* \ *file_name*	Use the specified response file. See "Using a response file with msiexec"
SAVEINI	*path* \ *file_name*	Generate a response file during installation. The file contains those parameters selected for this installation that a user might make during an interactive installation.
ONLYINI	1|yes| ""	1, yes or any value other than null. End the installation before updating the target system, but after generating a response file, if this is specified. "". Continue the installation and update the target system (the default).
TRANSFORMS	:InstanceId *x*.mst| *path* \ *file_name* | :InstanceId *x*.mst; *path* \ *file_name*	The :InstanceId *x*.mst value is only required for a subsequent installation of IBM MQ. The *path* \ *file_name* specifies what transform (.mst) files must be applied to the product. For example, `"1033.mst"` specifies the supplied U.S. English transform file.
MSINEWINSTANCE	1	This property is only required for subsequent installations of IBM MQ

Using a response file with msiexec:

About this task

You can use the **msiexec** command with a parameter which specifies additional properties that are defined in a response file. You can combine the msiexec command-line parameters described in “Specifying command line parameters with msiexec” on page 456.

A response file is an ASCII text file, with a format like a Windows .ini file, that contains the stanza [Response]. The [Response] stanza contains some or all the parameters that would normally be specified as part of an interactive installation. The parameters are given in a property=value pair format. Any other stanzas in the response file are ignored by **msiexec**. An example response file, Response.ini, is supplied with IBM MQ. It contains the default installation parameters.

Procedure

A typical example of an msiexec command is: `msiexec /i "path\MSI\IBM MQ.msi" /l*v c:\install.log TRANSFORMS= "1033.mst" USEINI= "C:\MQ\Responsefile"`
If a parameter is specified both on the command line and in a response file, the setting on the command line takes precedence. All the parameters available for use in a response file can also be used on the command line, for a list of these see Table 64.
In the response file, all text is in English, and comments begin with a **;** character.
For information about creating a response file, see “Creating a response file for server installation” on page 463.

Example

An example of a typical response file:

```
[Response]
PGMFOLDER="c:\mqm"
DATFOLDER="c:\mqm\data"
LOGFOLDER="c:\mqm\log"
AGREETOLICENSE="yes"
LAUNCHWIZ=""
WIZPARMFILE="d:\MQParms.ini"
ADDLOCAL="Server,Client"
REMOVE="Toolkit"
```

Table 64. Response file parameters

Property	Values	Meaning
PGMFOLDER	*path*	Folder for the IBM MQ program files. For example, c:\mqm.
DATFOLDER	*path*	Folder for the IBM MQ data files. For example, c:\mqm\data. **Note:** Multiple installations of IBM MQ all use the same **DATFOLDER**.
LOGFOLDER	*path*	Folder for the IBM MQ queue manager log files. For example, c:\mqm\log. **Note:** Multiple installations of IBM MQ all use the same **LOGFOLDER**.

Table 64. Response file parameters (continued)

Property	**Values**	**Meaning**
USERCHOICE	0|no	If the command line or response file specifies parameters to install features, a dialog can be displayed to prompt the user to accept the preselected options, or review and possibly change them. 0 or no. Suppresses display of the dialog. Anything else. Dialog is displayed. Not used for a silent installation.
AGREETOLICENSE	yes	Accept the terms of the license. Set to `yes` before a silent installation. If the installation is not silent, this parameter is ignored.
KEEPQMDATA	**keep** |delete	If the Server feature is to be uninstalled, whether to delete any existing queue managers. delete removes any existing queue managers. keep, or any other value, keeps them. **Note:** This property is only valid on a final server uninstallation. Otherwise this property is ignored.
LAUNCHWIZ	0|1|yes|no| **""**	0 or no. Do not launch the Prepare IBM MQ wizard after IBM MQ is installed. 1 or yes. Launch the Prepare IBM MQ wizard if the Server feature is installed. "". Launch the Prepare IBM MQ wizard to install the Server (the default). If this option is to launch the Prepare IBM MQ wizard, you can specify the WIZPARMFILE, either in this file, or on the command line. The Prepare IBM MQ wizard must be run to make your IBM MQ installation operational. If you choose not to launch it here, you must run it before using IBM MQ.
WIZPARMFILE	*path* \ *file_name*	When specified, the file that contains the parameters to pass to the Prepare IBM MQ wizard when it is launched. These are in the [Services].
ADDLOCAL	*feature, feature, All* | ””	A comma-separated list of features to install locally. For a list of valid feature names, see “IBM MQ features for Windows systems” on page 436. All installs all features "" installs the typical features. If you do not want a feature use `REMOVE="`*`feature`*`"` **Note:** If this is a new installation the typical features are installed by default irrespective of the feature list provided in the ADDLOCAL property. If you do not want a feature use `REMOVE="`*`feature`*`"`

Table 64. Response file parameters (continued)

Property	Values	Meaning
REMOVE	*feature*, *feature*, |All| ""	A comma-separated list of features to remove. For a list of valid feature names, see "IBM MQ features for Windows systems" on page 436. All uninstalls all features "" uninstalls no features (the default).
STARTSERVICE	0|no| ""	0 or no. Do not start the IBM MQ Service at the end of installation. "" (the default). Start the IBM MQ Service at the end of installation if it was running at the start, or if this is a new installation. Anything else. Start the Service at the end of the installation. Ignored if the server feature is not installed. If you do not start the IBM MQ Service, IBM MQ will not be operational and queue managers will not start. You must run the Prepare IBM MQ wizard for the service to be correctly configured. This parameter is only valid if LAUNCHWIZ is set to no.
STARTTASKBAR	0|no| ""	0 or no. Do not start the IBM MQ taskbar application at the end of installation. "" (the default). Start the IBM MQ taskbar application at the end of installation if it was running at the start, or if this is a new installation. Anything else. Start the taskbar application at the end of the installation. Ignored if the server feature is not installed. This parameter is only valid if LAUNCHWIZ is set to no.
INSTALLATIONDESC	"Description of installation"	Sets the installation description from the command line. Subject to the documented installation description length limitations
INSTALLATIONNAME	[INSTALLATION0,]Name	Sets the installation name from the command line. Subject to the documented installation name character and length limitations. **Note:** Supply INSTALLATION0,Name only when upgrading from versions of the product before IBM WebSphere MQ Version 7.1.
MAKEPRIMARY	0|1| ""	Makes the installation primary, if possible, or removes the primary flag. 1 = Make primary, 0 = Make non-primary, - use default algorithm **Note:** This option is ignored if a version of the product before IBM WebSphere MQ Version 7.1 is installed, or if another installation of IBM WebSphere MQ Version 7.1, or later, is present and set as the primary.

The typical features include the following features:
- Server
- MQ Explorer
- Java and .NET Messaging and Web Services V 9.0.1 Renamed to Extended Messaging APIs from Version 9.0.1
- V 9.0.1 Web Administration
- Development Toolkit
- V 9.0.2 Java Runtime Environment

Choosing MSI Instance IDs for multiple server installations: Windows

For multiple silent installations, for each version that is installed you must find an MSI instance ID that is available to use for that installation.

About this task

In order to support silent, or non-interactive, multiple installations, you need to find out whether the instance ID you want to use is already in use or not and choose the appropriate one. For each installation media (for example, each client and server), Instance ID 1 is the default ID which is used for single installations. If you want to install alongside Instance ID 1 you need to specify which instance you want to use. If you have already installed instance 1, 2, and 3 then you need to find out what the next available instance is, for instance, Instance ID 4. Similarly, if instance 2 has been removed, you need to find out that there is a gap that can be reused. You can find out which Instance ID is currently in use by using the **`dspmqinst`** command.

Procedure

1. Type **`dspmqinst`** to find a free MSI Instance in the media being installed by reviewing the MSIMedia and MSIInstanceId values for the versions already installed. For example:
   ```
   InstName: Installation1
   InstDesc:
   Identifier:    1
   InstPath:      C:\Program Files\IBM\MQ
   Version:       9.0.0.0
   Primary:       Yes
   State:         Available
   MSIProdCode:   {74F6B169-7CE6-4EFB-8A03-2AA7B2DBB57C}
   MSIMedia:      9.0 Server
   MSIInstanceId: 1
   ```
2. If MSI Instance ID 1 is in use and you want to use MSI Instance ID 2, the following parameters must be added to the msiexec call:
   ```
   MSINEWINSTANCE=1 TRANSFORMS=":instanceId7.mst;1033.mst"
   ```

What to do next

For multiple installations, the **INSTALLATIONNAME** or **PGMFOLDER** must be supplied as an additional parameter on any non-interactive installation command. Supplying the **INSTALLATIONNAME** or **PGMFOLDER** ensures that you do not work with the wrong installation in case you omit or incorrectly specify the **TRANSFORMS** parameter.

Using transforms with msiexec for server installation: Windows

MSI can use transforms to modify an installation. During IBM MQ installation, transforms can be used to support different national languages. IBM MQ is supplied with transform files in the `\MSI` folder of the Server image. These files are also embedded in the IBM MQ Windows installer package, `IBM MQ.msi`.

On the **msiexec** command line, you can specify the required language by using the TRANSFORMS property in a property=value pair. For example:

```
TRANSFORMS="1033.mst"
```

You can also specify the full path and file name of the transform file. Again, the quotation marks surrounding the value are optional. For example:

```
TRANSFORMS="D:\Msi\1033.mst"
```

Table 65 shows the locale identifier, language, and the transform file name to use in the **msiexec** command line.

You might need to merge transforms to install multiple installations of the same version, for example:

```
TRANSFORMS=":InstanceId2.mst;D:\Msi\1033.mst"
```

You can also specify the required language by using the MQLANGUAGE property with the **MQParms** command. For information about the msiexec property=value parameters, see “MQParms parameter file - server installation” on page 465.

Parameters

Table 65. Supplied transform files for various language support. This table shows the supplied transform files, the resulting language, and the numeric value to use in the **msiexec** command line.

Language	Transform File name	Value
U.S. English	1033.mst	1033
German	1031.mst	1031
French	1036.mst	1036
Spanish	1034.mst	1034
Italian	1040.mst	1040
Brazilian Portuguese	1046.mst	1046
Japanese	1041.mst	1041
Korean	1042.mst	1042
Simplified Chinese	2052.mst	2052
Traditional Chinese	1028.mst	1028
Czech	1029.mst	1029
Russian	1049.mst	1049
Hungarian	1038.mst	1038
Polish	1045.mst	1045

Creating a response file for server installation: Windows

A response file is used with **msiexec**. You can create it in three ways.

About this task

A response file is used with the **msiexec** command. For further information, see "Using a response file with msiexec" on page 457.

Procedure

There are three ways to create a response file for installation:
- Copy and edit the file `Response.ini` that is supplied on the IBM MQ Windows Server DVD, using an ASCII file editor.
- Create your own response file using an ASCII file editor.
- Use the **msiexec** command with the **SAVEINI** (and optionally, the **ONLYINI**) command line parameters to generate a response file that contains the same installation options. See Table 63 on page 457.

Example

A typical example of using **msiexec** with the **SAVEINI** parameter is here:

```
msiexec /i "path\IBM MQ.msi" /q SAVEINI="response_file"
TRANSFORMS="1033.mst" AGREETOLICENSE="yes"
```

Installing the server using the MQParms command: Windows

You can use the **MQParms** command to invoke installation or uninstallation of the IBM MQ server.

Before you begin

The **MQParms** command can use parameters on a command line, or those specified in a parameter file. The parameter file is an ASCII text file that contains the parameter values that you want to set for the installation. The **MQParms** command takes the specified parameters and generates the corresponding **msiexec** command line.

This means that you can save all the parameters that you want to use with the **msiexec** command in a single file.

If you are running IBM MQ on Windows systems with User Account Control (UAC) enabled, you must invoke the installation with elevated privileges. If you are using the Command prompt or IBM MQ Explorer elevate privileges by using a right-click to start the program and selecting **Run as administrator**. If you try to run the `MQParms` program without using elevated privileges, the installation fails with an error of AMQ4353 in the installation log.

For silent operations, this must include the **/q** or **/qn** parameter, either on the command line, or in the [MSI] stanza of the parameter file. You must also set the AGREETOLICENSE parameter to "yes".

You can specify many more parameters in the parameter file that you use with the `MQParms` command than you can in the response file that you use directly with the **msiexec** command. Also, as well as parameters that the IBM MQ installation uses, you can specify parameters that can be used by the Prepare IBM MQ wizard.

If you do not complete the Prepare IBM MQ Wizard directly after IBM MQ installations or if for any reason your machine is rebooted between completing IBM MQ installation and completing the Prepare

IBM MQ Wizard, ensure that the wizard is run with Administrator privilege afterward, otherwise the installation is incomplete, and might fail. You might also see Open File - Security Warning dialog boxes that list International Business Machines Limited as the publisher. Click **Run** to allow the wizard to continue

An example of the file `MQParms.ini` is supplied with IBM MQ. This file contains default installation parameters.

There are two ways to create a parameter file for installation:
- Copy and edit the file `MQParms.ini` that is supplied with the product, using an ASCII file editor.
- Create your own parameter file using an ASCII file editor.

About this task

To invoke installation using the **`MQParms`** command:

Procedure

1. From a command line, change to the root folder of the IBM MQ Server DVD (that is, the location of the file MQParms.exe).
2. Enter the following command:
   ```
   MQParms parameter_file parameters ]
   ```
   where:

   parameter_file
      is the file that contains the required parameter values. If this file is not in the same folder as MQParms.exe, specify the full path and file name. If you do not specify a parameter file, the default is `MQParms.ini`. For silent installation, the `MQParms_silent.ini` parameter file can be used. For further details, see "MQParms parameter file - server installation" on page 465.

   parameters
      are one or more command-line parameters, for a list of these, see the MSDN Command-Line Options web page.

Example

A typical example of an **`MQParms`** command is:
```
MQParms "c:\MyParamsFile.ini" /l*v c:\install.log
```

A typical example of an **`MQParms`** command when you are installing a second copy of IBM MQ is:
```
MQParms "c:\MyParamsFile.ini" /l*v c:\install.log TRANSFORMS=":InstanceId2.mst;1033.mst" MSINEWINSTANCE=1
```

Alternatively, TRANSFORMS and MSINEWINSTANCE can be specified in the MSI stanza of the parameter file.

If you specify a parameter both on the command line and in the parameter file, the setting on the command line takes precedence.

If you specify a parameter file, you might want to run the encryption utility before you use the **`MQParms`** command (see "Encrypting a parameter file" on page 468).

If you do not specify `/i`, `/x`, `/a`, or `/j`, **`MQParms`** defaults to standard installation using the IBM MQ Windows Installer package, IBM MQ.msi. That is, it generates the following part of the command line:
```
/i " current_folder \MSI\IBM MQ.msi"
```

If you do not specify a WIZPARMFILE parameter, **MQParms** defaults to the current parameter file. That is, it generates the following part of the command:

```
WIZPARMFILE=" current_folder \ current_parameter_file "
```

MQParms parameter file - server installation: Windows

A parameter file is an ASCII text file that contains sections (stanzas) with parameters that can be used by the **MQParms** command. Typically, this is an initialization file such as `MQParms.ini`.

The **MQParms** command takes parameters from the following stanzas in the file:

[MSI] Contains general properties related to how the **MQParms** command runs and to the installation of IBM MQ.

The properties that you can set in this stanza are listed in “Installing the server using msiexec” on page 455, and Table 66 on page 466.

[Services]
Contains properties related to IBM MQ account configuration, in particular, the user account required for IBM MQ Services. If you are installing IBM MQ on a network where the domain controller is on a Windows 2003 server, you probably need details of a special domain account. For further information, see “Configuring IBM MQ accounts” on page 475 and “Configuring IBM MQ with the Prepare IBM MQ wizard” on page 471.

The properties that you can set in this stanza are listed in Table 68 on page 467.

MQParms ignores any other stanzas in the file.

The stanza parameters are in the form property=value, where property is always interpreted as uppercase, but value is case sensitive. If a value string includes a blank, it must be enclosed in double quotation marks. Most other values can be enclosed in double quotation marks. Some properties can take more than one value, for example:

```
ADDLOCAL="Server,Client"
```

To clear a property, set its value to an empty string, for example:

```
REINSTALL=""
```

The following tables show the properties that you can set. The default is shown in bold.

For the [MSI] stanza, you can enter standard MSI command line options and properties. For example:

```
- /q
- ADDLOCAL="server"
- REBOOT=Suppress
```

Refer to Table 66 on page 466, Table 67 on page 466, and Table 68 on page 467 for the properties used to install IBM MQ.

Table 66 on page 466 shows additional properties in the stanza that affect how the `MQParms` command runs, but that do not affect the installation.

Table 66. Properties used by MQParms in the MSI stanza

Property	Values	Description
MQPLOG	*path* | *file_name*	**MQParms** generates a text log file with the specified name and location.
MQPLANGUAGE	**system** | user | *transform_value* | existing	The installation language. system. Install using the language of the default system locale (the default). user. Install using the language of the default locale of the user. *transform_value*. Install using the language specified by this value. See Table 67. existing. If IBM MQ already exists on the system, the same language will be used by default, otherwise system is used.
MQPSMS	**0** | no	0 or no. **MQParms** does not wait for the **msiexec** command to end (the default). Any other value. **MQParms** waits for the **msiexec** command to end.
MQPINUSE	**0** | 1	If MQPINUSE is set to 1, **MQParms** continues installing even if IBM MQ files are in use. If this option is used a reboot will be required to complete the installation.

Table 67. Valid values for the MQPLANGUAGE property

Language	Valid values		
U.S. English	English	en_us	1033
German	German	de_de	1031
French	French	fr_fr	1036
Spanish	Spanish	es_es	1034
Italian	Italian	it_it	1040
Brazilian Portuguese	Brazilian Portuguese	pt_br	1046
Japanese	Japanese	ja_jp	1041
Korean	Korean	ko_kr	1042
Simplified Chinese	Simplified Chinese	zh_cn	2052
Traditional Chinese	Traditional Chinese	zh_tw	1028
Czech	Czech	cs_cz	1029
Russian	Russian	ru_ru	1049
Hungarian	Hungarian	hu_hu	1038
Polish	Polish	pl_pl	1045

For the [Services] stanza, you can enter parameters in property=value format. You might want to encrypt the values in this stanza. See “Encrypting a parameter file” on page 468.

Table 68. Properties used in the Services stanza

Property	Values	Description
USERTYPE	**local** | domain | onlydomain	The type of user account to use: **local** Creates a local user account. **domain** Creates a local user account. If this does not have the required security authorities, it uses the domain user account specified by DOMAINNAME, USERNAME, and PASSWORD. **onlydomain** Does not create a local user account, but immediately uses the domain user account specified by DOMAINNAME, USERNAME and PASSWORD. If any of these three properties are missing, a USERTYPE of local is assumed. The properties DOMAINNAME, USERNAME, and PASSWORD are required if USERTYPE is set to onlydomain.
DOMAINNAME	*domain_name* 1	The domain for the domain user account. Required if USERTYPE is set to domain or onlydomain.
USERNAME	*user_name* 1	The user name for the domain user account. Required if USERTYPE is set to domain or onlydomain..
PASSWORD	*password* 1	The password for the domain user account. Required if USERTYPE is set to domain or onlydomain.
1. Do not enclose this value in double quotation marks.		

A typical example of a parameter file is:

```
[MSI]
MQPLANGUAGE=1033
MQPLOG=%temp%\MQParms.log
MQPSMS=no
ADDLOCAL=Server
/m miffile
REMOVE=""
/l*v c:\install.log

[Services]
USERTYPE=domain
DOMAINNAME=mqm*df349edfcab12
USERNAME=mqm*a087ed4b9e9c
PASSWORD=mqm*d7eba3463bd0a3
```

Encrypting a parameter file: Windows

If the DOMAINNAME, USERNAME, and PASSWORD values in the [Services] stanza of a parameter file are not already encrypted, you can encrypt them by running the `setmqipw` utility.

About this task

Use the `setmqipw` utility to encrypt the DOMAINNAME, USERNAME, and PASSWORD values in the [Services] stanza of a parameter file, if they are not already encrypted. (These values might be encrypted if you have run the utility before.) `setmqipw` will also encrypt the QMGRPASSWORD and CLIENTPASSWORD values in the [SSLMigration] stanza of a parameter file.

This encryption means that, if you need a special domain account to configure IBM MQ (see “Configuring IBM MQ accounts” on page 475), or you need to keep key database passwords secret, details are kept secure. Otherwise, these values, including the domain account password, flow across the network as clear text. You do not have to use this utility, but it is useful if security in your network is an issue.

To run the script:

Procedure

1. From a command line, change to the folder that contains your parameter file.
2. Enter the following command:
   ```
   CD_drive:\setmqipw
   ```
   Note: You can run the command from a different folder, by entering the following command, where *parameter_file* is the full path and file name of the parameter file:
   ```
   CD_drive:\setmqipw parameter_file
   ```

Results

If you view the resulting parameter file, the encrypted values start with the string `mqm*`. Do not use this prefix for any other values; passwords or names that begin with this prefix are not supported.

The utility creates a log file, `setmqipw.log`, in the current directory. This file contains messages related to the encryption process. When encryption is successful, messages are similar to:

```
Encryption complete
Configuration file closed
Processing complete
```

What to do next

After you encrypt the parameter file, you can use it in the normal way with the `MQParms` command (see “Installing the server using the MQParms command” on page 463).

Modifying a server installation

Windows

You can modify an IBM MQ server installation interactively using the launchpad or non-interactively using msiexec.

Related concepts:

"Modifying a server installation silently using msiexec" on page 470
You can silently remove or install IBM MQ features on Windows by using `msiexec`.

Related tasks:

"Modifying a server installation using the Installation Launchpad"
You can interactively remove or install IBM MQ features on Windows by using IBM MQ Installation Launchpad.

Modifying a server installation using the Installation Launchpad: Windows

You can interactively remove or install IBM MQ features on Windows by using IBM MQ Installation Launchpad.

Before you begin

To modify an installation, some features of IBM MQ must already be installed.

About this task

To remove or install IBM MQ features follow the instructions. This procedure is the only way to interactively remove or install IBM MQ features on Windows Server 2008:

Procedure

1. Insert the IBM MQ for Windows Server DVD into the DVD drive.
2. If autorun is installed, the installation process starts.

   Otherwise, double-click the **Setup** icon in the root folder of the DVD to start the installation process.

   The IBM MQ Installation Launchpad window is displayed.
3. Click the **IBM MQ Installation** option.
4. Click **Launch IBM MQ Installer**. Wait until the IBM MQ Setup window is displayed with a welcome message.
5. If you have multiple installations on your system, you must choose the installation you want to modify. Do this by selecting the **Maintain or upgrade an existing instance** option and choosing the appropriate instance. If you are upgrading a IBM WebSphere MQ Version 7.0.1 installation (or earlier) to Version 7.1.0, and you already have a Version 7.1.0 or greater installation, you need to select **Install a new instance**. A subsequent panel then allows you to choose the installation you would like to upgrade.
6. Click **Next** to continue. The Program Maintenance panel is displayed.
7. Select **Modify**, then click **Next**.

   The Features panel is displayed.
8. Click the **+** symbol next to a feature to show any dependent features (subfeatures).
9. To change the installation of a feature:
   a. Click the symbol next to the feature name to display a menu.
   b. Select the required option from:
      - Install this feature
      - Install this feature and all its subfeatures (if any)

- Do not install this feature (remove if already installed)

  The symbol next to the feature name changes to show the current installation option.
10. Stop the web server before removing the web feature. If you do not do this, you receive an error message.
11. When your selections are complete, click **Next**. IBM MQ installation begins.

What to do next

After modifying the installation, you might need to run **setmqenv** again as described in *What to do next* in "Installing IBM MQ server on Windows" on page 453.

Modifying a server installation silently using msiexec: Windows

You can silently remove or install IBM MQ features on Windows by using **msiexec**.

To silently modify an installation using **msiexec**, set the ADDLOCAL parameter to include the features you want to add, and set the REMOVE parameter to the features you want to remove.

For example if you use ADDLOCAL="JavaMsg" and REMOVE="" it modifies the installation to include the Java Messaging and Web Services feature.

```
msiexec /i {product code} /q ADDLOCAL="JavaMsg" REMOVE="" INSTALLATIONNAME="Installation1"
```

where *product_code* is the value shown for MSIProdCode in the output of the following command:

```
dspmqinst -n installation_name
```

An example of a product code is `{0730749B-080D-4A2E-B63D-85CF09AE0EF0}`.

The instructions for msiexec begin here: "Installing the server using msiexec" on page 455.

Configuring an IBM MQ server

Windows

After installing IBM MQ server, it is necessary to configure it.

The configuration described in this section is for an environment that uses TCP/IP. The configuration procedure is the same for environments that use other communications protocols (for example, SNA, SPX, or NetBIOS). However, not all of the functions and facilities of IBM MQ for Windows are available in these environments. The items that are not available are:
- IBM MQ Postcard
- IBM MQ Explorer

If you are setting up IBM MQ for use with the Microsoft Cluster Service (MSCS), see Supporting the Microsoft Cluster Service (MSCS) for more information.

Using IBM MQ remotely: Windows

To create and start queue managers when connected remotely, you must have the **`Create global objects`** user access.

If you are connecting to a Windows machine using either Terminal Services or a Remote Desktop Connection and you have problems creating, starting or deleting a queue manager this might be because of the user access **`Create global objects`**.

The **`Create global objects`** user access limits the users authorized to create objects in the global namespace. In order for an application to create a global object, it must either be running in the global namespace, or the user under which the application is running must have the **`Create global objects`** user access applied to it.

When you connect remotely to a Windows machine using either Terminal Services or Remote Desktop Connection, applications run in their own local namespace. If you attempt to create or delete a queue manager using IBM MQ Explorer or the **`crtmqm`** or **`dltmqm`** command, or to start a queue manager using the **`strmqm`** command, it results in an authorization failure. This creates an IBM MQ FDC with Probe ID XY132002.

Starting a queue manager using the IBM MQ Explorer, or using the **`amqmdain qmgr start`** command works correctly because these commands do not directly start the queue manager. Instead the commands send the request to start the queue manager to a separate process running in the global namespace.

If you need to perform any of these operations on a queue manager when connected remotely to a Windows machine, you must have the **`Create global objects`** user access. For information on how to assign a user this access, see your operating system documentation.

Administrators have the **`Create global objects`** user access by default, so if you are an administrator you can create and start queue managers when connected remotely without altering your user rights.

Configuring IBM MQ with the Prepare IBM MQ wizard: Windows

The Prepare IBM MQ wizard helps you to configure IBM MQ files and a user account for your network, and migrate any queue managers and data from a previous installation.

About this task

You must run the Prepare IBM MQ wizard to configure the IBM MQ Service before you can start any queue managers.

The Prepare IBM MQ wizard window is displayed when IBM MQ installation completes. Follow the instructions given by the wizard to configure IBM MQ. At any time while the wizard is running you can click **More Information** in the wizard to view online help about the task you are doing.

On Windows systems, you must do this task under a Windows administrator account, or domain administrator account in case your workstation is a member of a Windows domain.

On Windows systems with UAC enabled, if you do not complete the Prepare IBM MQ Wizard directly after IBM MQ is installed, or if for any reason your machine is rebooted between completing IBM MQ installation and completing the Prepare IBM MQ Wizard, you must accept the Windows prompt when it appears to allow the wizard to run as elevated.

Procedure

1. When the IBM MQ installation completes, the Prepare IBM MQ Wizard window is displayed with a welcome message. To continue, click **Next**
2. If you have run the Prepare IBM MQ wizard before, this step is skipped. If you have not run the Prepare IBM MQ wizard before, the Prepare IBM MQ Wizard window displays a progress bar with the following message:

   ```
   Status: Setting up IBM MQ Configuration
   ```

   Wait until the progress bar completes.
3. The Prepare IBM MQ Wizard window displays a progress bar with the following message:

   ```
   Status: Setting up the IBM MQ Service.
   ```

   Wait until the progress bar completes.
4. IBM MQ attempts to detect whether you must configure IBM MQ for use with Windows Active Directory Server or later domain users. Depending on the results of the detection, IBM MQ does one of the following things:
   - If IBM MQ detects that you need to configure IBM MQ for Windows Active Directory Server or later domain users, the Prepare IBM MQ Wizard window displays a message that starts:

     ```
     IBM MQ does not have the authority to query information about
     your user account
     ```

     Optionally, to see online help about configuring the domain account, select More Information. When you are finished, close the IBM MQ Help Center window to return to the current window.

     Click **Next**, and go to step 5.
   - If you are not installing on a Windows Active Directory Server or later domain server and IBM MQ cannot detect whether you need to configure IBM MQ for Windows Active Directory Server or later domain users, the Prepare IBM MQ Wizard window displays the following message:

     ```
     Are any of the domain controllers in your network running
     Windows 2000 or later domain server?
     ```

     If you select Yes, click **Next**, then go to step 5.

     If you select No, click **Next**, then go to step 9.

     If you select **Don't know**, you cannot continue. Select one of the other options, or click **Cancel** and contact your domain administrator.
   - If IBM MQ detects that you do not need to configure IBM MQ for Windows Active Directory Server or later domain users, go to step 9.

   Note: At any time, you can click **More Information** to view online help about configuring the domain account, or see “Configuring IBM MQ accounts” on page 475. When you are finished, close the IBM MQ Help Center window to return to the current window.
5. The Prepare IBM MQ Wizard window displays the following message:

   ```
   Do you need to configure IBM MQ for users defined on Windows 2000
   or later domain controllers?
   ```

   If you select Yes, click **Next**, then go to step 6.

   If you select No, click **Next**, then go to step 9.

   If you select Don't know, you cannot continue. Select one of the other options, or click **Cancel** and contact your domain administrator.

   Note: At any time, you can click **More Information** to view online help about configuring the domain account, or see “Configuring IBM MQ accounts” on page 475. When you are finished, close the IBM MQ Help Center window to return to the current window.
6. Give the domain user that you obtained from your domain administrator the access to run as a service.

   a. Click **Start** > **Run...**, type the command **secpol.msc** and click **OK**.
   b. Open **Security Settings** > **Local Policies** > **User Rights Assignments**. In the list of policies, right-click **Log on as a service** > **Properties**.
   c. Click **Add User or Group...** and type the name of the user you obtained from your domain administrator, and click **Check Names**
   d. If prompted by a Windows Security window, type the user name and password of an account user or administrator with sufficient authority, and click **OK** > **Apply** > **OK**. Close the Local Security Policy window.
7. In the next window, enter the Domain and user ID of the domain user account that you obtained from your domain administrator. Either enter the Password for this account, or select the option **This account does not have a password**. Click **Next**.
8. The Prepare IBM MQ Wizard window displays a progress bar with the following message:

   ```
   Status: Configuring IBM MQ with the special domain user account
   ```

   Wait until the progress bar completes.

   If there are any problems with the domain user account, a further window is displayed. Follow the advice on this window before you continue with this procedure.
9. The Prepare IBM MQ Wizard window displays a progress bar with the following message:

   ```
   Status: Starting IBM MQ services
   ```

   Wait until the progress bar completes.
10. Next, select the options that you require. The Prepare IBM MQ Wizard window displays the following message:

    ```
    You have completed the Prepare IBM MQ Wizard
    ```

    Select the options that you require, then click **Finish**. Select one or more from:
    - **Remove the shortcut to this wizard from the desktop**

      This option is available only if you have previously attempted installation, but you canceled the procedure from the Prepare IBM MQ wizard and you created a desktop shortcut to this wizard. Select this option to remove the shortcut. You do not need it now that you have completed the Prepare IBM MQ wizard.
    - **Launch IBM MQ Explorer**

      The IBM MQ Explorer allows you to view and administer your IBM MQ network.
    - **Launch Notepad to view the release notes**

      The release notes contain information about installing IBM MQ and also late-breaking news that is available after the published documentation is produced.
11. Follow the procedure described in "Checking for problems after installing" on page 474.

Related information:
User rights required for an IBM MQ Windows Service

Checking for problems after installing: Windows

There are some optional tasks that you can use to check the installation if you believe there was a problem, or to verify installation messages after an unattended (silent) installation for example.

About this task

Use these steps as a guide to check the following files for messages:

Procedure

1. `MSI` *`nnnnn`*`.LOG`. This file is in your user `Temp` folder. It is an application log that contains English messages written during installation. The log includes a message indicating whether the installation was successful and complete.

   This file is created if you have set up default logging.
2. If you used the launchpad to install IBM MQ, check `MQv7_Install_YYYY-MM-DDTHH-MM-SS.log` in your user `Temp` folder, where:

   YYYY This is the year that you installed IBM WebSphere MQ Version 7.0

   MM This is the month that you installed IBM MQ, for example this would be 09 if you installed in September

   DD This is the day that you installed IBM MQ

   HH-MM-SS
   This is the time at which IBM MQ was installed

   You can get to your user Temp directory by entering the following command at the command prompt:

   ```
   cd %TEMP%
   ```
3. `amqmjpse.txt`. This file is in the IBM MQ data files folder (default `C:\ProgramData\IBM\MQ`). It is an application log that contains English messages written during installation by the Prepare IBM MQ wizard.

What to do next

1. Verify your installation, as described in *Verifying your IBM MQ installation* for the platform, or platforms, that your enterprise use.

Configuring IBM MQ accounts: Windows

The IBM MQ service and queue managers check that any users attempting to access queue managers or queue manager resources such as queues, have the permission to access them.

Most networked Windows systems are members of a Windows domain where user accounts, other security principals, and security groups are maintained and managed by a directory service, Active Directory, running on a number of domain controllers. IBM MQ checks that only authorized users can access queue managers or queues.

In such networks, IBM MQ queue manager processes access the Active Directory information to find the security group membership of any users attempting to use IBM MQ resources. The accounts under which IBM MQ services run must be authorized to look up such information from the directory. In most Windows domains, local accounts defined at individual Windows servers cannot access directory information, so the IBM MQ services must run under a domain account that has the appropriate permission.

If the Windows server is not a member of a Windows domain or the domain has a reduced security or functional level, then the IBM MQ services can run under a local account that was created during installation.

Assuming that a domain account is needed, provide the information described in the Information for domain administrator to your domain administrator, and ask for one of the special accounts it describes. When you install the product, towards the end of the installation procedure, in the Prepare IBM MQ wizard, you are asked to enter details of this account (domain, user name, and password).

If a domain account is needed and you install IBM MQ without a special account (or without entering its details), many or all parts of IBM MQ do not work, depending upon the particular user accounts involved. Also, IBM MQ connections to queue managers that run under domain accounts on other systems might fail. The account can be changed by running the Prepare IBM MQ wizard and specifying the details of the account to be used.

For information about the user rights required to take advantage of the Active Directory support, see Using Active directory (Windows only).

For information about the user rights required to take advantage of the Kerberos authentication support, see Securing.

Information for domain administrators: Windows

Use this topic to understand how IBM MQ services check the authorization of user accounts attempting to access IBM MQ.

The user account must either have an individual IBM MQ authorization set or belong to a local group that has been authorized. A domain account can also be authorized through membership of a domain group included under an authorized local group through a single level of nesting.

The account under which the IBM MQ services are run must have the ability to query group memberships of domain accounts and have the authority to administer IBM MQ. Without the ability to query group memberships the access checks made by the services fail.

On most Windows domains, with domain controllers running Windows Active Directory, local accounts do not have the required authorization and a special domain user account with the required permissions must be used. The IBM MQ installer must be given the userid and password details so that they can be used to configure the IBM MQ service after the product is installed.

Typically, this special account has the IBM MQ administrator rights through membership of the domain group `DOMAIN\Domain mqm`. The domain group is automatically nested by the installation program under the local mqm group of the system on which IBM MQ is being installed.

See "Creating and setting up domain accounts for IBM MQ" for instructions on creating a suitable domain account.

Note: If an installer configures IBM MQ without a special account, many or all parts of IBM MQ do not work, depending upon the particular user accounts involved, as follows:
- An installer currently logged on with a domain user account is not be able to complete the Default Configuration, and the Postcard application does not work.
- IBM MQ connections to queue managers running under domain accounts on other systems might fail.
- Typical errors include "AMQ8066: Local mqm group not found" and "AMQ8079: Access was denied when attempting to retrieve group membership information for user 'abc@xyz'".

Creating and setting up domain accounts for IBM MQ: Windows

The following information is intended at Domain Administrators. Use this information to create and set up domain accounts for IBM MQ.

About this task

Repeat Steps 1 and 2 on page 477 for each domain that has user names that will install IBM MQ, to create an account for IBM MQ on each domain:

Procedure
1. Create a domain group with a special name that is known to IBM MQ and give members of this group the authority to query the group membership of any account:
   a. Log on to the domain controller as an account with domain administrator authority.
   b. From the Start menu, open Active Directory Users and Computers.
   c. Find the domain name in the navigation pane, right-click it and select **New Group**.
   d. Type a group name into the **Group name** field.

      Note: The preferred group name is `Domain mqm`. Type it exactly as shown.
      - Calling the group `Domain mqm` modifies the behavior of the "Prepare IBM MQ" wizard on a domain workstation or server. It causes the "Prepare IBM MQ" wizard automatically to add the group `Domain mqm` to the local `mqm` group on each new installation of IBM MQ in the domain.
      - You can install workstations or servers in a domain with no `Domain mqm` global group. If you do so, you must define a group with the same properties as `Domain mqm` group. You must make that group, or the users that are members of it, members of the local `mqm` group wherever IBM MQ is installed in a domain. You can place domain users into multiple groups. Create multiple domain groups, each group corresponding to a set of installations that you want to manage separately. Split domain users, according to the installations they manage, into different domain groups. Add each domain group or groups to the local `mqm` group of different IBM MQ installations. Only domain users in the domain groups that are members of a specific local `mqm` group can create, administer, and run queue managers for that installation.
      - The domain user that you nominate when installing IBM MQ on a workstation or server in a domain must be a member of the `Domain mqm` group, or of an alternative group you defined with same properties as the `Domain mqm` group.
   e. Leave **Global** clicked as the **Group scope**, or change it to **Universal**. Leave **Security** clicked as the **Group type**. Click **OK**.

f. Follow these steps to assign permissions to the group based on the Windows version of the domain controller:

   On Windows Server 2012 and Windows Server 2012 R2

   1) In the Server Manager, click **Tools** then select **Active Directory Users and Computers** from the list box.
   2) Select **View** > **Advanced Features**
   3) Expand your domain name, then click **Users**
   4) In the Users window, right-click **Domain mqm** > **Properties**
   5) Click **Security** > **Advanced** > **Add...**
   6) Click **Select principle**, then type `Domain mqm` and click **Check names** > **OK**

      The **Name** field is prefilled with the string `Domain mqm` (*domain name*`\Domain mqm`)
   7) In the **Applies to** list, select **Descendant User Objects**
   8) In the **Permissions** list, select the **Read group membership** and **Read groupMembershipSAM** check boxes.
   9) Click **OK** > **Apply** > **OK** > **OK**.

   On Windows Server 2008 and Windows 2008 R2:

   1) In the Server Manager navigation tree, click **Users**.
   2) In the Server Manager action bar, click **View** > **Advanced features**
   3) In the Users window, right-click **Domain mqm** > **Properties**
   4) Click **Security** > **Advanced** > **Add**, then type `Domain mqm` and click **Check names** > **OK**

      The **Name** field is prefilled with the string `Domain mqm` (*domain name*`\Domain mqm`)
   5) Click **Properties**. In the **Apply to** list, select **Descendant User Objects**
   6) In the **Permissions** list, select the **Read group membership** and **Read groupMembershipSAM** check boxes.
   7) Click **OK** > **Apply** > **OK** > **OK**.

2. Create one or more accounts, and add them to the group:
   a. In **Active Directory Users and Computers**, create a user account with a name of your choosing and add it to group `Domain mqm` (or a group that is a member of the local `mqm` group).
   b. Repeat for all the accounts you want to create.
3. Repeat Steps 1 on page 476 and 2 for each domain that has user names that will install IBM MQ, to create an account for IBM MQ on each domain.
4. Use the accounts to configure each installation of IBM MQ:
   a. Either use the same domain user account (as created in Step 1 on page 476) for each installation of IBM MQ, or create a separate account for each one, adding each to the `Domain mqm` group (or a group that is a member of the local `mqm` group).
   b. When you have created the account or accounts, give one to each person configuring an installation of IBM MQ. They must enter the account details (domain name, user name, and password) into the Prepare IBM MQ wizard. Give them the account that exists on the same domain as their installing userid.
   c. When you install IBM MQ on any system on the domain, the IBM MQ installation program detects the existence of the `Domain mqm` group on the LAN, and automatically adds it to the local `mqm` group. (The local `mqm` group is created during installation; all user accounts in it have authority to manage IBM MQ). Thus all members of the "`Domain mqm`" group will have authority to manage IBM MQ on this system.
   d. However, you do still need to provide a domain user account (as created in Step 1 on page 476) for each installation, and configure IBM MQ to use it when making its queries. The account details must be entered into the Prepare IBM MQ wizard that runs automatically at the end of installation (the wizard can also be run at any time from the **start** menu).

5. Set the password expiry periods:
   - If you use just one account for all users of IBM MQ, consider making the password of the account never expire, otherwise all instances of IBM MQ will stop working at the same time when the password expires.
   - If you give each user of IBM MQ their own user account you will have more user accounts to create and manage, but only one instance of IBM MQ will stop working at a time when the password expires.

   If you set the password to expire, warn the users that they will see a message from IBM MQ each time it expires - the message warns that the password has expired, and describes how to reset it.
6. Running IBM MQ as a service. If you need to run IBM MQ as a service, and then give the domain user (that you obtained from your domain administrator) the access to run as a service, carry out the following procedure:
   a. Click **Start > Run...**. Type the command `secpol.msc` and click **OK**.
   b. Open **Security Settings > Local Policies > User Rights Assignments**. In the list of policies, right-click **Log on as a service > Properties**.
   c. Click **Add User or Group...** Type the name of the user you obtained from your domain administrator, and click **Check Names**
   d. If prompted by a Windows Security window, type the user name and password of an account user or administrator with sufficient authority, and click **OK > Apply > OK**. Close the Local Security Policy window.

   Note: On Windows Server 2008 and Windows Server 2012 the User Account Control (UAC) is enabled by default.

   The UAC feature restricts the actions users can perform on certain operating system facilities, even if they are members of the Administrators group. You must take appropriate steps to overcome this restriction.

Using the Default Configuration wizard: ▶ Windows

You can use the Default Configuration wizard to add the first configured queue manager to this system. This enables you to connect easily with other queue managers in the same IBM MQ cluster.

About this task

You can use the Default Configuration wizard to create, view, or alter your default configuration. You can also use this wizard to alter or display details of an existing queue manager that was created by the default configuration.

For a new installation of IBM MQ, creating a default configuration enables you to explore features of IBM MQ using the Postcard application, and the IBM MQ Explorer.

The Postcard application provides a fast and simple way to verify that your IBM MQ installation completed successfully. It uses the default queue manager that is created during the default configuration. If you want to use the Postcard application for verification, and you do not have any existing queue managers, run the Default Configuration wizard first.

If you have migrated existing queue managers, or created any queue managers since installing IBM MQ, you might not want to run the Default Configuration wizard. This is because you cannot create the default configuration if other queue managers already exist. If you have previously created any other queue managers on this system and you still want to set up a default configuration, you must delete them before you run the Default Configuration wizard.

Start the Default Configuration wizard by selecting **Create the Default Configuration** on the Welcome to IBM MQ Explorer Content view page.

Using the Welcome to IBM MQ Explorer Content view page: ▶ Windows

The Welcome to IBM MQ Explorer Content view page points you to any relevant applications, documentation, tutorials, and education. This page is displayed the first time you launch IBM MQ Explorer.

You can use the items in the Welcome to IBM MQ Explorer Content view page to explore the facilities in IBM MQ. This page is launched the first time the IBM MQ Explorer is launched. The Welcome page can be viewed at any time from the IBM MQ Explorer by clicking **IBM MQ** in the Navigator view. There are links to the following subjects from this page:

Create the Default Configuration

Allows you to add a configured queue manager to this system for connecting easily with other queue managers in the same IBM MQ cluster. You can also use it to alter or display details of an existing queue manager created by the default configuration. This feature is available only using TCP/IP.

Note: If you migrated existing queue managers, or if you have created any queue managers after you installed IBM MQ, you might not want to use this facility. This is because you can only set up a default configuration if there are no queue managers already, and you might not want to delete your existing queue managers.

Launch Postcard

Allows you to try out IBM MQ messaging quickly and easily. You can send a message either to your own machine or to another named user's machine. It is described in detail in "Verifying a server-to-server installation using the Postcard application on Windows" on page 503.

Using the Help Center: ▶ Windows

The Help Center gives you access to all task-oriented help, information on the IBM website, and a link to the IBM MQ product documentation.

The IBM MQ Help Center can be accessed from the IBM MQ Explorer by selecting **Help** > **Help Contents**.

Converting a trial license on Windows

▶ Windows

Convert a trial license to a full license without reinstalling IBM MQ.

When the trial license expires, the "count-down" displayed by the `strmqm` command informs you the license has expired, and the command does not run.

Before you begin

1. IBM MQ is installed with a trial license.
2. You have access to the installation media of a fully licensed copy of IBM MQ.

About this task

Run the **setmqprd** command to convert a trial license to a full license.

If you do not want to apply a full license to your trial copy of IBM MQ, you can uninstall it at any time.

Procedure

1. Obtain the full license from the fully licensed installation media.

   The full license file is `amqpcert.lic`. On Windows it is in the `\`*MediaRoot*`\licenses` directory on the installation media. It is installed into the `bin` directory on the IBM MQ installation path.
2. Run the **setmqprd** command from the installation that you are upgrading:

   ```
   MQ_INSTALLATION_PATH\bin\setmqprd \MediaRoot\licenses\amqpcert.lic
   ```

Related information:

setmqprd

Displaying messages in your national language on Windows systems

Windows

To display messages from a different national language message catalog, you must either set the **MQS_FORCE_NTLANGID** environment variable, or change a regional setting.

About this task

Messages in U.S. English are automatically installed with IBM MQ

Messages in the national languages that IBM MQ supports are automatically installed. Messages are displayed in the national language, based on the following order:

1. The value of the **MQS_FORCE_NTLANGID** environment variable, if set.
2. The regional format of the user that is displaying the message, if the language specified by the regional format is supported by IBM MQ.
3. The Administrative system locale if the language specified by the system locale is supported by IBM MQ.
4. US English, if no other supported language can be determined.

Note: The queue manager is usually launched by a service on the machine, and hence is running under its own user account (for example MUSR_MQADMIN) or a specific domain account provided during install time. See Security on Windows for more information.

If you require messages in a language other than the one associated with the regional format of a user account, perform the following steps:

Procedure

1. Globally set the **MQS_FORCE_NTLANGID** environment variable, to the language identifier of the desired language, for messages displayed by the queue manager. You should set the **MQS_FORCE_NTLANGID** system wide. Otherwise, every user displaying messages needs to have the environment variable set individually.

   The language identifier values, represented in hexadecimal notation, are listed in the following Microsoft document: Language Identifier Constants and Strings
2. Reboot machines where queue managers are running as a service, for the environment variable to take effect.

Installing an IBM MQ client on Windows

Windows

This topic describes how to install IBM MQ client on Windows systems. This procedure can be used for installing a first or a subsequent installation.

Before you begin

To install an IBM MQ client, you must be logged on to Windows as an administrator.

About this task

Follow these instructions to perform an interactive compact, typical, or custom installation of IBM MQ. To view all the installation types and the features that are installed with each option consult Features installed with each type of interactive installation.

Attention: From IBM MQ Version 9.0, if you are using **`msiexec`** to install the client, the installation is automatically set to be the primary installation.

Procedure

1. Access the IBM MQ installation image. The location might be the mount point of the DVD, a network location, or a local file system directory.
2. Locate `setup.exe` in the Windows directory of the IBM MQ installation image.
   - From a DVD, this location might be:
     `E:\Windows\setup.exe`
   - From a network location, this location might be:
     `m:\instmqs\Windows\setup.exe`
   - From a local file system directory, this location might be:
     `C:\instmqs\Windows\setup.exe`
3. Double-click the **Setup** icon to start the installation process. It is possible to run either by:
   - Running `setup.exe` from the command prompt. Or
   - Double-clicking `setup.exe` from Windows Explorer.

   If you are installing on a Windows system with UAC enabled, accept the Windows prompt to allow the launchpad to run as elevated. During installation, you might also see Open File - Security Warning dialog boxes that list International Business Machines Limited as the publisher. Click **Run** to allow the installation to continue.

   The IBM MQ Installation window is displayed.
4. Continue to follow the instructions as shown on screen.

Results

A new sample IBM MQ MQI client configuration file is created in the IBM MQ installation directory (for example `C:\Program Files\IBM\MQ\`, by the IBM MQ MQI client package, during installation, but only if this file does not exist. This file contains the `ClientExitPath` stanza. An example `mqclient.ini` file is shown in Configuring a client using a configuration file.

Note:

If you are using a common configuration file for multiple clients, either in the IBM MQ installation directory or in another location using the MQCLNTCF environment variable, you must grant read access to all user identifiers under which the IBM MQ client applications run. If the file cannot be read, the failure is traced and the search logic continues as if the file had not existed.

What to do next

- If you have chosen this installation to be the primary installation on the system, when using `setup.exe`, you must now set it as the primary installation. Enter the following command at the command prompt:

```
MQ_INSTALLATION_PATH\bin\setmqinst -i -p MQ_INSTALLATION_PATH
```

  You can have only one primary installation on a system. If there is already a primary installation on the system, you must unset it before you can set another installation as the primary installation. For more information, see Changing the primary installation.
- You might want to set up the environment to work with this installation. You can use the **setmqenv** or **crtmqenv** command to set various environment variables for a particular installation of IBM MQ. For more information, see setmqenv and crtmqenv.
- For instructions on how to verify your installation, see "Testing communication between a client and a server on Windows" on page 512.

Related concepts:

"Modifying a client installation using Add/Remove Programs" on page 492
On some versions of Windows, you can modify an installation by using Add/Remove Programs.

Related tasks:

"Installing a client using msiexec"
IBM MQ on Windows uses the MSI technology to install software. MSI provides both an interactive installation and a non interactive installation.

"Installing a client using the MQParms command" on page 489
You can use the **MQParms** command to invoke installation or uninstallation of an IBM MQ client.

"Uninstalling IBM MQ on Windows" on page 514
You can uninstall the IBM MQ MQI clients and servers on Windows systems by using the control panel, the command line (**msiexec**), **MQParms**, or by using the installation media, in which case you can optionally remove queue managers as well.

Installing a client using msiexec

Windows

IBM MQ on Windows uses the MSI technology to install software. MSI provides both an interactive installation and a non interactive installation.

About this task

IBM MQ on Windows uses the MSI technology to install software. MSI provides both an interactive installation and a non interactive installation. An interactive installation displays panels and ask questions.

The **msiexec** command uses parameters to give MSI some or all of the information that can also be specified through panels during an interactive installation. This means that a user can create a reusable automated or semi-automated installation configuration. Parameters can be given through the command line, a transform file, a response file, or a combination of the three.

Procedure

To install using msiexec, at the command line, enter the **msiexec** command in the following format:

```
msiexec parameters [USEINI="response-file"] [TRANSFORMS="transform_file"]
```

Where:

parameters
: are either command-line parameters preceded by a / character, or property=value pairs (if using both forms of parameter always put the command-line parameters first). For further information, see "Specifying command line parameters with msiexec."

For an unattended installation, you must include the /q or /qn parameter in the command line. Without this parameter, the installation is interactive.

Note: You must include the **/i** parameter and the file location of the IBM MQ installer package.

response-file
: is the full path and file name of the file that contains the [Response] stanza and the required property=value pairs, for example `C:\MyResponseFile.ini`. An example response file, `Response.ini`, is supplied with IBM MQ. This file contains default installation parameters. For further information, see "Using a response file with msiexec" on page 484.

transform_file
: is the full path and file name of a transform file. For further information, see "Using transforms with msiexec for client installation" on page 487 and "Choosing MSI Instance IDs for multiple server installations" on page 461.

Note: For a silent installation to succeed, the AGREETOLICENSE="yes" property must be defined either on the command line or in the response file.

Results

After the command has been entered, the command prompt immediately reappears. IBM MQ is installing as a background process. If you have entered parameters to produce a log, check this file to see how the installation is progressing. If the installation completes successfully, you see the message `Installation operation completed successfully` in the log file.

Specifying command line parameters with msiexec:
About this task

The **msiexec** command can accept two types of parameters on the command line, as follows:

- Standard command line parameters, preceded by a / character.

  For a table of the **msiexec** command line parameters, see the MSDN Command-Line Options web page.
- Property=value pair parameters on the command line. All the parameters available for use in a response file can be used on the command line, for a list of these, see Table 70 on page 485. In addition there are some extra property=value pair parameters that are only for use on the command line, for details see Table 69 on page 484.

  When using the property=value pair parameters note that:
  - Property strings must be in uppercase.
  - Value strings are not case-sensitive, except for feature names. You can enclose value strings in double quotation marks. If a value string includes a blank, enclose the blank value string in double quotation marks.
  - For a property that can take more than one value, use the format:

    ```
    ADDLOCAL="Server,Client"
    ```
  - For properties taking paths and filenames, for example PGMFOLDER, you must supply the paths as absolute paths and not relative; that is, `C:\folder\file` and not `.\folder\file`.

  When using property=value pair and command line parameters with the **msiexec** command, enter command line parameters first.

  If a parameter is specified both on the command line and in a response file, the setting on the command line takes precedence.

Example

A typical example of an **msiexec** command is:

```
msiexec /i "path\MSI\IBM MQ.msi" /l*v c:\install.log
/q TRANSFORMS="1033.mst" AGREETOLICENSE="yes" ADDLOCAL="Client"
```

A typical example of an **msiexec** command when you are installing a second copy of the IBM MQ product is:

```
msiexec /i "path\MSI\IBM MQ.msi" /l*v c:\install.log
/q TRANSFORMS=":InstanceId2.mst;1033.mst" AGREETOLICENSE="yes"
ADDLOCAL="Client" MSINEWINSTANCE=1
```

The following table shows the parameters which can only be provided on the command line and not in a response file.

Table 69. msiexec property=value parameters

Property	**Values**	**Meaning**
USEINI	*path* \ *file_name*	Use the specified response file. See "Using a response file with msiexec"
SAVEINI	*path* \ *file_name*	Generate a response file during installation. The file contains those parameters selected for this installation that a user might make during an interactive installation.
ONLYINI	1|yes| ""	1, yes or any value other than null. End the installation before updating the target system, but after generating a response file, if this is specified. "". Continue the installation and update the target system (the default).
TRANSFORMS	:InstanceId *x*.mst| *path* \ *file_name* | :InstanceId *x*.mst; *path* \ *file_name*	The :InstanceId *x*.mst value is only required for a subsequent installation of IBM WebSphere MQ Version 7.1 or later. The *path* \ *file_name* specifies what transform (.mst) files must be applied to the product. For example, "1033.mst" specifies the supplied U.S. English transform file.
MSINEWINSTANCE	1	This property is only required for subsequent installations of IBM WebSphere MQ Version 7.1 or later.
REMOVEFEATURES	yes	Required with value "yes" for a silent installation, otherwise ignored. Allows obsolete features, no longer part of IBM MQ, to be deleted.

Using a response file with msiexec:
About this task

You can use the **msiexec** command with a parameter which specifies additional properties are defined in a response file. You can combine the `msiexec` command-line parameters described in "Specifying command line parameters with msiexec" on page 483.

A response file is an ASCII text file, with a format like a Windows `.ini` file, that contains the stanza [Response]. The [Response] stanza contains some or all the parameters that would normally be specified as part of an interactive installation. The parameters are given in a property=value pair format. Any other stanzas in the response file are ignored by **`msiexec`**. An example response file, `Response.ini`, is supplied with IBM MQ. It contains the default installation parameters.

Procedure

A typical example of an `msiexec` command is: `msiexec /i "`*`path`*`\MSI\IBM MQ.msi" /l*v c:\install.log TRANSFORMS="1033.mst" USEINI="C:\MQ\Responsefile"`
If a parameter is specified both on the command line and in a response file, the setting on the command line takes precedence. All the parameters available for use in a response file can also be used on the command line, for a list of these see Table 70.
In the response file, all text is in English, and comments begin with a **;** character.
For information about creating a response file, see "Creating a response file for server installation" on page 463.

Example

An example of a typical response file:

```
[Response]
PGMFOLDER="c:\mqm"
DATFOLDER="c:\mqm\data"
AGREETOLICENSE="yes"
ADDLOCAL="Client"
REMOVE="Toolkit"
```

Table 70. Response file parameters

Property	Values	Meaning
PGMFOLDER	*path*	Folder for the IBM MQ program files. For example, `c:\mqm`.
DATFOLDER	*path*	Folder for the IBM MQ data files. For example, `c:\mqm\data`.
USERCHOICE	0|no	If the command line or response file specifies parameters to install features, a dialog can be displayed to prompt you to accept the preselected options, or review and possibly change them. 0 or no. Suppresses display of the dialog. Anything else. Dialog is displayed and you can amend the options. Not used for a silent installation.
AGREETOLICENSE	yes	Accept the terms of the license. Set to `yes` before a silent installation. If the installation is not silent, this parameter is ignored.

Table 70. Response file parameters (continued)

Property	Values	Meaning
ADDLOCAL	*feature, feature, All*| ""	A comma-separated list of features to install locally. For a list of valid feature names, see "IBM MQ features for Windows systems" on page 436. All installs all features "" installs the typical features. If you do not want a feature use `REMOVE="`*`feature`*`"` **Note:** If this is a new installation the typical features (Client, Java, .NET Messaging, and Development Toolkit) are installed by default irrespective of the feature list provided in the ADDLOCAL property. If you do not want a feature use `REMOVE="`*`feature`*`"`
REMOVE	*feature, feature,* |All| ""	A comma-separated list of features to remove. For a list of valid feature names, see "IBM MQ features for Windows systems" on page 436. All uninstalls all features "" uninstalls no features (the default).
INSTALLATIONDESC	"Description of installation"	Sets the installation description from the command line. Subject to the documented installation description length limitations
INSTALLATIONNAME	[INSTALLATION0,]Name	Sets the installation name from the command line. Subject to the documented installation name character and length limitations. **Note:** Supply INSTALLATION0,Name only when upgrading from a release earlier than IBM WebSphere MQ Version 7.1.
MAKEPRIMARY	0|1| ""	Makes the installation primary, if possible, or removes the primary flag. 1 = Make primary, 0 = Make non-primary, - use default algorithm **Note:** This option is ignored if a release earlier than IBM WebSphere MQ Version 7.1 is installed, or if another Version 7.1 or later installation is present and set as the primary.

Related tasks:

"Installing a client using the MQParms command" on page 489
You can use the **`MQParms`** command to invoke installation or uninstallation of an IBM MQ client.

Related reference:

"Using transforms with msiexec for client installation" on page 487

Choosing MSI Instance IDs for multiple client installations: Windows

For multiple silent installations, for each version that is installed you must find an MSI instance ID that is available to use for that installation.

About this task

In order to support silent, or non-interactive, multiple installations, you need to find out whether the instance ID you want to use is already in use or not and choose the appropriate one. For each installation media (for example, each client and server), Instance ID 1 is the default ID which is used for single installations. If you want to install alongside Instance ID 1 you need to specify which instance you want to use. If you have already installed instance 1, 2, and 3 then you need to find out what the next available instance is, for instance, Instance ID 4. Similarly, if instance 2 has been removed, you need to find out that there is a gap that can be reused. You can find out which Instance ID is currently in use by using the **dspmqinst** command.

Procedure

1. Type **dspmqinst** to find a free MSI Instance in the media being installed by reviewing the MSIMedia and MSIInstanceId values for the versions already installed. For example:

   ```
   InstName: Installation1
   InstDesc:
   Identifier:    1
   InstPath:      C:\Program Files\IBM\MQ
   Version:       9.0.0.0
   Primary:       Yes
   State:         Available
   MSIProdCode:   {74F6B169-7CE6-4EFB-8A03-2AA7B2DBB57C}
   MSIMedia:      9.0 Server
   MSIInstanceId: 1
   ```

2. If MSI Instance ID 1 is in use and you want to use MSI Instance ID 2, the following parameters must be added to the msiexec call:

   ```
   MSINEWINSTANCE=1 TRANSFORMS=":instanceId7.mst;1033.mst"
   ```

What to do next

For multiple installations, the **INSTALLATIONNAME** or **PGMFOLDER** must be supplied as an additional parameter on any non-interactive installation command. Supplying the **INSTALLATIONNAME** or **PGMFOLDER** ensures that you do not work with the wrong installation in case you omit or incorrectly specify the **TRANSFORMS** parameter.

Using transforms with msiexec for client installation: Windows

MSI can use transforms to modify an installation. During IBM MQ installation, transforms can be used to support different national languages. IBM MQ is supplied with transform files in the `\MSI` folder of the client image. These files are also embedded in the IBM MQ Windows installer package, `IBM MQ.msi`.

On the **msiexec** command line, you can specify the required language by using the TRANSFORMS property in a property=value pair. For example:

```
TRANSFORMS="1033.mst"
```

You can also specify the full path and file name of the transform file. Again, the quotation marks surrounding the value are optional. For example:

```
TRANSFORMS="D:\Msi\1033.mst"
```

Table 71 on page 488 shows the locale identifier, language, and the transform file name to use in the **msiexec** command line.

You might need to merge transforms to install multiple installations of the same version, for example:

```
TRANSFORMS=":InstanceId2.mst;D:\Msi\1033.mst"
```

You can also specify the required language by using the MQLANGUAGE property with the **MQParms** command. For information about the msiexec property=value parameters, see “MQParms parameter file - client installation” on page 490.

Parameters

Table 71. Supplied transform files for various language support. This table shows the supplied transform files, the resulting language, and the numeric value to use in the **msiexec** command line.

Language	Transform File name	Value
U.S. English	1033.mst	1033
German	1031.mst	1031
French	1036.mst	1036
Spanish	1034.mst	1034
Italian	1040.mst	1040
Brazilian Portuguese	1046.mst	1046
Japanese	1041.mst	1041
Korean	1042.mst	1042
Simplified Chinese	2052.mst	2052
Traditional Chinese	1028.mst	1028
Czech	1029.mst	1029
Russian	1049.mst	1049
Hungarian	1038.mst	1038
Polish	1045.mst	1045

Creating a response file for client installation: Windows

A response file is used with **msiexec** on a client. You can create it in three ways.

About this task

A response file is used with the **msiexec** command. For further information, see "Using a response file with msiexec" on page 457.

Procedure

There are three ways to create a response file for installation:
- Copy and edit the file `Response.ini` that is supplied on the IBM MQ Windows Server DVD, using an ASCII file editor.
- Create your own response file using an ASCII file editor.
- Use the **msiexec** command with the **SAVEINI** (and optionally, the **ONLYINI**) command line parameters to generate a response file that contains the same installation options. See Table 63 on page 457.

Example

A typical example of using **msiexec** with the **SAVEINI** parameter is here:

```
msiexec /i "path\IBM MQ.msi" /q SAVEINI="response_file"
TRANSFORMS="1033.mst" AGREETOLICENSE="yes"
```

Installing a client using the MQParms command: Windows

You can use the **MQParms** command to invoke installation or uninstallation of an IBM MQ client.

Before you begin

The **MQParms** command can use parameters on a command line, or those specified in a parameter file. The parameter file is an ASCII text file that contains the parameter values that you want to set for the installation. The **MQParms** command takes the specified parameters and generates the corresponding **msiexec** command line.

This means that you can save all the parameters that you want to use with the **msiexec** command in a single file.

If you are running IBM MQ on Windows systems with User Account Control (UAC) enabled, you must invoke the installation with elevated privileges. If you are using the Command prompt or IBM MQ Explorer elevate privileges by using a right-click to start the program and selecting **Run as administrator**. If you try to run the `MQParms` program without using elevated privileges, the installation fails with an error of AMQ4353 in the installation log.

For silent operations, this must include the **/q** or **/qn** parameter, either on the command line, or in the [MSI] stanza of the parameter file. You must also set the AGREETOLICENSE parameter to "yes".

You can specify many more parameters in the parameter file that you use with the `MQParms` command than you can in the response file that you use directly with the **msiexec** command. Also, as well as parameters that the IBM MQ installation uses, you can specify parameters that can be used by the Prepare IBM MQ wizard.

If you do not complete the Prepare IBM MQ Wizard directly after IBM MQ installations or if for any reason your machine is rebooted between completing IBM MQ installation and completing the Prepare IBM MQ Wizard, ensure that the wizard is run with Administrator privilege afterward, otherwise the installation is incomplete, and might fail. You might also see Open File - Security Warning dialog boxes that list International Business Machines Limited as the publisher. Click **Run** to allow the wizard to continue

An example of the file `MQParms.ini` is supplied with IBM MQ. This file contains default installation parameters.

There are two ways to create a parameter file for installation:
- Copy and edit the file `MQParms.ini` that is supplied with the product, using an ASCII file editor.
- Create your own parameter file using an ASCII file editor.

About this task

To invoke installation using the `MQParms` command:

Procedure

1. From a command line, change to the root folder of the IBM MQ client CD (that is, the location of the file MQParms.exe).
2. Enter the following command:

   `MQParms [ `*`parameter_file`*` ] [ `*`parameters`*` ]`

   where:

   parameter_file

   is the file that contains the required parameter values. If this file is not in the same folder as

MQParms.exe, specify the full path and file name. If you do not specify a parameter file, the default is MQParms.ini. For further details, see "MQParms parameter file - client installation."

parameters
: are one or more command-line parameters, for a list of these, see the MSDN Command-Line Options web page.

Example

A typical example of an MQParms command is:

```
MQParms "c:\MyParamsFile.ini" /l*v c:\install.log
```

If you specify a parameter both on the command line and in the parameter file, the setting on the command line takes precedence.

If you do not specify `/i`, `/x`, `/a`, or `/j`, MQParms defaults to standard installation using the IBM MQ Windows Installer package, IBM IBM MQ.msi. That is, it generates the following part of the command line:

```
/i " current_folder \MSI\IBM MQ.msi"
```

MQParms parameter file - client installation: Windows

A parameter file is an ASCII text file that contains sections (stanzas) with parameters that can be used by the **MQParms** command. Typically, this is an initialization file such as `MQParms.ini`.

The **MQParms** command takes parameters from the following stanzas in the file:

[MSI] Contains general properties related to how the **MQParms** command runs and to the installation of IBM MQ.

The properties that you can set in this stanza are listed in "Installing a client using msiexec" on page 482, and Table 72 on page 491.

`MQParms` ignores any other stanzas in the file.

The stanza parameters are in the form property=value, where property is always interpreted as uppercase, but value is case sensitive. If a value string includes a blank, it must be enclosed in double quotation marks. Most other values can be enclosed in double quotation marks. Some properties can take more than one value, for example:

```
ADDLOCAL="Server,Client"
```

To clear a property, set its value to an empty string, for example:

```
REINSTALL=""
```

The following tables show the properties that you can set. The default is shown in bold.

For the [MSI] stanza, you can enter standard MSI command line options and properties. For example:

```
- /q
- ADDLOCAL="client"
- REBOOT=Suppress
```

Refer to Table 72 on page 491, and Table 73 on page 491 for the properties used to install IBM MQ.

Table 72 on page 491 shows additional properties in the stanza that affect how the `MQParms` command runs, but that do not affect the installation.

Table 72. Properties used by MQParms in the MSI stanza

Property	Values	Description
MQPLOG	*path* | *file_name*	**MQParms** generates a text log file with the specified name and location.
MQPLANGUAGE	**system** |user| *transform_value* |existing	The installation language. system. Install using the language of the default system locale (the default). user. Install using the language of the default locale of the user. *transform_value*. Install using the language specified by this value. See Table 73. existing. If MQ already exists on the system, the same language will be used by default, otherwise system is used.
MQPSMS	**0** |no	0 or no. **MQParms** does not wait for the `msiexec` command to end (the default). Any other value. **MQParms** waits for the `msiexec` command to end.
MQPINUSE	**0** |1	If MQPINUSE is set to 1, **MQParms** continues installing even if IBM MQ files are in use. If this option is used a reboot will be required to complete the installation.

Table 73. Valid values for the MQPLANGUAGE property

Language	Valid values		
U.S. English	English	en_us	1033
German	German	de_de	1031
French	French	fr_fr	1036
Spanish	Spanish	es_es	1034
Italian	Italian	it_it	1040
Brazilian Portuguese		pt_br	1046
Japanese	Japanese	ja_jp	1041
Korean	Korean	ko_kr	1042
Simplified Chinese		zh_cn	2052
Traditional Chinese		zh_tw	1028
Czech	Czech	cs_cz	1029
Russian	Russian	ru_ru	1049
Hungarian	Hungarian	hu_hu	1038
Polish	Polish	pl_pl	1045

A typical example of a parameter file is:

```
[MSI]
MQPLANGUAGE=1033
MQPLOG=%temp%\MQParms.log
MQPSMS=no
```

```
ADDLOCAL=CLIENT
/m miffile
REMOVE=""
/l*v c:\install.log
```

Modifying a client installation on Windows

Windows

You modify the installation when an IBM MQ for Windows client is installed and you want to remove or install some IBM MQ client features.

1. Insert the IBM MQ client DVD into the DVD drive.
2. If autorun is installed, the installation process starts.

   Otherwise, double-click **Setup** in the root folder of the DVD to start the installation process.

   The IBM MQ client Setup window is displayed. Click **Next** to continue.
3. Select **Modify**, then click **Next**.

   The Features panel is displayed.
4. To change the installation of a feature:
   a. Click the symbol next to the feature name to display a menu.
   b. Select the required option from:
      - Install this feature
      - Install this feature and all its subfeatures (if any)
      - Do not install this feature (remove if already installed).

      The symbol next to the feature name changes to show the current installation option.
5. When your selections are complete, click **Next**.
6. The IBM MQ client Setup window displays a summary of the installation you selected.

   To continue, click **Modify**.
7. Wait until the progress bar is complete.

   When the IBM MQ client is successfully installed, the IBM MQ client Setup window displays the following message: `Installation Wizard Completed Successfully`

   Click **Finish** to close the window.

Modifying a client installation using Add/Remove Programs: Windows

On some versions of Windows, you can modify an installation by using Add/Remove Programs.

For Windows 7 follow these steps.

1. From the Windows taskbar, select **Start** > **Control Panel**.
2. Select **Add/Remove Programs**.
3. Select **IBM MQ**.
4. Select **Change**.

   The IBM MQ Setup window with the Program Maintenance panel is displayed. Follow the procedure for modifying the installation by using the process from step 3 to the end.

   For Windows 8, the **Add/Remove Programs** option uninstalls the whole product.

   You need to run the `setup.exe` file from the original installation media to make any modifications to the installation.

Modifying a client installation silently using msiexec: Windows

You can use msiexec to modify an IBM MQ client installation.

To silently modify an IBM MQ client installation using msiexec, follow the instructions on the installation pages, but set the ADDLOCAL parameter to include the features you want to add, and set the REMOVE parameter to the features you want to remove.

For example if you used ADDLOCAL="JavaMsg" and REMOVE="" it would modify the installation to include the Java Messaging and Web Services feature.

The instructions for msiexec begin here: "Installing a client using msiexec" on page 482

Modifying a client installation silently using MQParms: Windows

You can use the **`MQParms`** command to modify an IBM MQ client installation.

To silently modify an IBM MQ client installation using **`MQParms`**, follow the instructions on the installation pages, but set the ADDLOCAL parameter to include the features you want to add, and set the REMOVE parameter to the features you want to remove.

For example if you used ADDLOCAL="JavaMsg" and REMOVE="" it would modify the installation to include the Java Messaging and Web Services feature.

For details of the **`MQParms`** command, see "Installing a client using the MQParms command" on page 489.

Redistributable clients on Windows

Windows

The Windows 64-bit image is shipped in a `Win64.zip` file.

File names

The archive or .zip file names describe the file contents and equivalent maintenance levels. For example, in IBM MQ Version 8.0.0, Fix Pack 4 the client images are available under the following file names:

Windows
`8.0.0.4-WS-MQC-Redist-Win64.zip`

Java - all platforms
`8.0.0.4-WS-MQC-Redist-Java.zip`

Choosing the runtime files to distribute with an application

A script file named **`genmqpkg`** is provided by the redistributable client under the `bin` directory.

You can use the **`genmqpkg`** script to generate a smaller subset of files that are tailored to the needs of the application, for which the files are intended to be distributed.

You are asked a series of interactive `Yes` or `No` questions to determine the runtime requirements for an IBM MQ application.

Finally, **`genmqpkg`** asks you to supply a new target directory, where the script duplicates the required directories and files.

Important: IBM support is only able to provide assistance with the full, unmodified set of files contained within the redistributable client packages.

Other considerations

There is a minor change to the default data path of a non-installed client, and now the path is, on:

Windows
: `%HOMEDRIVE%%HOMEPATH%\IBM\MQ\data`

A redistributable client runtime co-exists with a full IBM MQ client or server installation, provided that they are installed in different locations.

Important: Unpacking a redistributable image into the same location as a full IBM MQ installation is not supported.

Classpath changes

The classpath used by **`dspmqver`**, **`setmqenv`**, and **`crtmqenv`** commands, add the `com.ibm.mq.allclient.jar` to the environment, immediately following the `com.ibm.mq.jar` and `com.ibm.mqjms.jar`.

An example of **`dspmqver`** output from the redistributable client on Windows:

```
Name:        IBM MQ
Version:     8.0.0.4
Level:       p800-804-L150909
BuildType:   IKAP - (Production)
Platform:    IBM MQ for Windows (x64 platform)
Mode:        64-bit
O/S:         Windows 7 Professional x64 Edition, Build 7601: SP1
InstName:    MQNI08000004
InstDesc:    IBM MQ V8.0.0.4 (Redistributable)
Primary:     No
InstPath:    C:\Users\johndoe\Desktop\Redist
DataPath:    C:\Users\johndoe\IBM\MQ\data
MaxCmdLevel: 802
```

Related concepts:
"Redistributable clients" on page 212
The IBM MQ redistributable client is a collection of runtime files that are provided in a `.zip` or `.tar` file that can be redistributed to third parties under redistributable license terms, which provides a simple way of distributing applications and the runtime files that they require in a single package.

.NET application runtime - Windows only

Windows

Considerations when using the .NET application.

The runtime DLL files laid down in the *redistributable* images on Windows for .NET applications are normally registered with the global assembly cache (GAC) by a user with system administrator privileges, when installing the primary installation. However, this severely limits the benefits of redistribution.

The *redistributable* package on the Windows platform does not provide any tooling to register DLLs with the GAC, so .NET applications have to locate the appropriate assemblies by other means. There are two options that work in this situation.

Probing

After checking the GAC, the .NET runtime attempts to locate required assemblies through probing. The first location checked is the application base, which is the root location where the application is being run. See the information on *How the Runtime Locates Assemblies* on the Microsoft Web site for more information.

Note that when using this approach, the maintenance level of the assemblies used when building the .NET application must match those used at runtime - for example an application built at IBM MQ Version 8.0.0, Fix Pack 4 must be run with the IBM MQ Version 8.0.0, Fix Pack 4 redistributable client runtime.

Using this approach, a .NET application placed in the `\bin` directory alongside the IBM MQ assemblies picks up assemblies from a primary IBM MQ installation (if one exists), falling back to the redistributable copies.

1. Compile the .NET application under a full IBM MQ installation, that is `csc \t:exe \r:System.dll \r:amqmdnet.dll \lib: \out:nmqwrld.exe nmqwrld.cs`.
2. Copy the `exe` file in the redistributable client zip file into the `\bin` directory.

DEVPATH environment variable

An alternative, that allows your application to be built, distributed, extracted and run as previously, is to use DEVPATH to locate the required assemblies. Unlike with the probing approach, this option overrides any matching assemblies from the GAC. However it is for this reason that Microsoft discourages its use in a production environment.

This approach can be effective where there is a possibility that a full IBM MQ installation is installed on the client. However, there is a good reason to always use the redistributable assemblies.

1. Compile the .NET application under a full IBM MQ installation, that is `csc \t:exe \r:System.dll \r:amqmdnet.dll \lib: \out:nmqwrld.exe nmqwrld.cs)`
2. Copy the `exe` file into, or alongside, the redistributable client zip file.
3. In the same directory as the `exe`, create an application configuration file with the name of the `exe` file suffixed by `.config`, that is `nmqwrld.exe.config` with the following contents:
   ```
   <configuration>
       <runtime>
         <developmentMode  developerInstallation="true" />
       </runtime>
   </configuration>
   ```
4. Call **`setmqenv -s`** and set the *DEVPATH* environment variable to specify the `\bin` directory from the redistributable image before running the application, that is:
   ```
   set DEVPATH=%MQ_INSTALLATION_PATH%\bin
   ```

Starting and stopping trace for the .NET redistributable managed client

You generate trace for the .NET redistributable managed client in the same way as for the stand-alone .NET client. For more information, see Using the stand-alone IBM MQ .NET client.

More information on .NET

For more information on .NET, see Writing and deploying IBM MQ .NET programs.

Verifying an IBM MQ installation on Windows

Windows

The topics in this section provide instructions on how to verify a server or a client installation of IBM MQ on Windows systems.

About this task

You can verify a local (stand-alone) server installation or a server-to-server installation of the IBM MQ server:
- A local server installation has no communication links with other IBM MQ installations.
- A server-to-server installation does have links to other installations.

You can also verify that your IBM MQ MQI client installation completed successfully and that the communication link is working.

Procedure

- To verify a local server installation, see "Verifying a local server installation on Windows."
- To verify a server-to-server installation, see "Verifying a server-to-server installation on Windows" on page 500.
- To verify a client installation, see "Verifying a client installation on Windows" on page 505.

Verifying a local server installation on Windows

Windows

You can use either the command line or the postcard application to verify a local (stand-alone) installation on Windows.

About this task

You can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a local server installation using the command line on Windows" on page 497.
- To use the postcard application to verify an installation, see "Verifying a local server installation using the Postcard application on Windows" on page 498.

Verifying a local server installation using the command line on Windows: ▶ Windows

On Windows systems, you can verify a local installation by using the command line to create a simple configuration of one queue manager and one queue. You can also verify an installation using the postcard application.

Before you begin

To verify the installation, you must first install the samples package.

Before beginning the verification procedure, you might want to check that you have the latest fixes for your system. For more information about where to find the latest updates, see "Checking requirements on Windows" on page 444.

About this task

Use the following steps to configure your default queue manager from the command line. After the queue manager is configured, use the `amqsput` sample program to put a message on the queue. You then use the `amqsget` sample program to get the message back from the queue.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Set up your environment:
   a. Set up environment variables for use with a particular installation by entering the following command:
      ```
      MQ_INSTALLATION_PATH\bin\setmqenv -s
      ```
      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
   b. Check that the environment is set up correctly by entering the following command:
      ```
      dspmqver
      ```
      If the command completes successfully, and the expected version number and installation name are returned, the environment is set up correctly.
2. Create a queue manager called `QMA` by entering the following command:
   ```
   crtmqm QMA
   ```
   Messages indicate when the queue manager is created, and when the default IBM MQ objects are created.
3. Start the queue manager by entering the following command:
   ```
   strmqm QMA
   ```
   A message indicates when the queue manager starts.
4. Start MQSC by entering the following command:
   ```
   runmqsc QMA
   ```
   A message indicates when MQSC starts. MQSC has no command prompt.
5. Define a local queue called `QUEUE1` by entering the following command:
   ```
   DEFINE QLOCAL (QUEUE1)
   ```
   A message indicates when the queue is created.

6. Stop MQSC by entering the following command:

```
end
```

Messages are shown, followed by the command prompt.

Note: Subsequent steps require that the samples package is installed.

7. Put a message on the queue by entering the following command:

```
amqsput QUEUE1 QMA
```

The following messages are shown:

```
Sample AMQSPUT0 start
target queue is QUEUE1
```

8. Type some message text on one or more lines, where each line is a different message. Enter a blank line to end the message input. The following message is shown:

```
Sample AMQSPUT0 end
```

Your messages are now on the queue and the command prompt is shown.

9. Get the messages from the queue, by entering the following command:

```
amqsget QUEUE1 QMA
```

The sample program starts, and your messages are displayed.

Results

You have successfully verified your local installation.

Verifying a local server installation using the Postcard application on Windows: ▶ Windows

Sending messages successfully between two Postcard applications verifies a local installation.

Before you begin

The postcard application is Java based and requires a system with the ability to view a graphical display.

You must ensure that you are a member of the IBM MQ administrators group (**mqm**).

Note: Using Postcard to verify an IBM MQ installation is only possible if there is one IBM MQ installation on that box. The Default Configuration wizard will not create a default configuration if a queue manager already exists on the box. The Default Configuration wizard will run on any installation on a box but only one default configuration can be created per box. Using Postcard to verify second and subsequent installations of IBM MQ on the same box is not possible.

To verify that the local installation is working, you can run two instances of the Postcard application on the same server. The postcard application can send messages to, and receive messages from, other postcard applications. Successful sending and receiving of messages verifies that IBM MQ is installed and working correctly on the server.

Procedure

1. Log on as a user in group **mqm**.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *MQ_INSTALLATION_PATH*\java\bin. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.

   2) Run the postcard application by entering the following command:
      ```
      postcard
      ```
   b. From the IBM MQ Explorer: On Windows systems, you can start IBM MQ Explorer by using the system menu, the **`MQExplorer`** command (preferred command), or the `MQExplorer` executable file. The **`strmqcfg`** command is still usable.
      1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
      2) Click **Launch Postcard** to start the Postcard.
3. At the Postcard - Sign On window, type in a nickname to use to send messages within the Postcard application (for example, `User1`).
4. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Launching the Default Configuration creates a default queue manager.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK** to display your first Postcard window.
5. Run a second instance of the Postcard application by following the steps used to open the first instance of the Postcard application.
6. The Postcard - Sign On panel is displayed again. Type in a second nickname to use to send messages within this second Postcard application (for example, `User2`).
7. Repeat the selection of the queue manager that you want to use as the mailbox (as described in step 4). The queue manager you select for this second Postcard must be the same queue manager as used for the first instance of the Postcard application.
8. In the first Postcard, (User1), enter the nickname (`User2`) for the second Postcard application in the **To:** field. Because the sender and receiver are on the same server, you can leave the **On:** field blank.
9. Type a message in the **Message:** field and click **Send**.
10. The **Postcards sent and received** area of the Postcard shows details of the message. In the sending Postcard, the message is displayed as sent. In the receiving Postcard, the message is displayed as received.
11. In the receiving Postcard, (User2), double-click the message in the **Postcards sent and received** area to view it. When this message arrives, it verifies that IBM MQ is correctly installed.

What to do next

Depending on your situation, you might want to do the following tasks:
- Install IBM MQ on other servers. Follow the installation procedure for the appropriate platform. Ensure that you use the **Join Default Cluster** window in the Default Configuration wizard to add the other servers to the cluster on your first server.
- Install the IBM MQ MQI client on other servers.

- Continue with further administration tasks, see Administering IBM MQ.

Verifying a server-to-server installation on Windows

Windows

You can use either the command line or the postcard application to verify a server-to-server installation on Windows.

Before you begin

For a server-to-server verification, the communication links between the two systems must be checked. Before you can do the verification, you must therefore ensure that the communications protocol is installed and configured on both systems.

On Windows, IBM MQ supports TCP, SNA, NetBios, and SPX.

The examples in this task use TCP/IP. If you do not use TCP, see Setting up communication for Windows.

About this task

For a server-to server installation, you can use the command line to verify that IBM MQ is successfully installed, and that the associated communication links are working properly.

You can also verify an installation using the postcard application. The postcard application is Java based and requires a system with the ability to view a graphical display.

Procedure

- To use the command line to verify an installation, see "Verifying a server-to-server installation using the command line on Windows."
- To use the postcard application to verify an installation, see "Verifying a server-to-server installation using the Postcard application on Windows" on page 503.

Verifying a server-to-server installation using the command line on Windows: Windows

You can verify a server-to-server installation using two servers, one as a sender and one as a receiver.

Before you begin

- Make sure that TCP/IP and IBM MQ are installed on both servers (see "Verifying a server-to-server installation on Windows").
- Make sure that you are a member of the IBM MQ administrators group (**`mqm`**) on each server.
- Decide which installation is the sender server and which installation is the receiver server. The installations might be on the same system, or on different systems.

About this task

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. On the **`receiver`** server:
   a. Check which ports are free, for example by running **`netstat`**. For more information about this command, see the documentation of your operating system.

If port 1414 is not in use, make a note of 1414 to use as the port number in step 2 g. Use the same number for the port for your listener later in the verification. If it is in use, note a port that is not in use; for example 1415.

b. Set up the environment for the installation you are using by entering the following command at the command prompt:

   ```
   MQ_INSTALLATION_PATH\bin\setmqenv -s
   ```

   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.

c. Create a queue manager called `QMB` by entering the following command at the command prompt:

   ```
   crtmqm QMB
   ```

   Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.

d. Start the queue manager by entering the following command:

   ```
   strmqm QMB
   ```

   A message tells you when the queue manager has started.

e. Start MQSC by entering the following command:

   ```
   runmqsc QMB
   ```

   A message tells you that MQSC has started. MQSC has no command prompt.

f. Define a local queue called `RECEIVER.Q` by entering the following command:

   ```
   DEFINE QLOCAL (RECEIVER.Q)
   ```

   A message tells you the queue has been created.

g. Define a listener by entering the following command:

```
DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT ( PORT_NUMBER )
```

   Where *port_number* is the name of the port the listener runs on. This number must be the same as the number used when defining your sender channel.

h. Start the listener by entering the following command:

   ```
   START LISTENER (LISTENER1)
   ```

   Note: Do not start the listener in the background from any shell that automatically lowers the priority of background processes.

i. Define a receiver channel by entering the following command:

   ```
   DEFINE CHANNEL (QMA.QMB) CHLTYPE (RCVR) TRPTYPE (TCP)
   ```

   A message tells you when the channel has been created.

j. End MQSC by typing:

   ```
   end
   ```

   Some messages are displayed, followed by the command prompt.

2. On the **sender** server:

   a. Set up the environment for the installation you are using by entering the following command at the command prompt:

      ```
      MQ_INSTALLATION_PATH\bin\setmqenv -s
      ```

      where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.

   b. Create a queue manager called `QMA` by entering the following command at the command prompt:

      ```
      crtmqm QMA
      ```

Messages tell you that the queue manager has been created, and that the default IBM MQ objects have been created.

c. Start the queue manager, by entering the following command:

```
strmqm QMA
```

A message tells you when the queue manager has started.

d. Start MQSC by entering the following command:

```
runmqsc QMA
```

A message tells you that an MQSC session has started. MQSC had no command prompt.

e. Define a local queue called `QMB` (to be used as a transmission queue) by entering the following command:

```
DEFINE QLOCAL (QMB) USAGE (XMITQ)
```

A message tells you when the queue has been created.

f. Define a local definition of the remote queue by entering the following command:

```
DEFINE QREMOTE (LOCAL.DEF.OF.REMOTE.QUEUE) RNAME (RECEIVER.Q) RQMNAME ('QMB') XMITQ (QMB)
```

g. Define a sender channel by entering the following command:

```
DEFINE CHANNEL (QMA.QMB) CHLTYPE (SDR) CONNAME ('CON-NAME(PORT)') XMITQ (QMB) TRPTYPE (TCP)
```

con-name is the TCP/IP address of the receiver system. If both installations are on the same system, the *con-name* is `localhost`. *port* is the port you noted in 1 a. If you do not specify a port, the default value of 1414 is used.

h. Start the sender channel by entering the following command:

```
START CHANNEL(QMA.QMB)
```

The receiver channel on the receiver server starts automatically when the sender channel starts.

i. Stop MQSC by entering the following command:

```
end
```

Some messages are displayed, followed by the command prompt.

j. If both the sender server and receiver server are installations on the same system, check that the queue managers have been created on different installations by entering the following command:

```
dspmq -o installation
```

If the queue managers are on the same installation, move either QMA to the sender installation or QMB to the receiver installation by using the **setmqm** command. For more information, see setmqm.

k. Put a message on the local definition of the remote queue, which in turn specifies the name of the remote queue. Enter the following command:

```
amqsput LOCAL.DEF.OF.REMOTE.QUEUE QMA
```

A message tells you that `amqsput` has started.

l. Type some message text on one or more lines, followed by a blank line. A message tells you that `amqsput` has ended. Your message is now on the queue and the command prompt is displayed again.

3. On the **receiver** server:

a. Get the message from the queue on the receiver by entering the following command:

```
amqsget RECEIVER.Q QMB
```

The sample program starts, and your message is displayed. After a pause, the sample ends. Then the command prompt is displayed.

Results

You have now successfully verified the server-to-server installation.

Verifying a server-to-server installation using the Postcard application on Windows: Windows

You can use two instances of the Postcard application to verify that a server-to-server installation is working.

Before you begin

You can use the Postcard application on two servers, one instance of the Postcard application on each server, to verify that a server-to-server installation is working. Successful sending and receiving of messages verifies that IBM MQ is successfully installed, and that communication between the two servers is working correctly.

Note:

- If the system has multiple IBM MQ installations, ensure that Postcard has not been run before on any installations on that server. As the default configuration can only exist on one IBM MQ MQ installation per system, the Default Configuration wizard and Postcard can not be used for verification of a second or any subsequent installation.
- The two server installations must be on different systems to do a server-to-server verification using the postcard application. To verify a server-to-server installation on the same machine, you can use the command line.
- Make sure that TCP/IP and IBM MQ are installed on both servers.
- Make sure that your systems are able to view a graphical display.
- Make sure that you are a member of the IBM MQ administrators group (**mqm**) on each server.
- Check that one of the following scenarios applies:
  - Neither server has had any queue managers created.
  - Use the Default Configuration wizard to create default queue managers on each server and link them to the default cluster.

    Details on how to use the Default Configuration wizard are provided in this topic.
  - Both servers have existing queue managers and these queue managers are in the same cluster.

    If your queue managers are not in the same cluster, create new queue managers on both servers. Then create a cluster, and ensure that the queue managers that you create on each server belong to that cluster.
  - You have configured channels to communicate between the two servers.

    For instructions on how to set up the channels, see "Verifying a server-to-server installation using the command line on Windows" on page 500. After you have set up the channels, follow the instructions in this topic to verify your server-to-server installation.

Procedure

1. On the first server, log on as a user in group **mqm**.
2. Start the postcard application in one of the following ways:
   a. From the command line:
      1) Change the directory to *MQ_INSTALLATION_PATH*`\java\bin`. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
      2) Run the postcard application by entering the following command:
      ```
      postcard
      ```
   b. From the IBM MQ Explorer: On Windows systems, you can start IBM MQ Explorer by using the system menu, the `MQExplorer` executable file, or the **strmqcfg** command.

1) If the Welcome to IBM MQ Explorer Content view page does not show, click **IBM MQ** in the Navigator view to show the Welcome page.
2) Click **Launch Postcard** to start the Postcard.

3. At the Postcard - Sign On window, type a nickname to use to send messages within the Postcard application. For example, `User1` for the first server, and `User2` for the second server.
4. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Work through the Default Configuration wizard. When you get to the option to join the queue manager to the default cluster, tick the check box. On the next screen:
     - For the first server, select **yes, make it the repository for the cluster**.
     - For the second server, select **No another computer has already joined the cluster as a repository**. When requested, enter the location of the repository, by typing the name of the sender server.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK**.
5. Select the queue manager to use as the mailbox:
   - If you do not have any queue managers, you are prompted to either launch the Default Configuration or close the Postcard application. Work through the Default Configuration wizard. When you get to the option to join the queue manager to the default cluster, tick the check box. On the next screen:
     - For the first server, select **yes, make it the repository for the cluster**.
     - For the second server, select **No another computer has already joined the cluster as a repository**. When requested, enter the location of the repository, by typing the name of the sender server.
   - If the only queue manager on your server is the default queue manager, this queue manager is used automatically for the postcard application. The default queue manager is created by running the Default Configuration wizard
   - If you have created your own queue managers, but you have not run the Default Configuration wizard, select an appropriate queue manager from the list.
   - If you have run the Default Configuration wizard and you want to use the default queue manager, but there are other queue managers on your server, select the **Advanced** check box. Then select **Use Default Configuration as mailbox**.
   - If you have run the Default Configuration wizard and also created your own queue managers, and you do not want to use the default queue manager, select the **Advanced** check box. Then select **Choose queue manager as mailbox**, and then select the appropriate queue manager from the list.

   When your selection is complete, click **OK**.
6. Complete steps 1 - 5 for the second server.
7. In the Postcard on the first server:
   a. Enter the nickname (`user2`) for the Postcard application on the second server in the **To:** field.

   b. Enter the queue manager on the second server in the **On:** field.
   c. Type a message in the **Message:** field and click **Send**.
8. In the Postcard on the second server:
   a. In the **Postcards sent and received**, double-click the message marked as received to view the message from the first server.
   b. Optional: Send a postcard to the first server by adapting the instructions in step 7. You must enter details of the first server in the **To:** field and the **On:** field.

   The messages verify that IBM MQ is correctly installed and that your communication link between the two servers is working correctly.

Verifying a client installation on Windows

Windows

You can verify that your IBM MQ MQI client installation completed successfully and that the communication link is working.

About this task

The verification procedure shows how to create a queue manager called `queue.manager.1`, a local queue called `QUEUE1`, and a server-connection channel called `CHANNEL1` on the server.

It shows how to create the client-connection channel on the IBM MQ MQI client workstation. It then shows how to use the sample programs to put a message onto a queue, and get the message from the queue.

The example does not address any client security issues. See Setting up IBM MQ MQI client security for details if you are concerned with IBM MQ MQI client security issues.

The verification procedure assumes that:
- The full IBM MQ server product has been installed on a server.
- The server installation is accessible on your network.
- The IBM MQ MQI client software has been installed on a client system.
- The IBM MQ sample programs have been installed.
- TCP/IP has been configured on the server and client systems. For more information, see Configuring connections between the server and client.

Procedure

1. Set up the server and client:
   - To set up the server and client by using the command line, follow the instructions in “Setting up the server and client using the command line on Windows” on page 506.
   - To set up the server and client by using IBM MQ Explorer, follow the instructions in “Setting up the server and client using IBM MQ Explorer on Windows” on page 509.
2. Test the communications between client and server, using the instructions in “Testing communication between a client and a server on Windows” on page 512.

Related tasks:

"Installing an IBM MQ client on Windows" on page 481
This topic describes how to install IBM MQ client on Windows systems. This procedure can be used for installing a first or a subsequent installation.

Setting up the server and client using the command line on Windows: Windows

You can use the command line to create the objects that you need to use to verify a client installation on Linux. On the server you create a queue manager, a local queue, a listener, and a server-connection channel. You must also apply security rules to allow the client to connect and make use of the queue defined. On the client you create a client-connection channel. After setting up the server and client, you can then use the sample programs to complete the verification procedure.

Before you begin

Before starting this task, review the information in "Verifying a client installation on Windows" on page 505.

About this task

This task explains how to use the command line to set up the server and client so that you can verify your client installation.

If you prefer to use IBM MQ Explorer, see "Setting up the server and client using IBM MQ Explorer on Windows" on page 509.

Procedure

1. Set up the server by following the instructions in "Setting up the server using the command line on Windows."
2. Set up the client by following instructions in "Connecting to a queue manager, using the `MQSERVER` environment variable on Windows" on page 508.

What to do next

Test the communications between client and server by following the instructions in "Testing communication between a client and a server on Windows" on page 512.

Setting up the server using the command line on Windows: Windows

Follow these instructions to create a queue manager, queue, and channel on the server. You can then use these objects to verify the installation.

About this task

These instructions assume that no queue manager or other IBM MQ objects have been defined.

IBM MQ object definitions are case-sensitive. Any text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Create a user ID on the server that is not in the `mqm` group. This user ID must exist on the server and client. This is the user ID that the sample applications must be run as, otherwise a 2035 error is returned.

2. You must set various environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:

```
MQ_INSTALLATION_PATH\bin\setmqenv -s
```

   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed
3. Create a queue manager called QUEUE.MANAGER.1 by entering the following command:

   ```
   crtmqm QUEUE.MANAGER.1
   ```

   You see messages telling you that the queue manager has been created.
4. Start the queue manager by entering the following command:

   ```
   strmqm QUEUE.MANAGER.1
   ```

   A message tells you when the queue manager has started.
5. Start MQSC by entering the following command:

   ```
   runmqsc QUEUE.MANAGER.1
   ```

   A message tells you that an MQSC session has started. MQSC has no command prompt.
6. Define a local queue called QUEUE1 by entering the following command:

   ```
   DEFINE QLOCAL(QUEUE1)
   ```

   A message tells you when the queue has been created.
7. Allow the user ID that you created in step 1 to use QUEUE1 by entering the following command:

   ```
   SET AUTHREC PROFILE(QUEUE1) OBJTYPE(QUEUE) PRINCIPAL(' non_mqm_user ') AUTHADD(PUT,GET)
   ```

   where *non_mqm_user* is the user ID created in step 1. A message tells you when the authorization has been set. You must also run the following command to give the user ID authority to connect:

   ```
   SET AUTHREC OBJTYPE(QMGR) PRINCIPAL(' non_mqm_user ') AUTHADD(CONNECT)
   ```

   If this command is not run, a 2305 stop error is returned.
8. Define a server-connection channel by entering the following command:

   ```
   DEFINE CHANNEL (CHANNEL1) CHLTYPE (SVRCONN) TRPTYPE (TCP)
   ```

   A message tells you when the channel has been created.
9. Allow your client channel to connect to the queue manager and run under the user ID that you created in step 1, by entering the following MQSC command:

   ```
   SET CHLAUTH(CHANNEL1) TYPE(ADDRESSMAP) ADDRESS(' client_ipaddr ') MCAUSER(' non_mqm_user ')
   ```

   where *client_ipaddr* is the IP address of the client system, and *non_mqm_user* is the user ID created in step 1. A message tells you when the rule has been set.
10. Define a listener by entering the following command:

    ```
    DEFINE LISTENER (LISTENER1) TRPTYPE (TCP) CONTROL (QMGR) PORT (port_number)
    ```

    where *port_number* is the number of the port the listener is to run on. This number must be the same as the number used when defining your client-connection channel in "Installing an IBM MQ client on Windows" on page 481.

    Note: If you omit the port parameter from the command, a default value of 1414 is used for the listener port. If you want to specify a port other than 1414, you must include the port parameter in the command, as shown.
11. Start the listener by entering the following command:

    ```
    START LISTENER (LISTENER1)
    ```
12. Stop MQSC by entering:

```
end
```

You see some messages, followed by the command prompt.

What to do next

Follow the instructions to set up the client. See "Connecting to a queue manager, using the `MQSERVER` environment variable on Windows."

Connecting to a queue manager, using the `MQSERVER` environment variable on Windows: Windows

When an IBM MQ application is run on the IBM MQ MQI client, it requires the name of the MQI channel, the communication type, and the address of the server to be used. Provide these parameters by defining the `MQSERVER` environment variable.

Before you begin

Before you start this task, you must complete the task, "Setting up the server using the command line on Windows" on page 506, and save the following information:
- The host name or IP address of the server and port number that you specified when creating the listener.
- The channel name of the server-connection channel.

About this task

This task describes how to connect an IBM MQ MQI client, by defining the `MQSERVER` environment variable on the client.

You can give the client access to the generated client channel definition table, `amqclchl.tab` instead; see Accessing client-connection channel definitions.

Alternatively, on Windows, if Active Directory support is enabled, the client discovers the client-connection information dynamically from the Active Directory.

Procedure
1. Log in as the userid that you created in Step 1 of "Setting up the server using the command line on Windows" on page 506.
2. Check the TCP/IP connection. From the client, enter one of the following commands:
   - `ping server-hostname`
   - `ping n.n.n.n`

     `n.n.n.n` represents the network address. You can set the network address in IPv4 dotted decimal form, for example, `192.0.2.0`. Alternatively, set the address in IPv6 hexadecimal form, for example `2001:0DB8:0204:acff:fe97:2c34:fde0:3485`.

   If the **`ping`** command fails, correct your TCP/IP configuration.
3. Set the `MQSERVER` environment variable. From the client, enter the following command:
   ```
   SET MQSERVER=CHANNEL1/TCP/server-address (port)
   ```
   Where:
   - *CHANNEL1* is the server-connection channel name.
   - *server-address* is the TCP/IP host name of the server.
   - *port* is the TCP/IP port number the server is listening on.

If you do not give a port number, IBM MQ uses the one specified in the `qm.ini` file, or the client configuration file. If no value is specified in these files, IBM MQ uses the port number identified in the TCP/IP services file for the service name `MQSeries`. If an `MQSeries` entry in the services file does not exist, a default value of `1414` is used. It is important that the port number used by the client and the port number used by the server listener program are the same.

What to do next

Use the sample programs to test communication between the client and server; see "Testing communication between a client and a server on Windows" on page 512.

Setting up the server and client using IBM MQ Explorer on Windows: Windows

You can use IBM MQ Explorer to create the objects that you need to use to verify a client installation on Windows. On the server, you create a queue manager, a local queue, a listener and a server-connection channel. On the client system you create a client-connection channel. Then from the command line you use the sample PUT and GET programs to complete the verification procedure.

Before you begin

Before starting this task, review the information in "Verifying a client installation on Windows" on page 505.

About this task

This task explains how to use IBM MQ Explorer to set up the server and client so that you can verify your client installation.

If you prefer to use the command line, see "Setting up the server and client using the command line on Windows" on page 506.

Procedure

1. Set up the server by following the instructions in "Setting up the server using IBM MQ Explorer on Windows" on page 510.
2. Set up the client by following instructions in "Setting up the client using IBM MQ Explorer on Windows" on page 511.

What to do next

Test the communications between client and server by following the instructions in "Testing communication between a client and a server on Windows" on page 512.

Related tasks:

"Installing an IBM MQ client on Windows" on page 481
This topic describes how to install IBM MQ client on Windows systems. This procedure can be used for installing a first or a subsequent installation.

Setting up the server using IBM MQ Explorer on Windows: ▶ Windows

On the server, you create a queue manager, a local queue, a listener and a server-connection channel. On the client system you create a client-connection channel. Then from the command line you use the sample PUT and GET programs to complete the verification procedure.

About this task

You can use the IBM MQ Explorer to create a queue manager, queue and server-connection channel on Windows. This topic describes the tasks necessary to set up the server.

Procedure

1. Create a queue manager:
   a. Open IBM MQ Explorer.
   b. Right-click the folder called **Queue Managers**, select **New** > **Queue Manager**.
   c. In the first entry field, type the queue manager name, *QUEUE.MANAGER.1*, and click **Finish**.
2. Create a local queue:
   a. Expand the queue manager you have just created and right-click **queues**.
   b. Select **New** > **Local Queue**.
   c. Enter the queue name, *QUEUE1*, and click **Finish**.
3. Define the server-connection channel:
   a. Right-click **Channels**.
   b. Select **New** > **Server Connection Channel**.
   c. Enter the channel name, *CHANNEL1*, and click **Next**.
   d. In the dialog navigation pane, click **MCA** to open the MCA page.
   e. In the MCA User ID field, enter a userid that is a member of the mqm group, typically your own.
   f. Click **Finish**.
4. Run the listener.

   The listener is automatically started when the queue manager is configured. To check that the listener is running, open **Listeners** and look for `LISTENER.TCP`.

What to do next

Set up the client. See "Setting up the client using IBM MQ Explorer on Windows" on page 511.

Related tasks:

"Testing communication between a client and a server on Windows" on page 512
On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

"Installing an IBM MQ client on Windows" on page 481
This topic describes how to install IBM MQ client on Windows systems. This procedure can be used for installing a first or a subsequent installation.

Setting up the client using IBM MQ Explorer on Windows: Windows

You can use IBM MQ Explorer to define the client-connection if you are setting up the client and server on the same workstation on a Windows system.

Procedure

1. Select the queue manager, *QUEUE.MANAGER.1*
2. Open the **Channels** folder, then right-click **Client Connections** > **New** > **Client-connection Channel...**
3. Enter the channel name, *CHANNEL1*, for the client connection, and click **Next**.
4. Enter the queue manager name, *QUEUE.MANAGER.1*
5. Enter the following string as the connection name:
   ```
   server-address (port)
   ```
   Where:
   - `server-address` is the TCP/IP host name of the server
   - `port` is the TCP/IP port number the server is listening on
6. Click Finish.
7. From the command line, set the `MQCHLLIB` environment variable. Enter the following command:
   ```
   SET MQCHLLIB= MQ_INSTALLATION_PATH\qmgrs\QUEUE!MANAGER!1\@ipcc
   ```
   where `MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed

   Note: The queue manager name contains "**.**". IBM MQ creates the queue manager directory with the name, `QUEUE!MANAGER!1`

What to do next

Use the sample programs to test communication between the client and server. See "Testing communication between a client and a server on Windows" on page 512.

Related tasks:

"Setting up the server and client using IBM MQ Explorer on Windows" on page 509
You can use IBM MQ Explorer to create the objects that you need to use to verify a client installation on Windows. On the server, you create a queue manager, a local queue, a listener and a server-connection channel. On the client system you create a client-connection channel. Then from the command line you use the sample PUT and GET programs to complete the verification procedure.

"Installing an IBM MQ client on Windows" on page 481
This topic describes how to install IBM MQ client on Windows systems. This procedure can be used for installing a first or a subsequent installation.

Testing communication between a client and a server on Windows: Windows

On the IBM MQ MQI client workstation, use the amqsputc sample program to put a message on the queue at the server workstation. Use the amqsgetc sample program to get the message from the queue back to the client.

Before you begin

Complete the previous topics in this section:
- Set up a queue manager, channels, and queue.
- Open a command window.
- Set system environment variables.

About this task

Note that IBM MQ object definitions are case-sensitive. Text entered as an MQSC command in lowercase is converted automatically to uppercase unless you enclose it in single quotation marks. Make sure that you type the examples exactly as shown.

Procedure

1. Change into the *MQ_INSTALLATION_PATH*\Tools\C\Samples\Bin directory for 32 bit systems or the *MQ_INSTALLATION_PATH*\Tools\C\Samples\Bin64 directory for 64 bit systems. *MQ_INSTALLATION_PATH* represents the high-level directory in which IBM MQ is installed.
2. You must set certain environment variables so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
   MQ_INSTALLATION_PATH\bin\setmqenv -s
   ```
   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed
3. Start the PUT program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:
   ```
   amqsputc QUEUE1 QUEUE.MANAGER.1
   ```
   If the command is successful, the following messages are displayed:
   ```
   Sample AMQSPUT0 start target queue is QUEUE1
   ```
   Tip: You might get the error, MQRC_NOT_AUTHORIZED (2035). By default, channel authentication is enabled when a queue manager is created. Channel authentication prevents privileged users accessing a queue manager as an IBM MQ MQI client. For verifying the installation, you can either change the MCA user ID to a non-privileged user, or disable channel authentication. To disable channel authentication run the following MQSC command:
   ```
   ALTER QMGR CHLAUTH(DISABLED)
   ```
   When you finish the test, if you do not delete the queue manager, re-enable channel authentication:
   ```
   ALTER QMGR CHLAUTH(ENABLED)
   ```

4. Type some message text, then press **Enter** twice. The following message is displayed:
   ```
   Sample AMQSPUT0 end
   ```
   Your message is now on the queue that is on the server queue manager.
5. Start the GET program for QUEUE1 on QUEUE.MANAGER.1 by entering the following command:
   ```
   amqsgetc QUEUE1 QUEUE.MANAGER.1
   ```
   The sample program starts, and your message is displayed. After a short pause (approximately 30 seconds), the sample ends and the command prompt is displayed again.

Results

You have now successfully verified the client installation.

What to do next

1. You must set various environment variables on the server so that the installation can be used in the current shell. You can set the environment variables by entering the following command:
   ```
     MQ_INSTALLATION_PATH\bin\setmqenv -s
   ```
   where *MQ_INSTALLATION_PATH* refers to the location where IBM MQ is installed.
2. On the server, stop the queue manager by entering the following command:
   ```
   endmqm QUEUE.MANAGER.1
   ```
3. On the server, delete the queue manager by entering the following command:
   ```
   dltmqm QUEUE.MANAGER.1
   ```

Verifying the installation of MQ Telemetry

There are three ways to verify the installation of MQ Telemetry. Any can be used, regardless of whether MQ Telemetry was installed as a custom installation of IBM MQ, or added to an existing installation of IBM MQ.

About this task

Within IBM MQ you can verify the installation of MQ Telemetry either by using IBM MQ Explorer, or by using the command line.

You can also verify the installation by using the MQTT messaging client for JavaScript in a browser that supports the RFC 6455 (WebSocket) standard. A version of this client is installed with MQ Telemetry, and the latest version is available as part of the IBM Messaging Telemetry Clients SupportPac. To verify the MQ Telemetry installation you do not need the latest version of the client, so you should omit step 1.

Procedure

Verify your installation in one of the following ways:
- By using IBM MQ Explorer as described in “Verifying the installation of MQ Telemetry by using IBM MQ Explorer” on page 540.
- By using the command line as described in “Verifying the installation of MQ Telemetry using the command line” on page 542.

Uninstalling IBM MQ on Windows

Windows

You can uninstall the IBM MQ MQI clients and servers on Windows systems by using the control panel, the command line (**msiexec**), **MQParms**, or by using the installation media, in which case you can optionally remove queue managers as well.

Before you begin

By default, uninstallation logging is not enabled on Windows. To ensure that you receive an uninstallation log, carry out the following procedure:

1. In a command prompt, open the registry editor by issuing the command **regedit**.
2. Create, or edit, the appropriate registry key: `HKEY_LOCAL_MACHINE\Software\Policies\Microsoft\Windows\Installer`
3. Under this registry key add the following information:

   Name Logging

   Data type
   REG_SZ

   Value voicewarmup
4. Save the updated registry key.

Procedure

The first part of the procedure ensures that there are no IBM MQ programs or processes running:

1. If you are running IBM MQ with the Microsoft Cluster Service (MSCS), remove the queue managers from MSCS control before uninstalling IBM MQ. Perform the following steps for each queue manager currently under MSCS control :
   a. Take the queue manager resource offline.
   b. Destroy the resource instance.
   c. Migrate the queue manager files back from shared drives. This step is shown as optional in Removing a queue manager from MSCS control. However, it is mandatory in this case.
2. Stop all IBM MQ applications associated with the installation you are uninstalling.
3. Close all Managed File Transfer agents. If you have a Managed File Transfer Agent running, close it by using the **fteStopAgent** command; see fteStopAgent (stop a Managed File Transfer Agent).
4. For a server installation, end all IBM MQ activity:
   a. Log in as a user in the group mqm.
   b. Stop all running queue managers and listeners by using the IBM MQ Explorer, or by entering the following commands:
      1) Set up your environment to work with the installation you want to uninstall by entering the following command:
      ```
      MQ_INSTALLATION_PATH\bin\setmqenv -s
      ```
      where *MQ_INSTALLATION_PATH* is the location where IBM MQ is installed.
      2) For each queue manager, enter the following command to stop the queue manager:
      ```
      endmqm queue_manager_name
      ```
      3) For each queue manager, enter the following command to stop any listeners associated with the queue manager:
      ```
      endmqlsr -m queue_manager_name
      ```
5. Stop IBM MQ. To do this right-click the **IBM MQ** icon in the system tray, then select **Stop IBM MQ**.

6. Close all IBM MQ windows.
7. Stop any monitoring service.

When all processes associated with IBM MQ are no longer running, you can uninstall IBM MQ:

8. Uninstall IBM MQ by using one of the following methods:
   - Use the Windows Control Panel. This process is described in: "Uninstalling IBM MQ using the control panel" on page 516. This method does not remove the queue manager data.
   - Use the command line by running the **msiexec** command as described in: "Uninstalling IBM MQ using the command line" on page 516. This method does not remove the queue manager data.
   - Use the appropriate parameters with **MQParms**. This process is described in "Uninstalling IBM MQ using MQParms" on page 518. This method does not remove the queue manager data.
   - Use the installation media, by selecting the appropriate option as described in: "Uninstalling IBM MQ on Windows using the installation media" on page 518. The option to remove queue manager data is displayed in the Removing Server feature panel, if appropriate.

   If you have to cancel the uninstallation process before it is finished, you might have to reconfigure IBM MQ with the Prepare IBM MQ wizard because the rollback of the deletion of the IBM MQ service is unable to set the service's user account password. Use the following command to reconfigure IBM MQ:

   ```
   MQ_INSTALLATION_PATH\bin\amqmjpse.exe -r
   ```

   For more information about the Prepare IBM MQ wizard, see "Configuring IBM MQ with the Prepare IBM MQ wizard" on page 471.
9. Check the Windows event log and restart the system if necessary. If event ID 10005 is written to the Windows event log, you must restart the system to complete the uninstallation process.
10. Optional: If you are uninstalling the last or only installation of IBM MQ, you can remove all the information about previous installations that is retained on the system, if you want to.

    Two registry values remain after uninstallation:
    - 32 bit systems:
      – `My Computer\HKEY_LOCAL_MACHINE\SOFTWARE\IBM\WebSphere MQ\LogDefaultPath`
      – `My Computer\HKEY_LOCAL_MACHINE\SOFTWARE\IBM\WebSphere MQ\WorkPath`
    - 64 bit systems:
      – `My Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\IBM\WebSphere MQ\LogDefaultPath`
      – `My Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\IBM\WebSphere MQ\WorkPath`

    Data folders will also remain and are located at *MQ_DATA_PATH*`\Config`, where *MQ_DATA_PATH* is the location of the IBM MQ data directory. Most of the remaining files contain text such as INI files, error logs, and FDC files. The executable shared library `mqzsd.dll` also remains.

    If a client is installed on a system where the `LogDefaultPath` registry value remains from a previous server installation, a client installation will attempt to create this directory if it does not already exist. If this behavior is not wanted, remove the LogDefaultPath registry value before installing the client.

Uninstalling IBM MQ using the control panel

Windows

You can uninstall IBM MQ by using the control panel to remove all currently installed features.

Before you begin

Start the uninstalling process by following the steps described in "Uninstalling IBM MQ on Windows" on page 514.

If you no longer require the queue managers that are on the system, delete them by using the IBM MQ Explorer or the **dltmqm** command.

Procedure

1. From the Windows taskbar, open the control panel by clicking **Start** > **Settings** > **Control Panel**, or **Start** > **Control Panel**.
2. Open **Programs and Features**.
3. Click **IBM MQ (*installation_name*)**, where *installation_name* is the name of the installation you want to remove.
4. Click **Remove** or **Uninstall** and click **Yes** to confirm. If User Account Control (UAC) is enabled, accept the Windows prompt to allow the uninstallation to run as elevated. The program then begins and runs to completion.

What to do next

Complete the steps that you started in "Uninstalling IBM MQ on Windows" on page 514.

Uninstalling IBM MQ using the command line

Windows

You can uninstall IBM MQ by running the **msiexec** command from the command line to remove all currently installed features.

Before you begin

Start the uninstalling process by following the steps described in "Uninstalling IBM MQ on Windows" on page 514.

If you no longer require the queue managers that are on the system, delete them by using the IBM MQ Explorer or the **dltmqm** command.

About this task

To start uninstalling, use the **msiexec** command.

If you are running IBM MQ on Windows with User Account Control (UAC) enabled, you must invoke the silent uninstallation from an elevated command prompt. Elevate a command prompt by using a right-click to start the command prompt and choose **Run as administrator**.

In all of the examples of commands shown, the variable names used are as follows:

- *installation_name* is the name of the installation you want to remove.
- *product_code* is the value shown for MSIProdCode in the output of the following command:

```
dspmqinst -n installation_name
```

An example of a product code is {0730749B-080D-4A2E-B63D-85CF09AE0EF0}.

- *response_file* is the file that contains the [Response] stanza and the required *property* = *value* pairs. For details about how to create a response file, see “Creating a response file for server installation” on page 463. For details of the parameters you can specify in a response file, see Table 64 on page 458 in “Installing the server using msiexec” on page 455. This is an example of a simple uninstallation [Response] stanza:

  ```
  [Response] REMOVE="ALL"
  ```

Procedure

To uninstall all IBM MQ features, use one of the following methods:

- Run the msiexec command with a parameter that calls a response file.

  A response file is an ASCII text file that contains the parameter values that you want to set for the uninstallation. The response file has a format similar to a Windows .ini file, and contains the stanza [Response]. This stanza contains parameters that the **msiexec** command can use, in the form of *property* = *value* pairs. The **msiexec** command ignores any other stanzas in the file.

  You can set which features to uninstall, and set whether to keep existing queue managers.

  To silently uninstall IBM MQ using a response file, enter the following command:

  ```
  msiexec /x {product_code} /l*v "c:\removal.log" /q USEINI="response_file" INSTALLATIONNAME="installation_name"
  ```

- Enter one of the following commands on the command line:
  - To invoke an interactive uninstallation giving you the option to remove queue manager data (providing there are no other IBM MQ installations remaining):

    ```
    msiexec /x {product_code} /l*v "c:\removal.log" REMOVE="All" INSTALLATIONNAME="installation_name"
    ```

    If you are running IBM MQ on a Windows system with User Account Control (UAC) enabled, you might see Open File - Security Warning dialog boxes during uninstallation that list International Business Machines Limited as the publisher. Click **Run** to allow the uninstallation to continue.
  - To invoke a silent uninstallation that does not remove any queue manager data:

    ```
    msiexec /x {product_code} /l*v "c:\removal.log" /q REMOVE="All" INSTALLATIONNAME="installation_name"
    ```

  - To invoke a silent uninstallation and remove any queue manager data (only valid when removing the final server installation):

    ```
    msiexec /x {product_code} /l*v "c:\removal.log" /q REMOVE="All" KEEPQMDATA="delete"
    INSTALLATIONNAME="installation_name"
    ```

  - To monitor the progress of the uninstalling process and not remove any queue manager data:

    ```
    msiexec /x {product_code} /l*v "c:\removal.log" INSTALLATIONNAME="installation_name"
    ```

    If you are running IBM MQ on a Windows system with User Account Control (UAC) enabled, you might see Open File - Security Warning dialog boxes during uninstallation that list International Business Machines Limited as the publisher. Click **Run** to allow the uninstallation to continue.
  - To invoke a silent uninstallation and not remove any queue manager data:

    ```
    msiexec /x {product_code} /l*v "c:\removal.log" /q INSTALLATIONNAME="installation_name"
    ```

Results

After the command is entered, the command prompt immediately reappears and IBM MQ is uninstalled as a background process. If you entered parameters to produce a log, check this file to see how the uninstallation is progressing. If the uninstallation finishes successfully, you see the message `Removal completed successfully` in the log file.

What to do next

Complete the steps that you started in “Uninstalling IBM MQ on Windows” on page 514.

Uninstalling IBM MQ using MQParms

Windows

You can uninstall IBM MQ by running the **MQParms** command from the command line to remove all currently installed features.

Before you begin

Start the uninstalling process by following the steps described in “Uninstalling IBM MQ on Windows” on page 514.

Procedure

1. Follow the instructions on the MQParms installation pages to uninstall IBM MQ non-interactively. See: “Installing the server using the MQParms command” on page 463.
   a. Set the ADDLOCAL parameter to empty (ADDLOCAL="").
   b. Set the REMOVE parameter to "ALL" (REMOVE="ALL").
2. If you have multiple versions of IBM MQ installed on your system, specify the product code that identifies the installation you want to remove. Type the following command:
   ```
   MQParms.exe parameter_file/i "{product_code}"
   ```
   where
   - *parameter_file* is the file that contains the required parameter values. If this file is not in the same folder as `MQParms.exe`, specify the full path and file name. If you do not specify a parameter file, the default is `MQParms.ini`.
   - *product_code* is the value shown for MSIProdCode in the output of the following command:
     ```
     dspmqinst -n installation_name
     ```
     where *installation_name* is the name of the installation you want to remove. An example of a product code is `{0730749B-080D-4A2E-B63D-85CF09AE0EF0}`.

What to do next

Complete the steps that you started in “Uninstalling IBM MQ on Windows” on page 514.

Uninstalling IBM MQ on Windows using the installation media

Windows

You can uninstall IBM MQ by using the installation media to remove all currently installed features and optionally remove existing queue managers and their data.

Before you begin

Start the uninstalling process by following the steps described in “Uninstalling IBM MQ on Windows” on page 514.

Procedure

1. Insert the IBM MQ for Windows Server DVD into the DVD drive.
2. Start the installation process.
   - If autorun is enabled, the installation process starts automatically.
   - If autorun is not enabled, double-click the **Setup** icon in the root folder of the DVD to start the installation process.

   The IBM MQ Installation Launchpad window opens.

3. Click **IBM MQ Installation**.
4. Click **Launch IBM MQ Installer** and click **Next** until the IBM MQ Program Maintenance panel is displayed with a welcome message. If this panel is not displayed, IBM MQ for Windows is not currently installed.
5. Click **Maintain or upgrade an existing instance** and if there is more than one installation of IBM MQ on the system, select which installation you want to remove. Click **Next** and in the Program Maintenance panel, click **Remove**, then **Next**.
6. If you are uninstalling the last or only server, and there are any queue managers on the system, the Removing Server feature panel is shown. Click one of the following options:
   - **Keep**: keep existing queue managers and their objects.
   - **Remove**: remove existing queue managers and their objects.

   Click **Next**. The Remove IBM MQ panel is displayed, with a summary of the installation to be removed.
7. Click **Remove** to continue. If there are any messages that state that locked files are found, ensure that there are no IBM MQ programs running; see “Uninstalling IBM MQ on Windows” on page 514. When IBM MQ has been uninstalled, a message indicates completion.
8. Click **Finish**.

What to do next

Complete the steps that you started in “Uninstalling IBM MQ on Windows” on page 514.

Installing IBM MQ Advanced for Multiplatforms

Multi MQ Adv.

Installation tasks associated with IBM MQ Advanced for Multiplatforms are grouped in this section.

About this task

IBM MQ Advanced is a single license entitlement that, in addition to IBM MQ itself, provides entitlement to:
- Advanced Message Security
- Managed File Transfer
- MQ Telemetry
- Linux Replicated data queue managers (RDQM)

For more information, see IBM MQ license information.

Procedure
- “Installing and uninstalling AMS on Multiplatforms” on page 520.
- “Installing Managed File Transfer” on page 528.
- “Installing MQ Telemetry” on page 538.
- Linux “Installing RDQM (replicated data queue managers)” on page 545.

Related tasks:

z/OS "Installing IBM MQ Advanced for z/OS" on page 560
Use this topic to understand how you install IBM MQ Advanced for z/OS on your system.

z/OS "Installing IBM MQ Advanced for z/OS, Value Unit Edition" on page 561
Use this topic to understand how you install IBM MQ Advanced for z/OS, Value Unit Edition (VUE) on your system.

Installing and uninstalling AMS on Multiplatforms

Multi

Installation and uninstallation, by platform, for Advanced Message Security (AMS) on Multiplatforms.

About this task

Advanced Message Security is a separately installed component of IBM MQ and is another option on the IBM MQ installer. Make sure that you purchase a license for using IBM MQ Advanced before the installation (see IBM MQ license information).

Procedure

- "Installing AMS on Multiplatforms"
- "Uninstalling AMS on Multiplatforms" on page 525

Related tasks:

"Installing Advanced Message Security on z/OS" on page 559
You can install Advanced Message Security component on z/OS by using SMP/E.

Installing AMS on Multiplatforms

Multi

Use the information for your platform to guide you through installing the Advanced Message Security (AMS) component.

Before you begin

Make sure the following IBM MQ components are installed in your environment:

- MQSeriesRuntime
- MQSeriesServer

About this task

For information about installing Advanced Message Security follow the guidance for the appropriate platform.

Procedure

- "Installing Advanced Message Security on AIX" on page 521
- "Installing Advanced Message Security on HP-UX" on page 521
- "Installing Advanced Message Security on IBM i" on page 522
- "Installing Advanced Message Security on Linux" on page 522

- “Installing Advanced Message Security on Windows” on page 524

Installing Advanced Message Security on AIX:

You can install Advanced Message Security component on AIX platforms using either system management interface tool (SMIT) or the command line.

Installing using SMIT:

Procedure

1. Log on as root.
2. Change the directory to the location of the installation packages.
3. Start the system management interface tool (SMIT). The system management menu is displayed.
4. Select the required SMIT window using the following sequence:
   ```
   Software Installation and Maintenance
   Install and Update Software
   Install Software
   ```
5. Enter the directory location of the installation package.
6. Press F4 to list the software in the **SOFTWARE name** option.
7. Select the `mqm.ams.rte` and press Enter.
8. Accept the default setting for the remaining options and press Enter.

Results

Advanced Message Security has been installed successfully.

Installing using command line:

Procedure

1. Log on as root.
2. Set your current directory to the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. Run the following command:
   ```
   installp -a -c -Y -d. mqm.ams.rte
   ```
   Note the period, signifying the current directory, following the **`-d`** parameter.

Results

Advanced Message Security component has been installed successfully.

Installing Advanced Message Security on HP-UX:

You can install Advanced Message Security component on HP-UX platforms.

Procedure

1. Log on as root.
2. Set your current directory to the location of the installation file. The location might be the mount point of the DVD, a network location, or a local file system directory.
3. In the command line, issue the following command:
   ```
   swinstall -s MQSERIES.MQM-AMS
   ```

Results

Advanced Message Security component has been installed successfully.

Installing Advanced Message Security on IBM i: IBM i

You can install Advanced Message Security component on IBM i.

Procedure

Install AMS using the command:

```
RSTLICPGM LICPGM(5724H72) DEV(installation device) OPTION(2) OUTPUT(*PRINT)
```

where the parameters of **RSTLICPGM** are:

LICPGM(5724H72)
: The product identifier for IBM MQ for IBM i.

DEV(installation device)
: The device from which the product is to be loaded, typically an optical drive, for example, OPT01.

OPTION(2)
: Install Advanced Message Security for IBM i

OUTPUT(*PRINT)
: The output is printed with the spooled output of the job.

Results

The AMS component has been installed successfully.

Once AMS is installed on an IBM MQ server installation, any:
- Queue managers that are subsequently started enable security policy management features.
- Applications that connect to the queue manager enable interceptors.

What to do next

See Setting up certificates and the keystore configuration file on IBM i for details on setting up your security policy.

Installing Advanced Message Security on Linux: Linux

You can install Advanced Message Security on Linux platforms.

Procedure
1. Log on as root.
2. Set your current directory to the location of the installation file. The location might be the mount point of the server CD, a network share, or a local file system directory.
3. If this installation is not the first installation on the system, you must run the **crtmqpkg** command to create a unique set of packages to install on the system. In order for the **crtmqpkg** command to run on Linux, the **pax** command or **rpmbuild** must be installed.

   Important: **pax** and **rpmbuild** are not supplied as part of the product. You must obtain these from your Linux distribution supplier.
   a. Enter the following command:
   ```
   ./crtmqpkg suffix
   ```

where *suffix* is a name of your choosing, that uniquely identifies the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.

Note: This command creates a full copy of the installation packages in a subdirectory of `/var/tmp`. You must ensure that the system has enough space before running the command.

b. Set your current directory to the location specified when the **`crtmqpkg`** command completes. This directory is a subdirectory of `/var/tmp/mq_rpms`, in which the unique set of packages is created. The packages have the *suffix* value contained within the filename. For example, using a suffix of "1":

```
./crtmqpkg 1
```

there is a subdirectory named `/var/tmp/mq_rpms/1/i386` and the packages are renamed, for example:

```
From: MQSeriesAMS-V.R.M-F.i386.rpm
To: MQSeriesAMS_1-V.R.M-F.i386.rpm
```

where:

V	Represents the version of the product that you are installing
R	Represents the release of the product that you are installing
M	Represents the modification of the product that you are installing
F	Represents the fix pack level of the product that you are installing

4. In the command line, issue the following command:

   This example shows a minimum installation:

   ```
   rpm -iv package_name
   ```

   where *`package_name`* is one of the following:

   - MQSeriesAMS-V.R.M-F.i386.rpm
   - MQSeriesAMS-V.R.M-F.x86_64.rpm
   - MQSeriesAMS-V.R.M-F.ppc.rpm
   - MQSeriesAMS-V.R.M-F.s390.rpm

Results

Advanced Message Security has been installed successfully.

Installing Advanced Message Security on Solaris: Solaris

You can install Advanced Message Security component on Solaris platforms.

Procedure

1. Log on as root.
2. If this installation is not the first installation on the system, you must run **`crtmqpkg`** to create a unique set of packages to install on the system:

   a. Enter the following command:

   ```
   ./crtmqpkg suffix
   ```

   where *suffix* is a name of your choosing, that will uniquely identify the installation packages on the system. *suffix* is not the same as an installation name, although the names can be identical. *suffix* is limited to 16 characters in the ranges A-Z, a-z, and 0-9.

   b. Set your current directory to the location specified when the **crtmqpkg** command completes. This directory is a sub-directory of `/var/spool`, in which the unique set of packages is created. The packages have the *suffix* value contained within the filename.
3. Start the installation process:
   - If the installation is the first installation on the system, enter the following command to start the installation process:
     ```
     pkgadd -d.
     ```
   - If the installation is not the first installation on the system, enter the following command to start the installation process:
     ```
     pkgadd mqm- suffix
     ```

     where *suffix* is the suffix chosen in the previous step.
4. You are prompted to choose a location for installation.
   - To install to the default location, `/opt/mqm`, enter `y`.
   - To install to a non-default directory, enter `n`. Then enter the required installation path, and confirm your choice.
5. Choose the `mqams` component.
6. If the path chosen in step 4 does not exist, you are asked if you want to create it. You must enter `y` to proceed.
7. A message is issued when the installation is complete. Enter `q` to exit the `pkgadd` program.

Results

Advanced Message Security component has been installed successfully.

Installing Advanced Message Security on Windows: Windows

You can install the Advanced Message Security component on Windows platforms.

Using the Launchpad:
Procedure
1. Access the IBM MQ installation image. The location might be the mount point of the DVD, a network location, or a local file system directory.
2. Locate `setup.exe` in the base directory of the IBM MQ installation image.
   - From a DVD, this location might be:
     ```
     E:\ setup.exe
     ```
   - From a network location, this location might be:
     ```
     m:\instmqs\ setup.exe
     ```
   - From a local file system directory, this location might be:
     ```
     C:\instmqs\ setup.exe
     ```
3. Double-click the **Setup** icon to start the installation process. It is possible to start the process by either:
   - Running `setup.exe` from the command prompt.
   - Double-clicking `setup.exe` from IBM MQ Explorer.

   Note: If you are installing on a Windows system with UAC enabled, accept the Windows prompt to allow the launchpad to run as elevated. During installation, you might also see Open File - Security Warning dialog boxes that list International Business Machines Limited as the publisher. Click **Run** to allow the installation to continue.

   The IBM MQ Installation Launchpad window is displayed.
4. Continue to follow the Launchpad instructions as shown on screen.

Uninstalling AMS on Multiplatforms

Multi

Use the information for your platform to uninstall the Advanced Message Security (AMS) component.

Procedure

- "Uninstalling AMS on AIX"
- "Uninstalling AMS on HP-UX" on page 526
- "Uninstalling AMS on Linux" on page 527
- "Uninstalling AMS on Windows" on page 528

Related tasks:

"Installing AMS on Multiplatforms" on page 520
Use the information for your platform to guide you through installing the Advanced Message Security (AMS) component.

Uninstalling AMS on AIX: AIX

On AIX platforms, you can remove Advanced Message Security component either using SMIT or the command line.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling:
   a. Log in as a user in the group mqm.
   b. Set up your environment to work with the installation you want to uninstall. Enter the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv
   ```
   where . MQ_INSTALLATION_PATH refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:
   ```
   dspmq -o installation
   ```
   d. Stop all running queue managers associated with the installation you want to uninstall. Enter the following command for each queue manager:
   ```
   endmqm QMgrName
   ```
   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:
   ```
   endmqlsr -m QMgrName
   ```
3. Log in as root.
4. Uninstall AMS component using either **installp** or **smit**. If AMS component was installed in a non-default location, you must use **installp** to uninstall.
   - Uninstall using **installp** by entering one of the following commands:
     - For an installation in the default location /usr/mqm
     ```
     installp -u mqm.ams.rte
     ```
     - For an installation in a non-default location:
     ```
     installp -R
     usil -u mqm.ams.rte
     ```
     where *usil* is the path of the User Specified Installation Location (USIL) specified when the product was installed.

- Uninstall using **smit**:
  a. Select the required **smit** window using the following sequence:
  ```
  Software Installation and Maintenance
  Software Maintenance and Utilities
  Remove Installed Software
  ```
  b. List the software in the **SOFTWARE name** field:
     1) Enter **.**
     2) Press **F4**
  c. Select the file sets to uninstall from the list (those beginning with mqm), and press **Enter**. There is an option at this stage to do a preview. Leave the option set to the default value of **Yes** to preview the file sets you are uninstalling, or select **No** to not preview these file sets.
  d. Press **Enter** on the **Remove Installed Software** panel, it asks whether you are sure, press **Enter**.

Results

The Advanced Message Security component has been uninstalled.

Uninstalling AMS on HP-UX: HP-UX

Use the `swremove` command to remove Advanced Message Security component on HP-UX platforms.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling:
   a. Log in as a user in the group `mqm`.
   b. Set up your environment to work with the installation you want to uninstall. Enter the following command:
   ```
   . MQ_INSTALLATION_PATH/bin/setmqenv
   ```
   where `. MQ_INSTALLATION_PATH` refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:
   ```
   dspmq -o installation
   ```
   d. Stop all running queue managers associated with the installation you want to uninstall. Enter the following command for each queue manager:
   ```
   endmqm QMgrName
   ```
   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:
   ```
   endmqlsr -m QMgrName
   ```
3. Log on as root.
4. Run the following command:
   ```
   swremove MQSERIES.MQM-AMS
   ```

Results

The Advanced Message Security component has been uninstalled.

Uninstalling AMS on Linux: Linux

Use the `rpm` command to remove Advanced Message Security component on Linux platforms.

Procedure

1. Stop all IBM MQ applications associated with the installation you are uninstalling.
2. For a server installation, end any IBM MQ activity associated with the installation you are uninstalling:
   a. Log in as a user in the group `mqm`.
   b. Set up your environment to work with the installation you want to uninstall. Enter the following command:
      ```
      . MQ_INSTALLATION_PATH/bin/setmqenv
      ```
      where `. MQ_INSTALLATION_PATH` refers to the location where IBM MQ is installed.
   c. Display the state of all queue managers on the system. Enter the following command:
      ```
      dspmq -o installation
      ```
   d. Stop all running queue managers associated with the installation you want to uninstall. Enter the following command for each queue manager:
      ```
      endmqm QMgrName
      ```
   e. Stop any listeners associated with the queue managers. Enter the following command for each queue manager:
      ```
      endmqlsr -m QMgrName
      ```
3. Log in as root.
4. Run the following command:
   ```
   rpm -e package_name
   ```
   where *package_name* is MQSeriesAMS-*V.R.M-F*

V	Represents the version of the product that you are uninstalling
R	Represents the release of the product that you are uninstalling
M	Represents the modification of the product that you are uninstalling
F	Represents the fix pack level of the product that you are uninstalling

Results

The Advanced Message Security component has been uninstalled.

Uninstalling on Solaris: Solaris

Use the pkgrm to uninstall IBM MQ on Solaris.

About this task

Restriction: On Solaris, you cannot remove components from an installation. There is no supported method of doing this.

For information about uninstalling IBM MQ on Solaris, see “Uninstalling IBM MQ on Solaris” on page 434.

Uninstalling AMS on Windows: Windows

You can uninstall Advanced Message Security component using the GUI uninstallation wizard, or a command-line interface.

Using the installation wizard:
Procedure

1. Insert the IBM MQ Server DVD into the DVD-ROM drive.
2. If autorun is enabled, the installation process starts.

   Otherwise, double-click the **Setup** icon in the root folder of the DVD to start the installation process.

   The IBM MQ Installation Launchpad window is displayed.
3. Click the **IBM MQ Installation**.
4. Click **Launch IBM MQ Installer**. Click **Next** until the IBM MQ Program Maintenance panel is displayed with a welcome message.

   If this panel is not displayed, IBM MQ for Windows, Version 7.5 is not installed on this machine. When presented with the option, select to remove/maintain or upgrade.
5. Select **Maintain or upgrade an existing instance**, then click **Next**.
6. If there are any existing queue managers, the Removing Server feature panel is displayed.

   Click one of the following options, then click **Next**:
   - **Keep** - keep existing queue managers and their objects.
   - **Remove** - remove existing queue managers and their objects.

   The Program Maintenance panel is displayed, with a summary of the installation to be removed.
7. Click **Modify** and click **Next**.
8. On the list of available IBM MQ features, click Advanced Message Security, select **Do not install this feature (remove if already intalled)**, and click **Next**. The Ready to modify IBM MQ panel appears with the summary of your changes.
9. Click **Modify** and **Next** on the following panel to continue.

Results

Selected features of Advanced Message Security component have been removed.

Installing Managed File Transfer

MQ Adv.

From Version 7.5 onwards, Managed File Transfer is installed as a component of IBM MQ on UNIX, Linux, and Windows. Managed File Transfer remains as a separate product on IBM i and z/OS.

Before you begin

Before you install Managed File Transfer, check that your system meets both the hardware and software requirements of the product. See System Requirements for IBM MQ.

For all platforms, you must have one IBM WebSphere MQ Version 7.0, or higher, queue manager available in your Managed File Transfer network to use as the coordination queue manager.

.

About this task

ULW The following steps describe installing Managed File Transfer as a component of IBM MQ on UNIX, Linux, and Windows.

Procedure

1. Decide which Managed File Transfer components to install. Managed File Transfer can be installed as four different options, depending on your operating system and overall setup. These options are Managed File Transfer Agent, Managed File Transfer Service, Managed File Transfer Logger, or Managed File Transfer Tools.

   To decide which components to install, review the product options and topology information in the following topics:
   - Managed File Transfer product options
   - Managed File Transfer topology overview
2. Install IBM MQ, including Managed File Transfer components. For information about which specific components to install for your platform, including Managed File Transfer, see "IBM MQ components and features" on page 192.

   For more information about installing IBM MQ on UNIX, Linux, and Windows, see the appropriate information for your platform:
   - AIX "Installing and uninstalling IBM MQ on AIX" on page 215
   - HP-UX "Installing and uninstalling IBM MQ on HP-UX" on page 263
   - Linux "Installing and uninstalling IBM MQ on Linux" on page 330
   - Solaris "Installing and uninstalling IBM MQ on Solaris" on page 398
   - Windows "Installing and uninstalling IBM MQ on Windows" on page 435

You install Managed File Transfer on your IBM MQ for z/OS system by using SMP/E.

Managed File Transfer topology overview

Installed command sets

Managed File Transfer product options

ULW

Managed File Transfer can be installed as four different options, depending on your operating system and overall setup. These options are Managed File Transfer Agent, Managed File Transfer Service, Managed File Transfer Logger, or Managed File Transfer Tools.

Managed File Transfer Agent

A file transfer agent connects to an IBM MQ queue manager, and transfers file data, as messages, to other file transfer agents.

You install an agent through either the Managed File Transfer Agent or Managed File Transfer Service installation options.

The Managed File Transfer Agent option installs an agent that has the following capabilities:

- Make client or bindings mode connections to queue managers.

  Note: When the file transfer agent and queue manager are on the same system, consider using the bindings mode connections.
- Transfer files to and from other Managed File Transfer agents.
- Transfer files to and from Connect:Direct® nodes.

The Managed File Transfer Service option, described in the next section, installs a file transfer agent that also has additional capability to transfer files to and from legacy FTP, FTPS, or SFTP protocol servers.

Managed File Transfer Service

The Managed File Transfer Service option installs an agent that has the following capabilities:

- Make client or bindings mode connections to queue managers.

  Note: When the file transfer agent and queue manager are on the same system, consider using the bindings mode connections.
- Transfer files to and from other Managed File Transfer agents.
- Transfer files to and from Connect:Direct nodes.
- Create protocol bridge agents that transfer files to and from legacy SFTP, FTP, or FTPS protocol servers.

Some capabilities are available on only a subset of supported platforms. For more information, see IBM MQ System Requirements.

A Managed File Transfer Service can only be installed on systems where the IBM MQ Server option is already installed.

Managed File Transfer Logger

A file transfer logger connects to an MQ queue manager, often the queue manager that is designated as the coordination queue manager, and logs audit-related file transfer data to either a database or a file. A logger can only be installed on systems where the IBM MQ Server installation option is already installed.

Managed File Transfer Tools

The Managed File Transfer Tools are command line tools that you use to interact with file transfer agents. The tools allow you to start file transfers, schedule file transfers and create resource monitors from the command line. The Managed File Transfer Tools need not be installed on the same system as the file transfer agents that they interact with.

UNIX

Managed File Transfer Base

On UNIX platforms, there is an additional Managed File Transfer Base installation component. This component contains files common to all of the installation options. You must install the Managed File Transfer Base component before installing any of the Agent, Logger, Service, or Tools components.

For more information about the IBM MQ components that are required for each product option on UNIX platforms, see the following topics:

- AIX “Required MFT components on AIX”
- HP-UX “Required MFT components on HP-UX” on page 532
- Linux “Required MFT components on Linux” on page 533
- Solaris “Required MFT components on Solaris” on page 534

Installing MQ Telemetry

AIX Linux Windows MQ Adv.

Installation tasks associated with MQ Telemetry are grouped in this section.

About this task

MQ Telemetry is installed as part of the IBM MQ server installation.

MQ Telemetry is a separately installed component of IBM MQ and is another option on the IBM MQ installer. Make sure that you purchase a license for using IBM MQ Advanced before the installation (see IBM MQ license information).

Procedure

Install IBM MQ, including MQ Telemetry. For information about which specific components to install for your platform, including MQ Telemetry, see “IBM MQ components and features” on page 192.
For more information about installing IBM MQ on AIX, Linux, or Windows, see the appropriate information for your platform:

- AIX “Installing and uninstalling IBM MQ on AIX” on page 215
- Linux “Installing and uninstalling IBM MQ on Linux” on page 330
- Windows “Installing and uninstalling IBM MQ on Windows” on page 435

Installation considerations for MQ Telemetry

From IBM WebSphere MQ Version 7.1, MQ Telemetry is a component of the main IBM MQ product, and is no longer a separate plugin. You can choose to install MQ Telemetry when you first install IBM MQ, or when you modify an existing IBM MQ installation. To get a set of client libraries that help you write messaging applications for telemetry, download the IBM Messaging Telemetry Clients SupportPac.

MQ Telemetry overview

See Introduction to MQ Telemetry for general details about MQ Telemetry.

Support for IBM MQ Explorer

You can use IBM MQ Explorer to configure and manage the MQ Telemetry runtime component. For a queue manager to accept connections from a telemetry device, one or more telemetry channels are needed. To enable MQTT, there is a `define sample configuration` wizard that can be run from IBM MQ Explorer. The wizard runs through a series of steps including defining and starting the telemetry (MQXR) service, setting up the default transmission queue, and configuring a telemetry channel. For more information about using the `define sample configuration` wizard, and any implications, see “Verifying the installation of MQ Telemetry by using IBM MQ Explorer” on page 540.

The IBM MQ Explorer support provides the following capabilities:

- Telemetry node and content panel - providing welcome information, define sample configuration wizard, run MQTT client utility, Help on MQ Telemetry, and status information about the MQ Telemetry Service.
- Define sample configuration wizard - quickly configures a queue manager to support MQTT.
- New Telemetry Channel wizard - gathers information required to create a telemetry channel object.
- Telemetry Channels node and content panel - displays telemetry channels in the IBM MQ Explorer Content view.
- Telemetry Channel Status node and content panel - displays telemetry channel status in the IBM MQ Explorer Content view.
- MQTT Client Utility - provides a simple GUI for publishing and subscribing to topics.
- Help on MQ Telemetry.

You can install the MQ Telemetry runtime component on one system and configure and manage it using the IBM MQ Explorer installed on another system. However, the components can be installed only on systems with the appropriate prerequisites. For information about these prerequisites, see IBM MQ system requirements.

MQ Telemetry client libraries and SDK

To help you write messaging applications for MQTT networks, you can install and use a set of free client libraries. After you develop your applications, these applications and the client libraries are then deployed together to the appropriate system.

In previous versions of IBM MQ, the client libraries were supplied with the product, in the Client Software Development Kit (SDK). From IBM MQ Version 8.0, this SDK is no longer supplied as part of the product. Instead, the current version of the SDK is available as the IBM Messaging Telemetry Clients SupportPac.

To use the telemetry MQTT clients, download the IBM Messaging Telemetry Clients SupportPac, then install the clients in a directory of your own choosing. The sample applications and client libraries are in client-specific directories under `CLIENTPACKDIR/SDK/clients`, where *CLIENTPACKDIR* is the directory in which you decompressed the client pack. Note that the example scripts included in IBM MQ assume that the clients are in the directories specified in Location of telemetry logs, error logs, and configuration files.

The IBM Messaging Telemetry Clients SupportPac provides you with the following resources:

- Sample MQTT client applications written in Java, in JavaScript, and in C.
- MQTT client libraries that support these client applications, and enable them to run on most platforms and devices, including Android devices and products from Apple.

Verifying the installation of MQ Telemetry

There are three ways to verify the installation of MQ Telemetry. Any can be used, regardless of whether MQ Telemetry was installed as a custom installation of IBM MQ, or added to an existing installation of IBM MQ.

About this task

Within IBM MQ you can verify the installation of MQ Telemetry either by using IBM MQ Explorer, or by using the command line.

You can also verify the installation by using the MQTT messaging client for JavaScript in a browser that supports the RFC 6455 (WebSocket) standard. A version of this client is installed with MQ Telemetry, and the latest version is available as part of the IBM Messaging Telemetry Clients SupportPac. To verify the MQ Telemetry installation you do not need the latest version of the client, so you should omit step 1.

Procedure

Verify your installation in one of the following ways:
- By using IBM MQ Explorer as described in "Verifying the installation of MQ Telemetry by using IBM MQ Explorer."
- By using the command line as described in "Verifying the installation of MQ Telemetry using the command line" on page 542.

Verifying the installation of MQ Telemetry by using IBM MQ Explorer: Linux Windows

Use the Define sample configuration wizard and the MQTT client utility in IBM MQ Explorer to verify that the MQ Telemetry components have installed. Also check that publish/subscribe works correctly.

Before you begin

The MQ Telemetry runtime and support for IBM MQ Explorer must be installed. The telemetry folder is part of a queue manager. To view the telemetry folder, you must start a queue manager.

Before running the define sample configuration wizard on an existing queue manager, review the information provided by the wizard about the configuration changes that are made. The changes might have implications for the configuration of the existing queue manager. Alternatively, run the sample configuration wizard on a newly created queue manager to avoid changing any security settings.

About this task

To configure MQ Telemetry there is a define sample configuration wizard that can be run from IBM MQ Explorer. The wizard runs through a series of steps, including defining and starting the telemetry (MQXR) service, setting up the default transmission queue, and configuring a telemetry channel.

If you would prefer to do this manually, see Configuring a queue manager for telemetry on Linux and AIX. For Windows, see Configuring a queue manager for telemetry on Windows.

You can open the define sample configuration wizard from the MQ Telemetry Welcome page in IBM MQ Explorer. The wizard determines which steps are required based on the current configuration.

For example, the following actions might be specified by the wizard:
- Define the telemetry (MQXR) service.
- Start the telemetry (MQXR) service.
- Define the telemetry transmit queue.
- Set the default transmit queue of the queue manager to `SYSTEM.MQTT.TRANSMIT.QUEUE`.

If telemetry is already configured for this queue manager, the link to open the wizard is replaced with static text. The text confirms that the sample configuration has been set up.

After the configuration has finished, you can use IBM MQ Explorer to open the MQTT client utility. Use the MQTT client utility to verify that MQ Telemetry is set up correctly.

The following items summarize the main goals that can be achieved using the MQTT client utility:
- Validation of a basic or custom MQ Telemetry configuration by connecting, subscribing to topics and publishing messages.
- Showcases the main features of MQTT protocol.
- Provides a simple tool to aid in debugging MQ Telemetry applications.

You can find additional information within the IBM MQ Explorer by using the **Help** menu or pressing the **F1** key.

Procedure

1. Start IBM MQ Explorer.

   On Windows and Linux systems, you can start IBM MQ Explorer by using the system menu, the `MQExplorer` executable file, the **`mqexplorer`** command, or the **`strmqcfg`** command.
2. Open the Welcome to MQ Telemetry page.
   - To use an existing queue manager, click on `IBM MQ\Queue Managers\`*`qMgrName`*`\Telemetry` folder to open the Welcome to MQ Telemetry page.
   - If, for the reasons mentioned, you decide to use a new queue manager,
     a. Click **Queue Managers** > **New** > **Queue Manager**.
     b. Type `MQTTVerification` as the **Queue manager name** > **Next** > **Next** > **Next**.
     c. Change the default port in **Listen on port number**, if the port is in use > **Finish**.
     d. When the queue manager starts, click on `IBM MQ\Queue Managers\MQTTVerification\Telemetry` folder to open the Welcome to MQ Telemetry page.
3. From the Welcome to MQ Telemetry page in IBM MQ Explorer, click **Define sample configuration**.

   If this link is not present, and instead you see the text, “The sample configuration has been set up for this queue manager”, then telemetry has already been configured. Proceed to step 6.

   If you clicked **Define sample configuration**, the page opens, and lists actions that are to be performed as part of the sample configuration.
4. Leave **Launch MQTT client utility** checked, if you want to automatically start the MQTT client utility. The check box is selected by default.
5. Click **Finish**.
6. Click **Connect**.

   In the MQTT client utility panel, ensure that the host and port names are correct.

   If you did not automatically start the MQTT client utility panel in step 4, you can start it either by using a direct link from the Welcome to MQ Telemetry panel, or by right-clicking a NON-TLS channel, which allows you to control the channel it runs on.

The client history records a `Connected` event.

7. Click **Subscribe**.

   The client history records a `Subscribed` event.

8. Click **Publish**.

   The client history records a `Published` and `Received` event.

Results

If the publish/subscribe finishes successfully, the MQ Telemetry installation is verified.

If you encounter problems during the installation process, view the error log:

- On Windows, the default location for this log is, *`IBM MQ data directory`*`\qmgrs\`*`qMgrName`*`\mqxr`
- On AIX and Linux, the default location for this log is, `/var/mqm/qmgrs/`*`qMgrName`*`/mqxr/`

Verifying the installation of MQ Telemetry using the command line:

Follow these instructions to run scripts and a sample application to verify that the MQ Telemetry components have installed, and are able to publish and subscribe.

Before you begin

The telemetry (MQXR) service must be started to run the sample programs. The user ID must be a member of the `mqm` group.

The `SampleMQM` script creates and uses a queue manager called `MQXR_SAMPLE_QM`. Therefore, do not run unaltered on a system that already has a `MQXR_SAMPLE_QM` queue manager. Any changes made might have implications for the configuration of the existing queue manager.

This task uses the MQTTV3 sample Java application, and the associated Java client library. These resources are no longer included in MQ Telemetry, they are now part of the IBM Messaging Telemetry Clients SupportPac. You install this SupportPac as part of this task.

There are two commands to run the MQTTV3 sample Java application. The first command creates a subscription, then waits for a message. The second command publishes to that subscription. Therefore the commands must be entered into different command lines or shell windows.

About this task

To perform verification on a server or device without a GUI, scripts are provided in the samples directory. The `SampleMQM` script performs the required steps to configure MQ Telemetry. The MQTTV3 sample Java application can then be run to validate the basic or custom MQ Telemetry configuration by connecting, subscribing to topics, and publishing messages. The `CleanupMQM` sample script can be run to delete the queue manager created by the `SampleMQM` script.

The following items summarize the main goals that can be achieved using this verification procedure:

- Validate a basic or custom MQ Telemetry configuration by connecting, subscribing to topics and publishing messages.
- Showcase the main features of the MQTT protocol.
- Provide a simple tool to aid in debugging MQ Telemetry applications.

Procedure

1. Download the IBM Messaging Telemetry Clients SupportPac.
2. Decompress the client pack into a directory of your own choosing.

The sample applications and client libraries are in client-specific directories under *CLIENTPACKDIR*/SDK/clients, where *CLIENTPACKDIR* is the directory in which you decompressed the client pack. This task uses the MQTTV3 sample Java application, and the associated Java client library. These resources are available in the following location:

```
CLIENTPACKDIR/SDK/clients/java
```

3. Configure MQ Telemetry.

   The SampleMQM script runs through a series of steps, including creating the MQXR_SAMPLE_QM queue manager, defining and starting the telemetry (MQXR) service, setting up the default transmission queue, and configuring a telemetry channel.

   For information about performing this manually, see Configuring a queue manager for telemetry on Linux and AIX , or Configuring a queue manager for telemetry on Windows .

   - On Windows systems, enter the following command in a command line:
     ```
     MQINSTDIR\mqxr\samples\SampleMQM.bat
     ```
   - On AIX or Linux systems, enter the following command in a shell window:
     ```
     MQINSTDIR/mqxr/samples/SampleMQM.sh
     ```

   where *MQINSTDIR* is the installation directory for this installation of IBM MQ. A queue manager called MQXR_SAMPLE_QM is created, and MQ Telemetry is configured.
4. Run the MQTTV3 sample Java application to create a subscription.
   - On Windows systems, enter the following commands in a command line:
     ```
     java -cp
     "CLIENTPACKDIR\SDK\clients\java\org.eclipse.paho.sample.mqttv3app.jar;
     CLIENTPACKDIR\SDK\clients\java\org.eclipse.paho.client.mqttv3.jar"
     org.eclipse.paho.sample.mqttv3app.Sample -a subscribe
     ```
   - On AIX or Linux systems, enter the following commands in a shell window:
     ```
     java -cp
     CLIENTPACKDIR/SDK/clients/java/org.eclipse.paho.sample.mqttv3app.jar:
     CLIENTPACKDIR/SDK/clients/java/org.eclipse.paho.client.mqttv3.jar
     org.eclipse.paho.sample.mqttv3app.Sample -a subscribe
     ```

   The subscription is created, and waits to receive a message.
5. Run the MQTTV3 sample Java application to publish to the subscription.
   - On Windows systems, enter the following command in a second command line:
     ```
     java -cp
     "CLIENTPACKDIR\SDK\clients\java\org.eclipse.paho.sample.mqttv3app.jar;
     CLIENTPACKDIR\SDK\clients\java\org.eclipse.paho.client.mqttv3.jar"
     org.eclipse.paho.sample.mqttv3app.Sample -m "Hello from an MQTT v3 application"
     ```
   - On AIX or Linux systems, enter the following command in a second shell window:
     ```
     java -cp
     CLIENTPACKDIR/SDK/clients/java/org.eclipse.paho.sample.mqttv3app.jar:
     CLIENTPACKDIR/SDK/clients/java/org.eclipse.paho.client.mqttv3.jar
     org.eclipse.paho.sample.mqttv3app.Sample -m "Hello from an MQTT v3 application"
     ```

   The message Hello from an MQTT v3 application, that you typed into the second command line or shell window, is published by that application and received by the application in the first window. The application in the first window shows it on the screen.
6. Press **Enter** in the first command line or shell window to end the subscribing application.
7. Remove the queue manager created by the SampleMQM script.
   - On Windows systems, enter the following command in a command line:
     ```
     MQINSTDIR\mqxr\samples\CleanupMQM.bat
     ```
   - On AIX or Linux systems, enter the following command in a shell window:
     ```
     MQINSTDIR/mqxr/samples/CleanupMQM.sh
     ```

Results

If the scripts finished, and messages can be sent and received, the MQ Telemetry installation is verified.

What to do next

If you encounter any problems during the verification process, see MQ Telemetry troubleshooting. You can also view the error log:

- On Windows systems, the default location for the queue manager log is `*MQINSTDIR*\qmgrs\MQXR_SAMPLE_QM\mqxr`
- On AIX and Linux systems, the default location for the queue manager log is `/var/mqm/qmgrs/MQXR_SAMPLE_QM/mqxr/`

Uninstalling MQ Telemetry components

AIX Linux Windows

Remove MQ Telemetry components from your computer.

Before you begin

Check that your user ID has the following authority to complete uninstallation tasks:

- Windows On all Windows operating systems and editions, your user ID must be a member of the Administrators group.
- AIX Linux On AIX and Linux systems, your user ID must have root authority to complete installation. Follow your local security guidelines to acquire root authority; either login as root, or log in as another user and become root.

Procedure

- Windows On Windows, to uninstall MQ Telemetry you must modify the existing IBM MQ. Deselect MQ Telemetry from the list of components that is installed in the main installation.
- AIX On AIX, run the command **`installp -u mqm.xr.service`**. For more information, refer to “Uninstalling or modifying IBM MQ on AIX” on page 247, but replace step 4 with the command in this step.
- Linux On Linux, run the command **`rpm -e MQSeriesXRService`**. For more information refer to “Uninstalling or modifying IBM MQ on Linux using rpm” on page 395, but replace step 4 with the command in this step.

Installing RDQM (replicated data queue managers)

Linux V 9.0.4 MQ Adv.

Installation tasks associated with RDQM are grouped in this section. RDQM is only available on RHEL 7.*x* on x86-64.

Before you begin

Pacemaker is one of the prerequisites for RDQM that you install as part of this task. Pacemaker requires that the following Linux packages are installed on the system:

- OpenIPMI-modalias.x86_64
- OpenIPMI-libs.x86_64
- libyaml.x86_64
- PyYAML.x86_64
- libesmtp.x86_64
- net-snmp-libs.x86_64
- net-snmp-agent-libs.x86_64
- openhpi-libs.x86_64
- libtool-ltdl.x86_64
- perl-TimeDate.x86_64

About this task

To install support for RDQM (replicated data queue managers), you perform the following tasks:

1. Install IBM MQ on each node.
2. Install DRBD and Pacemaker on each node.
3. Install RDQM on each node.
4. Configure the firewall on each node.

The DRBD and Pacemaker RPM packages are supplied on the IBM MQ media. You should install the versions supplied with IBM MQ. Do not download your own versions.

The DRBD and Pacemaker packages are signed with the LINBIT GPG key. Use the following command to import the public LINBIT GPG key:

```
rpm --import https://packages.linbit.com/package-signing-pubkey.asc
```

Without this step, an RPM install of these packages issues the following warnings:

```
warning: rpm-name: Header V4 DSA/SHA1 Signature, key ID 282b6e23: NOKEY"
```

The same installation location should be used on all three servers that are the nodes in the HA group, or both servers in a DR pair. You can have multiple IBM MQ installations on each server, but only one of these installations should be an RDQM installation.

The following installation script is supplied, you must run the script as `root`:

installRDQMsupport

By default, installs the IBM MQ runtime, server, samples, client, and RDQM RPM packages. Also installs the DRBD and Pacemaker RPM packages. (You can edit this file, if required, to add additional RPM packages to install; see "IBM MQ rpm components for Linux systems" on page 341 for a list of available RPM packages.)

A script for configuring the firewall for HA RDQM is supplied in the IBM MQ samples directory, you must run the script as `root`:

`MQ_INSTALLATION_PATH``/samp/rdqm/firewalld/configure.sh`

Adds the following permanent firewallD service rules for DRBD, Pacemaker, and IBM MQ:

- *`MQ_INSTALLATION_PATH`*`/samp/rdqm/firewalld/services/rdqm-drbd.xml` allows TCP ports 7000-7100.
- *`MQ_INSTALLATION_PATH`*`/samp/rdqm/firewalld/services/rdqm-pacemaker.xml` allows UDP ports 5404-5407
- *`MQ_INSTALLATION_PATH`*`/samp/rdqm/firewalld/services/rdqm-mq.xml` allows TCP port 1414 (you must edit the script if you require a different port)

V 9.0.5 For DR RDQM you specify the replication port when you create a DR RDQM, so must configure your firewall to add firewallD service rules accordingly.

Procedure

To install RDQM support, on each node:

1. Run the script `installRDQMsupport` to install IBM MQ, RDQM support, DRBD, and Pacemaker.
2. Run the script *`MQ_INSTALLATION_PATH`*`/samp/rdqm/firewalld/configure.sh` to configure the firewall for HA RDQM operation.

What to do next

You can now configure the Pacemaker cluster and replicated data queue managers, see RDQM high availability. Or you can configure disaster recovery replicated data queue managers, see RDQM disaster recovery.

Related information:

Migrating replicated data queue managers

Uninstalling RDQM (replicated data queue managers)

Linux V 9.0.4 MQ Adv.

You can uninstall RDQM by using the supplied uninstallation scripts.

About this task

Before you uninstall HA RDQM, you must first suspend the HA group, or remove it from the node altogether.

An uninstallation script is supplied in the root directory of the installation image, you must run the script as `root`:

`uninstallRDQMsupport`

By default, uninstalls the MQSeries Runtime, Server, Samples, Client and RDQM RPM packages along with the DRBD and Pacemaker RPM packages. You can edit the script, if required.

A script for undoing the firewall configuration is supplied in the IBM MQ samples directory, you must run the script as `root`:

`MQ_INSTALLATION_PATH``/samp/rdqm/firewalld/unconfigure.sh`

Removes firewallD service rules for DRBD, Pacemaker and IBM MQ.

Procedure

- To uninstall HA RDQM support, on each node:
  1. Suspend or delete the HA group. To suspend the HA group on the node, enter the following command:
     ```
     rdqmadm -s
     ```
     To delete the HA group from the node, enter the following command:
     ```
     rdqmadm -u
     ```
  2. Run the script *MQ_INSTALLATION_PATH*`/samp/rdqm/firewalld/unconfigure.sh` to undo the firewall configuration.
  3. Run the script `uninstallRDQMsupport` to uninstall IBM MQ, RDQM support, DRBD, and Pacemaker.
- V 9.0.5 To uninstall DR RDMQ support:
  1. Back up the queue manager running on the primary node, see Backing up and restoring IBM queue manager data.
  2. Delete the queue manager on both the primary and secondary nodes, see Deleting a DR RDQM.
  3. Run the script `uninstallRDQMsupport` to uninstall IBM MQ, RDQM support, DRBD, and Pacemaker.

Installing IBM MQ for z/OS

z/OS

Installation tasks that are associated with installing IBM MQ on z/OS systems are grouped in this section.

About this task

IBM MQ for z/OS uses the standard z/OS installation procedure. It is supplied with a Program Directory that contains specific instructions for installing the program on a z/OS system. You must follow the instructions in the appropriate Program Directory, which can be downloaded from the IBM Publications Center:

- LTS *Program directory for IBM MQ for z/OS Long Term Support Release V9.0.0 (GI13-3386)*
- CD *Program directory for IBM MQ for z/OS Continuous Delivery Release V9.0.x (GI13-3391)*

The Program Directory includes not only details of the installation process, but also information about the prerequisite products and their service or maintenance levels.

SMP/E, used for installation on the z/OS platform, validates the service levels and prerequisite and corequisite products, and maintains the SMP/E history records to record the installation of IBM MQ for z/OS. It loads the IBM MQ for z/OS libraries and checks that the loads have been successful. You then have to customize the product to your own requirements.

Before you install and customize IBM MQ for z/OS, you must decide the following:

- Whether you are going to install one of the optional national language features. See National language support.
- Which communications protocol and distributed queuing facility you are going to use. See Communications protocol and distributed queuing.
- What your naming convention for IBM MQ objects will be. See Naming conventions.
- What command prefix string (CPF) you are going to use for each queue manager. See Using command prefix strings.

- CD When upgrading from a previous Continuous Delivery release through the installation of PTFs, decide whether any USERMODs that have been applied to IBM MQ for z/OS will still be required. Remove the USERMODs before installation of the Continuous Delivery PTFs, or use the SMP/E BYPASS(ID) option on APPLY. If neither of these actions is performed, an `SMP/E MODID ERROR GIM38201E` will be received.

  The PTFs for the latest Continuous Delivery release can be determined by using SMP/E FIXCAT HOLDDATA category IBM.MQ.V9R0M*n*, where *n* is the modification level. For example, category IBM.MQ.V9R0M2 identifies fixes that upgrade IBM MQ for z/OS Version 9.0 Continuous Delivery to modification level 2.

You also need to plan how much storage you require in your z/OS system to accommodate IBM MQ; Planning your storage and performance requirements on z/OS helps you plan the amount of storage required.

Procedure

1. Check that your system hardware, and software levels meet the minimum requirements. See "Checking requirements on z/OS" on page 550.
2. Plan your installation See "Planning to install IBM MQ for z/OS" on page 550.
3. Install and configure IBM MQ for z/OS, by following the instructions detailed in the Program Directory. See also the information in the subtopics for further guidance.

z/OS installation overview

IBM MQ functions are provided as a number of different products, which are installed together to provide the capability required.

The different products are:

IBM MQ for z/OS
Provides IBM MQ capability, connectivity on and off the z/OS platform, and excellent integration with z/OS software, such as CICS, IMS, WebSphere Application Server, and Db2. Licensed under a Monthly License Charge (MLC) model.

IBM MQ for z/OS Value Unit Edition (VUE)
Same functionality as IBM MQ for z/OS, but intended for new workloads running within a zNALC LPAR only. Licensed under a One Time Charge (OTC) model. Can coexist and interact with IBM MQ MLC offerings in other LPARs.

Note, that from an installation perspective, the same FMIDs as for IBM MQ for z/OS are installed, then, an additional enablement feature is added, which changes product usage recording for billing purposes.

IBM MQ Managed File Transfer for z/OS (MFT)
Equivalent function as Managed File Transfer on Multiplatforms, though more closely integrated with base IBM MQ offering as of Version 8. Must be locally bound to a z/OS queue manager.

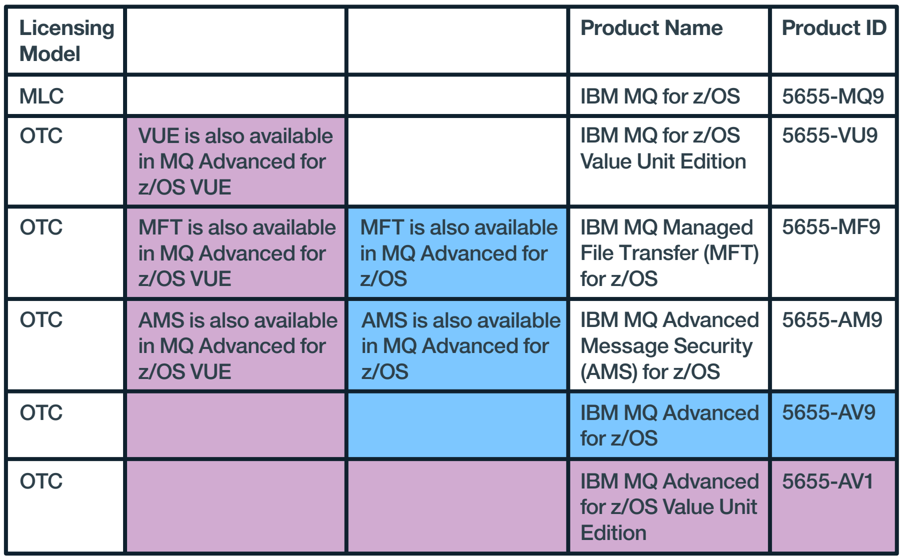
IBM MQ Advanced Message Security for z/OS (AMS)
Provides end to end encryption of messages throughout the IBM MQ network. Data is encrypted at rest, as well as when data is being transmitted.

Note, that from an installation perspective, AMS only provides an enablement feature, which permits encryption code integrated into the queue manager to be used.

IBM MQ Advanced for z/OS
Bundling of IBM MQ Managed File Transfer for z/OS and IBM MQ Advanced Message Security for z/OS only; that is, no IBM MQ for z/OS. Can be deployed with IBM MQ MLC or VUE offerings

IBM MQ Advanced for z/OS, Value Unit Edition
Bundling of IBM MQ for z/OS Value Unit Edition, together with IBM MQ Managed File Transfer for z/OS, and IBM MQ Advanced Message Security for z/OS

The two different licensing models, together with their associated bundles, are shown in the following table:



Licensing Model			Product Name	Product ID
MLC			IBM MQ for z/OS	5655-MQ9
OTC	VUE is also available in MQ Advanced for z/OS VUE		IBM MQ for z/OS Value Unit Edition	5655-VU9
OTC	MFT is also available in MQ Advanced for z/OS VUE	MFT is also available in MQ Advanced for z/OS	IBM MQ Managed File Transfer (MFT) for z/OS	5655-MF9
OTC	AMS is also available in MQ Advanced for z/OS VUE	AMS is also available in MQ Advanced for z/OS	IBM MQ Advanced Message Security (AMS) for z/OS	5655-AM9
OTC			IBM MQ Advanced for z/OS	5655-AV9
OTC			IBM MQ Advanced for z/OS Value Unit Edition	5655-AV1

Figure 58. IBM MQ for z/OS product bundles

Both the IBM MQ Advanced Message Security product, and IBM MQ for z/OS Value Unit Edition product, provide their own module that only enables their respective function. The functional code is integrated into the base IBM MQ for z/OS code for efficiency, and supplied and serviced through the base IBM MQ for z/OS code.

V 9.0.3 From IBM MQ Version 9.0.3, rather than separately install these enablement modules, a runtime configuration option is available. This provides simpler and more granular control of which functions are available, and better recording of the capabilities used in SMF billing data at an individual queue manager level. See "Product usage recording with IBM MQ for z/OS products" on page 555 for more information.

Program directories provide instructions for SMP/E installation of the program materials on to a target system. The Customizing IBM MQ for z/OS topics guide you through customization of the code, and creating customized execution units, for example the queue manager and file transfer agents.

Managed File Transfer product options

Checking requirements on z/OS

z/OS

Before you install IBM MQ on z/OS, you must check for the latest information and system requirements.

About this task

A summary of the tasks that you must complete to check system requirements is listed here with links to further information.

Procedure

1. Check that you have the latest information, including information on hardware and software requirements. See "Where to find product requirements and support information" on page 195.
2. Check that your systems meet the initial hardware and software requirements for z/OS. Before attempting to install, and run IBM MQ for z/OS, ensure that your system hardware, and software levels meet the minimum requirement. You can check the minimum required levels at IBM MQ for z/OS requirements.

   Note that the System Requirements page for IBM MQ Version 9.0 uses the Software Product Compatibility Reports (SPCR) tool. The SPCR tool enables you to go directly to the:
   - Supported operating systems
   - Prerequisites
   - System requirements, and
   - Optional supported software.
3. Check that you have the correct licenses. See "License requirements" on page 194 and IBM MQ license information.

Planning to install IBM MQ for z/OS

z/OS

To install the IBM MQ product your hardware, and software environment must meet minimum requirement levels. You must also consider the national language features, communications protocols, and naming conventions to be used.

National language support

You can choose one of the following national languages for the IBM MQ operator messages and the IBM MQ operations and control panels (including the character sets used). Each language is identified by one of the following language letters:

C	Simplified Chinese
E	U.S. English (mixed case)
F	French

K	Japanese
U	U.S. English (uppercase)

The samples, IBM MQ commands, and utility control statements are available only in mixed case U.S. English.

Communications protocol and distributed queuing

The distributed queuing facility provided with the base product feature of IBM MQ can either use APPC (LU 6.2), TCP/IP from IBM, or any TCP product which supports the z/OS Unix Sockets API. The distributed queuing facility is also known as the channel initiator and the mover.

You must perform the following tasks to enable distributed queuing:
- Choose which communications interface to use. This can be either, or both, of the following:
  - APPC (LU 6.2)
  - TCP/IP
- Customize the distributed queuing facility and define the IBM MQ objects required.
- Define access security.
- Set up your communications. This includes setting up your TCPIP.DATA data set if you are using TCP/IP, LU names, and side information if you are using APPC. This is described in Setting up communication for z/OS.

Naming conventions

It is advisable to establish a set of naming conventions when planning your IBM MQ systems. The names you choose will probably be used on different platforms, so you should follow the convention for IBM MQ, not for the particular platform.

IBM MQ allows both uppercase and lowercase letters in names, and the names are case sensitive. However, some z/OS consoles fold names to uppercase, so do not use lowercase letters for names unless you are sure that this will not happen.

You can also use numeric characters and the period (.), forward slash (/), underscore (_) and percent (%) characters. The percent sign is a special character to Security Server (previously known as RACF®), so do not use it in names if you are using Security Server as your External Security Manager. Do not use leading or trailing underscore characters if you are planning to use the Operations and Control panels.

For more information, see Rules for naming IBM MQ objects.

Choosing names for queue managers and queue-sharing groups

Each queue manager and queue-sharing group within a network must have a unique name. Do not use the same name for a queue manager and a queue-sharing group. On z/OS the names of queue managers and queue-sharing groups can be up to four characters long. Each Db2 system and data-sharing group within the network must also have a unique name.

The names of queue manager and queue-sharing groups can use only uppercase alphabetic characters, numeric characters, and dollar sign ($), number sign (#) or at sign (@); they must not start with a numeric character. Queue-sharing group names that are less than four characters long are padded internally with at signs, so do not use names ending in the at sign.

The queue manager name is the same as the z/OS subsystem name. You might identify each subsystem as a queue manager by giving it the name `QM` *xx* (where *xx* is a unique identifier), or you might choose a naming convention like `ADDX`, where `A` signifies the geographic area, `DD` signifies the company division, and `X` is a unique identifier.

You might want to use your naming convention to distinguish between queue managers and queue-sharing groups. For example, you might identify each queue-sharing group by giving it the name `QG` *`xx`* (where *`xx`* is the unique identifier).

Choosing names for objects

Queues, processes, name lists, and clusters can have names up to 48 characters long. Channels can have names up to 20 characters long and storage classes can have names up to 8 characters long.

If possible, choose meaningful names within any constraints of your local conventions. Any structure or hierarchy within names is ignored by IBM MQ, however, hierarchical names can be useful for system management. You can also specify a description of the object when you define it to give more information about its purpose.

Each object must have a unique name within its object type. However, each object type has a separate namespace, so you can define objects of different types with the same name. For example, if a queue has an associated process definition, it is a good idea to give the queue and the process the same name. It is also a good idea to give a transmission queue the same name as its destination queue manager.

You could also use the naming convention to identify whether the object definition is private or a global. For example, you could call a namelist `project_group.global` to indicate that the definition is stored on the shared repository.

Application queues

Choosing names that describe the function of each queue helps you to manage these queues more easily. For example, you might call a queue for inquiries about the company payroll `payroll_inquiry`. The reply-to queue for responses to the inquiries might be called `payroll_inquiry_reply`.

You can use a prefix to group related queues. This means that you can specify groups of queues for administration tasks like managing security and using the dead-letter queue handler. For example, all the queues that belong to the payroll application might be prefixed by `payroll_`. You can then define a single security profile to protect all queues with names beginning with this prefix.

You can also use your naming convention to indicate that a queue is a shared queue. For example, if the payroll inquiry queue was a shared queue, you might call it `payroll_inquiry.shared`.

Storage classes and coupling facility structures

The character set you can use when naming storage classes and coupling facility structures is limited to uppercase alphabetic and numeric characters. You should be systematic when choosing names for these objects.

Storage class names can be up to 8 characters long, and must begin with an alphabetic character. You will probably not define many storage classes, so a simple name is sufficient. For example, a storage class for IMS bridge queues could be called `IMS`.

Coupling facility structure names can be up to 12 characters long, and must begin with an alphabetic character. You could use the name to indicate something about the shared queues associated with the coupling facility structure (that they all belong to one suite of applications for example). Remember that in the coupling facility, the structure names are the IBM MQ name prefixed by the name of the queue-sharing group (padded to four characters with @ symbols).

Choosing names for channels

To help you manage channels, it is a good idea if the channel name includes the names of the source and target queue managers. For example, a channel transmitting messages from a queue manager called QM27 to a queue manager called QM11 might be called `QM27/QM11`.

If your network supports both TCP and SNA, you might also want to include the transport type in the channel name, for example `QM27/QM11_TCP`. You could also indicate whether the channel is a shared channel, for example `QM27/QM11_TCP.shared`.

Remember that channel names cannot be longer than 20 characters. If you are communicating with a queue manager on a different platform, where the name of the queue manager might contain more than 4 characters, you might not be able to include the whole name in the name of the channel.

Using command prefix strings

Each instance of IBM MQ that you install must have its own *command prefix* string (CPF). You use the CPF to identify the z/OS subsystem that commands are intended for. It also identifies the z/OS subsystem from which messages sent to the console originate.

You can issue all MQSC commands from an authorized console by inserting the CPF before the command. If you enter commands through the system command input queue (for example, using CSQUTIL), or use the IBM MQ operations and control panels, you do not use the CPF.

To start a subsystem called CSQ1 with CPF that is ' `+CSQ1` ', issue the command `+CSQ1 START QMGR` from the operator console (the space between the CPF and the command is optional).

The CPF also identifies the subsystem that is returning operator messages. The following example shows `+CSQ1` as the CPF between the message number and the message text.

```
CSQ9022I +CSQ1 CSQNCDSP ' DISPLAY CMDSERV' NORMAL COMPLETION
```

See Defining command prefix strings (CPFs) for information about defining command prefix strings.

Delivery media

z/OS

IBM MQ for z/OS is supplied on 3590 cartridge only.

One cartridge contains the product code together with the following language features; U.S. English (mixed case), U.S. English (uppercase), French, Chinese, and Japanese.

Customizing IBM MQ and its adapters

z/OS

IBM MQ requires some customization after installation to meet the individual and special requirements of your system, and to use your system resources in the most effective way.

For a list of tasks that you must perform when you customize your system, see Customizing IBM MQ for z/OS.

Using queue-sharing groups

If you want to use queue-sharing groups, you do not have to set them up when you install IBM MQ, you can do this at any time.

For details of how to manage your queue-sharing groups when you have set them up, see Managing queue-sharing groups.

Verifying your installation of IBM MQ for z/OS

z/OS

After the installation and customization has been completed, you can use the installation verification programs (IVPs) supplied with IBM MQ for z/OS to verify that the installation has been completed successfully.

The IVPs supplied are assembler language programs and you should run them after you have customized IBM MQ for z/OS to suit your needs. They are described in Running the basic installation verification program.

Macros intended for customer use

z/OS

The macros identified in this topic are provided as programming interfaces for customers in support of features that are specific to IBM MQ for z/OS.

The 'C' include files, COBOL copy files, PL/I include files and assembler macros that are provided as programming interfaces for customers in support of features that apply across many IBM MQ platforms are described in the Constants.

Note: Do not use as programming interfaces any IBM MQ macros other than those interfaces identified in this topic or in the Constants

General-use programming interface macros

The following assembler macros are provided to enable you to write programs that use the services of IBM MQ. The macros are supplied in library thlqual.SCSQMACS.

- CMQXCALA
- CMQXCFBA
- CMQXCFCA
- CMQXCFLA
- CMQXCDFA
- CMQXCINA
- CMQXCVCA

Product-sensitive programming interface macros

The following assembler macros are provided to enable you to write programs that use the services of IBM MQ. The macros are supplied in library thlqual.SCSQMACS. Product-sensitive interfaces are open to change between different releases of the product.

- CSQBDEF
- CSQDQEST

Product usage recording with IBM MQ for z/OS products

z/OS

To determine the product usage, the z/OS system records the amount of processor time that is used by the product when it processes.

z/OS can measure how much processing time is spent in doing work on behalf of the IBM MQ queue manager that is handling MQI calls, executing MQSC commands, or performing some other action to support the messaging and queuing functions that are used by your application programs. The amount of processing time is recorded in a file at hourly intervals, and the hourly records are totaled at the end of a month. In this way, the total amount of time used by the IBM MQ for z/OS product on your behalf is computed, and used to determine how much you pay for your use of the IBM MQ for z/OS product that month.

Product usage recording is implemented as follows:

- When IBM MQ for z/OS is installed, it identifies itself to z/OS and requests that the *System Management Facilities (SMF)* mechanism within z/OS is to automatically measure how much processor time is used by the IBM MQ for z/OS product.
- V 9.0.3 The default product used by registration must be overridden at run-time for particular software execution instances which are processing under the license provided by a particular software bundle.

  For example, if you are licensed to use IBM MQ Advanced for z/OS, Value Unit Edition (VUE), then:

  - Queue manager
  - Advanced message security, and
  - Managed file transfer

  instances must be identified as using the ADVANCEDVUE product identifier, so that month end usage reports correctly identify the product used.
- When enabled, the z/OS usage measurement facility collects usage figures for each hour of the day, and generates usage records that are added to a report file on disk.
- At the end of one full month, these usage records are collected by a program, which generates a report of product usage for the month. This report is used to determine the charge for the IBM MQ for z/OS product.

For more information about product usage recording and the Sub-Capacity Reporting Tool (SCRT), see IBM Z Software Pricing. For information about the MULCCAPT parameter see, Using CSQ6SYSP.

V 9.0.3

Over-riding the default product associated with usage

IBM MQ Version 9.0.3 introduces an improved method for associating IBM MQ usage with the licensed Product ID (PID) so that workload reporting tools, for example, SCRT and MWRT, correctly reflect usage.

Each of the following products uses a different PID:
- Base IBM MQ
- Advanced Message Security
- Managed File Transfer
- IBM MQ for z/OS Value Unit Edition (VUE)
- IBM MQ Advanced for z/OS, Value Unit Edition

There are two alternative mechanisms to associate the correct PID with a running instance of IBM MQ:
1. Most useful for a long term deployment of IBM MQ - The CSQ6USGP macro selects the correct PID, and is built into the queue manager zPARM parameter.
2. Most useful for a test system which needs to run for short times under different PIDs - Parameters on the START QMGR command select the PIDs. These run-time parameters, **QMGRPROD** and **AMSPROD**, can be entered on the command, or coded into the MSTR JCL.

   Note that a value entered on a START command overrides any values encoded into ZPARM.

In all cases, the selected PIDs are shown in startup messages CSQY036I and CSQ0619I.

For Managed File Transfer, the PID is selected using an fteSetProductId command.

If no value is set by the preceding mechanisms, a default PID is used.

Sample scenarios

You have MLC IBM MQ for z/OS and have purchased Advanced Message Security
: No changes are necessary, the default PIDs are correctly recorded, 5665-MQ9 for IBM MQ use and 5665-AM9 for Advanced Message Security usage.

You are migrating a single queue manager from MLC to VUE
: Use either the ZPARM or START QMGR mechanism, to select **QMGRPROD**=*VUE*

You have installed a new IBM MQ Advanced for z/OS, Value Unit Edition on a new LPAR
: Use either the ZPARM or START QMGR mechanisms to select both **QMGRPROD**=*ADVANCEDVUE* and **AMSPROD**=*ADVANCEDVUE*.

  For MFT deployments use **fteSetProductID ADVANCEDVUE**

IBM MQ for z/OS Value Unit Edition (VUE)

z/OS

IBM MQ for z/OS Value Unit Edition (VUE) provides all the function and capability of the base IBM MQ for z/OS, in a format that offers a one-time-charge (OTC) price metric for eligible workloads that are deployed in qualified IBM Z New Application License Charge (zNALC) logical partitions (LPARs).

The term, Eligible Workload, is defined as new workload that executes using the IBM MQ for z/OS VUE server environment, on condition that the workload is qualified and approved through the zNALC qualification process.

For further information on zNALC, see IBM Z Software Pricing

The OTC price metric provides an alternative pricing model for new IBM MQ for z/OS-connected applications and new IBM MQ for z/OS VUE service enablement workloads.

Support for the zNALC metric offers a reduced price for the z/OS operating system on LPARs that run a qualified application.

IBM MQ for z/OS VUE can connect to other supported versions of IBM MQ for z/OS (whether in zNALC or non-zNALC environments) for workload federation and systems management.

IBM MQ for z/OS VUE allows connections from IBM MQ clients, that run on other platforms.

Installing VUE

An order for VUE is fulfilled by delivery of two products:
- IBM MQ for z/OS (5655-MQ9), either Long Term Support (LTS) release or Continuous Delivery (CD) release.
- The VUE enabling product, IBM MQ for z/OS Value Unit Edition Version 9.0 (5655-VU9).

Note: The VUE enabling product enables either IBM MQ Version 9.0 LTS release or IBM MQ Version 9.0 CD release to conform with the licensing requirements of Value Unit Edition operation.
The products are separately installed using SMP/E following the process documented in their respective Program Directories which can be downloaded from the IBM Publications Center:

- LTS *Program directory for IBM MQ for z/OS Long Term Support Release V9.0.0 (GI13-3386)*
- LTS *Program directory for IBM MQ for z/OS Value Unit Edition Long Term Support Release V9.0.0 (GI13-3387)*
- CD *Program directory for IBM MQ for z/OS Continuous Delivery Release V9.0.x (GI13-3391)*
- CD *Program directory for IBM MQ for z/OS Value Unit Edition Continuous Delivery Release V9.0.x (GI13-3395)*

.

Enabling VUE

To enable a queue manager to run an eligible workload in a zNALC LPAR, the SCUEAUTH library created by installation of the VUE enabling product must be added to the STEPLIB concatenation of the xxxxMSTR procedure for that queue manager:
- The SCUEAUTH library should be APF authorized
- The SCUEAUTH libary must be concatenated ahead of the SCSQAUTH library,

For example, the CSQ4MSTR sample would be modified as follows:

```
//PROCSTEP EXEC PGM=CSQYASCP,REGION=0M,MEMLIMIT=2G
//*
//STEPLIB  DD DSN=hlq.SCSQANLE,DISP=SHR
//     DD DSN=hlq.SCUEAUTH,DISP=SHR
//     DD DSN=hlq.SCSQAUTH,DISP=SHR
-
```

When SCUEAUTH is added to the STEPLIB concatenation, the characters VUE appear in the release level shown by message CSQY000I during queue manager startup. The queue manager starts only in an LPAR configured for zNALC workload by name or IPL parameter.

Characteristics of a VUE-enabled queue manager

A VUE-enabled queue manager has all the function and capability of the base queue manager. Additionally, clients will be enabled during channel initiator startup.

A VUE-enabled queue manager records usage information in SMF89 records with the product name and identifier for IBM MQ for z/OS Value Unit Edition (VUE) instead of those for the IBM MQ product.

A VUE-enabled queue manager can:

- Connect to other queue managers and clients in a network, according to the connectivity capabilities of the base queue manager installation.
- Participate in a queue-sharing group with other queue managers provided the base queue manager versions are able to interoperate, regardless of whether other members are standard or VUE function queue managers.

Installing Managed File Transfer for z/OS

z/OS

You install Managed File Transfer on your IBM MQ for z/OS system by using SMP/E.

About this task

Managed File Transfer for z/OS uses the standard z/OS installation procedure. It is supplied with a Program Directory that contains specific instructions for installing the program. You must follow the instructions in the appropriate Program Directory, which can be downloaded from the IBM Publications Center:

- LTS *Program directory for Managed File Transfer for z/OS Long Term Support Release V9.0.0 (GI13-3389)*
- CD *Program directory for Managed File Transfer for z/OS Continuous Delivery Release V9.0.x (GI13-3392)*

The instructions in the Program Directory include not only details of the installation process, but also information about the prerequisite products and their service or maintenance levels.

SMP/E, used for installation on the z/OS platform, validates the service levels and prerequisite and corequisite products, and maintains the SMP/E history records to record the installation of Managed File Transfer. The process loads the appropriate libraries and checks that the loads have been successful. You then have to customize the product to your own requirements.

Note: For Version 9.0, the supported version of Java for Managed File Transfer for z/OS is Java 1.8.

Procedure

1. Plan your installation. See Planning for Managed File Transfer for items you need to consider before installing the component.
2. Install the product by following the instructions detailed in the Program Directory.
3. Check that the SMP/E installation process has created the product JCL library USERID.MFTV800.SBFGCMDS. If this JCL library has not been created during the installation process, create the library and submit the job USERID.ZOS.JCL(COPYJCL1).

What to do next

When you have installed the product, you must carry out some customization tasks. For more information, see Configuring Managed File Transfer for z/OS.

Related information:
Managed File Transfer for z/OS
Planning for Managed File Transfer

Installing Advanced Message Security on z/OS

z/OS

You can install Advanced Message Security component on z/OS by using SMP/E.

About this task

Advanced Message Security for z/OS (AMS) is a separately licensed enabling product that extends IBM MQ to provide a high level of protection for sensitive data flowing through the IBM MQ network using a public key cryptography model.

Advanced Message Security for z/OS is installed separately using SMP/E by following the process documented in the Program Directory, which can be downloaded from the IBM Publications Center:

- LTS Program directory for Advanced Message Security for z/OS Long Term Support Release V9.0.0 (GI13-3388)
- CD Program directory for Advanced Message Security for z/OS Continuous Delivery Release V9.0.x (GI13-3398)

When you have completed the SMP/E installation, it provides the SDRQAUTH library which contains the Advanced Message Security for z/OS enablement module. You must make the enablement module available for processing during queue manager startup, either by adding to the system linklist or LPA, or for individual queue managers, by including in the STEPLIB concatenation.

The enablement module can be used with either a Long Term Support release or Continuous Delivery release of IBM MQ for z/OS to activate the Advanced Message Security for z/OS functions.

Procedure

1. Install Advanced Message Security for z/OS using SMP/E. When installing Advanced Message Security for z/OS, you must follow the instructions in the appropriate Program Directory.
2. Enable Advanced Message Security for z/OS separately for each queue manager. Completing the additional customization tasks described in Customizing IBM MQ for z/OS.

   The following tasks are relevant when adding AMS support to a queue manager:
   - Task 2: APF authorize the IBM MQ load libraries
   - Task 3: Update the z/OS link list and LPA
   - Task 4: Update the z/OS program properties table
   - Task 13: Customize the initialization input data sets
   - Task 17: Tailor your system parameter module
     - Using CSQ6SYSP
   - Task 23: Create procedures for Advanced Message Security
   - Task 24: Set up the started task user Advanced Message Security
   - Task 25: Grant RACDCERT permissions to the security administrator for Advanced Message Security
   - Task 26: Grant users resource permissions for Advanced Message Security

   You also need to configure certificates and policies, which are described in
   - Using certificates on z/OS

- Security policies
- Example configurations on z/OS

Results

Advanced Message Security component has been installed successfully.

Installing IBM MQ Advanced for z/OS

z/OS V 9.0.0 MQ Adv.

Use this topic to understand how you install IBM MQ Advanced for z/OS on your system.

About this task

IBM MQ Advanced for z/OS is a bundling of the Advanced Message Security for z/OS and Managed File Transfer for z/OS products.

Procedure

For installation instructions, follow the guidance in "Installing Advanced Message Security on z/OS" on page 559 and "Installing Managed File Transfer for z/OS" on page 558. The Program Directories for IBM MQ Advanced for z/OS can be downloaded from the IBM Publications Center:

- LTS *Program directory for IBM MQ Advanced for z/OS Long Term Support Release V9.0.0 (GI13-3390)*
- CD *Program directory for IBM MQ Advanced for z/OS Continuous Delivery Release V9.0.x (GI13-3396)*

Installing IBM MQ Advanced for z/OS, Value Unit Edition

z/OS V 9.0.0 MQ Adv. VUE

Use this topic to understand how you install IBM MQ Advanced for z/OS, Value Unit Edition (VUE) on your system.

About this task

IBM MQ Advanced for z/OS, VUE is a bundling of the Advanced Message Security for z/OS, Managed File Transfer for z/OS, and IBM MQ for z/OS Value Unit Edition (VUE) products.

Procedure

For installation instructions, follow the guidance in “Installing Advanced Message Security on z/OS” on page 559, “Installing Managed File Transfer for z/OS” on page 558, and “IBM MQ for z/OS Value Unit Edition (VUE)” on page 556.

CD The *Program directory for IBM MQ Advanced for z/OS Value Unit Edition Continuous Delivery Release V9.0.x (GI13-3397)* can be downloaded from the IBM Publications Center.

Installing IBM MQ into IBM Cloud Private

Linux V 9.0.3 MQ Adv.

Add an IBM MQ image into an IBM Cloud Private cluster, then deploy a queue manager into IBM Cloud Private.

About this task

IBM Cloud Private offers managed container services in the cloud. You can run IBM MQ in an IBM Cloud Private container.

Procedure

1. Add an IBM MQ image into an IBM Cloud Private cluster.
2. Deploy a queue manager into IBM Cloud Private.

Adding an IBM MQ image into an IBM Cloud Private cluster

Linux V 9.0.3 MQ Adv.

Prepare your IBM Cloud Private cluster to deploy a production-ready image for IBM MQ.

About this task

IBM Cloud Private offers managed container services in the cloud. You can download an IBM MQ image from Passport Advantage and import it into an IBM Cloud Private container.

Procedure

1. Download the latest IBM MQ image from Passport Advantage.

   For details of available downloads, go to Downloading IBM MQ Version 9.0 then click the tab for the release that you want to download. The name and number of the part to download are listed in a table. For example, for IBM MQ Version 9.0.4 the part is *IBM MQ Advanced V9.0.4 Continuous Delivery Release for IBM Cloud Private 2.1*, part number *CNMV6ML*.
2. Import the downloaded archive file into IBM Cloud Private.

   See Installing bundled products in the IBM Cloud Private product documentation.

What to do next

You are now ready to Deploy a queue manager into IBM Cloud Private.

Deploying a queue manager into IBM Cloud Private

Linux V 9.0.3 MQ Adv.

Use the IBM Cloud Private management console to deploy a queue manager into IBM Cloud Private.

Before you begin

This task assumes that you have already added an IBM MQ image into an IBM Cloud Private cluster.

About this task

IBM Cloud Private offers managed container services in the cloud. After you have added an IBM MQ image into an IBM Cloud Private container, you can use the IBM Cloud Private management console to deploy a queue manager.

Procedure

1. Determine which *Storage Class* to use.

   IBM MQ stores queues, messages and configuration data on a *Persistent Volume*. A *Persistent Volume* can be created for you automatically during deployment, if you specify a *Storage Class* (for example, `silver` or `gold`).

   To check which storage classes are available in your IBM Cloud Private cluster, use the command **`kubectl get storageclasses`**. If no storage classes are defined, create a persistent volume manually. See Storage in the IBM Cloud Private product documentation.

   The default volume size for IBM MQ is 2 GB.
2. Open the IBM Cloud Private management console in a web browser, and click **Menu** > **Catalog**.

   See Accessing your IBM Cloud Private cluster by using the management console in the IBM Cloud Private product documentation.
3. Select the `ibm-mqadvanced-server-prod` chart from the list.

4. Select **Configure**, then complete the following configuration steps:
   a. Enter a release name.
   b. Read and accept the license agreements.
   c. Under the dataPVC section, set **storageclass** to the storage class name determined earlier. If your cluster does not use storage classes, set **useDynamicProvisioning** to `false`.
   d. Under the image section, set the repository to the full image path.

      For example `mycluster.icp:8500/default/ibm-mqadvanced-server-prod`
   e. Under the image section, set the tag to the image tag.

      For example `9.0.4-20171106-1625-x86_64`
   f. Optional: If you need a Kubernetes pull secret to access the image registry, add it as the **pullSecret**.
   g. Optional: Under the queueManager section, set the name of the queue manager.
5. Click **Install** to deploy your queue manager as a *Helm release*.

Maintaining and migrating IBM MQ

Maintenance, upgrade, and migration have three distinct meanings for IBM MQ. The definitions are described here. The following sections describe the various concepts associated with migration, followed by the various tasks needed; these tasks are platform-specific where needed.

About this task

Attention: The information in this section applies to both Continuous Delivery (CD) and Long Term Support (LTS) releases.

Any information that applies specifically to an LTS or CD release is marked with the appropriate icon.

IBM MQ uses the terms *maintenance*, *upgrade* and *migration* as follows:

Maintenance is the application of a fix pack, interim fix or Program Temporary Fix (PTF).
Maintenance has one main characteristic. Those fixes, whether they are applied using a maintenance installation tool, or installed using a manufacturing refresh on top of an installation, are at the same command level as the existing code. No migration is required after applying maintenance. The installation can be restored to its previous level and any changed queue managers or applications will continue to work at the restored code level. However, you should test applications with the new level of IBM MQ code.

For more information, see "Applying maintenance to IBM MQ" on page 570.

Upgrading is the process of taking an existing IBM MQ installation and upgrading to a new level of code.
Unless you are upgrading the fix level of IBM MQ, but not its command level, an upgrade must be followed by migration. Upgrades can be backed out, as long as no migration has taken place. The process of removing an upgrade varies by platform and how the upgrade was applied. Upgrades that change the command level of IBM MQ require queue manager migration before applications can reconnect.

For more information, see "Applying upgrades and fixes to IBM MQ" on page 618.

Migration is the process of updating queue manager data to match a newer level of code.
Migration occurs the first time a queue manager is started with the newer level of code, and always follows an upgrade that changes the queue manager command level, both automatic and manual changes. Migration is the transformation of queue manager data, applications, and the environment that the queue manager runs in. Once migration has occurred, the queue manager can no longer be started by an earlier code level. On most platforms, queue manager migration is not reversible:

- Multi Migration cannot be reversed on IBM MQ for Multiplatforms. This restriction applies whether your enterprise uses the Long Term Support (LTS) release or Continuous Delivery (CD) release model.
- z/OS From IBM MQ for z/OS Version 9.0, you can backwards migrate queue managers only if you are using the LTS release. For more information, see IBM MQ release types.

For more information, see "Migrating IBM MQ" on page 625.

Related information:
IBM MQ for z/OS Program directory PDF files

Where to find more information about maintaining and migrating

Where to look for more information, for example if you are getting started with migrating and maintaining IBM MQ.

Getting started with maintaining and migrating IBM MQ

If you are not familiar with IBM MQ migration, start by reading the following information:
- The "Migration concepts and methods" on page 645 section: use these topics to find out more about the concepts that you must understand before planning migration tasks, including the difference between maintenance, migration, and upgrading and which migration paths are supported.
- The "IBM WebSphere MQ / IBM MQ Migration Guides" on page 567: use these guides to find more information about planning the migration process for your release and platform.

New features and changes in this release

For information about new features and changes in this release, see the following topics:
- V 9.0.0 What's new and changed in IBM MQ Version 9.0
- CD What's new and changed in Version 9.0.x Continuous Delivery
- LTS What's new and changed in Version 9.0.0.x Long Term Support

New features and changes in earlier releases

Some new features and changes from earlier releases might have an impact on planning your migration because they affect the behavior of existing applications or the automation of management tasks. For information on where to find details of these changes in the product documentation for earlier releases, see What was new and changed in earlier releases.

Important: If you are migrating your system from a version of IBM WebSphere MQ before Version 7.0, you must migrate your system to Version 7.0.1, or Version 7.1 before you migrate to the latest version. See the appropriate version of the product documentation for information on how to carry out the task. For links to earlier versions of the product documentation not available in IBM Knowledge Center, see the IBM MQ documentation library web page.

System requirements and prerequisites

From IBM MQ Version 8.0, you can use the Software Product Compatibility Reports (SPCR) tool to find information on supported operating systems, system requirements, prerequisites, and optional supported software. For more information about the SPCR tool and links to reports for each supported platform, see the System Requirements for IBM MQ Version 9.0 web page.

For links to system requirements information for all releases of IBM WebSphere MQ or IBM MQ, see System Requirements for IBM MQ.

For information about limitations and known problems for IBM MQ Version 9.0 and its maintenance, see the product readme file, which is available from the IBM MQ, WebSphere MQ, and MQSeries product readmes web page.

IBM WebSphere MQ / IBM MQ Migration Guides

Multi The *IBM WebSphere MQ / IBM MQ Migration Guide* provides information to help you plan the process of migrating from an older version to a new version of IBM MQ for Multiplatforms.

- For an introduction to the guide and its contents, see the developerWorks® blog article IBM WebSphere MQ / IBM MQ Migration Guide.
- To view the guide in your web browser, click the following link: IBM WebSphere MQ / IBM MQ Migration Guide - HTML version.
- To download the guide as a PDF file, click the following link: IBM WebSphere MQ / IBM MQ Migration Guide - PDF file.

z/OS The *IBM WebSphere MQ/ IBM MQ for z/OS Migration Guide* provides information to help you plan the process of migrating from an older version to a new version of the product on z/OS.

- For an introduction to the guide and its contents, see the developerWorks blog article IBM WebSphere MQ / IBM MQ for z/OS Migration Guide.
- To view the guide in your web browser, click the following link: IBM WebSphere MQ / IBM MQ for z/OS Migration Guide - HTML version.
- To download the guide as a PDF file, click the following link: IBM WebSphere MQ / IBM MQ for z/OS Migration Guide - PDF file.

Downloadable versions of the IBM MQ product documentation

If you prefer to use the IBM MQ Version 9.0 product documentation offline, you can download it through the links on the IBM MQ documentation library web page, either as a downloadable package or as a set of PDF files. The PDF files are also available from the links in IBM MQ Version 9.0 PDF documentation.

The version naming scheme for IBM MQ for Multiplatforms

Multi

From IBM MQ Version 9.0, releases have a three digit Version, Release, and Modification (VRM) code or a four-digit Version, Release, Maintenance, and Fix (VRMF) level code.

From IBM MQ Version 9.0, the full version of IBM MQ is described by a three-digit or four-digit number.

LTS For the Long Term Support (LTS) release model, the number consists of a four-digit VRMF code.

CD For the Continuous Delivery (CD) release model, the number consists of a three-digit VRM code on z/OS and a four digit VRMF code on Multiplatforms, where the final digit is always a zero.

The VRMF acronym stands for:

`Version.Release.Modification.Fix`

The two release types are distinguishable by the modification number in the version.release.modification (`v.r.m`) release identifier.

IBM MQ Version 9.0.0 has a zero modification number and is designated as LTSR.

CD Continuous Delivery releases have a non-zero modification number, for example, 9.0.1, 9.0.2, and so on.

The version and release parts of the code are significant; they identify the service life of a release. To run a queue manager at a different VR level, you must migrate the queue manager, its applications, and the environment in which it runs. Depending on the migration path, the migration might require more or less effort.

`7.5`, `7.0.1.1`, and `8.0.0.4` are examples of IBM MQ version codes for previous versions.

You can find the full version level of an IBM MQ installation by typing the command **`DSPMQVER`**, or **`DSPMQMVER`** on IBM i. It returns the full three-digit VRM, or four-digit VRMF code.

Versions and releases of IBM MQ are known by the first two digits of the VRMF code. The two digits are sometimes prefixed by a `V`, such as `V9.0`. A version of IBM MQ always has a release level, even if it is the first release in a version.

The first release is normally labeled `V` *`x`*`.0`, for example, IBM MQ V8.0. Occasionally, the first release of a version on a specific platform is not labeled `V` *`x`*`.0`. It is numbered to correspond the command level that has been implemented on the platform.

The third digit in the VRMF identifies the modification level of a release. A change in the third digit does not change the release. For example, after upgrading IBM MQ to modification level `8.0.1`, the release of IBM MQ remains 8.0. However the command level does change to `801`.

Notes:

1. Multi Backward migration is not possible. To be able to restore an earlier version or release level of a queue manager, you must back it up before upgrading. If you do restore it, you restore the queue manager, and its data, to the state it was in when you backed it up.
2. z/OS Backward migration is possible only if you are using the LTSR model.

A new version or release has a new service end date. New modification levels generally do not result in a new service end date. But if a modification level is announced, then a new service end date might be announced too.

The fourth digit in the VRMF code represents the fix pack level. For example, the first fix pack of the IBM MQ Version 9.0.0 LTS release is numbered 9.0.0.1. Fix levels do not affect the command level of the queue manager. No migration is required, and fix levels do not affect the service end date of a release.

Attention: From IBM MQ Version 9.0, the name is changed, for example, to 9.0.0-IBM-MQ-Windows-FP0001.

Refresh packs and fix packs for a particular version/release are cumulative, from the initial release. You can apply any higher numbered refresh, or fix pack, of the same version/release to upgrade directly to that version level. You do not have to apply the intervening fixes. Refresh packs and fix packs are obtained as service through Fix Central.

The latest modification level is also used to refresh the version of IBM MQ available through Electronic Software Download using Passport Advantage, or on physical media.

When you order IBM MQ you receive the latest version of the LTS, or CD product, depending on which support model your enterprise is using.

The result of installing a manufacturing refresh is almost the same as applying the refresh pack to an earlier fix level of IBM MQ. There is one important difference. Refresh packs are applied using a maintenance procedure, manufacturing refreshes are installed using an installation procedure. You can "unapply" a refresh pack to return to the previous fix level you had installed. You can only uninstall a manufacturing refresh, which removes IBM MQ from your system.

In addition to fixes packaged as refresh packs and fix packs, you can also obtain interim fixes for IBM MQ. You get these from Fix Central. Interim fixes are also known as emergency or test fixes, and are known collectively as interim fixes. The naming scheme for refresh and fix packs extends to interim fixes. Interim fixes are known either by their fix name, or by the list of APARs they fix.

When you apply new fix packs or refresh packs, all interim fixes are removed. The documentation with the fix pack or refresh pack tells you if the APARS associated with the interim fixes you have applied have been fixed. If they have not, check to see if there are new interim fixes, at the new level, for the APARs that concern you. If there are not, consult service. They might either tell you to reapply the interim fix, or supply a new interim fix.

Related concepts:

"The version naming scheme for IBM MQ for z/OS"
On IBM MQ for z/OS, releases have a three digit Version, Release, and Modification (VRM) code. To run a queue manager at a different VRM level, you must migrate the queue manager, its applications, and the environment in which it runs. Depending on the migration path, the migration might require more or less effort.

Related tasks:

"Maintaining and migrating IBM MQ" on page 565
Maintenance, upgrade, and migration have three distinct meanings for IBM MQ. The definitions are described here. The following sections describe the various concepts associated with migration, followed by the various tasks needed; these tasks are platform-specific where needed.

The version naming scheme for IBM MQ for z/OS

z/OS

On IBM MQ for z/OS, releases have a three digit Version, Release, and Modification (VRM) code. To run a queue manager at a different VRM level, you must migrate the queue manager, its applications, and the environment in which it runs. Depending on the migration path, the migration might require more or less effort.

The release level of IBM MQ for z/OS is described by a three-digit VRM code. This applies to both the Long Term Support (LTS) release and the Continuous Delivery (CD) release model.

The two release types are distinguishable by the modification number in the version.release.modification (`v.r.m`) release identifier.

LTS IBM MQ Version 9.0.0 has a zero modification number and is designated as LTSR.

CD Continuous Delivery releases have a non-zero modification number, for example, 9.0.1, 9.0.2, and so on.

`7.0.1`, `7.1.0`, `8.0.0`, and `9.0.0` are examples of IBM MQ for z/OS release level codes.

On z/OS, a release of IBM MQ always has a three-digit VRM code, even if the release is the first release in a version, such as `8.0.0`. IBM MQ for z/OS follows a convention of changing the VRM when the product is installed by SMP/E with a new FMID.

You can modify existing libraries, without changing the FMID, by applying PTFs. You cannot upgrade existing libraries to an FMID or release level by applying PTFs.

The release level of a z/OS queue manager is written to the operator console in the message CSQY000I.

The command level of a queue manager is a three-digit VRM code. You can look at the queue manager command level in the queue manager property panel in IBM MQ Explorer. An IBM MQ program can call MQINQ, passing the `MQIA_COMMAND_LEVEL` selector, to obtain the command level of the queue manager it is connected to.

The VRM code, or release level, is significant in two respects. Changing the release level that a queue manager runs at, requires migration of the queue manager. It also requires attention to the PTF level of other queue managers that are in the same queue-sharing group. It is also significant because each release level has its own service life, and end of service date.

The service life depends on the VRM. Each release level has its own service end date. So, for example, `8.0.0`, on z/OS, has a different service end date from `8.0.1`. See IBM Software Support lifecycle policy. Click through to WebSphere product lifecycle dates, to find the service life and end of service for different releases of IBM MQ.

Note: Backward migration z/OS is possible only if you are using the Long Term Support model.

Related concepts:

"Upgrade and migration of IBM MQ on z/OS" on page 785
You can install new releases of IBM MQ to upgrade IBM MQ to a new release, or version level. Multiple installations at the same or different levels can coexist on the same z/OS instance. Running a queue manager at a higher level requires migration.

"The version naming scheme for IBM MQ for Multiplatforms" on page 567
From IBM MQ Version 9.0, releases have a three digit Version, Release, and Modification (VRM) code or a four-digit Version, Release, Maintenance, and Fix (VRMF) level code.

Migrating queue managers: new-function and maintenance fix packs

This topic has been removed, as the information contained is not compatible with the Continuous Delivery and Long Term Support release models used in IBM MQ Version 9.0, or later.

Applying maintenance to IBM MQ

Maintenance is the application of a reversible fix. Any changes to queue manager data are compatible with the previous code level.

About this task

LTS **Long Term Support releases**

Multi On Multiplatforms, if your enterprise is using the Long Term Support (LTS) release model, maintenance is the process of applying interim fixes or fix-packs.

z/OS On z/OS, from Version 9.0, if your enterprise is using the Long Term Support (LTS) release model, you use Program Temporary Fixes (PTFs) to apply maintenance to the installed code.

CD **Continuous Delivery releases**

On all supported platforms, if your enterprise is using the Continuous Delivery (CD) release model, you can select which updates your enterprise requires as each CD release replaces the prior one for that version of IBM MQ.

For more information about Long Term Support and Continuous Delivery releases, see IBM MQ Release Types.

An important characteristic of applying maintenance is that it must be reversible. Reversibility implies two things:

1. The previous level of code is fully restored.
2. Changes that are made to IBM MQ objects are compatible. Changes are things like the creation or deletion of persistent messages, changes to queue managers, channels, topics, and queues. New and modified objects continue to work correctly with the restored level of code.

The reversibility of a maintenance package limits the extent of functional changes that are included in a maintenance package. No irreversible changes are included in a maintenance package. But, reversibility has limits. A maintenance package might include new programming and administrative interfaces. If you build new or modified applications to use the new interfaces, those applications do not work, if the maintenance package is removed.

Multi-instance queue managers are a good example. Should you remove the Version 7.0.1 fix pack that upgraded Version 7.0, then multi-instance queue manager functions no longer work. However, the queue managers continue to function correctly as single instance queue managers in Version 7.0.

On a smaller scale, a fix pack or interim fix might introduce a new configuration parameter to solve a problem. If you remove the fix pack or interim fix, although the new interface introduced by the change is not available any more, IBM MQ works with any objects that have been changed by the configuration parameter. For example, a new Java system property might introduce a parameter to set a code page for queue manager data conversion. The fix does not change any existing persistent queue manager state information. It can be removed, and the queue manager continues to work as before, but without the capability introduced in the fix.

On different platforms, you employ different mechanisms to install and maintain software releases. Installing a release at a new maintenance level, and applying maintenance level updates to updatee an earlier release to the same maintenance level, have different results.

When you update the maintenance or fix level of IBM MQ by applying a regular maintenance level update, you can reverse the update by removing the fix. When you update the maintenance or fix level of IBM MQ by applying a maintenance level update containing a new function, you can reverse that update and all previously reversible updates until a queue manager associated with the installation enables the new function.

Maintenance levels and fix levels are both supplied from the service site, Fix Central. Fix central has a function to tell you what updates you can apply to the current level of your system. If you back out a maintenance level update, it returns IBM MQ code to the same level of code as before applying the maintenance level update.

Procedure

- Multi For information on how to apply and remove fix packs on Multiplatforms, follow the appropriate link in Applying and removing maintenance for the platform that your enterprise uses.

Table 75. Applying and removing maintenance

Apply	Remove
AIX AIX	AIX
HP-UX HP-UX	HP-UX
Linux Linux	Linux
Solaris Solaris	Solaris
IBM i IBM i	IBM i
Windows Windows	Windows

- z/OS For z/OS, see "Applying and removing maintenance on z/OS" on page 617.

Related concepts:

"The version naming scheme for IBM MQ for Multiplatforms" on page 567
From IBM MQ Version 9.0, releases have a three digit Version, Release, and Modification (VRM) code or a four-digit Version, Release, Maintenance, and Fix (VRMF) level code.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

Backing up and restoring a queue manager

IBM MQ maintenance tasks on Multiplatforms - general information

Multi

When you apply and remove maintenance level updates to IBM MQ, no migration is required. Maintenance level updates are applied either as a fix pack, or by manually applying an interim fix.

About this task

This information has moved. See "Applying maintenance to IBM MQ" on page 570.

New function in maintenance level updates

Multi

This topic has been removed, as the information contained is not compatible with the Continuous Delivery and Long Term Support release models used in IBM MQ Version 9.0, or later.

Querying the maintenance level

Query the IBM MQ maintenance level by running the **dspmqver** command

About this task

In previous versions of the product, after an update to the initial installation, the version indicates the maintenance level to which the product has been updated. For example, before applying any maintenance, the version is 8.0.0.2. As maintenance is applied the last digit is updated, for example to 8.0.0.3.

From IBM MQ Version 9.0 there are two types of release; a Long Term Support (LTS) release and Continuous Delivery (CD) release. For more information, see IBM MQ Release Types.

Procedure

To view the version use the `dspmqver` command. At a command prompt, enter the following command: `dspmqver`. The resulting messages include the IBM MQ version number, which shows the maintenance level.

Related information:

dspmqver

Applying and removing maintenance on Windows

Windows

Maintenance tasks associated with IBM MQ on Windows are grouped in this section.

Procedure

- To apply maintenance level server updates, see "Applying maintenance level server updates on Windows."
- To apply maintenance level client updates, see "Applying maintenance level client updates on Windows" on page 579.
- To remove updates and revert to the previous maintenance level using the Windows installer, see "Reverting to the previous maintenance level on Windows" on page 580.
- For information on how to use multiple installations of IBM MQ on the same server to control the release of maintenance fixes, see "Staging maintenance fixes on Windows" on page 583.
- For information on how to use use multi-instance queue managers to reduce the outage caused by applying maintenance updates, see "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577.

Related tasks:

"Querying the maintenance level" on page 572
Query the IBM MQ maintenance level by running the **`dspmqver`** command

Applying maintenance level server updates on Windows

Windows

You can apply maintenance level server updates to IBM MQ for Windows either interactively or silently.

Before you begin

1. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.
2. Download the maintenance package from the IBM MQ Support website.
3. If User Account Control (UAC) is enabled, the user who does the installation must have Administrative authority. You must elevate any command or command prompt by selecting **Run as Administrator**. If you do not, the error `AMQ4353` is written in the installation log.

Procedure

1. Log on as an Administrator.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:
      ```
      dspmq -o installation -o status
      dspmq -a
      ```
      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:
      ```
      echo DISPLAY LSSTATUS(*) STATUS | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.
      ```
                 ┌─-c─┐
      ►►─endmqm──┼─-w─┼─QmgrName──────────────────────────────────────────►◄
                 ├─-i─┤
                 └─-p─┘
      ```
      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.
   d. Stop any listeners associated with the queue managers, using the command:
      ```
      endmqlsr -m QMgrName
      ```
4. Stop the IBM MQ service for the installation.
   a. Right-click the **IBM MQ** icon in the taskbar > click **Stop IBM MQ**.
5. Load and apply the maintenance files for server installations:
   - Interactively:
     a. Open the folder where the maintenance package has been extracted.
     b. Right-click on the maintenance program and select **Run as administrator** to start the loading process.

c. Choose your installation language, and click **OK**.

d. Continue to follow the instructions on screen.

   If you choose to load the files without applying them to an installation, you can apply the files later, as described in step 6 on page 576

- Silently:

  a. Open the folder where the maintenance package has been extracted.

  b. Modify the response file, `silent_install.resp`. For details on the properties you can specify in the response file, see Table 76.

Table 76. Properties used to install or uninstall a maintenance update

Property	**Value**	**Description**
`MQPLOG`	*`path\file_name`*	Pass a valid path to specify the log to be used during installation/uninstallation, for example `MQPLOG="C:\TEMP\UPDATEINSTALL.LOG"` If `MQPLOG` is not specified (which is the case if you start maintenance by clicking the **Apply fix pack n.n.n.n** icon in the IBM MQ program group) the log name used by default will be `amqicsdn.txt` in your TEMP directory (`%TEMP%`).
`MQPINSTALLATIONNAME`	*`Installation name`*	The name of the installation to maintain. If there is only one installation (of any level) on the machine, this argument can be safely omitted. If there is more than one installation on the machine, `amqicsdn.exe` checks the value of `MQPINSTALLATIONNAME`. If one is not supplied, or the one that is supplied is unsuitable, then a GUI selection box appears. This selection box provides a list of installations to which this fix pack is applicable. If none is applicable, then `amqicsdn.exe` issues error message `AMQ4781` and ends.
`MQPBACKUPPATH`	*`path`*	Specifies the directory to back up into during installation, for example `MQPBACKUPPATH="C:\BACKUP"` The directory, and any intermediate directories, you specify must already exist. If any one of the directories does not already exist, the installation fails.
`MQPREBOOT`	`0|1`	Specifies what to do when a reboot is required, for example `MQPREBOOT=1`. If no value is supplied, you are prompted for what to do next. If `MQPREBOOT` is set to 0, a reboot is suppressed If `MQPREBOOT` is set to 1, the reboots go ahead without prompting.
`MQPINUSEOK`	`0|1`	Specifies whether to continue even if a file is found to be currently locked by another application. If you choose to continue even if a file is locked by another application, then you must reboot to complete fix pack installation. If no value is supplied, or if `MQPINUSEOK` is set to `0`, the installation fails if files are found to be in use by other applications. If `MQPINUSEOK` is set to `1`, the installation is deferred until you reboot.

  c. Open an elevated command prompt in the directory where the maintenance program was extracted.

   d. Start the silent loading by entering the following command:
      ```
      executableName -f responseFile
      ```
      where:
      - *executableName* is the name of the maintenance package. For example, for Version 9.0.0, Fix Pack 1: `9.0.0-IBM-MQ-Windows-FP0001.exe`.
      - *responseFile* is the full path and name of the response file.
6. Optional: Apply the maintenance to other server installations on the system:
   - Interactively:
     a. From the Windows start menu, select **Start > Programs > IBM MQ > Apply Fix Pack *V.R.M.L***.
        where
          V is the version number
          R is the release number
          M is the modification number
          L is the level of modification
     b. Continue to follow the instructions on screen.
   - Silently:
     a. Open an elevated command prompt and navigate to the directory where the maintenance program was loaded. By default, the path is `C:\Program Files (x86)\IBM\source\WebSphere MQ` *`V.R.M.L`*
        where
          V is the version number
          R is the release number
          M is the modification number
          L is the level of modification
     b. Enter the following command:
        ```
        amqicsdn MQPINSTALLATIONNAME= name MQPSILENT=1
        ```
        where *name* is the name of the installation that you want to apply maintenance to.
        You can add other properties to the command, as listed in Table 76 on page 575.
7. Optional: Uninstall the fix pack files from your machine. After installing the fix pack files and applying the maintenance to all the server installations that you want to update, you can either uninstall the fix pack files from your machine or leave them installed for future use.
   To uninstall the fix pack files use the **Control Panel... Programs and Features** panel, select the item **IBM MQ (fix pack 9.0.0.x) files**, and click **Uninstall**.
   - Uninstalling these files does NOT remove them from the installations to which you have already applied the maintenance. If that is what you intend, you should instead follow the instructions in "Reverting to the previous maintenance level on Windows" on page 580.
   - If you add any installable features at a later time, you must reapply the maintenance to update the added feature(s).

   Note: The fix pack files contain a JRE, so if you chose not to install a JRE in your IBM MQ installation for local policy reasons, you may want to uninstall the fix pack files as soon as you have finished applying the update to your installation(s).

What to do next

On a server installation, you must restart the IBM MQ taskbar application manually after the maintenance application completes.

The IBM MQ service is restarted automatically on the server, but the taskbar application is not restarted for any logged in sessions. Start the taskbar application in one of three ways:

1. Start the taskbar application manually from the start menu.
2. Log off and log back on again.
3. Run the command:
   ```
   MQ_INSTALLATION_PATH\bin\amqmtbrn.exe -Startup
   ```

Applying maintenance level updates to multi-instance queue managers on Windows

Applying maintenance level updates to multi-instance queue managers on Windows

Windows

On Windows platforms, you can use multi-instance queue managers to reduce the outage caused by applying maintenance updates.

Before you begin

Before starting this task, read through the prerequisites described in *Before you begin* in "Applying maintenance level server updates on Windows" on page 573

Before starting this task, see the Maintenance is applied to the IBM MQ installation on a server and not to individual queue managers. Before you apply maintenance, you must stop all the queue managers, and any IBM MQ service, on a server.

If you want a queue manager to keep running while maintenance is applied, you must configure it as a multi-instance queue manager, and have a standby instance running on another server. If the queue manager that you want to keep running is an existing single instance queue manager, you must convert it to a multi-instance queue manager. For prerequisites and guidance how to create a multi-instance queue manager, see Multi-instance queue managers.

You can create a multi-instance queue manager from Version 7.0.1 onwards. If you are running multi-instance queue managers, you then can apply a maintenance update to a running queue manager by switching the active instance to a different server.

Typically, active and standby installations are maintained at the same maintenance level. Consult the maintenance instructions for each update. Consult the instructions to see if it is possible to run the active and standby instances at different maintenance levels. Check whether fail over from higher to lower, or only lower to higher maintenance level is possible.

The instructions for applying a maintenance update might require you to stop a multi-instance queue manager completely.

If you have a primary server for running active queue manager instances, and a secondary server that runs standby instances, you have a choice of updating the primary or secondary server first. If you update the secondary server first, you must switch back to the primary server when both servers have been updated.

If you have active and standby instances on several servers, you must plan in what order you update the servers to minimize the disruption caused by ending the active instances on each server you update.

About this task

Follow these steps to apply maintenance to a multi-instance queue manager on Windows.

Procedure

1. Log on as an Administrator.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. Find out the current state of the queue managers and their associated listeners associated with the IBM MQ installation.
   a. From the installation that you are updating, use the **dspmq** command to list the state of the queue managers:
      - To display the installation name and status of queue managers associated with all installations of IBM MQ, run the following command:
        ```
        dspmq -o installation -o status
        ```
      - To display the status of active queue managers associated with the installation from which you are running the command, run the following command:
        ```
        dspmq -a
        ```
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:
      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
4. Use the **endmqm** command to stop each running queue manager associated with this installation.
   - If the queue manager is running as standby, run the **endmqm** command to end the standby as shown in the following example:
     ```
     endmqm -x QMgrName
     ```
   - If the queue manager is running as the active instance, run the **endmqm** command to end the active instance and transfer control to the standby instance as shown in the following example:
     ```
     endmqm -shutdown_option -s QMgrName
     ```

     where *-shutdown_option* is an optional parameter specifying the type of shutdown. For more information about optional parameters for the **endmqm** command, see endmqm.

     If there is no standby instance running, and the command fails, start a standby instance on a different server.
   - If a queue manager is running as a single instance queue manager, stop the queue manager. In the case of a single queue manager you have no alternative but to stop the queue manager before applying the maintenance update. For more information about how to stop a queue manager, see Stopping a queue manager.

   Stop any listeners associated with the queue managers by using the **endmqlsr** command as shown in the following example:
   ```
   endmqlsr -m QMgrName
   ```

   After you complete this step, no queue manager instances are left running on the server that you intend to update.
5. Apply maintenance to the IBM MQ server. Follow the instructions in “Applying maintenance level server updates on Windows” on page 573, starting from Step 4.

6. When you have completed the maintenance update, use the **strmqm** command to restart all the queue managers on the IBM MQ server, permitting standby instances, as shown in the following example:
   ```
   strmqm -x QmgrName
   ```
7. Repeat the procedure on the standby server, to update its maintenance level.
8. If necessary, switch the active instances back to the primary servers:
   a. Stop the instances by using the **endmqm** command as shown in the following example:
      ```
      endmqm -shutdown_option -s QMgrName
      ```
   b. Restart the instances by using the **strmqm** command as shown in the following example:
      ```
      strmqm -x QmgrName
      ```

Applying maintenance level client updates on Windows

Windows

You can apply maintenance level updates to IBM MQ for Windows clients either interactively or by performing a silent MSI update.

About this task

You can apply and remove maintenance from an IBM MQ client interactively or by using the **msiexec** command to perform a silent MSI update.

Interactive client update

On the client installation media, navigate to the `\Windows\MSI\` directory, then run the `Setup.exe` file.

Silent client update

As an alternative method for applying maintenance to IBM MQ client systems, you can use the command **msiexec** from the command line to perform a silent MSI update.

To update a computer with only a single installation, you can use a command similar to the following example:

```
msiexec /i "PATH\Windows\MSI\IBM MQ.msi" /l*v install_log_path
/q TRANSFORMS="1033.mst" REINSTALL=ALL REINSTALLMODE=vomus
```

For a multi installation computer with multiple clients, you can update a single client by using a command similar to the following example:

```
msiexec /i "PATH\Windows\MSI\IBM MQ.msi" /l*v install_log_path
/q TRANSFORMS=":InstanceId2.mst;1033.mst" REINSTALL=ALL REINSTALLMODE=vomus
```

Results

When the maintenance completes you can query the maintenance level by running the **dspmqver** command. For more details, see "Querying the maintenance level" on page 572.

Reverting to the previous maintenance level on Windows

Windows

You can remove updates and revert to the previous maintenance level of IBM MQ by using the Windows installer.

Before you begin

1. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.
2. If User Account Control (UAC) is enabled, the user who does the installation must have Administrative authority. You must elevate any command or command prompt by selecting **Run as Administrator**. If you do not, the error `AMQ4353` is written in the installation log.

About this task

If you applied maintenance to IBM MQ, you can restore IBM MQ to a previous level of maintenance.

If you installed IBM MQ at a particular maintenance level, a *Manufacturing Refresh*, you cannot restore IBM MQ to an earlier maintenance level.

Procedure

1. Log on as an Administrator.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo DISPLAY LSSTATUS(*) STATUS | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

      ```
                    ┌-c┐
      ►►─endmqm─────┼-w┼──QmgrName──────────────────────────────────►◄
                    ├-i┤
                    └-p┘
      ```

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

```
endmqlsr -m QMgrName
```

4. Stop the IBM MQ service for the installation.
   a. Right-click the **IBM MQ** icon in the taskbar > click **Stop IBM MQ**.
5. Remove the maintenance interactively, or silently using a command.
   - Interactively:
     a. For each installation of IBM MQ that has had maintenance applied, you are presented with one of the following icons in the Windows start menu:
        1) **Start > Programs > IBM MQ > Remove Refresh Pack *V.R.M.L* (*installation_name*)**
        2) **Start > Programs > IBM MQ > Remove Fix Pack *V.R.M.L* (*installation name*)**

        where

        V is the version number

        R is the release number

        M is the modification number

        L is the level of modification
     b. Select the installation you want to maintain and click **Remove** to start the process.

     This returns the installation to the state it was in before the maintenance package was applied.
   - Silently:
     a. Open an elevated command prompt and enter the following command:

        ```
        amqicsdn.exe MQPINSTALLATIONNAME= name MQPUNINST=1 MQPSILENT=1
        ```

        where *name* is the name of the installation that you want to remove maintenance from.

        You can add other properties to the command, as listed in Table 77.

Table 77. Properties used to install or uninstall a maintenance update

Property	**Value**	**Description**
MQPLOG	*path\file_name*	Pass a valid path to specify the log to be used during installation/uninstallation, for example MQPLOG="C:\TEMP\UPDATEINSTALL.LOG" If MQPLOG is not specified (which is the case if you start maintenance by clicking the **Apply fix pack n.n.n.n** icon in the IBM MQ program group) the log name used by default will be amqicsdn.txt in your TEMP directory (%TEMP%).

Table 77. Properties used to install or uninstall a maintenance update (continued)

Property	Value	Description
MQPINSTALLATIONNAME	*Installation name*	The name of the installation to maintain. If there is only one installation (of any level) on the machine, this argument can be safely omitted. If there is more than one installation on the machine, amqicsdn.exe checks the value of MQPINSTALLATIONNAME. If one is not supplied, or the one that is supplied is unsuitable, then a GUI selection box appears. This selection box provides a list of installations to which this fix pack is applicable. If none is applicable, then amqicsdn.exe issues error message AMQ4781 and ends.
MQPBACKUPPATH	*path*	Specifies the directory to back up into during installation, for example MQPBACKUPPATH="C:\BACKUP" The directory, and any intermediate directories, you specify must already exist. If any one of the directories does not already exist, the installation fails.
MQPREBOOT	0|1	Specifies what to do when a reboot is required, for example MQPREBOOT=1. If no value is supplied, you are prompted for what to do next. If MQPREBOOT is set to 0, a reboot is suppressed If MQPREBOOT is set to 1, the reboots go ahead without prompting.
MQPINUSEOK	0|1	Specifies whether to continue even if a file is found to be currently locked by another application. If you choose to continue even if a file is locked by another application, then you must reboot to complete fix pack installation. If no value is supplied, or if MQPINUSEOK is set to 0, the installation fails if files are found to be in use by other applications. If MQPINUSEOK is set to 1, the installation is deferred until you reboot.

6. Optional: If you no longer need the maintenance files that were loaded onto the system before maintenance was applied, you can remove them using **Add/Remove programs** or **Programs and Features** from the Control Panel. If you want to remove a maintenance file silently, run the following command:

```
patch_install_files\_IBM MQ (fix pack V.R.M.L files)_installation\Change IBM MQ
(fix pack V.R.M.L files) Installation.exe" -i silent
```

   where *patch_install_files* is the installation directory where maintenance files are installed.

   By default, this directory is C:\Program Files (x86)\IBM\source\WebSphere MQ *V.R.M.L*

   Notes:

   a. Run the command from outside the directory, otherwise the directory is not removed.
   b. If you omit **-i silent**, the command initiates the Graphical User Interface installer.

What to do next

On a server installation, you must restart the IBM MQ taskbar application manually after the maintenance application completes.

The IBM MQ service is restarted automatically on the server, but the taskbar application is not restarted for any logged in sessions. Start the taskbar application in one of three ways:

1. Start the taskbar application manually from the start menu.
2. Log off and log back on again.
3. Run the command:

```
MQ_INSTALLATION_PATH\bin\amqmtbrn.exe -Startup
```

Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Staging maintenance fixes on Windows

Windows

On Windows systems, you can use multiple installations of IBM MQ on the same server to control the release of maintenance fixes.

Before you begin

Set up your configuration modeled on the first row of Figure 59 on page 584. You can apply this scenario to any version of IBM MQ from IBM WebSphere MQ Version 7.1 onwards. In this scenario it is assumed you have a number of applications and two queue managers, `QM1` and `QM2`, running on a server. IBM WebSphere MQ Version 7.0.1 is not installed on the server.

1. Install two copies of IBM MQ. In the example, they are named `Inst_1` and `Inst_2`.
2. Make `Inst_1` primary by running **`setmqinst`**.
3. Associate all the queue managers on the server with `Inst_1` by running **`setmqm`**.
4. Start all the queue managers on the server.
5. Show and connect all direct connections with the queue managers associated with `Inst_1` in IBM MQ Explorer.
6. Set up remote connections to all the queue managers in each instance of IBM MQ Explorer.

About this task

You can install multiple copies of IBM MQ on a server to stage the release of IBM MQ fixes. Figure 59 on page 584 illustrates a way of using two installations to roll out fixes. In this approach, you maintain two fix levels on a server, with the aim of getting all queue managers and applications to the production fix level before replacing the previous level on fix pack with the next level.

Which installation an application uses is driven by the queue manager an application connects to. The **`setmqm`** command associates a queue manager with an installation. You can associate a queue manager with a different installation as long as the installation is at the same or higher command level. In this example, all the installations are at the same command level. You can associate or reassociate a queue manager with either of the installations running any of the fix packs.

In the example, an application links to the primary installation. When it connects to a queue manager, IBM MQ switches the linkage to the installation associated with the queue manager; see “Multi-installation queue manager coexistence on UNIX, Linux, and Windows” on page 668.

For applications built with the link options described in the product documentation, the simplest way to configure the link library search path for IBM MQ applications is to make an installation primary. Only if it is important to pick up a fix in the IBM MQ link library itself, must you review the search path. Either you must make the installation with the IBM MQ link library fix primary, or make a local adjustment for the application, perhaps by running the **setmqenv** command.

Running commands is a different matter. Commands are always run from the primary installation, or the installation you have selected by running the **setmqenv** command. If you run a command from the wrong installation, the command fails. For example, if `QM1` is associated with `Inst_1`, running the Windows command, `Inst_2_Installation_path/bin/strmqm QM1` fails.

If you are using IBM MQ Explorer and you have two installations, you also have two IBM MQ Explorer instances. One linked to one installation, and one to the other. Each IBM MQ Explorer shows locally connected queue managers that are associated with the same installation as the instance of IBM MQ Explorer. To monitor all the queue managers on a server, set up remote connections to the queue managers associated with the other installations.

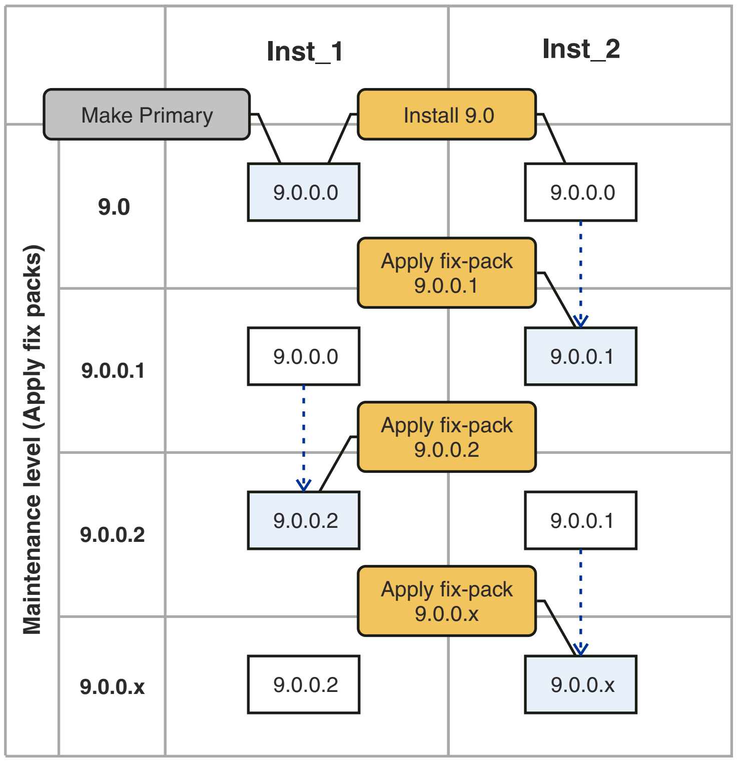

Figure 59. Rolling fix releases

Procedure

1. Download the first fix pack, for example, 7.1.0.1, when it is released.

   See Fix Central.
2. Apply the fix pack you downloaded to `Inst_2`. See "Applying and removing maintenance on Windows" on page 573.
3. Verify `Inst_2`.
4. Transfer the queue managers to `Inst_2` one at a time.
   a. Stop `QM1` and the applications connected to it.

The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

Note: The topic, "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577, describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

b. Set up the local environment to the installation `Inst_2`.

```
"Inst_2_INSTALLATION_PATH\bin\setmqenv" -s
```

The `-s` option sets up the environment for the installation that runs the **setmqenv** command.

c. Associate the queue manager with `Inst_2`.

```
setmqm -m QM1 -n Inst_2
```

d. Start `QM1`

```
strmqm QM1
```

e. Repeat substeps c and d for `QM2`.

f. Set up IBM MQ Explorer for `Inst_2`.

1) Start the `Inst_2` instance of IBM MQ Explorer

Tip: On Windows, hover over the IBM MQ icon in the system tray. The hover help shows the installation name associated with the IBM MQ Explorer instance.

2) Click **IBM MQ** > **Queue Managers** > **Show/Hide Queue Managers...** >

3) Click each directly connected queue manager listed in the Hidden Queue Managers list > **Show**.

4) Click **Close**.

5. Set `Inst_2` primary.

```
"Inst_2_INSTALLATION_PATH\bin\setmqinst" -i -n Inst_2
```

6. Download the next fix pack for the version of your product, for example, 7.1.0.2, when it is released.
   See Fix Central.
7. Apply the fix pack that you have just downloaded to `Inst_1`. See "Applying and removing maintenance on Windows" on page 573.
8. Verify `Inst_1`.
9. Transfer queue managers to `Inst_1` one at a time.
   a. Follow the procedure in step 4 on page 584
   Replacing `Inst_2` by `Inst_1` in the instructions.
10. Set `Inst_1` primary.

```
"Inst_1_INSTALLATION_PATH\bin\setmqinst" -i -n Inst_1
```

11. Repeat steps 1 on page 584 to 5 on page 585 for the odd-numbered fix packs of your product.
12. Repeat steps 6 on page 585 to 10 on page 585 for the even-numbered fix packs of your product.

Related concepts:

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

Related tasks:

"Migrating IBM MQ library loading from an earlier version of the product to the latest version" on page 684
No change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the latest version. You must have followed the instructions on building IBM MQ applications in the earlier version, and you must replace the earlier version with the latest version of the product. If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

Applying and removing maintenance on UNIX and Linux

UNIX Linux

Maintenance tasks associated with UNIX and Linux platforms are grouped in this section.

Related tasks:
"Querying the maintenance level" on page 572
Query the IBM MQ maintenance level by running the **dspmqver** command

Applying maintenance level updates on AIX

AIX

You apply maintenance level updates to IBM MQ for AIX by using **installp**.

Before you begin

1. Ensure that you have enough disk space to apply maintenance level updates. A maintenance level update requires hard disk space for installation. In addition, the installation process might require a similar amount of disk space to save the previous level. For example, a 16 MB update might require 32 MB of space. The additional space allows a maintenance level update to be removed, and the previous level to be restored automatically.
2. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

Stop applications using the installation and use the **installp** command, to install maintenance level updates to clients and servers. Alternatively, if the installation is in the default installation location, you can use the *System Management Interface Tool*, SMIT.

Important: You cannot go back from a later version of the product to a prior version of the product, for example from IBM MQ Version 8.0 to IBM WebSphere MQ Version 7.x.

You can apply and remove maintenance from a IBM MQ MQI client that is not installed on the same server as a queue manager. You do not have to stop any queue managers or logon as administrator. Because you do not have to stop any queue managers, do not do steps 1 to 3 in the following maintenance procedure.

Major full versions of the base product are COMMITTED by default. Fix packs on a full base version can be in APPLIED state, and you can go back one release level.

If you need the ability to revert to an earlier version, you should perform a side-by-side migration, and migrate your queue managers to the later version at any time. See "Migrating on UNIX and Linux: side-by side" on page 727 for further information.

However, if you start a queue manager under IBM MQ Version 8.0, that queue manager is automatically migrated, and cannot be downgraded to the previous version.

You require a backup of the IBM WebSphere MQ Version 7.x queue manager and data logs to restore if needed.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

Run either of the following commands from the installation that you are updating:

```
dspmq -o installation -o status
dspmq -a
```

dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

dspmq -a displays the status of active queue managers associated with the installation from which the command is run.

b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

```
echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
```

c. Run the **endmqm** command to stop each running queue manager associated with this installation.

```
           ┌─-c─┐
►►─endmqm──┼─-w─┼─QmgrName──────────────────────────────────────────────►◄
           ├─-i─┤
           └─-p─┘
```

The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

```
endmqlsr -m QMgrName
```

4. Log in as root, or switch to the superuser using the **su** command.
5. Install the update in one of the following ways:
   - Update the whole installation in the default location:
     ```
     installp -agXYd . all
     ```
   - Update selected filesets in the default location:
     ```
     installp -agXYd . list of file sets
     ```
   - Update the whole product in a non-default location using the -R flag:
     ```
     installp -R USIL_Directory -agXYd . all
     ```
   - Update selected filesets in a non-default location using the -R flag:
     ```
     installp -R USIL_Directory -agXYd . list of file sets
     ```

   USIL_Directory is the installation parent directory. IBM MQ is installed underneath the directory. For example, if /USIL1 is specified, the IBM MQ product files are located in /USIL1/usr/mqm. /USIL1/usr/mqm is known as the *MQ_INSTALLATION_PATH*.

dspmq

Stopping a queue manager

Reverting to the previous maintenance level on AIX

AIX

You can revert to a previous maintenance level by using the *System Management Interface Tool* (SMIT).

Before you begin

1. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

You can back out maintenance updates (fix packs) and restore your system to the previous maintenance or installation level, for any component of IBM MQ for AIX that is in the **APPLIED** state.

You can apply and remove maintenance from a IBM MQ MQI client that is not installed on the same server as a queue manager. You do not have to stop any queue managers or logon as administrator. Because you do not have to stop any queue managers, do not do steps 1 to 3 in the following maintenance procedure.

Use the following command to display the current state of the IBM MQ for AIX filesets:

```
lslpp [ -R usil ] -l "mqm*"
```

To back out a maintenance update, as the user root, issue the command:

```
installp [ -R usil ] -r "mqm*"
```

Otherwise:

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **`dspmq`** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      `dspmq -o installation -o status` displays the installation name and status of queue managers associated with all installations of IBM MQ.

      `dspmq -a` displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **`DISPLAY LSSTATUS`** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **`endmqm`** command to stop each running queue manager associated with this installation.

```
            ┌─-c─┐
►►──endmqm──┼─-w─┼──QmgrName──────────────────────────────────────────►◄
            ├─-i─┤
            └─-p─┘
```

The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

```
endmqlsr -m QMgrName
```

4. Log in as root, or switch to the superuser using the **su** command.
5. Open the appropriate **smit** panel using this sequence:

```
Software Installation and Maintenance
Software Maintenance and Utilities
Reject Applied Software Updates (Use Previous Version)
```

   Alternatively, use a fast path command, `smit[ty] install_update`.
6. Complete the **SOFTWARE** name field.

   Enter `mqm*` to restore all applicable file set updates to your installation.

   Note: If an option to restore only selected file set updates for IBM MQ for AIX appears, avoid it. The option results in all applicable file set updates for the maintenance update being restored.
7. Click **Enter** to reject the current maintenance level and reinstate the previous maintenance or installation level.

   a. Accept displayed default values for all other fields

   b. Dismiss the confirmation message

   The reject process starts. While the command runs, it displays progress messages terminating with an **Install Summary** table.

   a. Check the table to see which components of IBM MQ for AIX have been rejected

endmqlsr (end listener)
Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Applying maintenance level updates on HP-UX

HP-UX

You can apply maintenance level updates to IBM MQ for HP-UX by using **`swinstall`**.

Before you begin

1. Ensure that you have enough disk space to apply maintenance level updates. A maintenance level update requires hard disk space for installation. In addition, the installation process might require a similar amount of disk space to save the previous level. For example, a 16 MB update might require 32 MB of space. The additional space allows a maintenance level update to be removed, and the previous level to be restored automatically.
2. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

You can apply and remove maintenance from a IBM MQ MQI client that is not installed on the same server as a queue manager. You do not have to stop any queue managers or logon as administrator. Because you do not have to stop any queue managers, do not do steps 1 to 3 in the following maintenance procedure.

About this task

1. If you want to install both the base package and the maintenance update packages, install the base package separately first. Then install the maintenance update packages.
2. Turn off the autoselect dependencies feature:
   - If you are using the interactive installer, click **Options> Change Options**. Then clear the **autoselect dependencies when marking software** check box before selecting the maintenance update package for installation.
   - If you are using the command line, type the following command:
     ```
     swinstall -x autoselect_dependencies=false
     ```

   If you are installing a fix pack from a depot that also contains the base installation image, turn off the autoselect dependencies feature before starting the installation, otherwise the attempt will fail with an error message as shown in the following example:
   ```
   Could not apply the software selection "MQSERIES,r=9.0.0.2,a=HP-UX_B.11_IA,v=IBM" because a different variant of a  d
           for this product has already been selected
   ```
3. Error messages might be seen when running **`swinstall`**, even when successfully updating an installation.

   There are two approaches you can take to handling errors in the application of maintenance.
   a. Aim for an error-free update by applying maintenance only to those components that are installed.
   b. Apply the whole maintenance package and check the error logs, error by error, ignoring the insignificant errors.

   Both approaches are described.

Many of the insignificant errors are caused by **swinstall** trying to apply updates to components that are not installed. Consider whether there are any significant errors reported with the insignificant ones.

- The following errors might not indicate a serious problem. They are written to the console, or to the **swinstall** panel.

  ```
  ERROR:  "hpux11.mycompany.com:/":
  The software dependencies for 15 products or filesets cannot be resolved.
  ```

  ```
  ERROR:  "hpux11.mycompany.com:/":
  17 filesets were determined to be skipped in the analysis phase.
  The execution phase failed for "hpux11.mycompany.com:/".
  Analysis and Execution had errors.
  ```

- The following errors might not indicate a serious problem. They are written to the `swjob` output for a **swinstall** session.

  ```
  ERROR:   17 of 20 filesets had Errors.
  3 of 20 filesets had no Errors or Warnings.
  ```

  ```
  ERROR:   The Execution Phase had errors.
  See the above output for details.
  ```

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

      ```
                 ┌-c┐
      ▶▶─endmqm──┼-w┼─QmgrName──────────────────────────────────────────▶◀
                 ├-i┤
                 └-p┘
      ```

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

```
endmqlsr -m QMgrName
```

4. Log in as root, or switch to the superuser using the **su** command.
5. Make your current directory the location of the *Service_update_package*.

   The file name of the *Service_update_package* follows the pattern `hp-Uxxxx.v11`. You must prefix *Service_update_package* with the absolute path to the installation file. To save typing, construct the path using the `$PWD` variable.
6. Run the HP-UX command **swlist** `l= MQ_INSTALLATION_PATH MQSERIES` to list all of the IBM MQ components that are installed.
7. Decide whether to install the updates interactively, and if you want to control which components are updated.

   You can update in the following ways:
   - Silently update all the installed IBM MQ components by installing the whole maintenance package.

     ```
     swinstall -s $PWD/service_update_package
     MQSERIES,l= MQ_INSTALLATION_PATH
     ```

     The **swinstall** command attempts to find an installed component for every component in the update package, and updates it. **swinstall** writes out error messages for components that it cannot find.
   - Silently update some IBM MQ components by installing only the required updates from the maintenance package.

     If you specify *update_components* correctly, the update procedure can be error-free. **swinstall** only updates components that you have listed and components that are dependent on components you have listed.

     a. Using the list of installed IBM MQ components, create a space separated list of the components you want to update (*update_components*). This list requires the installation path of each component to be specified, in the form: *component* `,l= MQ_INSTALLATION_PATH`

     b. ```
        swinstall -s $PWD/service_update_package
        update_components
        ```
   - Interactively update some IBM MQ components from the maintenance package, selecting only the update components that are required.

     ```
     swinstall -s $PWD/service_update_package
     ```

     a. Open **MQSERIES** and mark the update components you want to apply. Correctly marked, there are no errors when the updates are applied. The installer resolves dependencies automatically.

     b. Select **Actions > Change Product Location** to change the IBM MQ installation you intend to update.

     c. Select **Actions > Install**. The log file tells you if there are any problems that need fixing.
     ```

Stopping a queue manager
DISPLAY LSSTATUS
endmqm (end queue manager)
endmqlsr (end listener)
Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Reverting to the previous maintenance level on HP-UX

HP-UX

You revert to a previous maintenance level of IBM MQ by using **swremove**.

Before you begin

1. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

You can apply and remove maintenance from a IBM MQ MQI client that is not installed on the same server as a queue manager. You do not have to stop any queue managers or logon as administrator. Because you do not have to stop any queue managers, do not do steps 1 to 3 in the following maintenance procedure.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:
      ```
      dspmq -o installation -o status
      dspmq -a
      ```
      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:
      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

```
              ┌─-c─┐
►►──endmqm────┼─-w─┼──QmgrName──────────────────────────────────────────────────►◄
              ├─-i─┤
              └─-p─┘
```

The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

   ```
   endmqlsr -m QMgrName
   ```

4. Log in as root, or switch to the superuser using the **su** command.
5. Run the `swremove` command to remove the maintenance package from the system.

   For example, to remove the 7.R.0.1 maintenance level, use the command:

   ```
   swremove MQSERIES,r=7.R.0.1,l= MQ_INSTALLATION_PATH
   ```

   where:

   - `R` is the number of the Release
   - *MQ_INSTALLATION_PATH* is the installation path for IBM MQ

   Details of the **swremove** command can be found in the *HP-UX Administration Guide* or by using the **man swremove** command.

DISPLAY LSSTATUS
endmqm (end queue manager)
endmqlsr (end listener)
Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Applying maintenance level updates on Linux

Linux

You can apply maintenance level updates to IBM MQ on Linux by using RPM. The same procedure applies to all Linux platforms, including Ubuntu.

Before you begin

If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

Maintenance level updates are delivered in the form of Red Hat Package Manager (RPM) update images, which are applied using the RPM installation tool.

You can apply and remove maintenance from a IBM MQ MQI client that is not installed on the same server as a queue manager. You do not have to stop any queue managers or logon as administrator. Because you do not have to stop any queue managers, do not do steps 1 to 3 in the following maintenance procedure.

Important: **`pax`** and **`rpmbuild`** are not supplied as part of the product. You must obtain these from your Linux distribution supplier.

Additional disk space is required for the update images to allow maintenance level updates to be removed and the previous level restored. The updated files are kept in *`MQ_INSTALLATION_PATH`*`/maintenance` directory. Do not delete or move this directory or the files it contains.

`MQ_INSTALLATION_PATH` represents the high-level directory in which IBM MQ is installed.

Updates are cumulative. You can apply your chosen update directly, without applying any previous updates first. The maintenance level updates might contain updates for one or more packages. You must apply those parts of an update that correspond to the packages that are applied in your installation.

Important: Although it is possible to install a fix pack at the same level as an installation performed from a manufacturing refresh image at that level, you should not attempt this process. Installing a fix pack at the same level as the one already on your system, can leave the package management database of your system in an inconsistent state with respect to the installation of IBM MQ.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.

3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:
      ```
      dspmq -o installation -o status
      dspmq -a
      ```
      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:
      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.
      ```
                 ┌-c─┐
      ►►─endmqm──┼-w─┼─QmgrName──────────────────────────────────────────►◄
                 ├-i─┤
                 └-p─┘
      ```
      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.
   d. Stop any listeners associated with the queue managers, using the command:
      ```
      endmqlsr -m QMgrName
      ```
4. Log in as root, or switch to the superuser using the **su** command.
5. Change into the directory containing the maintenance packages.
6. Run the `ls` command to list the available updates.

   For example, if there are level 1 maintenance updates for the Runtime, SDK and Server packages, you see the following:
   ```
   MQSeriesRuntime-Uxxxx-V.R.0-1.i386.rpm
   MQSeriesSDK-Uxxxx-V.R.0-1.i386.rpm
   MQSeriesServer-Uxxxx-V.R.0-1.i386.rpm
   ```
   where `V` is the version number and `R` is the number of the Release.
7. Run the **rpm** command to find out which packages are installed on your server.

   Enter the following command:
   ```
   rpm -qa | grep MQSeries
   ```

Note: If you are using Ubuntu, add the **--force-debian** attribute.

```
rpm --force-debian -qa | grep MQSeries
```

For example, if you have a minimum IBM MQ installation and SDK component, at level 0, the **rpm** command returns:

```
MQSeriesRuntime-V.R.0-0
MQSeriesSDK-V.R.0-0
MQSeriesServer-V.R.0-0
```

where `V` is the version number and `R` is the number of the Release.

8. If this fix pack is to be upgraded on an installation, other than the first installation on the system, run the **crtmqfp** command to create and use a unique set of packages to install on the system. Note, that if this is the first, or only, IBM MQ installation on the system, you can ignore this step. You must install the **pax** command in order for the **crtmqfp** command to run on Linux.
   a. Run the command `./crtmqfp` *suffixname* where *suffixname* is the same as the suffix used during renaming of the base level IBM MQ installation.
   b. Set your current directory to the location specified when the **crtmqfp** command completes. This directory is a subdirectory of `/var/tmp/mq_rpms`, in which the unique set of packages is created. The packages have the suffix value contained within the filename.

      For example, if you used suffix 1 during repackaging of the base level IBM MQ installation, enter the command: `./crtmqfp 1`.

      There is now a subdirectory named `/var/tmp/mq_rpms/1/xxxx`, and the packages will be renamed, for example, from `MQSeriesRuntime-V.R.0-1.xxxx.rpm` to `MQSeriesRuntime_1-V.R.0-1.xxxx.rpm`. Where `V` is the version number and `R` is the number of the Release.
9. Run the **rpm** command to apply all available updates for the packages you have on your system:
   - To update an installation in the default location, `/opt/mqm`:

     ```
     rpm -ivh MQSeriesRuntime-Uxxxx-V.R.0-1.i386.rpm
       MQSeriesSDK-Uxxxx-V.R.0-1.i386.rpm
       MQSeriesServer-Uxxxx-V.R.0-1.i386.rpm
     ```

     where `V` is the version number and `R` is the number of the Release.
   - To update an installation in a custom location, specify the **rpm** `prefix` option:

     ```
     rpm --prefix /opt/customLocation -ivh MQSeriesRuntime-Uxxxx-V.R.0-1.i386.rpm
       MQSeriesSDK-Uxxxx-V.R.0-1.i386.rpm
       MQSeriesServer-Uxxxx-V.R.0-1.i386.rpm
     ```

     where `V` is the version number and `R` is the number of the Release.

   You must apply all packages in a maintenance update that correspond to those packages that are currently installed on your system.
10. Repeat step 7 on page 597 to list the packages that are now available.

    The Runtime, SDK, and Server packages are now at level 1:

    ```
    MQSeriesRuntime-V.R.0-0
    MQSeriesSDK-V.R.0-0
    MQSeriesServer-V.R.0-0
    MQSeriesRuntime-Uxxxx-V.R.0-1
    MQSeriesSDK-Uxxxx-V.R.0-1
    MQSeriesServer-Uxxxx-V.R.0-1
    ```

    where `V` is the version number and `R` is the number of the Release.

    Note:

After the installation of IBM MQ fix packs, if you run the `rpm-verify` or `rpm -V` command, it does not return the correct results. It produces spurious results relating to missing files in *MQ_INSTALLATION_PATH*/maintenance.

This error message can be ignored because it is a known limitation in the IBM MQ fix pack installation code. For further information about this error, see IBM MQ Fix Pack installation errors - Linux reports errors

What to do next

For further information about using RPM to install software packages, see your Linux documentation.

Stopping a queue manager

DISPLAY LSSTATUS

endmqm (end queue manager)

endmqlsr (end listener)

Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Reverting to the previous maintenance level on Linux

Linux

You can remove updates and revert to the previous maintenance level of IBM MQ by using **RPM**. The same procedure applies to all Linux platforms, including Ubuntu.

Before you begin

If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

When maintenance is applied, the original versions of replaced files are saved to allow the updates to be removed if necessary. To restore the previous maintenance level, run an Red Hat Package Manager, RPM, uninstall command for all the packages that were updated by the maintenance package as follows:

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.

b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

```
echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
```

c. Run the **endmqm** command to stop each running queue manager associated with this installation.

```
               ┌─-c─┐
►►──endmqm─────┼─-w─┼──QmgrName──────────────────────────────────────────────────►◄
               ├─-i─┤
               └─-p─┘
```

The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

```
endmqlsr -m QMgrName
```

4. Log in as root, or switch to the superuser using the **su** command.
5. Run the **rpm** command to find out which packages are installed on your server.

   Enter the following command:

```
rpm -qa | grep MQSeries
```

Note: If you are using Ubuntu, add the **--force-debian** attribute.

```
rpm --force-debian -qa | grep MQSeries
```

Using the example given in "Applying maintenance level updates on Linux" on page 596, returns:

```
MQSeriesRuntime-V.R.0-0
MQSeriesSDK-V.R.0-0
MQSeriesServer-V.R.0-0
MQSeriesRuntime-Uxxxx-V.R.0-1
MQSeriesSDK-Uxxxx-V.R.0-1
MQSeriesServer-Uxxxx-V.R.0-1
```

where V is the version number and R is the number of the Release.

6. Run the **rpm** command to remove all the updates applied at level 1.

   Enter the following commands:

```
rpm -ev MQSeriesRuntime-Uxxxx-V.R.0-1 MQSeriesSDK-Uxxxx-V.R.0-1
MQSeriesServer-Uxxxx-V.R.0-1
```

where V is the version number and R is the number of the Release.

7. Repeat step 5 to check that the ptf packages have been removed, leaving only the original installation packages:

   ```
   MQSeriesRuntime-V.R.0-0
   MQSeriesSDK-V.R.0-0
   MQSeriesServer-V.R.0-0
   ```

   where `V` is the version number and `R` is the number of the Release.

What to do next

For further information on using RPM to install software packages, see your Linux documentation.

endmqm (end queue manager)
endmqlsr (end listener)
Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Applying maintenance level updates on IBM MQ on Solaris

Solaris

You can apply maintenance level updates to IBM MQ for Solaris using **`pkgadd`**.

Before you begin

1. Ensure that you have enough disk space to apply maintenance level updates. A maintenance level update requires hard disk space for installation. In addition, the installation process might require a similar amount of disk space to save the previous level. For example, a 16 MB update might require 32 MB of space. The additional space allows a maintenance level update to be removed, and the previous level to be restored automatically.
2. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

You can apply and remove maintenance from a IBM MQ MQI client that is not installed on the same server as a queue manager. You do not have to stop any queue managers or logon as administrator. Because you do not have to stop any queue managers, do not do steps 1 to 3 in the following maintenance procedure.

About this task

Stop applications using the installation and use **`pkgadd`** to install maintenance.

Important: Although it is possible to install a fix pack at the same level as an installation performed from a manufacturing refresh image at that level, you should not attempt this process. Installing a fix pack at the same level as the one already on your system, can leave the package management database of your system in an inconsistent state with respect to the installation of IBM MQ.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.

3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

      ```
                   ┌─-c─┐
      ►►──endmqm───┼─-w─┼──QmgrName──────────────────────────────────────►◄
                   ├─-i─┤
                   └─-p─┘
      ```

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.
   d. Stop any listeners associated with the queue managers, using the command:

      ```
      endmqlsr -m QMgrName
      ```
4. Log in as root, or switch to the superuser using the **su** command.
5. Change into the directory containing the maintenance packages.
6. Run the **crtmqfp** command to create and use a unique set of packages to install on the system, if this fix pack is to be upgraded on a installation that is not the first installation on the system. This command creates and uses a unique set of packages to install on the system.
   a. Run the command **crtmqfp** mqm- *suffixname* where *suffixname* is the same as the suffix used during renaming of the base level IBM MQ installation. Note that this command creates a full copy of the installation packages in a subdirectory of `/var/tmp`.
   b. Set your current directory to the location specified when the **crtmqfp** command completes. This directory is a subdirectory of `/var/spool`, in which the unique set of packages is created. The packages have the suffix value contained within the filename.
7. Proceed with installation using the following command: Enter the following command to start the installation process if this fix pack is to be upgraded on an installation that is

a. The first installation on the system:

   ```
   pkgadd -d packagename
   ```

   where `packagename` corresponds to the image file name. For example:

   ```
   mqm-U1234.img
   ```
b. Not the first installation on the system:

   ```
   pkgadd mqm-suffixname
   ```

   where `suffixname` is the name of the directory created in `/var/spool/pkg`.

   For example, if you install IBM WebSphere MQ Version 7.0 as a package called `mqm-main7` and create a package to upgrade to IBM WebSphere MQ Version 7.0.0.1, using the command **crtmqfp** `mqm-main7`, package *mqm-main7-07-00-00-01* is created in `/var/spool/pkg`.

   To install package *mqm-main7-07-00-00-01*, issue the command **pkgadd** `mqm-main7-07-00-00-01`.

For further information about using **pkgadd** to install software packages, see the Solaris documentation.

8. Follow the on-screen instructions.

endmqlsr (end listener)

Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Applying maintenance level updates in non-interactive mode on Solaris

You can install IBM MQ for Solaris non-interactively by creating a response file and an admin file.

Before you begin

1. Ensure that you have enough disk space to apply maintenance level updates. A maintenance level update requires hard disk space for installation. In addition, the installation process might require a similar amount of disk space to save the previous level. For example, a 16 MB update might require 32 MB of space. The additional space allows a maintenance level update to be removed, and the previous level to be restored automatically.
2. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

You can apply and remove maintenance from a IBM MQ MQI client that is not installed on the same server as a queue manager. You do not have to stop any queue managers or logon as administrator. Because you do not have to stop any queue managers, do not do steps 1 to 3 in the following maintenance procedure.

About this task

Stop applications using the installation and use **pkgadd** to install maintenance.

Important: Although it is possible to install a fix pack at the same level as an installation performed from a manufacturing refresh image at that level, you should not attempt this process. Installing a fix pack at the same level as the one already on your system, can leave the package management database of your system in an inconsistent state with respect to the installation of IBM MQ.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

      ```
                 ┌-c┐
      ►►─endmqm──┼-w┼──QmgrName─────────────────────────────────────────►◄
                 ├-i┤
                 └-p┘
      ```

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.
   d. Stop any listeners associated with the queue managers, using the command:

      ```
      endmqlsr -m QMgrName
      ```
4. Log in as root, or switch to the superuser using the **su** command.
5. Change into the directory containing the maintenance packages.
6. Run the **crtmqfp** command to create and use a unique set of packages to install on the system, if this fix pack is to be upgraded on a installation that is not the first installation on the system. This command creates and uses a unique set of packages to install on the system.

   a. Run the command **crtmqfp** mqm- *suffixname* where *suffixname* is the same as the suffix used during renaming of the base level IBM MQ installation. Note that this command creates a full copy of the installation packages in a subdirectory of `/var/tmp`.
   b. Set your current directory to the location specified when the **crtmqfp** command completes. This directory is a subdirectory of `/var/spool`, in which the unique set of packages is created. The packages have the suffix value contained within the filename.
7. Create the non-interactive installation response file using the **pkgask** command. Enter the following command to create the response file if this fix pack is to be upgraded on an installation that is:
   a. The first installation on the system:
      ```
      pkgask -d location_to_image/imagefile -r response.txt packagename
      ```
      where *imagefile* corresponds to the image file name, for example `mqm-U200403.img`, `response.txt` is the name of the response file to create, and *packagename* is the fix pack package name, for example `mqm-07-05-00-02`.
   b. Not the first installation on the system:
      ```
      pkgask -d /var/spool/pkg -r response.txt mqm-suffixname
      ```
      where `/var/spool/pkg` is the location of the new package, `response.txt` is the name of the response file to create, and *suffixname* is the name of the directory created in `/var/spool/pkg`.
8. Find the `admin_file` from the server installation media located at *install_media*/silent/admin or create an `admin_file` in the following format:
   ```
   mail=
   instance=unique
   partial=ask
   runlevel=ask
   idepend=ask
   rdepend=ask
   space=ask
   setuid=nocheck
   conflict=nocheck
   action=nocheck
   basedir=default
   ```
9. Run the **pkgadd** command to apply the maintenance level update IBM MQ for Solaris in non-interactive mode. Enter the following command to start the installation process if this fix pack is to be upgraded on an installation that is:
   a. The first installation on the system:
      ```
      pkgadd -v -n -r response.txt -a admin_file -d location_to_image/imagefile packagename
      ```
      where *admin_file* is a path qualified name of the admin file you created, and *packagename* corresponds to the fix pack package being installed.
   b. Not the first installation on the system:
      ```
      pkgadd -v -n -r response.txt -a admin_file -d /var/spool/pkg mqm-suffixname
      ```
10. Follow the on-screen instructions.

Stopping a queue manager
DISPLAY LSSTATUS
endmqm (end queue manager)
endmqlsr (end listener)
Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Reverting to the previous maintenance level on Solaris

Solaris

You can revert to a previous maintenance level of IBM MQ by stopping IBM MQ and using **pkgrm**.

Before you begin

If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

When maintenance is applied, the original versions of replaced files are saved to allow the updates to be removed if necessary. To restore the previous maintenance level, run **pkgrm** command for all the packages that were updated by the maintenance package as follows:

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:
      ```
      dspmq -o installation -o status
      dspmq -a
      ```
      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:
      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

```
            ┌─-c─┐
►►──endmqm──┼─-w─┼──QmgrName──────────────────────────────────────────►◄
            ├─-i─┤
            └─-p─┘
```

The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

```
endmqlsr -m QMgrName
```

4. Log in as root, or switch to the superuser using the **su** command.
5. Run the **pkgrm** command to remove the latest maintenance update from the system:

```
pkgrm packagename
```

packagename is the name of the package that you want to remove; for example, `mqm-07-R-00-01`, where `R` is the number of the Release.

Details of the **pkgrm** command can be found in the Solaris documentation, or by using the **man pkgrm** command.

If you do not know the name of the package to remove, try listing the packages that are installed using the following command: `pkginfo | grep mqm`

Note: Ignore any error messages of the form `shared pathname not removed`.

What to do next

If you have installed an IBM MQ MQI client, and the client was updated after installing the maintenance level that is being removed, you must specifically update your IBM MQ MQI client installation again, after the maintenance level has been removed

endmqlsr (end listener)
Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Staging maintenance fixes on UNIX and Linux

UNIX Linux

On UNIX and Linux, you can use multiple installations of IBM MQ on the same server to control the release of maintenance fixes.

Before you begin

Set up your configuration modeled on the first row of Figure 60 on page 609. You can apply this scenario to any version of IBM MQ from IBM WebSphere MQ Version 7.1 onwards. In this scenario it is assumed you have a number of applications and two queue managers, `QM1` and `QM2`, running on a server. IBM WebSphere MQ Version 7.0.1 is not installed on the server.

1. Install two copies of IBM MQ. In the example, they are named `Inst_1` and `Inst_2` and IBM WebSphere MQ Version 7.1 is being used.
2. Make `Inst_1` primary by running **`setmqinst`**.
3. Associate all the queue managers on the server with `Inst_1` by running **`setmqm`**.
4. Start all the queue managers on the server.
5. Show and connect all direct connections with the queue managers associated with `Inst_1` in IBM MQ Explorer.
6. Set up remote connections to all the queue managers in each instance of IBM MQ Explorer.

About this task

You can install multiple copies of IBM MQ on a server to stage the release of IBM MQ fixes. Figure 60 on page 609 illustrates a way of using two installations to roll out fixes. In this approach, you maintain two fix levels on a server, with the aim of getting all queue managers and applications to the production fix level before replacing the previous level on fix pack with the next level.

Which installation an application uses is driven by the queue manager an application connects to. The **`setmqm`** command associates a queue manager with an installation. You can associate a queue manager with a different installation as long as the installation is at the same or higher command level. In this example, all the installations are at the same command level. You can associate or reassociate a queue manager with either of the installations running any of the fix packs.

In the example, an application links to the primary installation. When it connects to a queue manager, IBM MQ switches the linkage to the installation associated with the queue manager; see "Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668.

For applications built with the link options described in the product documentation, the simplest way to configure the link library search path for IBM MQ applications is to make an installation primary. Only if it is important to pick up a fix in the IBM MQ link library itself, must you review the search path. Either you must make the installation with the IBM MQ link library fix primary, or make a local adjustment for the application, perhaps by running the **`setmqenv`** command.

Running commands is a different matter. Commands are always run from the primary installation, or the installation you have selected by running the **setmqenv** command. If you run a command from the wrong installation, the command fails. For example, if QM1 is associated with Inst_1, running the Windows command, Inst_2_Installation_path/bin/strmqm QM1 fails.

If you are using IBM MQ Explorer and you have two installations, you also have two IBM MQ Explorer instances. One linked to one installation, and one to the other. Each IBM MQ Explorer shows locally connected queue managers that are associated with the same installation as the instance of IBM MQ Explorer. To monitor all the queue managers on a server, set up remote connections to the queue managers associated with the other installations.

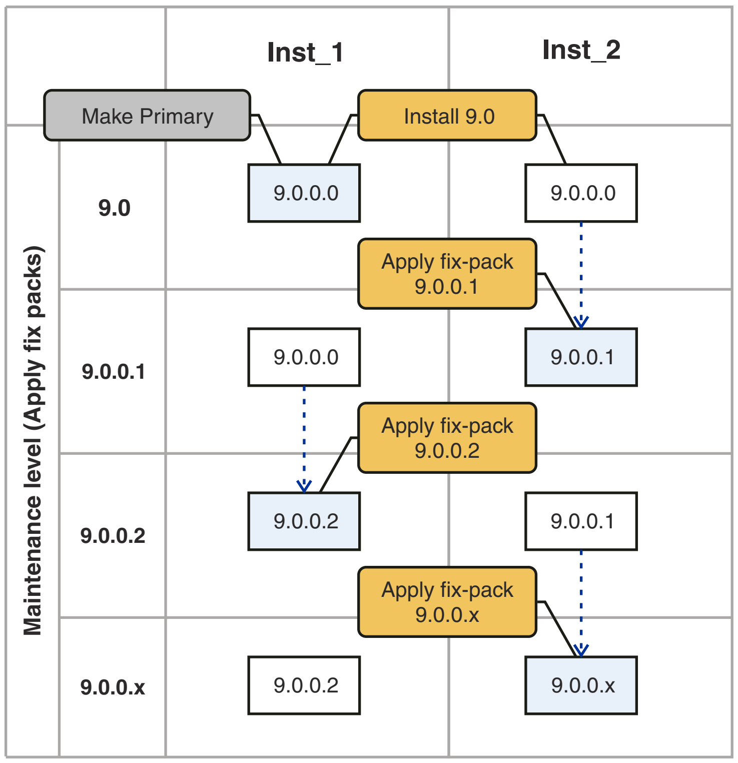

Figure 60. Rolling fix releases

Procedure

1. Download the first fix pack, for example, 7.1.0.1, when it is released.

   See Fix Central.
2. Apply the fix pack you downloaded to Inst_2. See "Applying and removing maintenance on UNIX and Linux" on page 586.
3. Verify Inst_2.
4. Transfer the queue managers to Inst_2 one at a time.
   a. Stop QM1 and the applications connected to it.

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      Note: The topic, "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577, describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

b. Set up the local environment to the installation `Inst_2`.

```
. Inst_2_INSTALLATION_PATH/bin/setmqenv -s
```

c. Associate the queue manager with `Inst_2`.

```
setmqm -m QM1 -n Inst_2
```

d. Start `QM1`

```
strmqm QM1
```

e. Repeat substeps c and d for `QM2`.

f. Set up IBM MQ Explorer for `Inst_2`.

1) Start the `Inst_2` instance of IBM MQ Explorer

Tip: On Windows, hover over the IBM MQ icon in the system tray. The hover help shows the installation name associated with the IBM MQ Explorer instance.

2) Click **IBM MQ** > **Queue Managers** > **Show/Hide Queue Managers...** >

3) Click each directly connected queue manager listed in the Hidden Queue Managers list > **Show**.

4) Click **Close**.

5. Set `Inst_2` primary.

```
Inst_2_INSTALLATION_PATH/bin/setmqinst -i -n Inst_2
```

6. Download the next fix pack for the version of your product, for example, 7.1.0.2, when it is released.

   See Fix Central.
7. Apply the fix pack that you have just downloaded to `Inst_1`. See “Applying and removing maintenance on UNIX and Linux” on page 586.
8. Verify `Inst_1`.
9. Transfer queue managers to `Inst_1` one at a time.

   a. Follow the procedure in step 4 on page 609

      Replacing `Inst_2` by `Inst_1` in the instructions.
10. Set `Inst_1` primary.

```
Inst_1_INSTALLATION_PATH/bin/setmqinst -i -n Inst_1
```

11. Repeat steps 1 on page 609 to 5 for the odd-numbered fix packs of your product.
12. Repeat steps 6 to 10 for the even-numbered fix packs of your product.

Related concepts:

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

Related tasks:

"Migrating IBM MQ library loading from an earlier version of the product to the latest version" on page 684
No change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the latest version. You must have followed the instructions on building IBM MQ applications in the earlier version, and you must replace the earlier version with the latest version of the product. If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

Applying maintenance level updates to multi-instance queue managers on UNIX and Linux

Linux UNIX

On UNIX and Linux, you can use multi-instance queue managers to reduce the outage caused by applying maintenance updates.

Before you begin

Before starting this task, read through the prerequisites described in *Before you begin* in "Applying maintenance level server updates on Windows" on page 573

Before starting this task, see the Maintenance is applied to the IBM MQ installation on a server and not to individual queue managers. Before you apply maintenance, you must stop all the queue managers, and any IBM MQ service, on a server.

If you want a queue manager to keep running while maintenance is applied, you must configure it as a multi-instance queue manager, and have a standby instance running on another server. If the queue manager that you want to keep running is an existing single instance queue manager, you must convert it to a multi-instance queue manager. For prerequisites and guidance how to create a multi-instance queue manager, see Multi-instance queue managers.

You can create a multi-instance queue manager from Version 7.0.1 onwards. If you are running multi-instance queue managers, you then can apply a maintenance update to a running queue manager by switching the active instance to a different server.

Typically, active and standby installations are maintained at the same maintenance level. Consult the maintenance instructions for each update. Consult the instructions to see if it is possible to run the active and standby instances at different maintenance levels. Check whether fail over from higher to lower, or only lower to higher maintenance level is possible.

The instructions for applying a maintenance update might require you to stop a multi-instance queue manager completely.

If you have a primary server for running active queue manager instances, and a secondary server that runs standby instances, you have a choice of updating the primary or secondary server first. If you update the secondary server first, you must switch back to the primary server when both servers have been updated.

If you have active and standby instances on several servers, you must plan in what order you update the servers to minimize the disruption caused by ending the active instances on each server you update.

About this task

Combine the steps in this task with the maintenance update procedure for applying maintenance to an IBM MQ server installation.

Procedure

1. Where the maintenance update procedure instructs you to stop all running queue managers, or quiesce IBM MQ do the following instead: See: "Applying and removing maintenance on UNIX and Linux" on page 586
   a. If the queue manager is running as standby:
      - End the standby with the **endmqm** -x *QMgrName* command.
   b. If the queue manager is running as the active instance: End the instance and transfer control to the standby instance with the **endmqm** command. For example, **endmqm** *-shutdown_option* -s *QMgrName*, where *-shutdown_option* is an optional parameter specifying the type of shutdown. For more information, see endmqm.

      If there is no standby instance running, the command fails, and you must start a standby instance on a different server.
   c. If a queue manager is running as a single instance queue manager, you have no alternative but to stop the queue manager before applying the maintenance update.

   When you complete this step, no queue manager instances are left running on the server you intend to update.
2. Continue with the maintenance update procedure, following the step to issue the **endmqm** command, or quiesce IBM MQ and apply maintenance to the IBM MQ server.
3. When you have completed the maintenance update, restart all the queue managers on the IBM MQ server, permitting standby instances: Use the following command:
   ```
   strmqm -x QmgrName
   ```
4. Repeat the procedure on the standby server, to update its maintenance level.
5. If necessary, switch the active instances back to the primary servers: Use the **endmqm** *-shutdown_option* -s *QMgrName* command, and the restart the instances using the **strmqm** -x *QmgrName* command.

Applying and removing maintenance on IBM i

IBM i

Maintenance tasks associated with IBM i platforms are grouped in this section.

Procedure

- To apply maintenance level updates, see "Applying maintenance level updates on IBM i."
- To restore a queue manager to the previous version of the product from the latest version, see "Restoring a queue manager to a previous release on IBM i" on page 615.
- For information on how to use use multi-instance queue managers to reduce the outage caused by applying maintenance updates, see "Applying maintenance updates to multi-instance queue managers on IBM i" on page 616.

Related tasks:

"IBM MQ maintenance tasks on Multiplatforms - general information" on page 572
When you apply and remove maintenance level updates to IBM MQ, no migration is required. Maintenance level updates are applied either as a fix pack, or by manually applying an interim fix.

Applying maintenance level updates on IBM i

IBM i

You apply maintenance level updates on the latest release by stopping IBM MQ and using the IBM i standard maintenance procedure.

Before you begin

To find out what version you have currently installed, use the following commands:

Table 78. IBM MQ commands to display the installed versions

IBM MQ Product	Version command
IBM MQ Server	`DSPMQMVER`

IBM MQ Java	IBM MQ classes for Java:
	`java com.ibm.mq.MQJavaLevel`
	
	Note: For this command to work, you might need to set your environment classpath to include:
	• `/QIBM/ProdData/mqm/java/lib/com.ibm.mq.jar`
	
	IBM MQ classes for Java Message Service:
	`java com.ibm.mq.jms.MQJMSLevel`
	
	Note: For this command to work, you might need to set your environment classpath to include:
	• `/QIBM/ProdData/mqm/java/lib/com.ibm.mqjms.jar`
	
	See Environment variables relevant to IBM MQ classes for Java and Environment variables relevant to IBM MQ classes for JMS.

IBM MQ Client	`DSPMQMVER`

About this task

Maintenance updates for IBM i are supplied as PTFs (Program Temporary Fixes). They are available for download from the web as save files, which are normally stored in the QGPL library. IBM i PTF's can be found in "Fix Central" at the following location:

FixCentral.

Procedure

1. Read the cover letter carefully to see if you need to take any special actions.
2. Sign on to a new interactive IBM i session, ensuring that you are not accessing any IBM MQ objects.
3. Ensure that you have:
   a. `*ALLOBJ` authority, or object management authority for the `QMQM` library.
   b. Sufficient authority to use the ENDSBS command.
4. Warn all users that you are going to stop IBM MQ.
5. Use the ENDMQM command to quiesce all queue managers:
   ```
   ENDMQM MQMNAME(*ALL) OPTION(*CNTRLD) ENDCCTJOB(*YES) RCDMQMIMG(*YES)
   TIMEOUT( 15 )
   ```
   Where *15* is a timeout value in seconds.

   If the ENDMQM command has not completed within a reasonable period (at least 10 minutes), use the WRKMQM command. This command identifies the queue managers that are still ending. Then force each one in turn to stop by issuing:
   ```
   ENDMQM MQMNAME( QMGRNAME ) OPTION(*IMMED)
   ```
   Where *QMGRNAME* is the name of the queue manager.

   Complete the tidying up of shared memory by issuing the command:
   ```
   ENDMQM MQMNAME(*ALL) OPTION(*IMMED) ENDCCTJOB(*YES) RCDMQMIMG(*NO)
   TIMEOUT( 15 )
   ```
6. If the command in the previous step does not complete, end the subsystem immediately by issuing:
   ```
   ENDSBS SBS(QMQM) OPTION(*IMMED)
   ```
7. If this command also fails, use the operating system command ENDJOB to end all jobs in the subsystem QMQM, as described in the following steps.

   Note: Do not use ENDJOBABN unless you intend to perform an IPL on the machine before starting IBM MQ. Ending IBM MQ jobs using ENDJOBABN can lead to damaged semaphores, which in turn can prevent your queue manager from starting.

   a. If a QMGR must be shut down manually, the recommended order of ending jobs (ENDJOB) is shown in the list that follows. Wait a few minutes for AMQA* or AMQZ* jobs to tidy up.
      1) `RUNMQLSR` - TCP listener (multi-threaded)
      2) `AMQCLMAA` - TCP listener (single-threaded)
      3) `AMQRMPPA` - Channel process pooling job
      4) `RUNMQCHI` - channel initiator
      5) `AMQCRSTA` - receiving MCA jobs
      6) `RUNMQCHL` - sending MCA jobs
      7) `AMQCRS6B` - LU62 receiver channel
      8) `AMQPCSEA` - command server
      9) `RUNMQTRM` - Application trigger monitor
      10) `RUNMQDLQ` - Dead letter queue handler
      11) `AMQFCXBA` - IBM Integration Bus Worker Job
      12) `AMQFQPUB` - Queued Publish/Subscribe Daemon
      13) `RUNMQBRK` - IBM Integration Bus Control Job
      14) `AMQZMUC0` ('0' is a zero) - Utility Manager

15) `AMQZMUF0` ('0' is a zero) - Utility Manager
16) `AMQZMUR0` ('0' is a zero) - Utility Manager
17) `AMQZMGR0` ('0' is a zero) - Process Controller
18) `AMQRRMFA` - cluster repository manager
19) `AMQZDMAA` - deferred message manager
20) `AMQALMPX` - Log Manager
21) `AMQZFUMA` - object authority manager
22) `AMQZLSA0` ('0' is a zero) - LQM agents
23) `AMQZLAA0` ('0' is a zero) - LQM agents
24) `AMQZXMA0` ('0' is a zero) - Execution Controller

b. Issue the following command:
```
ENDMQM MQMNAME( QMGRNAME ) OPTION(*IMMED)
```
c. Issue the following command:
```
ENDMQM MQMNAME(*ALL) OPTION(*CNTRLD) ENDCCTJOB(*YES) RCDMQMIMG(*NO)
TIMEOUT( 05 )
```
Where *05* is a timeout value in seconds.

d. Manually clean up shared memory. Issue the following command:
```
EDTF '/QIBM/UserData/mqm/qmgrs'
```
then:
1) Take option 5 for **&SYSTEM** and check that the following directories are empty: `isem`, `esem`, `msem`, `ssem`, and `shmem`.
2) Take option 5 for **QMGRNAME** and check that the following directories are empty:- `isem`, `esem`, `msem`, `ssem`, and `shmem`.
3) Take option 5 for **&ipcc** in the QMGRNAME directory and check that the following directories are empty:- `isem`, `esem`, `msem`, `ssem`, and `shmem`.
4) Take option 5 for **&qmpersist** in the QMGRNAME directory and check that the following directories are empty:- `isem`, `esem`, `msem`, `ssem`, and `shmem`.
5) Take option 5 for **&app** and check that the following directories are empty: `isem`, `esem`, `msem`, `ssem`, and `shmem`.

8. Load and apply a PTF

Restoring a queue manager to a previous release on IBM i

IBM i

On IBM i, you can restore a queue manager to the previous version of the product from the latest version, if you have made a backup of the system or queue manager. If you have started the queue manager and processed any messages, or changed the configuration, the task cannot give you any guidance on restoring the current state of the queue manager.

Before you begin

1. You must have made a backup of the system or queue manager before you upgraded to the later version. For more information see Backing up and restoring IBM MQ queue manager data
2. If any messages were processed after starting the queue manager, you cannot easily undo the effects of processing the messages. You cannot revert the queue manager to the earlier version of the product in its current state. The task cannot give you any guidance how to deal with subsequent changes that have occurred. For example, messages that were indoubt in a channel, or in a transmission queue on another queue manager, might have been processed. If the queue manager is part of a cluster, then configuration messages and application messages might have been exchanged.

About this task

When you revert to a earlier version of a queue manager, you revert the queue manager to its earlier code level. Queue manager data is reverted to the state it was in when the queue manager was backed up.

Procedure

1. Stop the queue manager.
2. If you performed a slip installation, you must reinstall IBM MQ.
   a. Uninstall the earlier installation.
   b. Reinstall the product from a manufacturing refresh.
   c. Apply the fix pack and interim fixes that restore IBM MQ to its previous level.
   d. Restore the queue manager data from the backup taken before installing the later version.
3. Restart the earlier version queue manager.

Related information:
Backing up and restoring a queue manager

Applying maintenance updates to multi-instance queue managers on IBM i

IBM i

On IBM i, you can use multi-instance queue managers to reduce the outage caused by applying maintenance updates.

Before you begin

Before starting this task, read through the prerequisites described in *Before you begin* in "Applying maintenance level server updates on Windows" on page 573

Before starting this task, see the Maintenance is applied to the IBM MQ installation on a server and not to individual queue managers. Before you apply maintenance, you must stop all the queue managers, and any IBM MQ service, on a server.

If you want a queue manager to keep running while maintenance is applied, you must configure it as a multi-instance queue manager, and have a standby instance running on another server. If the queue manager that you want to keep running is an existing single instance queue manager, you must convert it to a multi-instance queue manager. For prerequisites and guidance how to create a multi-instance queue manager, see Multi-instance queue managers.

You can create a multi-instance queue manager from Version 7.0.1 onwards. If you are running multi-instance queue managers, you then can apply a maintenance update to a running queue manager by switching the active instance to a different server.

Typically, active and standby installations are maintained at the same maintenance level. Consult the maintenance instructions for each update. Consult the instructions to see if it is possible to run the active and standby instances at different maintenance levels. Check whether fail over from higher to lower, or only lower to higher maintenance level is possible.

The instructions for applying a maintenance update might require you to stop a multi-instance queue manager completely.

If you have a primary server for running active queue manager instances, and a secondary server that runs standby instances, you have a choice of updating the primary or secondary server first. If you update the secondary server first, you must switch back to the primary server when both servers have been updated.

If you have active and standby instances on several servers, you must plan in what order you update the servers to minimize the disruption caused by ending the active instances on each server you update.

About this task

Combine the steps in this task with the maintenance update procedure for applying maintenance to an IBM MQ server installation.

Procedure

1. Where the maintenance update procedure instructs you to stop all running queue managers, or quiesce IBM MQ do the following instead: See: “Applying and removing maintenance on IBM i” on page 613.
   a. If the queue manager is running as standby: End the standby by adding the `INSTANCE(*STANDBY)` option to the **ENDMQM** command.
   b. If the queue manager is running as the active instance: End the instance and transfer control to the standby instance by adding the `ALWSWITCH(*YES)` option to the **ENDMQM** command.

      If there is no standby instance running, the command fails, and you must start a standby instance on a different server.
   c. If a queue manager is running as a single instance queue manager, you have no alternative but to stop the queue manager before applying the maintenance update.

   When you complete this step, no queue manager instances are left running on the server you intend to update.
2. Continue with the maintenance update procedure, following the step to issue the **endmqm** command, or quiesce IBM MQ and apply maintenance to the IBM MQ server.
3. When you have completed the maintenance update, restart all the queue managers on the IBM MQ server, permitting standby instances: Add the `STANDBY(*YES)` option to the **STRMQM** command.
4. Repeat the procedure on the standby server, to update its maintenance level.
5. If necessary, switch the active instances back to the primary servers: Use the **ENDMQM** command with the `ALWSWITCH(*YES)` option, and then restart the instances using the **STRMQM** command with the `STANDBY(*YES)` option.

Applying and removing maintenance on z/OS

z/OS

You can install new releases of IBM MQ to update IBM MQ to a new maintenance level.

About this task

LTS From IBM MQ for z/OS Version 9.0, you apply Program Temporary Fixes (PTFs) to the installed code if your enterprise is using the Long Term Support (LTS) release model.

CD If your enterprise is using the Continuous Delivery release (CD release) model, you can select which updates your enterprise requires as each CD release replaces the prior one for that version of IBM MQ.

For more information, see IBM MQ Release Types.

Applying PTFs does not change the version, release, or maintenance level of the code. No queue manager migration is required after applying maintenance. PTFs are grouped into Recommended Service Updates (RSUs) that have been tested together in a Consolidated Service Test (CST); see Consolidated Service Test and the RSU.

On the z/OS LTSR model, maintenance is supplied as Program Temporary Fixes, (PTFs), which are applied and removed using SMP/E. PTFs are specific to a particular set of libraries corresponding to specific release level. Apart from any exceptions documented with the PTFs, PTFs do not change the correct operation of IBM MQ. Nonetheless, you must check that the fixes have not changed the operation of critical programs unexpectedly.

PTFs that apply to a category of software fixes might be grouped together and identified using a fix category. For more information, see IBM Fix category values and descriptions.

When you apply maintenance in the form of PTFs, on z/OS, the impact of the change depends on the extent of the change in VRM level. The VRM codes are explained in "The version naming scheme for IBM MQ for z/OS" on page 569.

PTF updates do not require migration, and are reversible. From Version 7.0.1, all upgrades from Version 6.0 or later are reversible if the **`OPMODE`** has not been set to `NEWFUNC`.

Important: LTS Upgrades to LTS releases only, are reversible.

Related concepts:

"The version naming scheme for IBM MQ for z/OS" on page 569
On IBM MQ for z/OS, releases have a three digit Version, Release, and Modification (VRM) code. To run a queue manager at a different VRM level, you must migrate the queue manager, its applications, and the environment in which it runs. Depending on the migration path, the migration might require more or less effort.

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

Applying upgrades and fixes to IBM MQ

The term upgrade applies to changing the version `V`, release `R`, or modification `M` of a product. The term fix applies to a change in the `F` digit.

About this task

When you upgrade from one release to another, or apply fix packs, or interim fixes, the impact of the change depends on the extent of the change in the `V`, `R`, `M`, `F` level. The `V`, `R`, `M` codes are explained in "The version naming scheme for IBM MQ for Multiplatforms" on page 567.

At each change of `V`, `R`, or `M`, the command level on the queue manager changes, but on a change to `F`, the command level does not.

Multi On IBM MQ for Multiplatforms, after an upgrade has been applied, the only way to *back out* a `V.R.M` change is by:

- Uninstalling the product code and reinstalling the code, or
- Installing the old level of code alongside the existing code and using the setmqm command to associate the queue manager with the other installation.

The general rule, is that if you have carried out an install that causes the command level of the new installation to be updated, and started the queue manager, you cannot *back out* the changes.

Related concepts:

z/OS "Upgrade and migration of IBM MQ on z/OS" on page 785
You can install new releases of IBM MQ to upgrade IBM MQ to a new release, or version level. Multiple installations at the same or different levels can coexist on the same z/OS instance. Running a queue manager at a higher level requires migration.

"New function in maintenance level updates" on page 572
This topic has been removed, as the information contained is not compatible with the Continuous Delivery and Long Term Support release models used in IBM MQ Version 9.0, or later.

Related reference:

z/OS "OPMODE on z/OS" on page 781
The availability of new functions and backward migration for IBM MQ for z/OS is controlled by the **OPMODE** parameter in the **CSQ6SYSP** macro. IBM MQ Version 8.0 new functions that are restricted by **OPMODE** are not available at Version 9.0 unless enabled with **OPMODE**. There are no new functions in Version 9.0 that are restricted by **OPMODE**.

Characteristics of upgrades and fixes

For IBM MQ, the term upgrade applies to changing the version V, release R, or modification M of a product. The term fix applies to a change in the F digit.

Characteristics of fixes

Application of a fix pack, interim fix, or a program temporary fix (PTF) using a maintenance installation tool should be called a fix.

Fixes, applied using a maintenance installation tool, can be rolled back completely, as long as no queue manager migration has taken place on:

- AIX AIX
- Windows Windows
- z/OS z/OS

and IBM MQ is returned to its previous code level.

Attention: z/OS CD On z/OS Continuous Delivery releases, certain PTFs will increase the modification level, and therefore, should be considered an upgrade.

On all other platforms you must reinstall the product.

Characteristics of different types of upgrade

An upgrade can take one of three different forms:

1. Installation of new code on top of existing code. You might be able to roll back an upgrade applied in this way; it depends on the platform. Generally speaking, you cannot roll back the installation of new code. To restore the old code level, you must retain the old installation media, and any fixes you applied.
2. Removal of the old level of code, followed by installation of the new level. The installers on very few platforms require you to remove an old installation first. Needless to say, to restore the old code level, you must reinstall it and any fixes.
3. Side by side installation.

- On z/OS you can install different code levels alongside each other on the same server. In the Job Control Language to start a subsystem, you select the code level to use.
- On UNIX, Linux, and Windows, you associate a queue manager with an installation, and start the queue manager. In IBM MQ, running multiple queue managers at different command levels on the same server is termed queue manager coexistence.

  You must not infer from this, that you can select different installations to run a queue manager at different times. Once a queue manager has been run, it is subject to the rules regarding reverting to earlier or later command levels.

Note: The term upgrade does not imply that an IBM MQ installation can be directly upgraded from one level to another. On some platforms, an upgrade requires that you remove the previous IBM MQ installation. You can retain any queue managers that you have created.

On z/OS, reversibility of an upgrade has two parts; backout of the installation to the previous code level, and reversion of any queue managers that have been started at the new code level, to work with the previous code level again. See "Upgrade and migration of IBM MQ on z/OS" on page 785 for more information.

The rules regarding the reversibility of an queue manager to run on a previous code level is dependent on the platform.

On the following platforms, changes in version, release, or modification level are not fully reversible, but changes in fix level are reversible under certain conditions.
- UNIX
- Linux
- Windows
- IBM i

An irreversible upgrade implies that you must back up the queue managers, or your system, before upgrading, to be able to restore your queue managers. Taking a backup of a queue manager requires you to stop the queue manager. If you do not take a backup, you are not able to restore IBM MQ to its previous level. Any changes you make on the new level cannot be restored onto the backup system. Changes include the creation or deletion of persistent messages, and changes to queue managers, channels, topics, and queues.

There are no new functions in Version 9.0 that are restricted by **OPMODE**.

Upgrading an IBM MQ installation on Windows

To upgrade an IBM MQ server installation on Windows, from one version, release, and modification level to a later one, you can use either the Launchpad or msiexec. To upgrade a client installation, you can use either the GUI installer or msiexec.

About this task

Before you begin, ensure that you have backed up your data.

Important: If you want to apply maintenance instead, for example, from Version 9.0.0.0 to Version 9.0.0, Fix Pack 1, see "Applying and removing maintenance on Windows" on page 573.

Procedure

- To upgrade a server installation, see "Upgrading an IBM MQ server installation using the Launchpad" or "Upgrading an IBM MQ server installation using msiexec" on page 622.
- To upgrade a client installation, see "Upgrading an IBM MQ client installation using the GUI installer" on page 623 or "Upgrading an IBM MQ client installation using msiexec" on page 624.

Upgrading an IBM MQ server installation using the Launchpad

How you upgrade an IBM MQ server installation on Windows to a newer version, release, or modification, using the Launchpad.

Before you begin

Ensure that you have:
1. Stopped all your IBM MQ applications
2. Shut down your listeners
3. Stopped all your queue managers
4. Backed up your data

Important: If you want to apply maintenance instead, for example, from Version 9.0.0.0 to Version 9.0.0, Fix Pack 1, see "Applying and removing maintenance on Windows" on page 573.

Procedure

1. Access the IBM MQ installation image. The location might be the mount point of the DVD, a network location, or a local file system directory.
2. Locate `setup.exe` in the base directory of the IBM MQ installation image.
   - From a DVD, this location might be:
     `E:\setup.exe`
   - From a network location, this location might be:
     `m:\instmqs\setup.exe`
   - From a local file system directory, this location might be:
     `C:\instmqs\setup.exe`
3. Double-click the **Setup** icon to start the installation process. It is possible to run either by:
   - Running `setup.exe` from the command prompt. Or
   - Double-clicking `setup.exe` from Windows Explorer.

If you are installing on a Windows system with UAC enabled, accept the Windows prompt to allow the launchpad to run as elevated. During installation, you might also see Open File - Security Warning dialog boxes that list International Business Machines Limited as the publisher. Click **Run** to allow the installation to continue.

The IBM MQ Installation Launchpad window is displayed.

4. Continue to follow the Launchpad instructions as shown on screen.
5. Select **Installing a new instance**, if you see a panel asking you to choose between installing a new instance, or maintaining or upgrading an existing instance, when you click the **Launch IBM MQ Installer** button. You use the other option when adding or removing features from an already installed IBM MQ.
6. On the next panel, choose between **Install leaving the existing installation(s) untouched** or **Upgrade an existing named installation already on the machine**, and click **Next**.

   Attention: If you do not see this screen, it means that there was no IBM MQ server installation on the machine that could be upgraded by this installer.
7. Follow the installer prompts to upgrade your IBM MQ server installation.

Upgrading an IBM MQ server installation using msiexec

Windows

How you upgrade an IBM MQ server installation on Windows to a newer version, release, or modification, using msiexec.

Before you begin

Ensure that you have:

1. Stopped all your IBM MQ applications
2. Shut down your listeners
3. Stopped all your queue managers
4. Backed up your data

Important: If you want to apply maintenance instead, for example, from Version 9.0.0.0 to Version 9.0.0, Fix Pack 1, see "Applying and removing maintenance on Windows" on page 573.

Procedure

1. Access the IBM MQ installation image. The location might be the mount point of the DVD, a network location, or a local file system directory.
2. Locate `MSI file` in the MSI directory of the IBM MQ installation image.
   - From a DVD, this location might be:

     E:`\\MSI\IBM MQ.msi`
   - From a network location, this location might be:

     m:\instmqs`\\MSI\IBM MQ.msi`

- From a local file system directory, this location might be:

  `C:\instmqs\\MSI\IBM MQ.msi`

3. Optional: If you are upgrading the only IBM MQ server installation, where the installation has the default value `Installation1` issue the following command:

   ```
   msiexec /i "InstallationImage\MSI\IBM MQ.msi" /q AGREETOLICENSE=YES
   INSTALLATIONNAME="Installation1"
   ```

4. Optional: If you are upgrading an installation on a machine that already has one or more IBM MQ server installations of the level you are upgrading to, you must provide additional parameters to select a free MSI instance ID. See Choosing MSI Instance IDs for multiple server installations for more information.

   In this case, the command might look something like:

   ```
   msiexec /i "Installation Image\MSI\IBM MQ.msi" /q AGREETOLICENSE=YES
   INSTALLATIONNAME="Installation2" NEWINSTANCE=1
   TRANSFORMS=":InstanceId2.mst;1033.mst"
   ```

Migrating IBM MQ

Migration is the conversion of programs and data to work with a new code level of IBM MQ. Some types of migration are required, and some are optional. Queue manager migration is never required after applying a maintenance level update, that does not change the command level. Some types of migration are automatic, and some are manual. Queue manager migration is typically automatic and required after releases and manual and optional after a maintenance level upgrade that introduces a new function. Application migration is typically manual and optional.

Before you begin

Before upgrading your IBM MQ installation or migrating your queue managers, you must read "Changes that affect migration" on page 626 to identify what migration tasks you must plan for.

About this task

Whenever you upgrade IBM MQ to a new release that changes its command level, migration is performed by the queue manager. Whenever you upgrade IBM MQ to a new maintenance or fix level, which introduces a new function using a new command level, you can migrate the queue manager to use the new command level and thereby the new function.

If you start a queue manager running on a later release level, then migration of the queue manager to that release level is required. The migration tasks you must perform to migrate from one release to another are documented in "Migrating a queue manager on Windows" on page 691; see also "Changes that affect migration" on page 626.

Multi On IBM MQ for Multiplatforms, you cannot easily revert to a previous level of IBM MQ after installation. If you install a copy of IBM MQ obtained from Passport Advantage or from physical media, the installer uninstalls IBM MQ, if it is present. It then installs the new level of IBM MQ. To revert to the previous level of IBM MQ, you must keep the earlier installation image and any fixes you applied.

Then you must uninstall the new level, reinstall the previous release level, and reapply the required fixes. If you have started any queue managers at the later level, they will not work with the restored level of IBM MQ[1] . To restore IBM MQ to its previous level, after starting any queue managers, you must first back up the queue managers. You can then restore the backup queue managers after restoring the previous level of IBM MQ.

z/OS LTS On IBM MQ for z/OS, while **OPMODE** is set to COMPAT, it is possible to backwards migrate from a Long Term Support (LTS) release. For more information, see "Backward migration to earlier supported releases of IBM MQ for z/OS" on page 789.

z/OS CD Backwards migration is not supported for a Continuous Delivery (CD) release on z/OS.

Related concepts:

"The version naming scheme for IBM MQ for Multiplatforms" on page 567
From IBM MQ Version 9.0, releases have a three digit Version, Release, and Modification (VRM) code or a four-digit Version, Release, Maintenance, and Fix (VRMF) level code.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

Related information:

Backing up and restoring a queue manager

Changes that affect migration

Changes to the product might affect the migration of a queue manager from an earlier release to the current release of IBM MQ, or affect existing applications or configurations. Review these changes before upgrading queue managers to the latest product version and decide whether you must plan to make changes to existing applications, scripts, and procedures before starting to migrate your systems.

Changes in the current release

For details of changes in the current release, including those that affect migration, see the following information:

- V 9.0.0 What's new and changed in IBM MQ Version 9.0
- CD What's new and changed in Version 9.0.x Continuous Delivery
- LTS What's changed in Version 9.0.0.x Long Term Support
- LTS CD Readme for IBM MQ V9.0 and its maintenance

Changes in earlier releases

For information about what changed in an earlier release of the product, see the *What's changed* section in the product documentation for that release:

- What's changed in IBM MQ Version 8.0

1. Unless you installed a later maintenance level upgrade, not a new release or version: then you could revert to an earlier maintenance level by reinstalling the earlier maintenance level upgrade. Queue manager data is compatible between maintenance levels.

- What's changed in IBM WebSphere MQ Version 7.5
- What's changed in IBM WebSphere MQ Version 7.1
- What's changed in IBM WebSphere MQ Version 7.0.1

Restrictions on reversing queue manager migration

Attention:

Multi On IBM MQ for Multiplatforms, you cannot reverse queue manager migration to remove the effect of changes. This restriction applies whether your enterprise uses the Long Term Support (LTS) release or Continuous Delivery (CD) release model.

z/OS LTS On IBM MQ for z/OS, you can reverse queue manager migration as long as you have not enabled new function, and are using the LTS release model. You enable new function, for a queue manager on the LTS release model, by setting the **OPMODE** parameter to (NEWFUNC, 900).

For further information, see IBM MQ release types.

"Migration considerations for Version 8.0 or later on Windows" on page 686
From Version 8.0, a number of changes were made for IBM MQ for Windows. You must understand these changes before planning any migration tasks for Version 8.0 or later on Windows.

"Program and data directory locations on Windows" on page 688
The installation location for IBM MQ program binary and data files on Windows depends on the IBM MQ version you are installing and whether this is the first time IBM MQ is being installed.

What changed in IBM MQ Version 8.0

Changes to functions and resources, including stabilizations, deprecations and removals, that occurred in IBM MQ Version 8.0 are summarized in this section, with links to further information.

This information has moved. See What changed in IBM MQ Version 8.0.

APIs: change to the operation of API exits:

API exits which themselves make API calls, rather than using the **MQIEP** structure, should be linked with an IBM MQ API library, otherwise they will fail to load inside **runmqsc**.

This information has moved. See APIs: Change to the operation of API exits.

Change to STOPPED status on a SVRCONN channel:

From IBM MQ Version 8.0 STOPPED channel status is allowed to persist a queue manager restart. This behavior applies to all platforms excluding z/OS.

This information has moved. See Change to STOPPED status on a SVRCONN channel.

Command changes:

From IBM MQ Version 8.0, there is a change of behavior in a number of commands.

This information has moved. See:

- Command changes: crtmqenv command

- Command changes: dmpmqcfg output
- Command changes: results displayed in response to DISPLAY CONN command from runmqsc
- Changes to the runmqsc command: new client modes for MQSC
- Command changes: removal of migmbbrk and CSQUMGMB

Command level changes at Version 8.0:

The command level on all platforms changed to 800 in IBM MQ Version 8.0. On certain platforms it changed to 801 in IBM MQ Version 8.0.0, Fix Pack 2, and to 802 in IBM MQ Version 8.0.0, Fix Pack 3. The command level remained at 802 for those platforms in IBM MQ Version 8.0.0, Fix Pack 4.

This information has moved. See Command level: changes.

Deprecations:

A number of features are deprecated from IBM MQ Version 8.0.

This information has moved. See:

- Solaris Deprecation: linking with libmqmcs and libmqmzse libraries
- Deprecation: Managed File Transfer Web Gateway
- Deprecation: SSLv3 protocol
- Deprecation: weaker cryptographic algorithms
- Deprecation: IBM MQ Explorer Service Definition Wizard
- Deprecation: IBM MQ transport for SOAP client and HTTP bridge

Extended start events for multi-instance queue managers:

From IBM MQ Version 8.0.0, Fix Pack 3, start events for multi-instance queue managers are extended to allow system monitoring applications to see when a multi-instance queue manager has failed over and where it is now running.

This information has moved. See Extended start events for multi-instance queue managers.

Additions to supported features on IBM i: IBM i

From IBM MQ Version 8.0, IBM i supports split cluster transmission queues and Advanced Message Security.

This information has moved. See IBM i: changes for IBM MQ Version 8.0.

Java and JMS: changes to character string conversion:

From IBM MQ Version 8.0, some of the default behavior regarding character string conversion with Java and JMS clients has changed.

This information has moved. See Java and JMS: changes to character string conversion.

Java and JMS: changes to CipherSuite support:

From IBM MQ Version 8.0 the support for SSL/TLS CipherSuites in the IBM MQ classes for Java and IBM MQ classes for JMS has changed.

This information has moved. See Java and JMS: changes to CipherSuite support.

Java and JMS: resource adapter changes:

From IBM MQ Version 8.0.0, Fix Pack 6, the IBM MQ resource adapter IVT application is updated to support WildFly V10.

This information has moved. See Java and JMS: resource adapter changes.

Java: changes for Java 7:

In order to support Java 7, changes have been made to IBM MQ classes for Java and IBM MQ classes for JMS.

This information has moved. See Java: changes for Java 7.

Java: Changes to IBM MQ classes for Java:

From IBM MQ Version 8.0, an unwanted dependency on `connector.jar` has been removed and changes have been made to APIs for public classes.

This information has moved. See Java: changes to IBM MQ classes for Java.

Java: changes to Java tracing behavior:

From IBM MQ Version 8.0 the ways to control trace for Java-language clients has been updated.

This information has moved. See Java: changes to Java tracing behavior.

Java: changes to MQException and MQDataException class logging:

From IBM MQ Version 8.0, the logging functionality of the com.ibm.mq.MQException class, which wrote details of new MQExceptions to a log, has been removed.

This information has moved. See Java: changes to MQException and MQDataException class logging.

JMS: changes to Bytes and Stream message states:

From IBM MQ Version 8.0.0, Fix Pack 2, a property can be set to define whether IBM MQ classes for JMS should set the state of a message that has just been sent to read only, or write only.

This information has moved. See JMS: changes to Bytes and Stream message states.

JMS: Exception listener changes in Version 8.0:

In IBM MQ Version 8.0, when using IBM MQ classes for JMS, changes are made to the way in which an application's JMS ExceptionListener is invoked.

This information has moved. See JMS: Exception listener changes in Version 8.0.

JMS: changes to IBM MQ classes for JMS:

From IBM MQ Version 8.0, a number of changes are made to IBM MQ classes for JMS.

This information has moved. See JMS: changes to IBM MQ classes for JMS.

JMS: changes to JAR files for JMS 2.0:

From IBM MQ Version 8.0, the `jms.jar` file is a JMS 2.0 set of interfaces.

This information has moved. See JMS: changes to JAR files for JMS 2.0.

JMS: changes to `PROVIDERVERSION` property:

The JMS **`PROVIDERVERSION`** property selects whether a Java application publishes and subscribes using the queued command message interface, or the integrated call interface. For IBM MQ Version 8.0 in addition to normal mode and migration mode, you can also select normal mode with restrictions.

This information has moved. See JMS: changes to PROVIDERVERSION property.

Managed File Transfer: changes for Version 8.0.0, Fix Pack 6:

For IBM MQ Version 8.0.0, Fix Pack 6, a number of changes are made to Managed File Transfer.

This information has moved. See Managed File Transfer: changes for Version 8.0.0, Fix Pack 6.

Changes to cluster topic behavior:

From IBM MQ Version 8.0, the behavior has changed when the publication (**`PUB`**) parameter differs across clustered topic definitions of the same name.

This information has moved. See Changes to cluster topic behavior.

Publish/subscribe: changes to DISPLAY TOPIC and DISPLAY TPSTATUS output:

From IBM MQ Version 8.0 the output of the **`DISPLAY TOPIC`** command now includes the parameters **`CLROUTE`** and **`CLSTATE`** and the **`DISPLAY TPSTATUS`** command now includes the parameter **`CLROUTE`**.

This information has moved. See Publish/subscribe: changes to DISPLAY TOPIC and DISPLAY TPSTATUS output.

Publish/subscribe: changes to how the subscription selection string is evaluated:

From IBM MQ Version 8.0, message selection for publish/subscribe messaging is made on the message as sent by the publisher, rather than on the message as eventually received by the subscriber.

This information has moved. See Publish/subscribe: changes to how the subscription selection string is evaluated.

Publish/subscribe: changes to proxy subscription propagation using PROXYSUB(FORCE):

From IBM MQ Version 8.0, when you configure a topic object with the parameter **`PROXYSUB`** set to `FORCE`, IBM MQ automatically disables individual proxy subscriptions for topic strings below this point in the topic tree.

This information has moved. See Publish/subscribe: changes to proxy subscription propagation using PROXYSUB(FORCE).

Queue managers: change to default TCP buffer size:

From IBM MQ Version 8.0, there is a change to the TCP stanza values for send and receive buffer sizes for new queue managers, which without manual tuning, previously defaulted to a fixed size 32Kb buffer. z/OS This change does not apply to z/OS.

This information has moved. See Queue managers: change to default TCP buffer size.

Queue managers: Version attribute added for queue managers in a cluster:

From IBM MQ Version 8.0 you can display the version of IBM MQ with which the cluster queue manager is associated in the form of `VVRRMMFF` where `VV` is the version, `RR` is the release, `MM` is the maintenance level, and `FF` is the fix level.

This information has moved. See Queue managers: Version attribute added for queue managers in a cluster.

Security: certificate revocation checking:

From IBM MQ Version 8.0, you can determine how certificate revocation checking is configured if the client connect call uses an SSL/TLS channel by using the **`ClientRevocationChecks`** attribute in the SSL stanza of the client configuration file.

This information has moved. See Security: certificate revocation checking.

Security: changes to CipherSuite support:

From IBM MQ Version 8.0, the SHA-2 support that is already provided in earlier releases is extended.

This information has moved. See Security: changes to CipherSuite support.

Security: Deprecated CipherSpecs:

From IBM MQ Version 8.0.0, Fix Pack 6, the following CipherSpecs are deprecated:

This information has moved. See Security: deprecated CipherSpecs.

Security: GSKit version updated:

The GSKit version has been updated in IBM MQ Version 8.0.0, Fix Pack 6. The new version of GSKit alters the stash file format that is used when you generate an `.sth` file to stash the key database password. Stash files that are generated with this version of GSKit are not readable by earlier versions of GSKit.

This information has moved. See What's new and changed in Version 8.0.0, Fix Pack 6.

Security: new CONNAUTH CHCKLOCL parameter:

From IBM MQ Version 8.0, a new queue manager security parameter, **`CONNAUTH CHCKLOCL`**, is introduced.

This information has moved. See Security: new CONNAUTH CHCKLOCL parameter.

Security: OAM user-based permissions on UNIX and Linux systems:

From IBM MQ Version 8.0, on UNIX and Linux systems, the object authority manager (OAM) can now use user-based authorization as well as group-based authorization.

This information has moved. See Security: OAM user-based permissions on UNIX and Linux systems.

Security: Disable AMS at the client:

You can disable Advanced Message Security at the client, to prevent errors when they are connecting to queue managers that are running on IBM WebSphere MQ Version 7.1 or earlier. From IBM MQ Version 8.0, the environment variable that is used to disable AMS for C clients, is changed.

This information has moved. See Security: Disable IBM MQ AMS at the client.

Security: password protection on client applications:

From IBM MQ Version 8.0, any passwords that you send using the MQCSP structure can be either protected, by using IBM MQ functionality, or encrypted, by using SSL/TLS encryption.

This information has moved. See Security: password protection on client applications.

Security: reduction in channel send exit buffer space for SSL and TLS:

From IBM MQ Version 8.0, the maximum amount of space in the transmission buffer that an SSL or TLS channel send exit can reserve by the `MQCXP ExitSpace` field has been reduced by 924 bytes to 14,328 bytes.

This information has moved. See Security: reduction in channel send exit buffer space for SSL and TLS.

Solaris client: change in method of installation:

From IBM MQ Version 8.0 the *.img* file has been removed. The client is delivered in an unpacked form.

This information has moved. See Solaris client: change in method of installation.

Telemetry: changes to MQ Telemetry Clients Software Development Kit (SDK):

From IBM MQ Version 8.0 the MQ Telemetry SDK is no longer supplied as part of the product.

This information has moved. See Telemetry: changes to MQ Telemetry Clients Software Development Kit (SDK).

changes from IBM MQ Version 8.0 on Windows: Windows

From IBM MQ Version 8.0, changes have been made to the default installation location for the server and 64-bit client installations. There has also been a change in the default data path for all installations. The compiler that is used from IBM MQ Version 8.0 on Windows has been changed.

This information has moved. See Windows: changes for IBM MQ Version 8.0.

Change to display of mapped IP addresses in error message inserts on z/OS: z/OS

From IBM MQ Version 8.0, mapped IP addresses shown in error messages in the CHINIT address space on z/OS are shown without the mapped prefix.

This information has moved. See z/OS: change to display of mapped IP addresses in error message inserts.

Change to MAKECLNT on z/OS: z/OS

From IBM MQ Version 8.0, the MAKECLNT CSQUTIL tool is stabilized. You should use **runmqsc -n** instead.

This information has moved. See z/OS: change to MAKECLNT.

Changes to log RBA and URID lengths on z/OS: z/OS

From IBM MQ Version 8.0, log RBAs and Unit of Recovery Identifiers (URID) in console messages and command responses are 8 bytes long, displayed as 16 character hexadecimal values. This is the case regardless of whether Version 8.0 new functions have been enabled with OPMODE, and whether the queue manager has been migrated to use 8 byte log RBAs.

This information has moved. See z/OS: changes to log RBA and URID lengths.

Changes to Managed File Transfer on z/OS: z/OS

Changes have been made between WebSphere MQ File Transfer Edition on z/OS and Managed File Transfer on IBM MQ for z/OS.

This information has moved. See z/OS: changes to Managed File Transfer.

z/OS: channel initiator SMF records: z/OS

The channel initiator (CHINIT) can produce SMF statistics records and accounting records with information on tasks and channels.

This information has moved. See z/OS: channel initiator SMF records.

WLM/DNS no longer supported on z/OS: z/OS

WLM/DNS is no longer supported by the z/OS Communications Server, so the queue manager attributes DNSWLM and DNSGROUP are no longer used from IBM MQ for z/OS Version 8.0.

This information has moved. See z/OS: WLM/DNS no longer supported.

What changed in IBM WebSphere MQ Version 7.0.1, Version 7.1 and Version 7.5

Changes that affect the migration of a queue manager from Version 7.0.1, Version 7.1 and Version 7.5 to the latest release are listed.

This information has moved. See:
- What's changed in IBM WebSphere MQ Version 7.5
- What's changed in IBM WebSphere MQ Version 7.1
- What's changed in IBM WebSphere MQ Version 7.0.1

Version 7.0.1 features and their supported APIs:

Use this information to learn about the IBM WebSphere MQ Version 7.0.1 APIs with features and environments that might not be as fully supported as the C MQI.

This information has moved. See New features and their supported APIs for Version 7.0.1.

Version 7.0.1 features and their supported APIs: JMS:

Use this information to learn about the IBM WebSphere MQ Version 7.0.1 APIs with features and environments that might not be as fully supported as the C MQI.

This information has moved. See New features and their supported APIs for Version 7.0.1.

Version 7.0.1 features and their supported APIs: Java:

Use this information to learn about the IBM WebSphere MQ Version 7.0.1 APIs with features and environments that might not be as fully supported as the C MQI.

This information has moved. See New features and their supported APIs for Version 7.0.1.

Version 7.0.1 features and their supported APIs: XMS .NET:

Use this information to learn about the IBM WebSphere MQ Version 7.0.1 APIs with features and environments that might not be as fully supported as the C MQI.

This information has moved. See New features and their supported APIs for Version 7.0.1.

Version 7.0.1 features and their supported APIs: XMS C and C++:

Use this information to learn about the IBM WebSphere MQ Version 7.0.1 APIs with features and environments that might not be as fully supported as the C MQI.

This information has moved. See New features and their supported APIs for Version 7.0.1.

Version 7.0.1 features and their supported APIs: .NET:

Use this information to learn about the IBM WebSphere MQ Version 7.0.1 APIs with features and environments that might not be as fully supported as the C MQI.

This information has moved. See New features and their supported APIs for Version 7.0.1.

Channel authentication:

From IBM WebSphere MQ Version 7.1 onwards, when you migrate a queue manager from an earlier release, channel authentication using channel authentication records is disabled. Channels continue to work as before. If you create a queue manager in Version 9.0, channel authentication using channel authentication records is enabled, but with minimal additional checking. Some channels might fail to start.

This information has moved. See Channel authentication.

Change in behavior of the `endmqm` command:

From IBM WebSphere MQ Version 7.5 onwards, issuing an **`endmqm`** command and **`dspmq`** command immediately after each other might return misleading status.

This information has moved. See Change in behavior of the endmqm command.

Changes to cluster error recovery (on servers other than z/OS): Multi

From IBM WebSphere MQ Version 7.1 onwards, the queue manager reruns operations that caused problems, until the problems are resolved. If, after five days, the problems are not resolved, the queue manager shuts down to prevent the cache becoming more out of date.

This information has moved. See Changes to cluster error recovery (on servers other than z/OS).

Change in behavior of MQS_REPORT_NOAUTH:

In IBM WebSphere MQ Version 7.1, the default behavior of MQS_REPORT_NOAUTH was changed to *TRUE*.

This information has moved. See Change in behavior of MQS_REPORT_NOAUTH.

Connect to multiple queue managers and use `MQCNO_FASTPATH_BINDING`:

From Version 7.1 onwards, only the first connection can be set to `MQCNO_FASTPATH_BINDING`. Applications that connect to queue managers using the `MQCNO_FASTPATH_BINDING` binding option might fail with an error and reason code `MQRC_FASTPATH_NOT_AVAILABLE` if you do not follow the rules for using fast path connections.

This information has moved. See Connect to multiple queue managers and use `MQCNO_FASTPATH_BINDING`.

Custom scripts:

In IBM MQ for Windows, custom scripts that have been used in an earlier release to install packages might fail if any packages have been renamed, removed, or added in the later release to which you are migrating.

This information has moved. See Custom scripts.

Changes to data types:

A number of data types have changed between IBM WebSphere MQ Version 7.0.1 and later releases, and new data types have been added.

This information has moved. See
- Changes to data types (Version 7.1)
- Changes to data types (Version 7.5)

Default transmission queue restriction:

The product documentation in versions of IBM WebSphere MQ before Version 7.1 warned about defining the default transmission queue as `SYSTEM.CLUSTER.TRANSMIT.QUEUE`, but no error was reported. In Version 7.1, any attempt to set or use a default transmission queue that is defined as `SYSTEM.CLUSTER.TRANSMIT.QUEUE` results in an error.

This information has moved. See Default transmission queue restriction.

Display channel and cluster status: Switching:

From IBM WebSphere MQ Version 7.5 onwards, a cluster-sender channel that is switching its configuration to a different cluster transmission queue has a new channel state: Switching.

This topic has moved. See Display channel and cluster status: Switching.

Changes to `dspmqver` output:

From IBM WebSphere MQ Version 7.1 onwards, new types of information are displayed by **`dspmqver`** to support multiple installations. The changes might affect existing administrative scripts that you have written to manage a release of IBM WebSphere MQ before IBM WebSphere MQ Version 7.1.

This information has moved. See Changes to dspmqver output.

For information about the **`dspmqver`** command, see dspmqver.

Exits and installable services: Multi

When migrating to IBM WebSphere MQ Version 7.1 or later on Multiplatforms, if you install the product in a non-default location, you must update your exits and installable services. Data conversion exits generated using the **`crtmqcvx`** command must be regenerated using the updated command.

This information has moved. See Exits and installable services.

Fewer IBM MQ MQI client log messages:

Before Version 7.1, an IBM WebSphere MQ MQI client used to report every failed attempt to connect to a queue manager when processing a connection name list. From Version 7.1, only if the failure occurs with the last connection in the list is a message written to the queue manager error log.

This information has moved. See Fewer IBM WebSphere MQ MQI client log messages.

Java: Change in behavior of default value of MQEnvironment.userID:

From IBM WebSphere MQ Version 7.1, a change to the behavior of the default value of MQEnvironment.userID results in an exception if an application attempts to connect to a queue manager using the CLIENT transport through a channel that does not have a security exit defined.

This information has moved. See Java: Change in behavior of default value of MQEnvironment.userID.

Java: Different message property data type returned:

From IBM WebSphere MQ Version 7.1, if the data type of a message property is set, the same data type is returned when the message is received. This is different from IBM WebSphere MQ Version 7.0.1, where in some circumstances properties set with a specific type were returned with the default type String.

This information has moved. See Java: Different message property data type returned.

JMS: Change in behavior of the default user identifier value:

From IBM WebSphere MQ Version 7.1, a change to the behavior of the default user identifier value results in an exception if an application attempts to connect to a queue manager using the CLIENT transport through a channel that does not have a security exit defined.

This information has moved. See JMS: Change in behavior of the default user identifier value.

JMS: Exception listener changes:

In later releases of the product, JMS exception listeners behave differently than they did before Version 7.0. Applications might receive more or fewer exceptions than they did in earlier releases.

This information has moved. See:

- JMS: Exception listener changes in Version 7.0.
- .

JMS: some objects are no longer serializable:

JMS objects such as JMS Connections and JMS Sessions, which used to be serializable when using the IBM WebSphere MQ classes for JMS for IBM WebSphere MQ Version 7.0.1, are no longer serializable when using IBM WebSphere MQ Version 7.1 or later.

This information has moved. See JMS: some objects are no longer serializable .

JMS: Reason code changes:

From IBM WebSphere MQ Version 7.1, some reason codes returned in JMS exceptions have changed. The changes affect `MQRC_Q_MGR_NOT_AVAILABLE` and `MQRC_SSL_INITIALIZATION_ERROR`.

This information has moved. See JMS: reason code changes.

JMS: ResourceAdapter object configuration:

When WebSphere Application Server connects to IBM MQ it creates message driven beans (MDBs) using JMS connections. From Version 7.1, these MDBs can no longer share one JMS connection. The configuration of ResourceAdapter object is migrated so that there is a single MDB for each JMS connection.

This information has changed. See JMS: ResourceAdapter object configuration.

IBM MQ Explorer changes:

From Version 7.1, IBM WebSphere Eclipse Platform is not required to run IBM MQ Explorer and is therefore no longer shipped with the product. The change makes no difference to administrators who run IBM MQ Explorer. For developers who run IBM MQ Explorer in an Eclipse development environment, a change is necessary. You must install and configure a separate Eclipse environment to be able to switch between IBM MQ Explorer and other perspectives.

This information has moved. See IBM WebSphere MQ Explorer changes.

MQI and PCF reason code changes:

Some reason codes that affect some existing programs changed in IBM WebSphere MQ Version 7.1.

This information has moved. See MQI and PCF reason code changes.

Publish/Subscribe: Delete temporary dynamic queue:

If a subscription is associated with a temporary dynamic queue, when the queue is deleted, the subscription is deleted. Publish/subscribe applications migrated from WebSphere Message Broker are unchanged. The change does not affect the behavior of integrated publish/subscribe applications, which are written using the MQI publish/subscribe interface.

This information has moved. See Publish/Subscribe: Delete temporary dynamic queue.

Queue manager logs: Default sizes increased:

From IBM WebSphere MQ Version 7.1, the default size of a queue manager log files changed to 4096. The queue manager error log increased from 256 KB to 2 MB on some platforms. The change affects both new and migrated queue managers.

This information has moved. See Queue manager log files and error logs: Default sizes increased.

Removal of `dspmqsver` command:

Before IBM WebSphere MQ Version 7.5, the **`dspmqsver`** command was used to display the version of Advanced Message Security.

This information has moved. See Removal of dspmqsver command.

Security: `SSLPEER` and `SSLCERTI` changes:

IBM WebSphere MQ Version 7.1 or later obtains the Distinguished Encoding Rules (DER) encoding of the certificate and uses it to determine the subject and issuer distinguished names. The subject and issuer distinguished names are used in the `SSLPEER` and `SSLCERTI` fields. A `SERIALNUMBER` attribute is also included in the subject distinguished name and contains the serial number for the certificate of the remote partner. Some attributes of subject and issuer distinguished names are returned in a different sequence from releases before Version 7.1.

This information has moved. See SSLPEER and SSLCERTI changes.

Security: Disable AMS at the client:

From Version 7.5, you can disable Advanced Message Security at the client, for Java and C clients, to prevent errors when they are connecting to queue managers that are running on earlier versions of the product.

This information has moved. See What's changed in IBM WebSphere MQ Version 7.5 Fix Packs.

Telemetry: Installer integrated with IBM MQ:

From Version 7.1, MQ Telemetry is no longer installed separately from IBM MQ. It is installed as a component of the main product. If you installed MQ Telemetry with Version 7.0.1, you must uninstall it before installing Version 7.1 or later.

This information has moved. See Telemetry: Installer integrated with IBM WebSphere MQ.

Telemetry: Support for the MQTT protocol over WebSockets:

IBM WebSphere MQ Version 7.5.0, Fix Pack 1 and later supports the MQTT protocol over WebSockets. This enables it to be a server for clients using the MQTT messaging client for JavaScript.

This information has moved. See What's changed in IBM WebSphere MQ Version 7.5 Fix Packs.

Shared objects on AIX: AIX

On AIX, for Version 7.1. and later, the `.a` shared objects in the `lib64` directory contains both the 32 bit and 64 bit objects. A symlink to the `.a` file is also placed in the `lib` directory. The AIX loader can then correctly pick up the correct object for the type of application being run.

This means that IBM MQ applications can run with the `LIBPATH` containing either the `lib` or `lib64` directory, or both.

This information has moved. See AIX: Shared objects.

`/usr/lpp/mqm` symbolic link removed on AIX: AIX

Before Version 6.0, IBM WebSphere MQ placed a symbolic link in `/usr/lpp/mqm` on AIX. The link ensured queue managers and applications migrated from IBM WebSphere MQ versions before Version 5.3 continued to work, without change. However, this link is not created in Version 7.1, or later.

This information has moved. See AIX: /usr/lpp/mqm symbolic link removed.

Building applications for TXSeries on AIX, HP-UX, and Solaris:

From Version 7.1, applications that link to TXSeries® must load the `mqzi_r` library, not the `mqz_r` library. These applications must load `mqzi_r` from the installation that is associated with the queue manager to which the application is connected.

This information has moved. See AIX, HP-UX, and Solaris: Building applications for TXSeries.

GSKit: Recompile LinuxC++ applications and update run time libraries: Multi

C++ IBM MQ MQI client and server applications on Linux must be recompiled using a supported version of the GNU Compiler Collection (GCC). The C++ run time libraries for this version of GCC must be installed in `/usr/lib` or `/usr/lib64`.

This information has moved. See GSKit: Recompile Linux C++ applications and update run time libraries.

Increased shared memory allocation required on Linux: Linux

The maximum amount of shared memory (`SHMMAX`) to allocate on Linux systems. The default system allocation is 32 MB. IBM MQ starts by allocating 64 MB and increases its allocation on demand by doubling its previous allocation. On a production system set `SHMMAX` to at least 256 MB to accommodate additional allocations.

This information has moved. See Linux: Increased shared memory allocation required.

UNIX and Linux : `crtmqlnk` and `dltmqlnk` removed:

Before Version 7.1 , the **`crtmqlnk`** and **`dltmqlnk`** commands created symbolic links in subdirectories of `/usr`. From Version 7.1 onwards, you must use the **`setmqinst`** command instead.

This information has moved. See UNIX and Linux: crtmqlnk and dltmqlnk removed.

UNIX and Linux: Message catalogs moved:

From Version 7.1, message catalogs are no longer stored in the system directories. To support multiple installations, copies of the message catalogs are stored with each installation. If you are migrating from a release before Version 7.1 and you want messages only in the locale of your system, the change has no affect on your system. If you have customized the way in which the search procedure selects a message catalog, then the customization might no longer work correctly.

This information has moved. See UNIX and Linux: Message catalogs moved.

UNIX and Linux: MQ services and triggered applications:

From Version 7.1, both `LD_LIBRARY_PATH` and `$ORIGIN` work for MQ services and triggered applications. For this reason, for Version 7.1 or later, MQ Services and triggered applications run under the user ID that started the queue manager and not `setuid` or `setgid`.

This information has moved. See UNIX and Linux: MQ services and triggered applications.

UNIX and Linux: `ps -ef | grep amq` interpretation:

From Version 7.1, the interpretation of the list of IBM MQ processes that results from filtering a scan of UNIX or Linux processes has changed. The results can show IBM MQ processes running for multiple installations on a server. Before Version 7.1, the search identified IBM MQ processes running on only a single installation of the product on a UNIX or Linux server.

This information has moved. See UNIX and Linux: `ps -ef | grep amq` interpretation.

UNIX and Linux: `/usr` symbolic links removed:

From Version 7.1, on all UNIX and Linux platforms, the links from the `/usr` file system are no longer made automatically. In order to take advantage of these links, you must set an installation as the primary installation.

This information has moved. See UNIX and Linux: /usr symbolic links removed.

Configurable certificate validation policy on Windows and UNIX: UNIX Windows

From, Version 7.1.0, Fix Pack 2 you configure the product to specify which SSL or TLS certificate validation policy is used to validate digital certificates received from remote partner systems.

This information has moved. See What's changed in IBM WebSphere MQ Version 7.1 Fix Packs.

`amqmsrvn.exe` process removed on Windows: Windows

From Version 7.1, the `amqmsrvn.exe` DCOM process was replaced by a Windows service, `amqsvc.exe`. This change is unlikely to cause any problems. However, you might have to make some changes. You might have configured the user that runs the Windows service `MQSeriesServices` without the user right to `Log on as a service`. Alternatively, the user might not have `List Folder` privilege on all the subdirectories from the root of the drive to the location of the service `amqsvc.exe`.

This information has moved. See Windows:`amqmsrvn.exe` process removed.

IgnoredErrorCodes registry key on Windows: Windows

From Version 7.1, the registry key used to specify error codes that you do not want written to the Windows Application Event Log has changed.

This information has moved. See Windows: IgnoredErrorCodes registry key.

Installation and infrastructure information on Windows: Windows

From Version 7.1, the location of Windows installation and infrastructure information has changed.

This information has moved. See Windows: Installation and infrastructure information.

Local queue performance monitoring on Windows: Windows

On Windows, from Version 7.1, it is no longer possible to monitor local queues using the Windows performance monitor.

This information has moved. See Windows: Local queue performance monitoring.

Logon as a service required on Windows:

From Version 7.1, the user ID that runs the IBM MQ Windows service must have the user privilege to `Logon as a service`. If the user ID does not have the privilege to run the service, the service does not start and it returns an error in the Windows system event log. Typically, you will have run the Prepare IBM MQ wizard, and set up the user ID correctly. Only if you have configured the user ID manually is it possible that you might have a problem in Version 7.1 or later.

This information has moved. See Windows: “Logon as a service” required.

MSCS restriction with multiple installations on Windows: Windows

When you install or upgrade to Version 7.1 or later, the first installation of the product on the server is the only one that can be used with Microsoft Cluster Server (MSCS). No other installations on the server can be used with MSCS. This restriction limits the use of MSCS with multiple installations of the product.

This information has moved. See Windows: MSCS restriction with multiple installations.

Migration of registry information on Windows: Windows

Before Version 7.1, all IBM MQ configuration information, and most queue manager configuration information, was stored in the Windows registry. From Version 7.1 onwards, all queue manager configuration information (for example, `mqs.ini`, `qmstatus.ini`, and `qm.ini`) is stored in files; the same files as in UNIX and Linux platforms.

This information has moved. See Windows: Migration of registry information.

Relocation of the mqclient.ini file on Windows: Windows

From Version 7.1, the `mqclient.ini` file has moved from FilePath to WorkPath. This is similar to the model already used on UNIX and Linux systems.

This information has moved. See Windows: Relocation of the mqclient.ini file.

Task Manager interpretation on Windows: Windows

From Version 7.1, the interpretation of the processes that are listed by the Windows Task Manager has changed. The results can show IBM MQ processes running for multiple installations on a server. Before Version 7.1, the process list identified IBM MQ processes running on only a single installation of the product on a Windows server.

This information has changed. See:
- Windows: Task manager interpretation
- Windows: changes from IBM MQ Version 8.0

IBM MQ Active Directory Services Interface on Windows: Windows

From Version 7.1, the IBM WebSphere MQ Active Directory Services Interface is no longer available.

This information has moved. See Windows: IBM WebSphere MQ Active Directory Services Interface.

GSKit: Changes from GSKit Version 7.0 to Version 8.0: Multi

For Multiplatforms, from IBM WebSphere MQ Version 7.1, GSKit Version 8.0 is integrated with IBM WebSphere MQ and is the only version of GSKit provided with the product. GSKit Version 7.0 is no longer provided.

This information has moved. See GSKit: Changes from GSKit V7.0 to GSKit V8.0.

GSKit: Some FIPS 140-2 compliant channels do not start: Multi

From IBM WebSphere MQ Version 7.1 three CipherSpecs are no longer FIPS 140-2 compliant. If a client or queue manager is configured to require FIPS 140-2 compliance, channels that use the following CipherSpecs do not start after migration.

This information has moved. See GSKit: Some FIPS 140-2 compliant channels do not start.

GSKit: Certificate Common Name (CN) not mandatory: Multi

In GSKit Version 8.0, the **iKeyman** command accepts any element of the distinguished name (DN), or a form of the subject alternative name (SAN). It does not mandate that you provide it with a common name. In GSKit Version 7.0, if you create a self-signed certificate using the **iKeyman** command you had to specify a common name.

This information has moved. See GSKit: Certificate Common Name (CN) not mandatory.

GSKit: Commands renamed: Multi

The command name **gsk7cmd** is replaced with **runmqckm** ; **gsk7ikm** is replaced with **strmqikm**, and **gsk7capicmd** is replaced with **runmqakm**. All the commands start the GSKit Version 8.0 certificate administration tools, and not the GSKit Version 7.0 tools.

This information has moved. See GSKit: Commands renamed.

GSKit: The **iKeyman** *commands to insert a certificate do not check that all required CA certificates are present:* Multi

The **iKeyman** command in GSKit V8.0 does not validate a certificate when it is inserted into a key repository. **iKeyman** in GSKit V7.0, validated a certificate before it inserted the certificate into a certificate store.

This information has moved. See GSKit: The **iKeyman** commands to insert a certificate do not check that all required CA certificates are present.

GSKit: PKCS#11 and IBM MQ JRE addressing mode: Multi

If you use **iKeyman** or **iKeycmd** to administer certificates and keys for PKCS#11 cryptographic hardware note that the addressing mode of the IBM MQ JRE for these tools has changed from IBM WebSphere MQ Version 7.1.

This information has moved. See GSKit: PKCS#11 and IBM MQ JRE addressing mode.

GSKit: Import of a duplicate PKCS#12 certificate: Multi

In GSKit V8.0, the **iKeyman** command does not report an attempt to import a duplicate PKCS#12 certificate as an error. In GSKit V7.0, the **iKeyman** command reported an error. In neither version is a duplicate certificate imported. For GSKIT V8.0, a duplicate certificate is a certificate with the same label and public key.

This information has moved. See GSKit: Import of a duplicate PKCS#12 certificate.

GSKit: Certificate stores created by **iKeyman** *and* **iKeycmd** *no longer contain CA certificates:* Multi

The **iKeyman** and **iKeycmd** utilities in GSKit V8.0 create a certificate store without adding pre-defined CA certificates to the store. To create a working certificate store, you must now add all the certificates that you require and trust. In GSKit V7.0 **iKeyman** and **iKeycmd** created a certificate store that already contained CA certificates. Existing data bases created by GSKit V7.0 are unaffected by this change.

This information has moved. See GSKit: Certificate stores created by **iKeyman** and **iKeycmd** no longer contain CA certificates.

GSKit: Password expiry to key database deprecated: Multi

In GSKit V8.0, the password expiry function in **iKeyman** continues to work the same as in GSKit V7.0, but it might be withdrawn in future versions of GSKit. Use the file system protection provided with the operating system to protect the key database and password stash file.

This information has moved. See GSKit: Password expiry to key database deprecated.

GSKit: Recompile LinuxC++ applications and update run time libraries: Multi

C++ IBM MQ MQI client and server applications on Linux must be recompiled using a supported version of the GNU Compiler Collection (GCC). The C++ run time libraries for this version of GCC must be installed in `/usr/lib` or `/usr/lib64`.

This information has moved. See GSKit: Recompile Linux C++ applications and update run time libraries.

GSKit: Signature algorithm moved out of settings file: Multi

In GSKit V8.0, the default signature algorithm used when creating self-signed certificates or certificate requests or selected in the creation dialogs is passed as a command-line parameter. In GSKit V7.0, the default signature algorithm was specified in the settings file.

This information has moved. See GSKit: Signature algorithm moved out of settings file.

GSKit: Signed certificate validity period not within signer validity: Multi

In GSKit V8.0, the **iKeyman** command does not check whether the validity period of a resulting certificate is within the validity period of the signed certificate. In GSKit V7.0, **iKeyman** checked that the validity period of the resulting certificate was within the validity period of the signed certificate.

This information has moved. See GSKit: Signed certificate validity period not within signer validity.

GSKit: Stricter default file permissions: Multi

The default file permissions set by **runmqckm** and **strmqikm** in IBM WebSphere MQ Version 7.1 or later on UNIX and Linux are stricter than the permissions that are set by **runmqckm**, **strmqikm**, **gsk7cmd**, and **gsk7ikm** in earlier releases of IBM MQ.

This information has moved. See GSKit: Stricter default file permissions.

Migration paths

You can find topics about direct migration to the current release of IBM MQ in this release of the IBM MQ product documentation. Paths between other releases are described in previous releases of the product documentation, which are available on the web.

Multi

Migration paths: IBM MQ for Multiplatforms

Note: Backward migration is not possible.

It is impossible to restore a queue manager from Version 7.0.1 to an earlier version. If a queue manager has not been started, it is possible to uninstall the current version and reinstall a different version of IBM MQ. It does not matter what versions of IBM MQ are installed between when a queue manager was last started and when it is next started.

Table 79. Migration paths: IBM MQ for Multiplatforms

From / To	**Version 7.1, Version 7.5, or Version 8.0**	**Version 9.0**
Prior to Version 7.0.1	Follow the instructions for your current version. For more information about where to find the documentation for older versions of the product, see Documentation for older versions of IBM MQ. **Note:** In the case of migration to Version 8.0, direct migration is not possible. You must follow an indirect migration path, which involves migrating IBM MQ more than once.	Direct migration is not possible. You must follow an indirect migration path, which involves migrating IBM MQ more than once.
Version 7.0.1 or later	Follow the instructions for your current version. See the IBM MQ product documentation in IBM Knowledge Center. From / To	Version 7.1 or Version 8.0	Version 9.0
Prior to Version 7.0.1	Follow the instructions on the web for your current version. See the IBM MQ documentation library web page for further details. **Note:** In the case of Version 8.0, direct migration is not possible. You must follow an indirect migration path, which involves migrating IBM MQ more than once.	Direct migration is not possible. You must follow an indirect migration path, which involves migrating IBM MQ more than once. See "Migrating from earlier unsupported releases of IBM WebSphere MQ for z/OS" on page 789 for further information.
Version 7.0.1 or later	Follow the instructions for your current version. See the IBM MQ product documentation in IBM Knowledge Center.	"Planning to migrate to the latest release on z/OS" on page 772

To revert an IBM MQ for z/OS queue manager to an earlier version, see "Reverting a queue manager to a previous release on z/OS" on page 801.

Migration concepts and methods

An overview of the various concepts and methods for migrating from one release of the product to another.

Objects to consider during migration

It is important to consider four types of object during migration:

Operating environment migration
Upgrading the operating environment, or components in the environment such as installing a new level of JRE; see "IBM MQ operating environment migration" on page 648

Queue manager migration
Migrating a queue manager following an upgrade of the IBM MQ installation to a new command level; see "Queue manager migration" on page 648.

IBM MQ MQI client migration
Migrating a client configuration following installation of a new version or release of the IBM MQ MQI client ; see "IBM MQ MQI client migration" on page 650.

Application migration
Relinking, recompiling, or recoding an IBM MQ server or client application; see "Application migration and interoperation" on page 652. Application migration also includes migrating any API or channel exits

Impact of migration on other queue managers or clients

In addition, you must consider the impact of migrating one queue manager, or IBM MQ MQI client, on other queue managers or clients:

Compatibility, coexistence, and interoperability
See "Coexistence, compatibility, and interoperability" on page 663 for information about the compatibility of IBM MQ applications connected to queue managers and IBM MQ MQI client clients on different command levels. The section also explains the concept of queue manager coexistence, and the interoperability of IBM MQ JMS applications with WebSphere Application Server.

Queue manager clusters

Can a queue manager cluster contain queue managers at different command levels? See "Migrating a queue manager cluster" on page 808 to answer this question, and how to migrate a cluster of queue managers.

z/OS **Queue-sharing groups**

Queue-sharing groups involve multiple queue managers running on z/OS. How do you migrate queue managers that are part of a queue-sharing group to a new command level; see "Queue-sharing group migration" on page 805.

High-availability clusters

How do you migrate queue managers that are part of a high-availability cluster to a new command level, and maintain continuous and reliable service? See "Migrating a queue manager in a high-availability configuration" on page 814, which covers both migration of multi-instance queue managers, and the migration of queue managers operating in high-availability clusters.

IBM MQ application migration model

Figure 61 on page 647 shows two runtime operating system environments. One environment is called `Server`, and contains an IBM MQ server and server application. The other is called `Client`, and contains an IBM MQ MQI client application. The server environment has one or more queue managers represented by **`QM`** using the installation of IBM MQ installed on the server.

The queue manager labeled `QM-n?` coexists on the same server as `QM`, but runs at a different release level. Multiple releases of IBM MQ installed in the same operating environment are called coexistent [2] . The IBM MQ installations for different release levels are not shown. The question-mark in the queue manager name indicates this capability might not be present in your environment.

z/OS Only z/OS supports multiple queue managers coexisting at different release levels in the same operating environment.

Queue manager coexistence is important for migration in two respects:

1. It can be used to reduce the risk involved in migrating to a new command level, and reduce the downtime during the migration process.
2. You must consider any configuration implications of running some applications or clusters on the same server with queue managers at different command levels.

For more information, see "Queue manager coexistence" on page 664.

The queue manager, `QM*`, represents queue managers of various levels installed on other servers.

The following diagram shows a client and server, each of which contains a number of software components, such as databases, application servers, and the language or subsystem run time environment. The environment contains an IBM MQ application, the IBM MQ MQI client or server library, and IBM MQ channel and API exit programs. These components are connected to a queue manager component, either locally in the server, or remotely to the same server queue manager from the client. The application is linked to the IBM MQ library by the MQI. The libraries are shown linked to the queue manager either by an SPI, which describes the connection between the process running the MQI and the queue manager processes, or by an IBM MQ MQI client connection. The diagram also shows the queue manager linked to another queue manager at a different level on another server, and also a queue manager, QM-n, on the same server. The queue manager called QM-n is running at a lower level. It represents a number of queue managers of different versions, coexisting on the same server.

2. It is not necessary, but it is usual, for coexistent installations to be at different release levels.

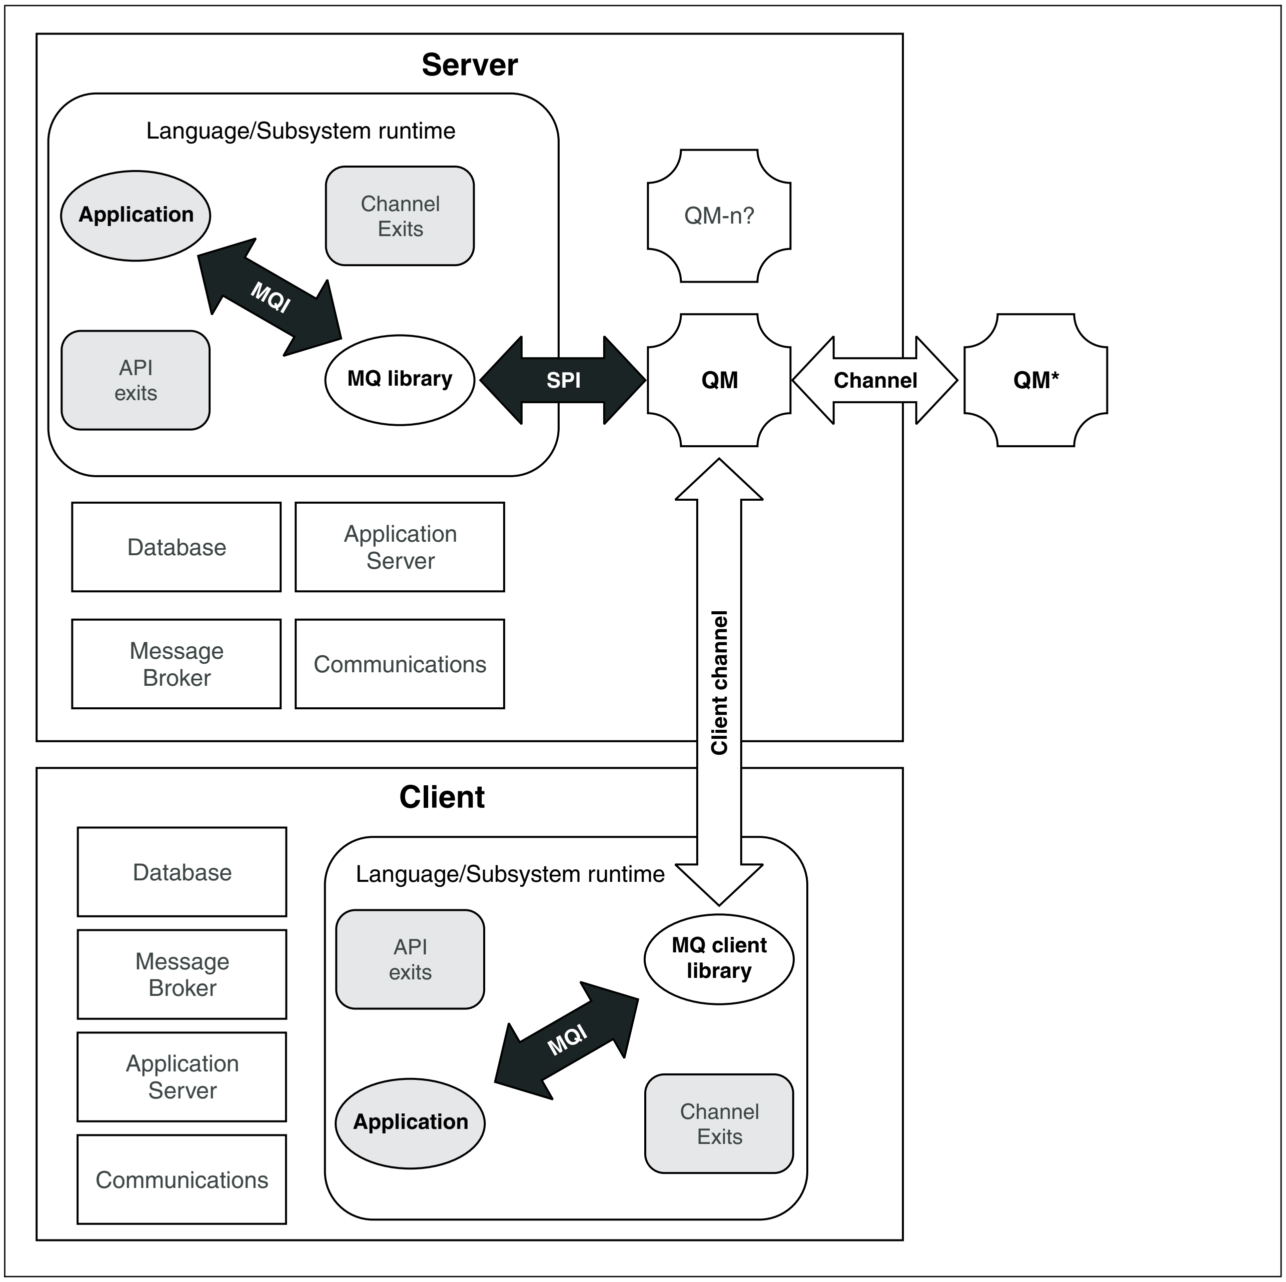

Figure 61. IBM MQ application migration model

IBM MQ operating environment migration

You might need to perform some migration tasks for IBM MQ as a result of upgrading the operating environment.

To find out what operating environment upgrades you must make before upgrading IBM MQ, compare the requirements for different releases. For more information about system requirements, see System Requirements for IBM MQ.

Note that the System Requirements page for IBM MQ Version 9.0 uses the Software Product Compatibility Reports (SPCR) tool.

By selecting the appropriate link on the web page, the SPCR tool enables you to go directly to the following information for the specific operating system, or systems, that your enterprise uses.

- Supported operating systems
- Prerequisites
- System requirements
- Optional supported software

For details about operating environment changes in the latest release that directly affect the migration to a new version of IBM MQ, see the following information:

- V 9.0.0 What's new and changed in IBM MQ Version 9.0
- CD What's new and changed in Version 9.0.x Continuous Delivery
- LTS What's changed in Version 9.0.0.x Long Term Support
- LTS CD Readme for IBM MQ V9.0 and its maintenance

For information about what changed in an earlier release of the product, see the *What's changed* section in the product documentation for that release:

- What's changed in IBM MQ Version 8.0
- What's changed in IBM WebSphere MQ Version 7.5
- What's changed in IBM WebSphere MQ Version 7.1
- What's changed in IBM WebSphere MQ Version 7.0.1

Some changes might affect IBM MQ migration indirectly. For example, the runtime linkage conventions for applications, or the way memory is allocated, might change.

Queue manager migration

After upgrading an installation, queue manager migration might be required. Migration takes place when you start a queue manager. You can remove an upgrade before you have started a queue manager. However, if you remove the upgrade after a queue manager has been started, the queue manager will not work.

Migrating a queue manager to a later release

z/OS On IBM MQ for z/OS, queue manager migration is required after upgrading to a different version, release, or maintenance level of the product. The upgrade changes the command level. The current command, or VRM, level is shown in the z/OS console log.

Multi On IBM MQ for Multiplatforms, queue manager migration is always required for changes in the first two digits of the VRMF code. Changes in the maintenance and fix level, M and F in the VRMF code, never cause automatic queue manager migration. No migration was required for the upgrade from Version 7.0 to Version 7.0.1. The change from Version 7.0 to Version 7.0.1 did change the command level from 700 to 701. From Version 7.1 onwards, a change in the command level always requires queue manager migration, but if the change is shipped in a maintenance or fix pack, you have the choice of whether to increase the command level, and cause queue manager migration.

Command level always increases with a change in version or release. If you decide to use new function introduced in a maintenance level upgrade, you must change the command level. The converse is not the case. You do not have to change the command level when the fix level changes. You can decide to install the fix pack, but not use the new function. Whether or not you use the new function, the installation of the fix pack increases the maximum command level supported by the installation. Run the **dspmqver** command to display the current maximum supported command level.

Queue manager migration is the process of converting persistent queue manager data from one version to another. Persistent queue manager data includes log files and data in the queue manager directory. The data records changes to objects such as messages, subscriptions, publications, queue managers, channels, queues, and topics.

Queue manager migration is required and largely automatic.

z/OS On z/OS, you must migrate queue managers manually between compatibility mode and new function mode by setting the **OPMODE** parameter.

You can reduce the downtime and risk caused by queue manager migration, by verifying the new version first, using a different queue manager. Unless the platform supports queue manager coexistence, you need to perform the verification on a different server, or in a virtualized environment on the same server. If the platform you are upgrading supports queue manager coexistence, you can install the new version of IBM MQ on the same server, verify it, and minimize downtime to the time required to stop, backup, and restart the queue manager.

Note: If you are migrating a queue manager through multiple release levels, one level at a time, you must start the queue manager after each upgrade to migrate it. You must also start all the channels, to ensure they are migrated.

Restoring a queue manager to an earlier release

Multi For IBM MQ for Multiplatforms, you cannot restore a queue manager to an earlier release level after you have migrated it to a new release. You must back up your system before starting backwards migration. You can either back up queue manager data, or use a backup queue manager; see Backing up and restoring IBM MQ. Before backing up, you must stop the queue manager.

z/OS For IBM MQ for z/OS, the following considerations apply to migration:

- Before Version 7.0.1, it is possible to revert to an earlier level, as long as you have applied the correct PTFs. However, from Version 7.0.1 onwards, it is impossible to revert to an earlier release after switching a queue manager to new function mode by running with **OPMODE** *NEWFUNC*. Provided that you have not switched the queue manager to new function mode, you can backwards migrate, as described in Migration PTFs.
- LTS From Version 9.0, you can backwards migrate queue managers only if you are using the Long Term Support (LTS) release model, and provided that you have not set the **OPMODE** to NEWFUNC. For more information, see IBM MQ release types.
- On z/OS, you must migrate queue managers manually between compatibility mode and new function mode by setting the **OPMODE** parameter. If you have never switched a queue manager to new function mode, you can still run it against the earliest release it is compatible with. You must have applied compatibility PTFs to the earlier release before starting a queue manager at the new command level. The compatibility level is shown in the log.

Related concepts:

Multi "The version naming scheme for IBM MQ for Multiplatforms" on page 567
From IBM MQ Version 9.0, releases have a three digit Version, Release, and Modification (VRM) code or a four-digit Version, Release, Maintenance, and Fix (VRMF) level code.

z/OS "The version naming scheme for IBM MQ for z/OS" on page 569
On IBM MQ for z/OS, releases have a three digit Version, Release, and Modification (VRM) code. To run a queue manager at a different VRM level, you must migrate the queue manager, its applications, and the environment in which it runs. Depending on the migration path, the migration might require more or less effort.

z/OS "Upgrade and migration of IBM MQ on z/OS" on page 785
You can install new releases of IBM MQ to upgrade IBM MQ to a new release, or version level. Multiple installations at the same or different levels can coexist on the same z/OS instance. Running a queue manager at a higher level requires migration.

Related tasks:

The procedures for migrating a queue manager to a later version of the product, and for restoring a queue manager to an earlier version of the product are detailed in this section.

IBM i "Migrating a queue manager to a later version on IBM i" on page 751
Follow these instructions to migrate a queue manager from an earlier release to a later release.

Related reference:

z/OS "OPMODE on z/OS" on page 781
The availability of new functions and backward migration for IBM MQ for z/OS is controlled by the **OPMODE** parameter in the **CSQ6SYSP** macro. IBM MQ Version 8.0 new functions that are restricted by **OPMODE** are not available at Version 9.0 unless enabled with **OPMODE**. There are no new functions in Version 9.0 that are restricted by **OPMODE**.

Related information:

Restoration of a queue manager to an earlier version on all platforms:

You can remove an upgrade before you have started a queue manager. However, if you remove the upgrade after a queue manager has been started, the queue manager will not work.

This information has moved. See "Queue manager migration" on page 648.

IBM MQ MQI client migration

IBM MQ MQI client migration is the process of converting IBM MQ MQI client configurations, and client and server channels from one version to another. Client migration can take place after upgrading the IBM MQ MQI client, and is reversible.

Client migration on the client workstation is optional and manual. Client migration on the server is required and automatic. See "Changes that affect migration" on page 626 for links to further information about any client changes. You must upgrade an IBM MQ MQI client before migrating a client workstation to make use of new configuration options. You can make configuration changes to client and server connection channels on the server, but they have no effect on a client workstation, until the client is upgraded.

An example of client migration performed at the client workstation is to manually migrate configuration settings to the `mqclient.ini` configuration file.

An example of combined client and server migration is the deployment of a new client connection definition table (CCDT). To use a new version of the CCDT, generate the table on a queue manager that is at the new code level. Deploy the table to clients that are going to use it. To deploy the table to a client, you first must update the client to at least the same level as the queue manager that created the table.

An IBM MQ MQI client can interoperate with earlier and later versions of IBM MQ. Upgrading the IBM MQ MQI client makes new function available to client applications, and is important to maintain the service level. Migrating an IBM MQ MQI client gives it access to new configuration options.

The IBM MQ MQI client libraries, such as `mqic.dll`, are dynamic, and the application linkages to the libraries do not normally change. You do not relink a client application to pick up new IBM MQ client libraries. The client picks up the new library next time the library is loaded by the client application. Do not move libraries from their installed directory. Linking to libraries in anything other than their installed directory is an unsupported configuration.

Related concepts:

"Application compatibility and interoperability with earlier versions of IBM MQ" on page 676
Connecting an application that is built against libraries shipped with a later version of IBM MQ to an earlier version IBM MQ is not supported. Avoid building applications against a later version, and redeploying them to a queue manager running at an earlier version, although some applications do work in practice.

"Application compatibility and interoperability with later versions of IBM MQ" on page 678
IBM MQ applications run against later versions of a queue manager without recoding, recompiling, or relinking. You can connect an application that is built against libraries shipped with an earlier version of IBM MQ to a queue manager running at a later version of IBM MQ.

Related reference:

"MQI client: Client Channel Definition Table (CCDT)" on page 680
You can connect an IBM MQ MQI client application to any level of queue manager. If a client uses CCDT to connect to a queue manager, the CCDT can be at a version greater than, less than, or equal to that of the client.

"MQI client: Default behavior of client-connection and server-connection channels" on page 681
In Version 7.0 the default settings for client and server connection channels changed to use shared conversations. This change affects the behavior of heartbeats and channels exits, and can have an impact on performance.

"MQI client: MQPUT1 sync point behavior change" on page 683
An MQPUT1 call by an IBM MQ MQI client application that failed in IBM WebSphere MQ Version 6.0 can now sometimes succeed. The failure is returned to the application later, if it calls MQCMIT. For the

change in behavior to occur, the MQPUT1 must be in sync point.

Application migration and interoperation

IBM MQ supports running applications compiled and linked against previous versions of IBM MQ, with later levels of IBM MQ. IBM MQ applications might require migration between Version 7.1 and the latest version.

To migrate an application to run with a new level of IBM MQ, disconnect an application from the queue manager. Reconnect it when the queue manager is running again. However, it takes only one small difference in the interface between IBM MQ and the application to break an application, or make it behave wrongly. Sometimes a problem does not show up for a long time. For this reason, you must always test your applications against a new version of IBM MQ. The suggested extent of testing varies depending on the extent of the changes in IBM MQ ; see “Characteristics of different types of upgrade on z/OS” on page 786 or “Characteristics of different types of upgrade” on page 619.

Application migration refers to four kinds of changes.

1. Application changes that are consequent to upgrading the operating environment along with the queue manager. Rarely, linkage conventions change. The most likely reason for a linkage change is switching from 32 bit to a 64 bit environment. If you are using SSL or TLS you might have to relink with a new secure library.
2. Changes that you must make to the application in order to run an application against a new level of queue manager. Changes of this sort are uncommon. However, you must check “Changes that affect migration” on page 626 to see if any changes might affect your applications.
3. Changes that are not required, but that you might want to make in future, perhaps because you have a business reason to modify an application.
4. Changes to applications that are supplied by IBM, or other vendors, that require you to run migration utilities. The utilities convert the applications to running on the new version of IBM MQ.

Do not load IBM MQ libraries from an earlier level. IBM MQ does not support connecting server applications loading libraries from the earlier level to connect to a later level of queue manager. On UNIX, Linux, and Windows platforms, the application load path must be set up to the location of the IBM MQ server libraries. You do not have to recompile and relink an application. Applications compiled and linked against an earlier version of IBM MQ can load libraries from a later version.

Multi On Multiplatforms, from Version 7.1 onwards, IBM MQ loads the library from the installation the application is connecting to. An application must initially load a library of at least the same level as the application linked to. IBM MQ then loads the correct version of the library from the installation that the queue manager is associated with. If you have two installations of the same version, but at different fix levels, IBM MQ chooses which library to load. The choice is based on the queue manager the application is connected to. If an application is connected to multiple queue managers, it is possible that multiple libraries are loaded.

To help you write applications that can exchange messages with earlier versions of the product, IBM MQ provides data type versioning. Data type versioning assists you in exchanging messages that are compatible with target queue managers. A good programming practice is to set the version number of a data structure explicitly. Do not assume that the default version is the one you require. By setting the version explicitly, you are forced to look up what version to use. The description of the data type version tells you what level of queue manager supports that version.

It is poor practice to set the data type version to the current version. If you recompile your program against a new version of IBM MQ, the data type version might change with unexpected consequences.

Client applications are more likely to connect to different queue managers than applications written for a specific server. Plan carefully when writing an application that is to connect to different versions of a queue manager, and to queue managers on different platforms. The default values of some IBM MQ constants, such as `MQPMO_SYNCPOINT`, `MQPMO_NO_SYNCPOINT` differ between platforms. Some functions are not available on all platforms.

You must be aware of, and code to, the capabilities of all the queue managers the application interacts with. It requires planning and design to write an application that works with different versions of a queue manager. There is no API provided with IBM MQ to restrict an application to a function subset common to the set of queue managers it interacts with. To improve interoperability, some developers choose to provide an MQI wrapper layer, or use MQI API exits, to control the functions programs use.

Connection authentication

For a new IBM MQ Version 8.0, or later, installation, the **`CONNAUTH CHCKLOCL`** attribute will be set to `OPTIONAL`. This means that user IDs and passwords are not required, but if they are provided they must be a valid pair, or they will be rejected.

When you are migrating between IBM WebSphere MQ Version 7.1 and the latest version, the **`CONNAUTH CHCKLOCL`** attribute on each queue manager is set to `NONE`, ensuring version to version continuity, but switching connection authentication off.

For more information see Connection authentication: Configuration.

Related tasks:

UNIX Linux "Migrating IBM MQ library loading to a later version on UNIX and Linux" on page 739
On UNIX and Linux, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to a later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

Windows "Migrating IBM MQ library loading to a later version on Windows" on page 709
On Windows, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

Migration methods on IBM MQ for Multiplatforms

Multi

There are three main methods of migrating from one release to another: Single-stage migration (called a slip installation on IBM i), side-by-side migration, and multi-stage migration. Multi-stage migration is not an option for IBM i.

Single-stage migration

Single-stage migration is the term that is used to describe replacing the only installation of IBM MQ on a server, with a later release. Before IBM WebSphere MQ Version 7.1, single-stage was the only migration scenario.

The advantage of single-stage migration is that it changes the configuration of a queue manager on the earlier version as little as possible. Existing applications switch from loading the libraries from the earlier version, to loading the libraries of the later version, automatically. Queue managers are automatically associated with the installation on the later version. Administrative scripts and procedures are affected as little as possible by setting the installation to be the primary installation. If you set the installation of the later version to be the primary installation, commands such as **strmqm** work without providing an explicit path to the command.

Of the three approaches, single-stage migration preserves the greatest number of existing scripts and procedures for running IBM MQ. However, the other migration approaches support a gentler transition to the new version, which can reduce the overall impact on users.

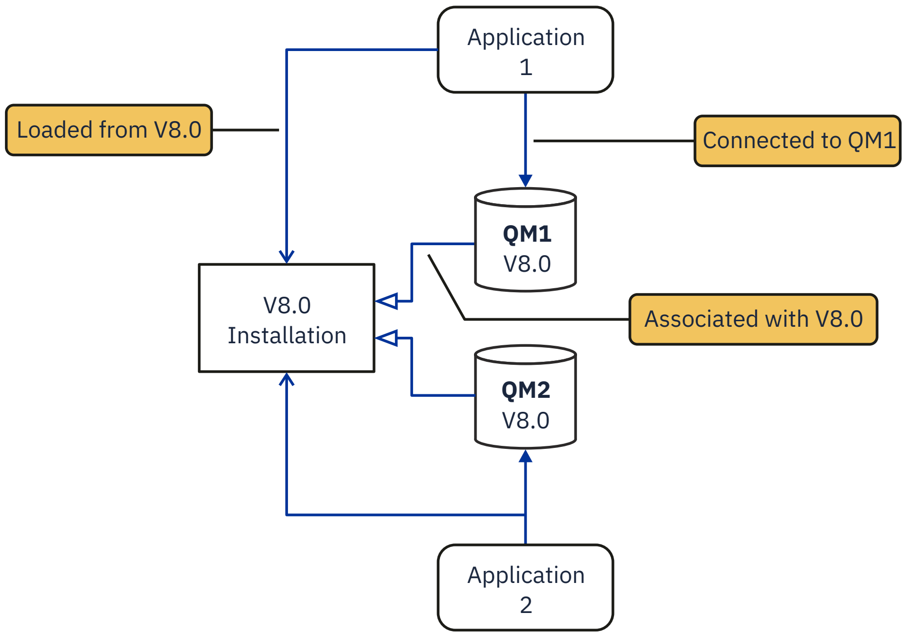

Figure 62. Single_stage migration: earlier version installed with connected queue managers and associated applications

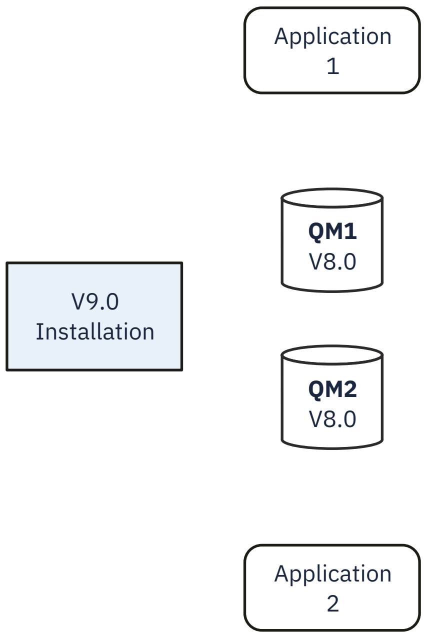

Figure 63. Single_stage migration: later version installed but queue managers not yet connected and applications not yet associated

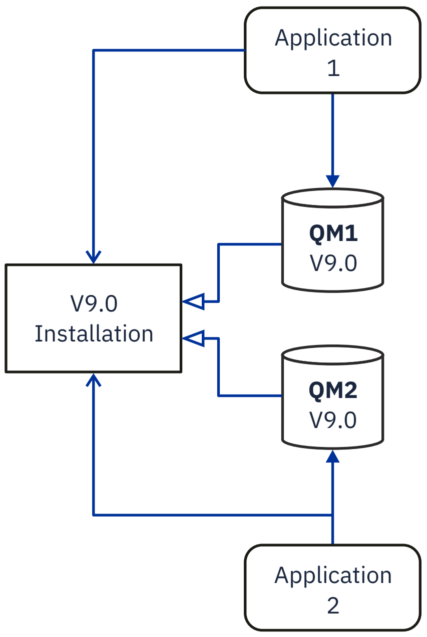

Figure 64. Single_stage migration: migrated queue managers connected to and applications associated with later version

For more information about single-stage migration, see:
- UNIX Linux "Migrating on UNIX and Linux: single-stage" on page 724
- Windows "Migrating on Windows: single stage" on page 694

- IBM i "Installation methods on IBM i" on page 752 (on IBM i, a single-stage migration is called a slip installation)

Side-by-side migration

On UNIX, Linux and Windows, side-by-side migration is the term that is used to describe installing a later version of IBM MQ alongside an older version on the same server. The side-by-side migration scenario sits half-way between the single-stage and multi-stage migration scenarios and is based on the following premise:

- Install additional IBM MQ code alongside existing installation while queue managers are still running.
- Move queue managers one at a time to the new installation.
- Migrate and test applications one at a time.

During the installation and verification of the later version of IBM MQ, queue managers continue running, and remain associated with the older version of IBM MQ.

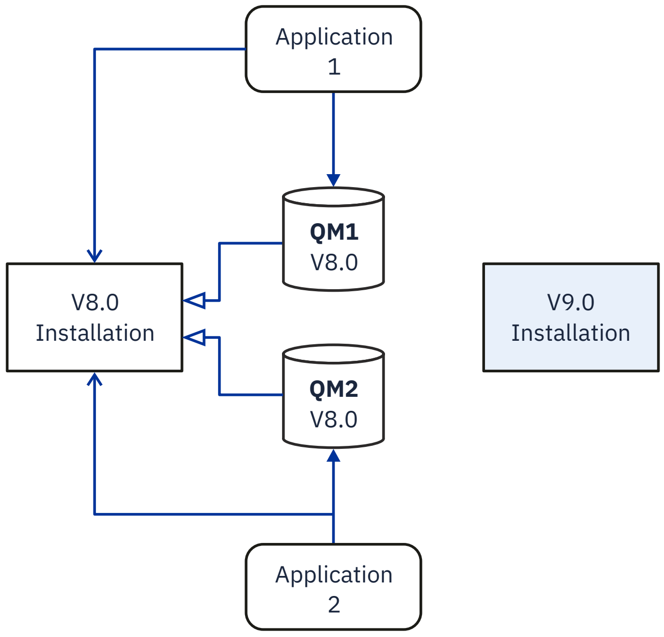

Figure 65. Side-by-side migration: later version installed but queue managers still connected to and applications still associated with earlier version

When you decide to migrate queue managers to the later version of IBM MQ, you stop all queue managers, migrate them all to the later version, and uninstall the earlier version of IBM MQ.

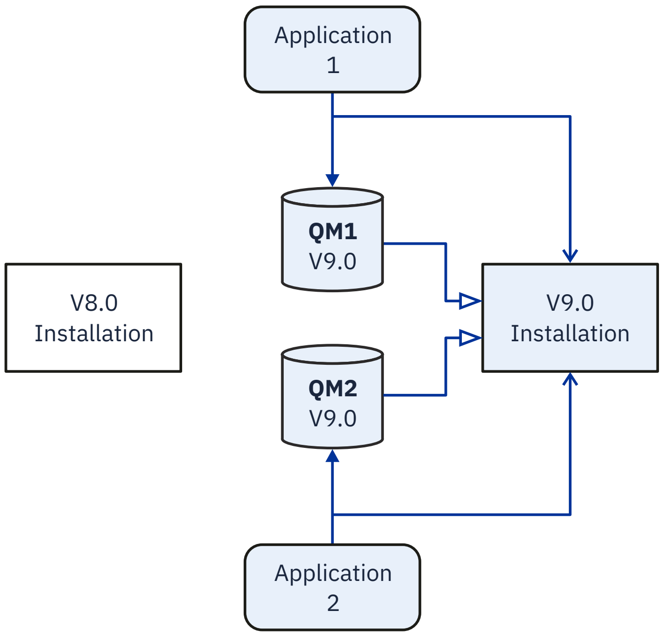

Figure 66. Side-by-side migration: migrated queue managers connected to and applications associated with later version

The advantage that the side-by-side migration has over the single-stage migration is that you can install and verify the later IBM MQ installation on the server before you switch over to it.

Although side-by-side migration is less flexible than multi-stage migration, it does have some advantages over the multi-stage approach. With the side-by-side approach, you can assign a later version of IBM MQ to be the primary installation, whereas, with the multistage approach, you cannot do so, if IBM WebSphere MQ Version 7.0.1 is installed, until you uninstall IBM WebSphere MQ Version 7.0.1. With a later version of IBM MQ set as the primary installation, many applications restart without having to reconfigure their environment, and IBM MQ commands work without providing a local search path.

For more information about side-by-side migration, see:
- UNIX Linux "Migrating on UNIX and Linux: side-by side" on page 727
- Windows "Migrating on Windows: side-by-side" on page 699

Note: IBM i Side-by-side migration has a different meaning on IBM i. A side-by-side installation upgrades IBM MQ on a different computer. For more information, see "Installation methods on IBM i" on page 752. Multiple installations are not applicable to IBM i.

ULW
Multi-stage migration

Multi-stage migration is the term that is used to describe running a later version of IBM MQ alongside an older version on the same server. Multi-stage migration is the most flexible approach.

After you install the later version alongside the earlier version, you can create new queue managers to verify the installation of the later version, and develop new applications. At the same time, you can migrate queue managers and their associated applications from the earlier version to the later version. By migrating queue managers and applications one by one, you can reduce the peak workload on your staff who are managing the migration.

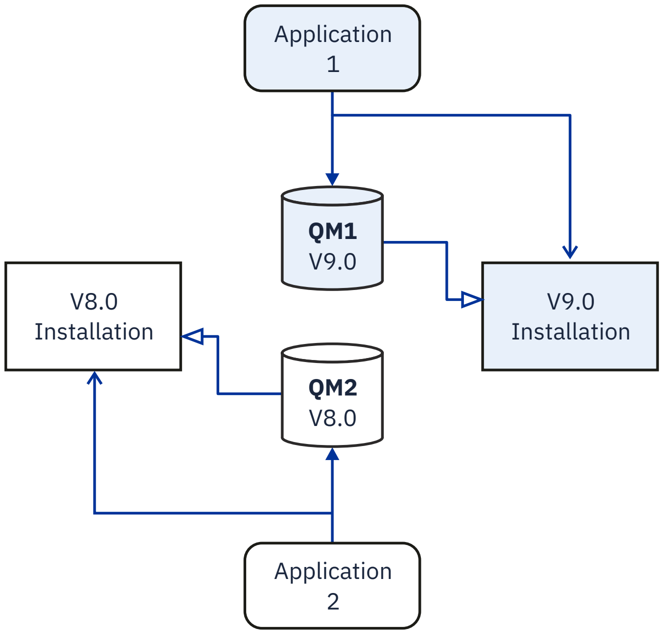

Figure 67. Multi-stage migration: one queue manager and application migrated to later version, and another queue manager and application still at earlier version

For more information about multi-stage migration, see:

- UNIX Linux "Migrating on UNIX and Linux: multi-stage" on page 730
- Windows "Migrating on Windows: multi-stage" on page 701

Related concepts:

z/OS "Upgrade and migration of IBM MQ on z/OS" on page 785
You can install new releases of IBM MQ to upgrade IBM MQ to a new release, or version level. Multiple installations at the same or different levels can coexist on the same z/OS instance. Running a queue manager at a higher level requires migration.

Primary installation on UNIX, Linux and Windows

ULW

On UNIX, Linux, and Windows, which support multiple installations of IBM MQ, you can optionally define one installation as the primary installation. The primary installation is the one to which IBM MQ system-wide locations refer.

Overview

From Version 7.1, you can install multiple versions of the product on UNIX, Linux, and Windows, and configure one of these installations as the primary installation. The primary installation is:

- The installation to which system-wide locations refer
- Optional, but convenient

Before Version 7.1, only one instance of the product could be installed at any time, and the only installation was the primary installation.

You cannot change the primary installation while Version 7.0.1 is installed. However, if you uninstall Version 7.0.1, and then install Version 7.1 or later, the new installation is not by default the primary installation. If all the installations on the system are at Version 7.1, or later, you can choose whether to have a primary installation.

UNIX Linux

UNIX and Linux

The primary installation:

- Has symbolic links in `/usr/lib` and `/usr/bin`

  If you have not set a primary installation there are no symbolic links.
- Must be configured manually using the following command:

```
$ MQ_INSTALLATION_PATH/bin/setmqinst -i -p MQ_INSTALLATION_PATH
```

To locate your various installations, you can:

- Use the platform installation tools to query what is installed and where on the system
- Use the dspmqver command to display IBM MQ version and build information.
- Use the dspmqinst command to display installation entries from `mqinst.ini`.
- Use the following command to list the installations:

```
cat /etc/opt/mqm/mqinst.ini
```

Windows

Windows

The primary installation is:

- By default the first installation.
- Pointed to by global environment variables.
- Used by some operating system features that require central registration of interface libraries.

  For example, .NET monitor (transactional mode) and COM/ActiveX interface classes.

To locate your various installations, you can use the:

- Use the platform installation tools to query what is installed and where on the system
- Use the dspmqver command to display IBM MQ version and build information.
- Use the dspmqinst command to display installation entries from `mqinst.ini`.
- Use the following command to query the registry:

```
reg.exe query "HKLM\Software\[Wow6432Node\]IBM\WebSphere MQ\Installation" /s
```

Windows

Migration of Windows registry information

IBM WebSphere MQ Version 7.1 onwards uses `mqs.ini` and `qm.ini`.

However, if IBM WebSphere MQ Version 7.0.1 is still installed, IBM WebSphere MQ Version 7.1 or later still uses the registry.

To uninstall IBM WebSphere MQ Version 7.0.1 with IBM WebSphere MQ Version 7.1 or later already installed, you must complete the following steps:

- End all the queue managers and listeners.
- Uninstall IBM WebSphere MQ Version 7.0.1, which migrates the registry information into `mqs.ini` and `qm.ini`.
- IBM WebSphere MQ Version 7.1 now starts using `mqs.ini` instead.

Note: If for some reason the uninstallation process is interrupted, and the automatic migration does not run, a tool is provided to migrate the information out of the registry manually.

Primary installation

Multiple IBM MQ installations

ULW z/OS

From IBM WebSphere MQ Version 7.1, multiple IBM MQ installations are supported on UNIX, Linux, and Windows. This gives you the option to install and select between one or more IBM MQ installations.

Overview

You can select between:

- Simplicity of maintaining a single IBM MQ installation.
- Flexibility, by allowing up to a maximum of 128 IBM MQ installations on a system. The first of these 128 installs is reserved for an (optional) IBM WebSphere MQ Version 7.0.1 installation of level Version 7.0.1, Fix Pack 6 or above. The other installations must be IBM WebSphere MQ Version 7.1 or later.

You can install multiple copies of the same code level; this is especially convenient for maintenance purposes.

LTS For example, if you want to upgrade IBM MQ Version 9.0.0.0 to IBM MQ Version 9.0.0, Fix Pack 1, you can install a second copy of IBM MQ Version 9.0.0.0, apply the maintenance to bring it to IBM MQ Version 9.0.0, Fix Pack 1, and then move the queue managers across to the new installation.

You still have the original installation, so it is a simple matter to move the queue managers back if you encounter any problems.

Notes:

1. Linux Solaris On Linux and Solaris only, you must ensure that each package installed has a unique name.

   You need to use a tool to create a unique set of packages:

   - `$ crtmqpkg PACKAGE_SUFFIX`
   - This takes the IBM MQ installation packages, and repackages them with a new name of your choice. You then install as usual.
2. All installations share a data directory; this is where `mqs.ini` is located for example.
3. All installations share the same namespace for queue managers. This means that you cannot create several queue managers of the same name in different installations.
4. IBM MQ installations are fully relocatable; each installation has a separate installation path. You can choose where you would like to install IBM MQ.
5. IBM MQ resources have installation-scope resource isolation, so operations on one installation do not affect the others.

   This means that the resources created by one installation are isolated from those created by other installations. It enables actions, such as removing an installation of IBM MQ, while queue managers are running under another installation.
6. Queue managers are "associated" with an installation You can move them, but you cannot migrate data back to earlier releases.

Working with multiple installations

To work with a queue manager, you need to use the commands from its installation. If you select the wrong installation, you see:

```
AMQ5691: Queue manager 'MYQM' is associated with a different installation (Inst1)
```

To work with a queue manager, you have to use the control commands from its associated installation. You have a choice of:

- Using the full path to the control commands, for example:

  ```
  $ MQ_INSTALLATION_PATH\bin\strmqm MYQM
  ```

  or
- Setting the environment variables for an installation with one of:

  ```
  $ MQ_INSTALLATION_PATH/bin/setmqenv 's
  $ setmqenv -m MYQM
  $ setmqenv -n InstallationName
  $ setmqenv -p MQ_INSTALLATION_PATH
  ```

You might consider using a shell script or batch file to set up the environment for each IBM MQ installation. You can use the **setmqenv** or **crtmqenv** commands to help with this.

- setmqenv sets the values of the environment variables, such as PATH, CLASSPATH and LD_LIBRARY_PATH, for use with an IBM MQ installation.
- crtmqenv creates a list of the environment variables and their values for use with a particular IBM MQ installation. You can then use this list to incorporate into a shell script or batch file.

Commands

To run a command, the operating system must find the command in an IBM MQ installation. In general, you must run a command from the installation that is associated with the correct queue manager. IBM MQ does not switch commands to the correct installation. However, there are some exceptions, such as the **setmqinst** command, where you can run the command from any installation that has the latest version of the product installed.

Commands that work across installations

- dspmq (display queue managers)
- dspmqinst (display IBM MQ installation)
- dspmqver (display version information)
- setmqinst (set IBM MQ installation)

Other control commands for multiple installations

- crtmqenv (create IBM MQ environment)
- dspmqinst (display IBM MQ installation)
- setmqenv (set IBM MQ environment)
- setmqinst (set IBM MQ installation)
- setmqm (set queue manager)

If an earlier version of the product is installed, the command that is run is the command for that version, unless the search path is overridden by a local setting. You can override the search path by running **setmqenv**. If Version 7.0.1 is not installed, you must set the correct path to run a command. If you have set a primary installation, the command that is run is the copy in the primary installation, unless you override the selection with a local search path.

z/OS

Multiple releases on z/OS

Multiple releases can exist on z/OS. You use STEPLIBs to control which level of IBM MQ is used. For more information, see "Coexistence" on page 664.

Related information:
Multiple installations

Multiple installations and application programs: ULW

When a local application connects to a queue manager, the application needs to load the libraries from the installation associated with the queue manager. Multiple installations introduce some complexity.

Using the `setmqm` command

When you use setmqm to change the installation associated with a queue manager, the libraries that need to be loaded change.

When an application connects to multiple queue managers owned by different installations, multiple sets of libraries need to be loaded.

Note: If you link your applications to IBM WebSphere MQ Version 7.1 or later libraries, the applications automatically load the appropriate libraries when the application connects to a queue manager.

Loading IBM MQ libraries in a multi-version environment

How libraries are located depends upon your environment.

If IBM WebSphere MQ Version 7.1 or later is installed in the default location, existing applications continue to work as before. Otherwise, you might need to rebuild the application or change your configuration.

The order in which libraries are searched, depends upon the platform you are using:
- Windows
  - The application's directory
  - The current directory
  - The global and your PATH variables
- Other platforms
  - LD_LIBRARY_PATH (or LIBPATH/SHLIB_PATH)
  - An embedded search path (RPath)
  - The default library path

Table 81. Options for loading libraries

Platform	Option	Benefits	Drawbacks
UNIX	Set/change the embedded runtime search path (RPath)	The path is explicit in the way the application is built	You need to recompile and link If you move IBM MQ, you must change RPath

Table 81. Options for loading libraries (continued)

Platform	Option	Benefits	Drawbacks
UNIX	Set LD_LIBRARY_PATH or equivalent using setmqenv	Overrides RPath No changes to existing applications Easy to change if you move IBM MQ	Depends on environment variables Possible impacts on other applications
Windows	Set PATH using setmqenv	No changes to existing applications Easy to change if you move IBM MQ	Depends on environment variables Possible impacts on other applications
All	Set the primary installation to IBM WebSphere MQ Version 7.1 or later	No changes to existing applications Easy to change the primary installation Similar behavior to previous versions of IBM MQ	While IBM WebSphere MQ Version 7.0.1 is installed, you cannot make IBM WebSphere MQ Version 7.1 the primary installation UNIX: Relies on `/usr/lib` in the default search path

Multiple installations

Coexistence, compatibility, and interoperability

The definitions of the IBM MQ terms coexistence, compatibility, and interoperability.

Coexistence
: Is being able to install and run two or more versions of the same program on the same server. For IBM MQ, it normally means installing and running multiple versions of IBM MQ on a server.

Compatibility
: Is the ability to run applications from one level of queue manager with an earlier, or previous level, of the queue manager.

  If you are using a message channel agent (MCA) channel, any version and release of an IBM MQ queue manager can connect, using an MCA channel, to any version and release of another IBM MQ queue manager.

  The MCA channel is automatically configured to the latest version of protocol that is supported by both ends of the channel.

  Compatibility is also the ability to run client applications with different versions of the IBM MQ MQI client, and different levels of the queue manager.

Interoperability
: Is mainly the ability to exchange messages between different versions of IBM MQ. It can also mean the interoperability between others things, such as publish/subscribe brokers, or between components such as the IBM MQ classes for JMS and WebSphere Application Server.

Maintaining the compatibility, coexistence, and interoperability of IBM MQ is important in order to preserve the investment you make in applications and administrative procedures.

Three areas to which this objective does not apply to as rigidly, are:

- GUI interfaces, such as IBM MQ Explorer.
- Information for service, such as FFST files and traces.

- Error messages. The text in an error message might change, to make the wording clearer or more accurate.

Coexistence

Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations. In addition to queue managers coexisting on a server, objects, and commands must work correctly with different queue managers running at different command levels.

z/OS

Multiple queue manager versions in z/OS

There can be several IBM MQ subsystems in a z/OS image, and they can use different versions of IBM MQ, provided that the IBM MQ early code modules are of the latest version being used. (These modules are loaded at z/OS IPL time and are shared among all the IBM MQ subsystems in the z/OS image.)

This means that you can run one queue manager at the latest version and another in the same image with an earlier version, provided that the early code is that of the latest version.

The coexistence section lists restrictions in the use of objects and commands when they are used with queue managers at multiple command levels. The queue managers might be running on a single server, or in a cluster.

Related concepts:

"Queue manager coexistence"
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

Related tasks:

"Migrating IBM MQ library loading from an earlier version of the product to the latest version" on page 684
No change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the latest version. You must have followed the instructions on building IBM MQ applications in the earlier version, and you must replace the earlier version with the latest version of the product. If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

Queue manager coexistence: ULW

Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

Single installation queue manager coexistence on all platforms

Single installation queue manager coexistence is useful in development and production environments. In development environments, you can set up different queue manager configurations to support different development activities. You can also work with multiple queue manager configurations on a single server, connected by channels, as if deployed on a network.

In production environments configuring multiple queue manager on a single server is less common. It has no performance or functional advantage over a single queue manager configuration. Sometimes, you must deploy multiple queue managers on server. It might be essential to meet the requirements of a particular software stack, governance, administration, or as a consequence of the consolidation of servers.

Queue manager coexistence in a multi-installation

ULW On UNIX, Linux, and Windows, multi-installation [3] queue manager coexistence became available in Version 7.1.

z/OS Multi-installation queue manager coexistence has always been supported on z/OS.

With multi-installation queue manager coexistence on the same server, you can run queue managers at different commands levels on the same server. You can also run multiple queue managers at the same command level, but associate them with different installations.

Multi-installation adds more flexibility to the coexistence of queue managers using a single installation. Any of the reasons behind running multiple queue managers, such as supporting different software stacks, might require different versions of IBM MQ.

The biggest benefit of multi-installation identified by early users, is in upgrading from one version of IBM MQ to another. Multi-installation makes upgrading less risky, less costly, and is more flexible in meeting the migration needs of applications running on a server.

The key to migration flexibility is being able to install a new version alongside an existing installation; see Figure 68 on page 666, which is extracted from “Migrating on UNIX and Linux: side-by side” on page 727 or “Migrating on Windows: side-by-side” on page 699.

3. Do not confuse multi-installation queue manager coexistence with multi-instance queue managers. They are completely different, though they sound similar in English.

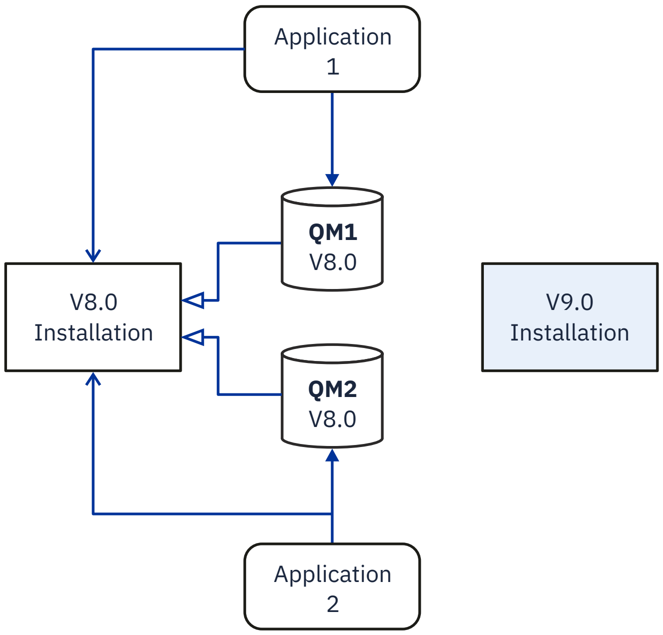

Figure 68. Side-by-side installation - step 2

When the installation is complete, and verified, migrate queue managers and applications to the new installation; see Figure 69. When migration is complete, uninstall the old installation.

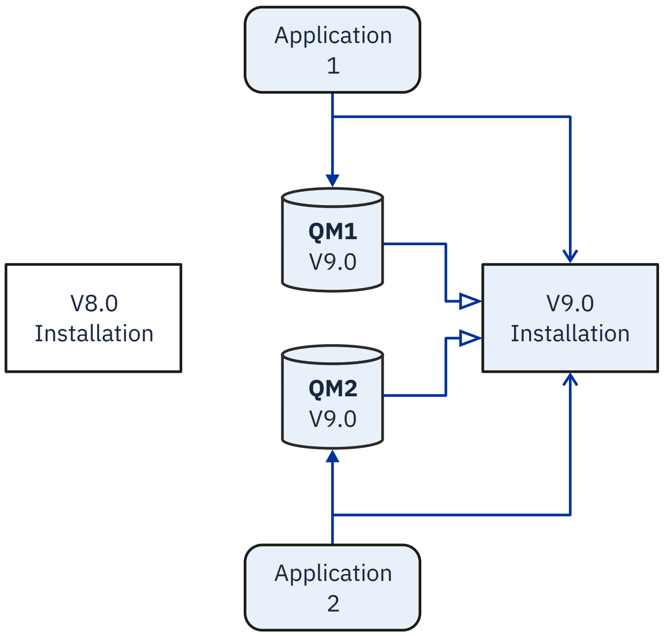

Figure 69. Side-by-side installation - step 4

Think of multi-installation as being the basis for a range of migration strategies. At one end is *single-stage*, in which you only have one installation on a server at a time. At the other end is *multi-stage* migration, in which you continue to run multiple installations at the same time. In the middle is side-by-side migration. Each of the three strategies is explained in the following tasks:

1. “Migrating on UNIX and Linux: single-stage” on page 724 or “Migrating on Windows: single stage” on page 694
2. “Migrating on UNIX and Linux: side-by side” on page 727 or “Migrating on Windows: side-by-side” on page 699
3. “Migrating on UNIX and Linux: multi-stage” on page 730 or or “Migrating on Windows: multi-stage” on page 701

LTS

Migration of queue managers to a new fix level

Another similar use of multi-installation is to support the migration of queue managers to a new fix level; see Figure 70. You maintain two installations, one of which has the latest fix pack applied, and the other has the previous maintenance levels. When you have moved all queue managers to the latest fix pack level, you can replace the previous fix pack with the next fix pack to be released. The configuration allows you to stage the migrating applications and queue managers to the latest fix pack level. You can switch the primary installation designation to the latest fix pack level.

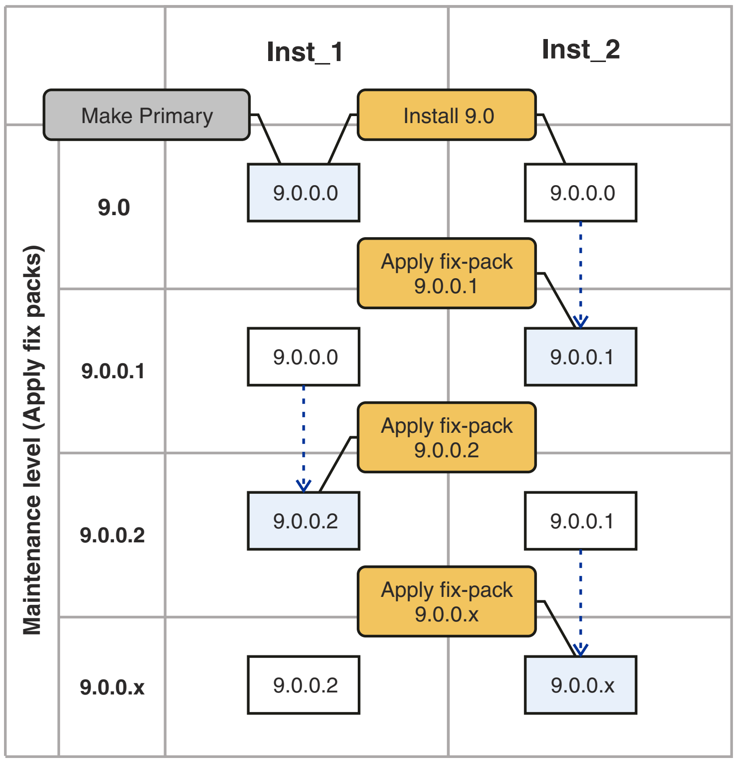

Figure 70. Rolling fix packs

Related concepts:

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows"
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

z/OS "Upgrade and migration of IBM MQ on z/OS" on page 785
You can install new releases of IBM MQ to upgrade IBM MQ to a new release, or version level. Multiple installations at the same or different levels can coexist on the same z/OS instance. Running a queue manager at a higher level requires migration.

If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

"Migrating IBM MQ library loading to a later version on UNIX and Linux" on page 739
On UNIX and Linux, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to a later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

"Staging maintenance fixes on Windows" on page 583
On Windows systems, you can use multiple installations of IBM MQ on the same server to control the release of maintenance fixes.

"Staging maintenance fixes on UNIX and Linux" on page 608
On UNIX and Linux, you can use multiple installations of IBM MQ on the same server to control the release of maintenance fixes.

"Migrating IBM MQ library loading to a later version on Windows" on page 709
On Windows, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

Multi-installation queue manager coexistence on UNIX, Linux, and Windows: ULW

You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

Figure 71 on page 669 shows two IBM MQ installations, two queue managers, and three applications. Applications 2 and 3 are connected to `QM2`, and application 1 is connected to `QM1`. Applications 1 and 3 load IBM MQ libraries from the `Inst_1` installation, and application 2 loads libraries from the Version 7.0.1 installation.

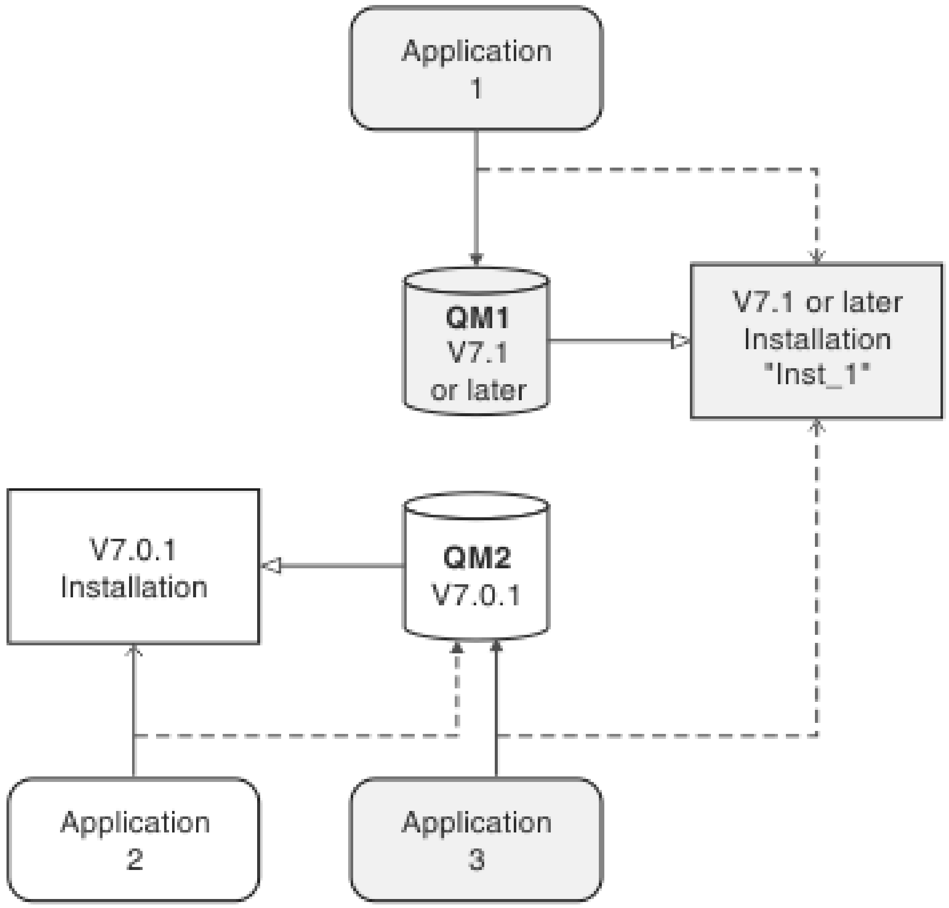

Figure 71. Coexistence of two queue managers using Version 7.0.1 and a later version installations

When you upgrade from Version 7.0.1 to a later version, you can choose to run Version 7.0.1 alongside the later version. The installation, illustrated in Figure 71, is called a multi-version installation. You can also install multiple copies of Version 7.1 alongside each other. That would be called multi-installation. Multi-installation is the more general term.

Version 7.0.1 did not support multi-installation on Multiplatforms. Before Version 7.1 becoming available, Version 7.0.1, Fix Pack 6 was shipped with some fixes to make Version 7.0.1 compatible with a later version on the same server. With Version 7.0.1, Fix Pack 6 installed, you can run one copy of Version 7.0.1 alongside multiple copies of the later version. You do not have to apply the fix pack to upgrade Version 7.0.1 to Version 7.1 “in-place” ; see “Migrating on UNIX and Linux: single-stage” on page 724 or “Migrating on Windows: single stage” on page 694.

A multi-version installation that includes Version 7.0.1, does not behave the same way as a multi-installation that does not. The differences primarily affect how you might choose to configure how applications load IBM MQ libraries, and run IBM MQ commands. Because of these differences, think of the multi-version support provided in Version 7.0.1, Fix Pack 6, as a migration aid to moving to a later version multi-installation environment. The topics that explain the restrictions in Version 7.0.1 multi-version are listed in related links.

If you run multiple installations of IBM MQ on a server you must consider three questions:

1. Which installation is a queue manager associated with; see “Queue manager association” on page 670?

2. Which installation does an application load; see "Loading IBM MQ libraries"?
3. Which installation is an IBM MQ command run from; see "Command association" on page 672?

Queue manager association

Before Version 7.1, queue managers on UNIX, Linux, or Windows were associated with the only installation on the server. With Version 7.1, or later, installed on the same server as Version 7.0.1, you can change the association of a queue manager to a later version by running **`setmqm`** ; see setmqm. You cannot change the association of a queue manager running a release of IBM MQ earlier than Version 7.0.1 because you cannot install a later version of the product on a server with an installation of IBM MQ earlier than Version 7.0.1.

A queue manager is permanently associated with an installation, until you choose to change the association with the **`setmqm`** command. You cannot associate a queue manager with an installation at a lower command level than the current command level of the queue manager.

In Figure 71 on page 669, `QM1` is associated with `Inst_1`. The association is made by running `setmqm -m QM1 -n Inst_1`. When `QM1` is first started, after running **`setmqm`**, if `QM1` was running Version 7.0.1, it is migrated to a later version. `QM2` is associated with Version 7.0.1 because the association has not been changed.

Loading IBM MQ libraries

The application connections to the queue managers are established by calling MQCONN or MQCONNX in the normal way.

Which IBM MQ library an application loads depends on the configuration of the operating system loader and on the IBM MQ installation the queue manager is associated with.

In Figure 71 on page 669, the operating system loads the IBM MQ library from the `Inst_1` installation for applications 1 and 3. It loads the IBM WebSphere MQ Version 7.0.1 library for application 2. The operating system has loaded the wrong library for application 3. Application 3 requires the IBM WebSphere MQ Version 7.0.1 libraries.

Figure 72 on page 671 shows what happens to application 3. Application 3 is connecting to `QM2`, and `QM2` is associated with the IBM WebSphere MQ Version 7.0.1 installation. IBM MQ detects that the operating system has loaded the wrong library to process calls from application 3 to `QM2`. IBM MQ loads the correct library from the IBM WebSphere MQ Version 7.0.1 installation. It transfers the MQCONN or MQCONNX call to the IBM WebSphere MQ Version 7.0.1 library. Subsequent MQI calls that use the connection handle returned by MQCONN or MQCONNX, call entry points in the IBM WebSphere MQ Version 7.0.1 library.

Because IBM WebSphere MQ Version 7.0.1 libraries cannot load IBM MQ libraries from other installations, there is no corresponding application in Figure 72 on page 671 that loads a IBM WebSphere MQ Version 7.0.1 library and connects to a queue manager running Version 7.1. If you attempt a connection to `QM1` with application 2, IBM MQ returns an error; see 2059 (080B) (RC2059): MQRC_Q_MGR_NOT_AVAILABLE.

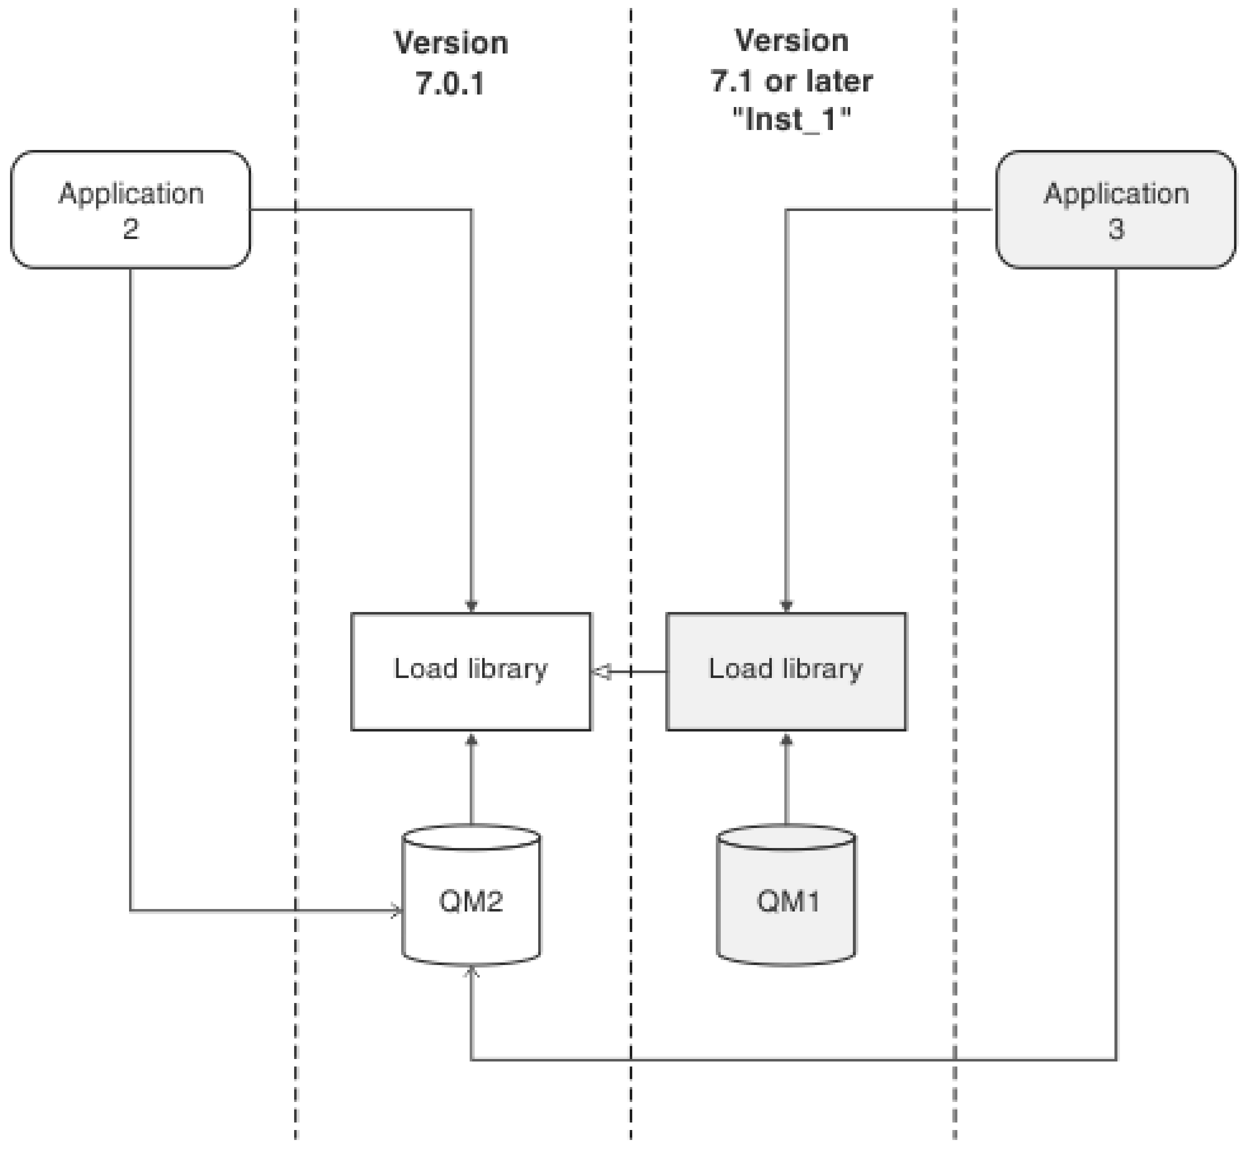

Figure 72. Loading calls in a different library

A Version 7.1, or later, IBM MQ library includes a routing capability that is based on the installation a queue manager is associated with. Earlier IBM MQ libraries do not have a routing capability. The operating system can load a library from any Version 7.1 installation, or later, and IBM MQ transfers MQI calls to the correct library.

The new loading capability of IBM MQ libraries in Version 7.1, or later, does not relax the restriction that an application compiled and linked at a later release level must not directly load an IBM MQ library at an earlier release level. In practice the restriction is of less significance than in earlier releases, because as long as the operating system loads a library at the same or later level than the library the application was compiled and linked with, IBM MQ can call any other level of IBM MQ on the same server from Version 7.0.1 upwards.

For example, suppose you recompile and link an application that is to connect to a Version 7.0.1 queue manager using the libraries shipped with Version 7.1. At run time the operating system must load the Version 7.1 libraries for the application, even though the application connects to a Version 7.0.1 queue manager. IBM WebSphere MQ Version 7.1 detects the inconsistency and loads the Version 7.0.1 library for the application. The same applies to any future release. If the application is recompiled and linked against a later release, then the application must load an IBM MQ library that matches the later release, even if it continues to connect to a Version 7.1 queue manager.

Your application might not be linked to an IBM MQ library, but instead calls the operating system directly to load an IBM MQ library. If the library that is loaded is from Version 7.1 or later, IBM MQ checks the library is from the installation that is associated with the queue manager. If it is not, IBM MQ loads the correct library.

Special migration considerations involving loading IBM MQ libraries

You might have been asked to modify the installation of an earlier IBM MQ release to satisfy the requirements of a build environment, or the IT standards in your organization. If you copied IBM MQ libraries to other directories, or created symbolic links, you ended up with an unsupported configuration. The requirement to move IBM MQ libraries to other directories was one of the reasons for changing the installation of IBM MQ on UNIX and Linux. You can now install IBM MQ into a directory of your choosing. You can also load IBM MQ libraries from the `/usr/lib` directory, which is normally on the default load path on UNIX and Linux systems.

A common IT standard or build environment requirement is to include IBM MQ libraries in the default load path on UNIX and Linux systems. IBM WebSphere MQ Version 7.1 has a solution. In Version 9.0 you can install IBM MQ into a directory of your own choosing, and IBM MQ can create symbolic links in `/usr` and its subdirectories. If you make a Version 7.1, or later, installation primary by using the **`setmqinst`** command, IBM MQ inserts symbolic links to the IBM MQ libraries into `/usr/lib`. As a result, the operating system finds the IBM MQ libraries in the default load path, if that includes `/usr/lib`.

Because IBM WebSphere MQ Version 7.1, or later, libraries transfer calls to the correct installation, defining that version installation as primary, also results in the correct libraries being loaded for any application that is built with a link to `/usr/lib`, regardless of which queue manager it connects to. Unfortunately, this solution does not work if you have a Version 7.0.1 installation on the server, because then you cannot define a Version 7.1, or later, installation as primary, and the Version 7.0.1 libraries do not load libraries from other installations. As an alternative to setting the later version installation primary, use **`setmqenv`** with the `-k` or `-l` options to achieve a similar result.

You can find more information in Connecting applications in a multiple installation environment.

Command association

Examples of commands are **`dspmqver`**, **`setmqinst`**, **`runmqsc`**, and **`strmqm`**. The operating system must find a command in an IBM MQ installation. Many commands also require a queue manager as an argument and assume the default queue manager, if a queue manager name is not provided as a parameter.

Unlike loading libraries, if a command includes a queue manager as a parameter, the command is not switched to the installation that is associated with the queue manager. You must use the **`setmqenv`** command to set up your environment correctly, so that any commands that you issue are run from the correct installation. You can provide a queue manager as a parameter to **`setmqenv`**, to set up the command environment for that queue manager; see Figure 73 on page 673.

On Windows, the **`setmqinst`** command sets global environment variables, and **`setmqenv`** local environment variables, including the `PATH` variable to find commands.

On UNIX and Linux, the **`setmqinst`** command copies symbolic links for a subset of the commands into `/usr/bin` ; see External library and control command links to primary installation on UNIX and Linux. The **`setmqenv`** command sets up local environment variables, including the search path to the binary folder in the installation directory.

setmqenv must be on the search path in order to run it. One reason for having a later version installation as primary is to be able to run setmqenv without having to configure the search path. If IBM WebSphere MQ Version 7.0.1 is installed on the server, no Version 7.1, or later, installation can be primary and IBM WebSphere MQ Version 7.0.1 does not have a setmqenv command. The consequence is, you must provide a path to run the setmqenv command to set up the command environment for any of the later version installations on the server.

Figure 73 shows two examples of running **`setmqenv`** to set up the command environment for the copy of IBM MQ that is associated with the queue manager, `QM1`.

IBM WebSphere MQ for Windows Version 7.1

```
" MQ_INSTALLATION_PATH\bin\setmqenv" -m QM1

"Migrating IBM MQ library loading from an earlier version of the product to the latest version" on page 684
No change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the latest version. You must have followed the instructions on building IBM MQ applications in the earlier version, and you must replace the earlier version with the latest version of the product. If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

"Staging maintenance fixes on Windows" on page 583
On Windows systems, you can use multiple installations of IBM MQ on the same server to control the release of maintenance fixes.

"Staging maintenance fixes on UNIX and Linux" on page 608
On UNIX and Linux, you can use multiple installations of IBM MQ on the same server to control the release of maintenance fixes.

"Migrating IBM MQ library loading to a later version on UNIX and Linux" on page 739
On UNIX and Linux, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to a later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

JMS: Administered objects:

Version 6.0 JMS administered objects, such as connection factories and destinations are compatible with later releases.

JMS applications can use connection factory or destination objects created in IBM WebSphere MQ Version 6.0. Any new properties, that did not exist in Version 6.0, assume their default value.

IBM WebSphere MQ Version 6.0 JMS applications can use connection factory or destination objects created in later releases. Any of the new properties that do not exist in Version 6.0 are ignored.

Mixed version cluster coexistence:

A cluster can contain queue managers running at IBM MQ Version 9.0, and any currently supported earlier level of the product. However new features cannot be exploited from queue managers at an earlier level.

Cluster workload balancing in a mixed version cluster

IBM MQ Version 7.1 added a new **DEFBIND** value called `GROUP` to queues. Applications on queue managers earlier than Version 7.1 must not open or put messages to queues specifying the new value. When an application ignores this limitation, the workload balancing behavior (for example: BIND_ON_OPEN or BIND_NOT_FIXED) is undefined.

Routing behavior in a mixed version publish/subscribe cluster

From IBM MQ Version 8.0, topic host routing is available for publish/subscribe clusters. The queue manager where the object is defined, and the full repository queue managers, must be at a level that supports the topic route hosting feature, that is Version 8.0 or later. Any queue manager in the cluster that is at an earlier level does not adhere to the topic route hosting behavior.

When a clustered topic is defined for topic host routing (by setting the topic **CLROUTE** parameter to `TOPICHOST`), only queue managers at the new level are aware of the clustered topic. Older queue managers do not receive the clustered topic definition and therefore behave as if the topic is not clustered. This means that all queue managers that need to work in a routed publish/subscribe manner must be at a version that supports this feature, not just the queue managers that host the routed topics.

Important notes:

- All full repositories must be at Version 8.0 or later to use this feature. If a full repository queue manager is at an earlier version, the **`CLROUTE`** of `TOPICHOST` is not recognized by the full repository, and the full repository propagates the topic definition to all queue managers in the cluster. Any pre-Version 8.0 queue managers then use the topic as if it is defined for `DIRECT` routing. This behavior is unsupported.
- If an older queue manager defines a direct routed clustered topic with the same name as an existing topic host routed clustered topic, the full repositories notice the conflicting definition and do not propagate the definition.

To find out the version of each queue manager in the cluster, specify the VERSION parameter with the DISPLAY CLUSQMGR command. If you issue this command from a queue manager with a full repository, the information returned applies to every queue manager in the cluster. Otherwise the information returned applies only to the queue managers in which it has an interest. That is, every queue manager to which it has tried to send a message and every queue manager that holds a full repository.

ISPF operations and control panels on z/OS: z/OS

When using the operations and control panels, the IBM MQ libraries you use in ISPF must be compatible with the queue manager you are working with.

Table 82 shows which versions of the operations and controls panels you use in ISPF are compatible with which levels of queue manager. Version 7.1, or later, panels are incompatible with any release before Version 6.0. CD

Table 82. Compatibility of queue manager versions with operations and control panel versions on z/OS

Version	Queue-sharing group containing a mixture of Version 7.1 Version 8.0, and Version 9.0 queue managers.	Version 9.0 queue manager	Version 8.0 queue manager	Version 7.1 queue manager
Version 9.0 panel	Compatible with restrictions and warnings	Compatible	Compatible	Compatible with restrictions and warnings
Version 8.0 panel	Not compatible	Not compatible	Compatible	Compatible with restrictions and warnings
Version 7.1 panel	Not compatible			Compatible

Queue-sharing group coexistence on z/OS: z/OS

A queue-sharing group can contain queue managers running on IBM WebSphere MQ Version 7.1.0, and on later releases. The queue managers can access the same shared queues and other shared objects. Queue managers running earlier versions of the product must have the coexistence PTF applied for the latest release.

Notes:

1. After the coexistence PTF has been applied, the earlier version queue managers must be started at least once.
2. Long Term Support release and Continuous Delivery release queue managers, with the same version and release numbers, can coexist in a queue-sharing group without the need for a coexistence PTF.

Only run queue managers in a mixed-version queue-sharing group for the time it takes to migrate all queue managers to the later version. If the queue-sharing group contains queue managers with a mixture of versions, new functions on the latest version, that are restricted by OPMODE, will not be available.

Properties of objects in a mixed queue-sharing group on z/OS: z/OS

Attributes that did not exist in earlier versions can be created and altered on queue managers of a later version in a mixed queue-sharing group. The attributes are not available to queue managers in the group that are at an earlier level.

Any **`QSGDISP`**`(GROUP) TOPIC` objects having the **`CLROUTE`**`(TOPICHOST)` attribute set, and any **`QSGDISP`**`(GROUP) AUTHINFO` objects with **`AUTHTYPE`**`(IDPWOS)`, are hidden from queue managers earlier than Version 8.0 in a mixed queue-sharing group.

MQSC commands in a mixed queue-sharing group on z/OS: z/OS

Existing **`MQSC`** commands using new keywords and attribute values can be entered for routing to a migrated queue manager. You can enter the commands on any queue manager. Route the commands using **`CMDSCOPE`**. Commands with new keywords and attribute values, or new commands, routed to a previous version of queue manager, fail.

Application compatibility and interoperability with earlier versions of IBM MQ

Connecting an application that is built against libraries shipped with a later version of IBM MQ to an earlier version IBM MQ is not supported. Avoid building applications against a later version, and redeploying them to a queue manager running at an earlier version, although some applications do work in practice.

IBM MQ applications do interoperate with applications running on earlier versions of IBM MQ, as long as they use no new function. IBM MQ clients can connect to queue managers running at an earlier version than the client, as long as the client uses no new functions.

An IBM MQ application that uses only functions provided by an earlier version of a queue manager can continue to send messages to the earlier version. It does not matter what version of IBM MQ an application is built on and connected to. It can exchange messages with an application connected to an earlier version of IBM MQ, as long as it does not use new function.

Consider these four cases; the first two cases are not supported though they might work in practice, the last two cases are supported. The first two cases require compatibility with an earlier version of IBM MQ. The last two cases rely on the interoperability between all versions of IBM MQ

1. Running an IBM MQ server application, built with a later version of IBM MQ, connecting to a queue manager running on a server with an earlier version of IBM MQ installed.

2. Running an IBM MQ client application, built with a later version of IBM MQ, on a client platform with an earlier client installation, connecting to a queue manager running on a server with a later version of IBM MQ installed.
3. Running an IBM MQ client application, built with a later version of IBM MQ, on a client platform with the later client installation, connecting to a queue manager running on a server with an earlier version of IBM MQ installed.
4. Exchanging messages between an IBM MQ client or server application, connected to a queue manager running on a server with a later version of IBM MQ installed, with applications connected to a queue manager running on a server with an earlier version of IBM MQ installed.

Plan to avoid the first two cases, as they are not guaranteed to work all the time. If you are running an incompatible configuration and you encounter a problem, you must rebuild your applications with the correct level of IBM MQ. You can then continue with problem diagnosis.

Multi-installation and application loading

The new loading capability of IBM MQ libraries in Version 7.1, or later, does not relax the restriction that an application compiled and linked at a later release level must not directly load an IBM MQ library at an earlier release level. In practice the restriction is of less significance than in earlier releases, because as long as the operating system loads a library at the same or later level than the library the application was compiled and linked with, IBM MQ can call any other level of IBM MQ on the same server from Version 7.0.1 upwards.

For example, suppose you recompile and link an application that is to connect to a Version 7.0.1 queue manager using the libraries shipped with Version 7.1. At run time the operating system must load the Version 7.1 libraries for the application, even though the application connects to a Version 7.0.1 queue manager. IBM WebSphere MQ Version 7.1 detects the inconsistency and loads the Version 7.0.1 library for the application. The same applies to any future release. If the application is recompiled and linked against a later release, then the application must load an IBM MQ library that matches the later release, even if it continues to connect to a Version 7.1 queue manager.

Examples

1. You decide to rebuild a client application. Can you deploy it to your production environment that contains some earlier versions of client and server platforms?

   The answer is no, you must upgrade all the client workstations you deploy to, at least to the version of the client you have built. The queue managers running on earlier versions of IBM MQ do not have to be upgraded. In practice all the clients are likely to work, but for maintainability you must avoid running incompatible levels of an application and the IBM MQ client.
2. You deploy some IBM MQ queue managers at a new version level. You have an existing IBM MQ application that you use to send messages between the servers. Do you rebuild the application to deploy it onto the new servers? Can you deploy the old version onto the new servers?

   The answer is, either. You can continue to deploy the existing version of the application onto all your servers, or you can deploy the rebuilt application onto the new servers. Either configuration works. IBM MQ supports running the existing application on later servers and sending messages from later application versions to earlier ones. What you must not do is to rebuild the application on the later version and redeploy it onto both the earlier and newer servers. IBM MQ does not support compatibility with earlier versions.

z/OS

z/OS application stubs

The stub modules that are listed are link-edited with applications and exits. The version 7 stub modules might not work with Version 6.
- `CSQASTUB`

- CSQBRSSI
- CSQBRSTB
- CSQBSTUB
- CSQCSTUB
- CSQQSTUB
- CSQXSTUB

To take advantage of the new APIs introduced in Version 7.0, for example MQSUB and MQCB, you must link-edit your application with stubs shipped with Version 7.0 or later, for an LE program, the sidedeck, see Building z/OS batch applications using Language Environment . Such an application will not run on an earlier version of the queue manager.

Application compatibility and interoperability with later versions of IBM MQ

IBM MQ applications run against later versions of a queue manager without recoding, recompiling, or relinking. You can connect an application that is built against libraries shipped with an earlier version of IBM MQ to a queue manager running at a later version of IBM MQ.

If you upgrade a queue manager to a later version, existing applications built against its earlier version work without change. Exceptions are noted in “Changes that affect migration” on page 626. Likewise applications connected to the IBM MQ Client, run against later versions of the client without recoding, recompiling, or relinking. You can deploy client applications built against earlier versions of the IBM MQ Client libraries to connect using later versions of the libraries.

All the following four cases are supported. The first two cases rely on the compatibility of later version of IBM MQ with applications built against earlier versions. The last two cases rely on the interoperability between all versions of IBM MQ.

You might change the operating environment as a prerequisite of migrating to a new level of queue manager. The operating environment changes, rather than changes in IBM MQ itself, might require application change, recompilation, or relinking. Sometime the operating environment change affects only the development environment, and the operating environment supports applications built at an earlier level. In which case, you might be able to run existing applications built at the older level of the operating environment. You might not be able to build any new applications until the operating environment is upgraded.

In the future, after you have migrated queue managers and clients to the latest release level, consider changing your applications to take advantage of new capabilities.

z/OS

z/OS application stubs

The stub modules that are listed are link-edited with applications and exits. The Version 6.0 stub modules continue to work with Version 9.0.
- CSQASTUB
- CSQBRSSI
- CSQBRSTB
- CSQBSTUB
- CSQCSTUB
- CSQQSTUB
- CSQXSTUB

To take advantage of the new APIs introduced in Version 7.0, for example MQSUB and MQCB, you must link-edit your application with stubs shipped with Version 7.0 or later, for an LE program, the sidedeck, see Building z/OS batch applications using Language Environment . Such an application will not run on an earlier version of the queue manager.

Compatibility between different versions of an IBM MQ MQI client and a queue manager

Any version and release of an IBM MQ MQI client can connect to any version and release of an IBM MQ queue manager. The MQI channel is automatically configured to the latest version that both the client and server support. If the client and server are different versions, the client application must use only the functions in the earlier version.

The compatibility between clients and queue managers applies only to the version and release (`V.R`) of the product. The statement of compatibility does not necessarily apply to the modification and fix pack level (`M.F`) of the product.

If there are known problems at a specific `V.R.M.F` of the product, an upgrade to a more recent fix pack for the same `Version.Release` is necessary.

When you upgrade a queue manager to a different version, you automatically upgrade IBM MQ libraries. The libraries are used by IBM MQ MQI client and server applications running on the same server as the queue manager. To access new functions from remote clients, you must also upgrade the IBM MQ MQI client installation on remote workstations. The IBM MQ MQI client includes the IBM MQ MQI client libraries.

Remote clients that have not been upgraded continue to work with an upgraded queue manager. The behavior of the client application might, in rare cases change. You must consult "Changes that affect migration" on page 626, to find out whether changes in the current version affect your client applications.

Remote clients that are connected to upgraded queue managers can use the new functions in the release. If an upgraded remote client is connected to a queue manager that has not been upgraded, it must not use new functions. In rare cases, the behavior of the client might change; see "Changes that affect migration" on page 626.

You can generally assume that upgrading the IBM MQ MQI client does not require you to recompile or relink the client application. You can also continue to use the same connection to the queue manager. If changes are required, they are identified in "Migrating a queue manager on Windows" on page 691, for the particular migration path and platform you are concerned with.

The Client Channel Definition Table (CCDT) is an interface to customize the connection between an IBM MQ Client and a queue manager. Entries in the tables are client connections, which are defined using a queue manager. The version of a CCDT is the version of the queue manager used to define the client connections. If an IBM MQ MQI client uses CCDT to connect to a queue manager, the CCDT can be at a version greater than, less than, or equal to that of the client.

You can connect to a queue manager with an earlier IBM MQ Client or an earlier CCDT. If you are using a CCDT, and you plan to use new client channel configuration options, such as shared conversations, you must upgrade the CCDT, and therefore the IBM MQ MQI client installation to the new version.

MQI client: Client Channel Definition Table (CCDT):

You can connect an IBM MQ MQI client application to any level of queue manager. If a client uses CCDT to connect to a queue manager, the CCDT can be at a version greater than, less than, or equal to that of the client.

Version of originating queue manager for a CCDT

In earlier releases before IBM MQ Version 9.0, clients can use a CCDT built by the same or earlier version queue manager, but there was previously a restriction on clients using a CCDT built by a later version queue manager. However, this restriction is removed in Version 9.0.

From Version 9.0, if a client uses a CCDT, it can use a CCDT built by a later version queue manager, as well as a CCDT built by the same, or earlier version of queue manager.

The same restriction on the use of CCDTs originating from later version queue managers is also removed in Version 8.0, Version 7.5, and Version 7.1 by APARs IT10863 and IT11547. for more information, see the technote MQ 7.x, MQ 8.0 and MQ 9.0 compatibility with previous versions - including usage of CCDT files, JMS .bindings, SSL/TLS.

Common migration scenarios

If, for example, you upgrade a queue manager from an earlier release to a later release, and you do not create new CCDTs for its clients, the clients connect to the later release queue manager without any changes being required. Client behavior might change as a result of changes to the queue manager.

Another common migration scenario is to update some queue managers and some clients to a later release, leaving other queue managers and clients at the earlier release. In this scenario, you want to update the CCDT for the IBM MQ MQI clients that are connected to the later release queue managers to that later release so that those clients can fully use the function in the later release. The new clients can also connect to the earlier release queue managers. Existing clients connect to queue managers in both releases. In order that the clients in the later release can use the new function in that release, you must deploy a CCDT that has been generated by a queue manager in that new release. Clients in the earlier release can continue to use the CCDT for that earlier release. Both sets of clients can connect to both sets of queue managers, regardless of the CCDT they are using.

IBM MQ MQI clients

If the client is an IBM MQ MQI client, the version of the IBM MQ MQI client libraries that are linked to by the client must be the same or greater than the version of the queue manager that was used to build the CCDT.

To upgrade an IBM MQ MQI client from an earlier release to use a CCDT for a later release, you must upgrade the IBM MQ MQI client installation to the later release. Unless you decide to do so for other reasons, do not rebuild the client application.

Java or JMS client

If the client is a Java or JMS client, then the client must be built with versions of the IBM MQ JAR files that are the same or greater than the queue manager that was used to build the CCDT.

To upgrade a Java or JMS client from an earlier release to use a CCDT for a later release, redeploy the IBM MQ JAR files to the client workstation. You do not need to rebuild the Java or JMS client with the new JAR files.

Related information:

Client channel definition table

V 9.0.0 Web addressable access to the client channel definition table

Accessing client-connection channel definitions

MQI client: Client configuration stanzas moved into a new configuration file:

Client configuration information is moved from existing configuration stanzas into a new configuration file, `mqclient.ini`.

Moving client configuration information affects existing settings; for example:

- Set the TCP `KeepAlive` attribute for client connections in `mqclient.ini` ; for example:

  ```
  TCP:
  KeepAlive = Yes
  ```

  An existing setting in `qm.ini` is ignored.
- Set `ClientExitPath` in `mqclient.ini` ; for example:

  ```
  ClientExitPath:
  ExitsDefaultPath=/var/mqm/exits
  ExitsDefaultPath64=/var/mqm/exits64
  ```

  An existing setting in `mqs.ini` is moved to the client configuration file when you upgrade the client. If you add values to `mqs.ini`, they are ignored.
- Set `JavaExitsClasspath` in `mqclient.ini`.

  Do not continue to use the Java system property `com.ibm.mq.exitClasspath`. Existing settings continue to work, but they are deprecated. The setting in `mqclient.ini` has precedence over the Java system property.

Assigning channel exits for IBM MQ classes for JMS

IBM MQ client configuration file

MQI client: Default behavior of client-connection and server-connection channels:

In Version 7.0 the default settings for client and server connection channels changed to use shared conversations. This change affects the behavior of heartbeats and channels exits, and can have an impact on performance.

Before Version 7.0, each conversation was allocated to a different channel instance. From Version 7.0, the default for client and server connections is to share an MQI channel. You use the **SHARECNV** (sharing conversations) parameter to specify the maximum number of conversations that can be shared over a particular TCP/IP client channel instance. The possible values are as follows:

SHARECNV(0)
: This value specifies no sharing of conversations over a TCP/IP socket. The channel instance behaves exactly as if it was a Version 6.0 server or client connection channel, and you do not get the extra features such as bi-directional heartbeats that are available when you set **SHARECNV** to 1 or greater. Only use a value of `0` if you have existing client applications that do not run correctly when you set **SHARECNV** to 1 or greater.

SHARECNV(1)
: This value specifies no sharing of conversations over a TCP/IP socket. Performance on distributed

servers is similar to that for a value of 0. Client heartbeating (whether in an MQGET call or not) and read ahead are available, and channel quiescing is more controllable. You can usually use this setting with existing Version 6.0 client applications.

SHARECNV(2) to SHARECNV(999999999)
Each of these values specifies the number of shared conversations. If the client-connection **SHARECNV** value does not match the server-connection **SHARECNV** value, then the lowest value is used. The default value is SHARECNV(10), which specifies 10 threads to run up to 10 client conversations per channel instance. However, on distributed servers there are performance issues with SHARECNV channels that can be eased by using SHARECNV(1) wherever possible.

For all **SHARECNV** values of 1 or greater, the channel supports the following features:
- Bi-directional heartbeats
- Administrator stop-quiesce
- Read-ahead
- Asynchronous-consume by client applications

You can also set the MQCONNX option, MQCNO_NO_CONV_SHARING and connect the application to a channel with **SHARECNV** set to a value greater than 1. The result is the same as connecting the application to a channel with **SHARECNV** set to 1.

Performance

The change in Version 7.0 to use shared conversations, and further enhancements introduced in Version 8.0, can impact performance on distributed servers. See Tuning client and server connection channels.

Heartbeats

From Version 7.0, heartbeats can flow across the channel at any time in either direction. The SHARECNV(0) and Version 6.0 behavior is for heartbeats to flow only when an MQGET call is waiting.

Channel exits

The behavior of a client or server connection channel exit changes when the channel is sharing conversations (that is, when you set **SHARECNV** to a value greater than 1). It is unlikely, but possible, that the change affects the behavior of existing exits. The change is as follows:
- Send or receive exits can alter the MQCD structure on an MQXR_INIT call. The effect of these exits differs, depending on whether the conversation is shared with other conversations on the same channel:
  - If the MQCXP SharingConversations field passed to the exit instance is set to FALSE, this exit instance is the first, or only, conversation on the channel instance. No other exit can be changing the MQCD at the same time, and changes that are made to the MQCD can affect the way that the channel runs.
  - If the MQCXP SharingConversations field passed to the exit instance is set to TRUE, this exit instance is a subsequent conversation. It is sharing the channel instance with other conversations. Changes made to the MQCD in the exit instance are retained in the MQCD but do not affect the way the channel runs.
- Send, receive, and security exit instances can alter the MQCD, when the MQCXP SharingConversations field is set to TRUE. Exit instances on other conversations might be changing the MQCD at the same time. Updates written by one exit instance can be overwritten by another instance. It might be necessary to serialize access to the MQCD across these different exit instances to maintain the consistency of fields in MQCD.

Updating MQCD when the SharingConversations field is set to TRUE does not affect the way the channel runs. Only alterations made when the MQCXP SharingConversations field is set to FALSE, on an MQXR_INIT call, change channel behavior.

The Asynchronous consume sample program

MQI client: MQPUT1 sync point behavior change:

An MQPUT1 call by an IBM MQ MQI client application that failed in IBM WebSphere MQ Version 6.0 can now sometimes succeed. The failure is returned to the application later, if it calls MQCMIT. For the change in behavior to occur, the MQPUT1 must be in sync point.

In the scenario, "Example call sequence that demonstrates the change in behavior," an MQPUT1 call can succeed where it failed in Version 6.0. The result occurs when all the following conditions are met:
- Both client and queue manager are later than Version 6.0.
- The application program is connected to the queue manager as a client application
- `MQPMO_SYNCPOINT` is set in the Put Message Options structure, `MQPMO`

You can make the IBM MQ MQI client behave like Version 6.0. Set **`Put1DefaultAlwaysSync`** to `YES` in the **`CHANNELS`** stanza of the client configuration file; see Figure 74.

```
Channels:
Put1DefaultAlwaysSync=YES
```

Figure 74. Add **`Put1DefaultAlwaysSync`** *to `mqclient.ini`*

Example call sequence that demonstrates the change in behavior

1. MQCONN to queue manager from an IBM MQ MQI client application.
2. MQPUT1 to a nonexistent queue with the `MQPMO_SYNCPOINT` option
3. MQDISC

In IBM WebSphere MQ Version 6.0 the MQPUT1 call ends with `MQCC_FAILED` and `MQRC_UNKNOWN_OBJECT_NAME(2085)`. Running with a client and server later than Version 6.0, the MQPUT1 call ends with `MQRC_NONE` and `MQCC_OK`.

Overview of migration requirements

An overview of migration requirements, on all platforms, are grouped in this section.

This information has moved. See "Migration concepts and methods" on page 645.

Related concepts:
"Migration concepts and methods" on page 645
An overview of the various concepts and methods for migrating from one release of the product to another.

Migrating MQ Telemetry to the latest version

Migrate MQ Telemetry to the latest version of the product by completing the tasks in this section. You must stop all IBM MQ activity on the system before migrating.

About this task

This information has moved. See "Migrating MQ Telemetry on Windows" on page 716 and "Migrating MQ Telemetry on Linux" on page 748.

Migrating IBM MQ library loading from an earlier version of the product to the latest version

No change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the latest version. You must have followed the instructions on building IBM MQ applications in the earlier version, and you must replace the earlier version with the latest version of the product. If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

About this task

This information has moved. See "Migrating IBM MQ library loading to a later version on Windows" on page 709 and "Migrating IBM MQ library loading to a later version on UNIX and Linux" on page 739.

Migrating IBM MQ on Windows

Windows

IBM MQ migration tasks associated with Windows platforms are grouped in this section.

Procedure

- For information about creating a migration plan, see "Planning to migrate to a later version on Windows" on page 685.
- For information about migrating a queue manager from an earlier version to the latest version, see "Migrating a queue manager to a later version on Windows" on page 691.
- For information about reverting a queue manager to an earlier version, see "Reverting a queue manager to an earlier version on Windows" on page 705.
- For information about migrating an IBM MQ MQI client to the latest version, see "Migrating an IBM MQ MQI client to a later version on Windows" on page 707.
- For information about converting a single instance queue manager to a multi-instance queue manager, see "Migrating from a single instance to a multi-instance queue manager on Windows" on page 712.

- For information about reverting a multi-instance queue manager to a single instance queue manager, see “Reverting to a single-instance queue manager on Windows” on page 715.
- For information about migrating IBM MQ library loading to the latest version, see “Migrating IBM MQ library loading to a later version on Windows” on page 709.
- For information about migrating MQ Telemetry to the latest version, see “Migrating MQ Telemetry on Windows” on page 716.
- For information about migrating an MSCS configuration to the latest version, see “Migrating an MSCS configuration on Windows” on page 717.
- V 9.0.4 For information about Migrating logs to an Advanced Format disk, see “Migrating logs to an Advanced Format disk on Windows” on page 719.

z/OS “Migrating IBM MQ on z/OS” on page 770
Migration tasks associated with z/OS are grouped in this section.

Related reference:

“Changes that affect migration” on page 626
Changes to the product might affect the migration of a queue manager from an earlier release to the current release of IBM MQ, or affect existing applications or configurations. Review these changes before upgrading queue managers to the latest product version and decide whether you must plan to make changes to existing applications, scripts, and procedures before starting to migrate your systems.

Planning to migrate to a later version on Windows

Windows

Before migrating from one version of IBM MQ to another on Windows, read this topic, then create your own migration plan based on the outline in this topic.

If there are concepts about migration you do not understand, read “Migration concepts and methods” on page 645, and the subsections you need, first.

About this task

Use the following steps as a guide to creating a migration plan.

Procedure

1. Review the IBM MQ system requirements for the later version of the product. See System Requirements for IBM MQ.
2. Decide whether to run the earlier version and the later version of the product on the same server, and also which migration method you want to use. See “Migration methods on IBM MQ for Multiplatforms” on page 653.

   Important: Note that if you require a multi-version installation, and you are using a version of the product prior to IBM WebSphere MQ Version 7.0.1, Fix Pack 6, you must install Version 7.0.1, Fix Pack 6 first before installing the later version.

3. Review all the changes in IBM MQ that affect you. For more information, see “Changes that affect migration” on page 626.
4. Review performance changes. See IBM MQ Family - Performance Reports.
5. Review the readme file for the product that you are working with. See IBM MQ, WebSphere MQ, and MQSeries product readmes.
6. Plan the sequence and timing of queue manager upgrades.
   - If the queue manager is part of a queue manager cluster, you must migrate the queue managers that are full repositories first.
   - If the queue manager is part of a high availability cluster, plan the migration to minimize downtime and maximize availability; see “Migrating a queue manager in a high-availability configuration” on page 814.
7. Plan to migrate your queue manager to the later version. See “Migrating a queue manager to a later version on Windows” on page 691.

   Backing up queue manager data is part of the queue manager migration task. An alternative approach to backing up queue manager data, is to install and configure a new server. Test the later version with a new queue manager on the new server. When you are ready to go into production on the later version, copy the queue manager configuration and data, to the new server.
8. Plan to update any manual or automated procedures you have written with changes to messages and codes.
9. Decide on what regression tests to perform before putting the queue manager into production on the later version. Include the procedures and applications you identified in steps 6 and 7 in your regression tests.
10. Plan to upgrade your IBM MQ MQI client installations to the later version.
11. Plan to upgrade your client and server applications to use new functions in the later version.

Migration considerations for Version 8.0 or later on Windows: Windows

From Version 8.0, a number of changes were made for IBM MQ for Windows. You must understand these changes before planning any migration tasks for Version 8.0 or later on Windows.

Installing a single copy of the product

If you have an existing previous version of the product on your system, and want to upgrade to the latest version, you have various options. You can either:
- Uninstall the previous version and then install the latest version,
- Install the new copy alongside the currently installed one and uninstall the original at a later time. See “Installing the product alongside an existing version,” or
- Perform a migration installation, electing to replace the currently installed version when prompted.

After you have installed the product, start each queue manager and its data migration takes place. This includes the migration of queue managers from 32-bit to 64-bit.

Installing the product alongside an existing version

If you want to install another version of the product alongside your existing product you can do so. See “Multiple IBM MQ installations” on page 660 and “Migrating on Windows: side-by-side” on page 699 for further information.

When you install the new version of the product, run the setmqm command to associate the queue managers with the new installation.

Start each queue manager in turn and its data migration takes place.

Upgrading one of a pair of (or more) installations

If you already have, for example, an IBM MQ Version 8.0 installation and an IBM MQ Version 9.0 installation on a machine, upgrading the Version 8.0 installation to Version 9.0 requires the following additional step.

When you start the Version 9.0 installer, you are asked whether you want to **Install a new instance** or **Maintain or upgrade an existing instance**.

However, only the other Version 9.0 installation, or installations, are displayed; not the Version 8.0 installation in the selection box. At this point, select **Install a new instance**.

After the splash screen has been displayed, a second panel appears, which lists any older installations that you can upgrade to Version 9.0 using the Version 9.0 installer.

On this panel, select **Upgrade 8.0.0.n Installation 'Installation m'**, and then click **Next**.

Change of digital signature algorithm

The IBM MQ programs and installation image are digitally signed on Windows to confirm that they are genuine and unmodified.

In older releases before IBM MQ Version 8.0, the product was signed using the SHA-1 with RSA algorithm.

From Version 8.0, the SHA-256 with RSA algorithm is used. Some older versions of Windows do not support the new digital signature algorithm, but those versions are not supported by IBM MQ Version 8.0 or later.

See Hardware and software requirements on Windows systems, and ensure that you install IBM MQ Version 8.0 or later on a supported version of Windows.

Existing applications

All applications that were built with previous versions of the product continue to work in Version 8.0 or later with a 64 bit queue manager.

All applications using the C++ object interface need to be rebuilt; applications using the C interface are not affected.

Exits

Queue manager exits on Windows 64-bit operating systems must be compiled as 64-bit exits. Any 32-bit queue manager exits must be recompiled before they can be used with a 64-bit queue manager. If you try to use a 32-bit exit with a 64-bit queue manager on IBM MQ Version 8.0 or later, an AMQ9535 "invalid exit" error message is issued.

Clients

32-bit client applications can connect transparently to queue managers from all supported versions of the product. This includes 64-bit IBM MQ Version 8.0 or later.

Samples

From IBM MQ Version 8.0, the samples for the C and C++ languages are compiled as 64-bit.

Related concepts:

"changes from IBM MQ Version 8.0 on Windows" on page 632
From IBM MQ Version 8.0, changes have been made to the default installation location for the server and 64-bit client installations. There has also been a change in the default data path for all installations. The compiler that is used from IBM MQ Version 8.0 on Windows has been changed.

Related information:

Directory structure on Windows systems

Hardware and software requirements on Windows systems

Program and data directory locations on Windows: Windows

The installation location for IBM MQ program binary and data files on Windows depends on the IBM MQ version you are installing and whether this is the first time IBM MQ is being installed.

First-time installations

When you install IBM MQ for the first time, you can accept default installation locations. You can also select the custom installation option by choosing the location for the IBM MQ binary files and the location for the IBM MQ data and logs.

Before Version 8.0, if the default option was chosen, both the IBM MQ program binary and the data files were installed in the same directory. From Version 8.0, default locations are changed.

Table 83. Default program and data directory locations on different versions of IBM MQ on Windows

IBM MQ Version	IBM MQ program binary files installation location	IBM MQ data files location
IBM WebSphere MQ Version 7.0.1, Version 7.1, and Version 7.5	Program and data files are in one location: `C:\Program Files (x86)\IBM\WebSphere MQ`	
IBM MQ Version 8.0	`C:\Program Files\IBM\WebSphere MQ`	`C:\ProgramData\IBM\MQ`
IBM MQ Version 9.0	`C:\Program Files\IBM\MQ`	`C:\ProgramData\IBM\MQ`

Subsequent installations and reinstallations

After the data directory is specified, during the installation process of any installation, it cannot be changed for subsequent installations. IBM MQ is only installed as a 64-bit version when it is installed on a 64-bit operating system.

For Version 9.0, the default data directory is `C:\ProgramData\IBM\MQ`, unless a version of the product was previously installed, in which case the new installation continues to use the existing data directory.

Existing IBM WebSphere MQ Version 7.0.1 installation

By default, the Version 7.0.1 data and program binary files are installed into `C:\Program Files (x86)\IBM\WebSphere MQ`.

Three upgrade paths are possible:

- Uninstall Version 7.0.1 first and then install Version 9.0.
- Upgrade Version 7.0.1 at the beginning of the Version 9.0 installation process, without first uninstalling the earlier version.
- Install Version 9.0 alongside Version 7.0.1, Fix Pack 6 or later and then uninstall Version 7.0.1.

Installing Version 9.0 after uninstalling Version 7.0.1
If you install IBM MQ Version 9.0 after uninstalling Version 7.0.1, the installation program looks

in the `C:\ProgramData\IBM\MQ` directory for any existing data, which will not exist. The Version 9.0 program files are installed into `C:\Program Files\IBM\MQ` and the program data by default uses `C:\ProgramData\IBM\MQ`.

If data exists from a previous installation, you must choose the custom installation option and manually set the data path to the location that Version 7.0.1 was previously using, as the data path for the new installation, in order to pick up any existing queue managers.

Upgrading Version 7.0.1 at the beginning of the Version 9.0 installation process

If you install Version 9.0 without uninstalling Version 7.0.1 and choose to upgrade the Version 7.0.1 installation, the new program binary files replace the Version 7.0.1 binary files, hence by default the location of the binary files is `C:\Program Files (x86)\IBM\WebSphere MQ`.

The existing data path is kept so, by default, the data path is also `C:\Program Files (x86)\IBM\WebSphere MQ`.

Installing Version 9.0 to coexist with Version 7.0.1

If you install Version 9.0 without uninstalling Version 7.0.1 and choose to install alongside the Version 7.0.1 installation, the new program binary files are put in the new default location `C:\Program Files\IBM\MQ`.

The existing data path is kept so, by default, the data path is `C:\Program Files (x86)\IBM\WebSphere MQ`.

Existing IBM WebSphere MQ Version 7.5 or Version 7.1 installation

Three upgrade paths are possible:

- Uninstall Version 7.1 or Version 7.5 first and then install the latest version.
- Upgrade Version 7.1 or Version 7.5 at the beginning of the Version 9.0 installation process, without first uninstalling the earlier version.
- Install Version 9.0 alongside Version 7.1 or Version 7.5 and then uninstall the earlier version.

When IBM WebSphere MQ Version 7.5 or Version 7.1 is installed, both the program binary files and data are installed by default into `C:\Program Files (x86)\IBM\WebSphere MQ`.

When you uninstall IBM WebSphere MQ Version 7.5 or Version 7.1, information about the location of the data directory is left in the registry.

Installing Version 9.0 after uninstalling IBM WebSphere MQ Version 7.5 or Version 7.1

After uninstalling Version 7.5 or Version 7.1, Version 9.0 is installed using the same installation name but using the Version 9.0 default program binary files location of `C:\Program Files\IBM\MQ`. That is, the program files move from the Windows 32-bit program location to the Windows 64-bit program location.

Optional: You can use the custom installation option to modify the installation path, including modifying it back to `C:\Program Files (x86)\IBM\WebSphere MQ`.

Upgrading IBM WebSphere MQ Version 7.5 or Version 7.1 at the beginning of the Version 9.0 installation process

If you install Version 9.0 without uninstalling Version 7.1 or Version 7.5 and choose to upgrade the Version 7.1 or Version 7.5 installation, the new program binary files replace the Version 7.1 or Version 7.5 binary files so, by default, the new binary files are in `C:\Program Files (x86)\IBM\WebSphere MQ`. The existing data path is kept so, by default, the data path is also `C:\Program Files (x86)\IBM\WebSphere MQ`.

Installing Version 9.0 to coexist with IBM WebSphere MQ Version 7.5 or Version 7.1

If you install Version 9.0 alongside Version 7.1 or Version 7.5, a unique path is chosen, which by default is `C:\Program Files\IBM\MQ`. The existing data path is kept so, by default, the data path is `C:\Program Files (x86)\IBM\WebSphere MQ`.

Existing IBM MQ Version 8.0 installation

Three upgrade paths are possible:

- Uninstall IBM MQ Version 8.0 first and then install Version 9.0.
- Upgrade IBM MQ Version 8.0 at the beginning of the Version 9.0 installation process, without first uninstalling the earlier version.
- Install Version 9.0 alongside IBM MQ Version 8.0 and then uninstall IBM MQ Version 8.0.

When IBM MQ Version 8.0 is installed, the product binary files are put by default into `C:\Program Files\IBM\WebSphere MQ` and the product data and logs are put by default into `C:\ProgramData\IBM\MQ`.

When you uninstall IBM MQ Version 8.0, information about the location of the data directory is left in the registry. After uninstalling IBM MQ Version 8.0 and before installing Version 9.0, you can run the `ResetMQ.cmd` script to tidy up files and data left behind by the uninstallation process.

Important: You should use this script with caution. `ResetMQ.cmd` can remove the existing queue manager configuration. For more information, read Clearing IBM MQ installation settings.

Installing Version 9.0 after uninstalling IBM MQ Version 8.0

After uninstalling IBM MQ Version 8.0, the Version 9.0 is installed using the same installation name but using the Version 9.0 default program binary files location `C:\Program Files\IBM\MQ`. That is, the program files change location after the upgrade.

Optional: You can use the custom installation option to modify the installation path, including modifying it back to `C:\Program Files (x86)\IBM\WebSphere MQ`.

The default data path is `C:\ProgramData\IBM\MQ`.

Upgrading IBM MQ Version 8.0 at the beginning of the Version 9.0 installation process

If you install Version 9.0 without uninstalling IBM MQ Version 8.0 and choose to upgrade the IBM MQ Version 8.0 installation, the new program binary files replace the IBM MQ Version 8.0 binary files so, by default, the new binary files are in `C:\Program Files (x86)\IBM\WebSphere MQ`. The existing data path is kept so, by default, the data path is `C:\ProgramData\IBM\MQ`.

Installing Version 9.0 to coexist with IBM MQ Version 8.0

If you install Version 9.0 alongside IBM MQ Version 8.0, a unique path is chosen, which by default is `C:\Program Files\IBM\MQ`. The existing data path is kept so, by default, the data path is `C:\ProgramData\IBM\MQ`.

Migrating a queue manager on Windows

Windows

The procedures for migrating a queue manager to a later version of the product, and for restoring a queue manager to an earlier version of the product are detailed in this section.

Related tasks:

UNIX Linux "Migrating a queue manager on UNIX and Linux" on page 721
The procedures for migrating a queue manager to a later version of the product, and for restoring a queue manager to an earlier version of the product are detailed in this section.

IBM i "Migrating a queue manager to a later version on IBM i" on page 751
Follow these instructions to migrate a queue manager from an earlier release to a later release.

z/OS "Migrating IBM MQ on z/OS" on page 770
Migration tasks associated with z/OS are grouped in this section.

Migrating a queue manager to a later version on Windows: Windows

On Windows platforms, follow these instructions to migrate a queue manager from an earlier version to a later version of IBM MQ.

Before you begin

If you have installed early support program code on the server, you must delete all the queue managers created with the installation. Uninstall the code before proceeding with installing the production level code.

1. Create a migration plan; see "Planning to migrate to a later version on Windows" on page 685.
2. Review the IBM MQ system requirements for the latest version, including information about the versions of Windows that IBM MQ supports. See System Requirements for IBM MQ.
3. Back up your system before you install a later version of IBM MQ over an earlier version. Once you have started a queue manager you cannot revert to the previous version. If you must restore the system, you cannot recover any work, such as changes to messages and objects, performed by the later version of IBM MQ. For more information about backing up your system, see Backing up and restoring IBM MQ queue manager data.
4. Review any other installed SupportPacs for their applicability to the later version.
5. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

To run a command, the operating system must find the command in an IBM MQ installation. For some commands, you must run the command from the installation that is associated with the correct queue manager. IBM MQ does not switch commands to the correct installation. For other commands, such as **setmqinst**, you can run the command from any installation that has the later version of the product installed.

If an earlier version of the product is installed, the command that is run is the command for that version, unless the search path is overridden by a local setting. You can override the search path by running **setmqenv**. If Version 7.0.1 is not installed, you must set the correct path to run a command. If you have set a primary installation, the command that is run is the copy in the primary installation, unless you override the selection with a local search path.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

      ```
                  ┌-c┐
      ►►──endmqm──┼-w┼──QmgrName──────────────────────────────────────►◄
                  ├-i┤
                  └-p┘
      ```

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.
   d. Stop any listeners associated with the queue managers, using the command:

      ```
      endmqlsr -m QMgrName
      ```

4. Back up the queue manager. Take copies of all the queue manager's data and log file directories, including all subdirectories, and also the `qm.ini` file and the registry entries. For more information, see Backing up and restoring IBM MQ queue manager data.
5. Stop the IBM WebSphere MQ or IBM MQ Service and exit the Service icon application.
6. Optional: If you are doing a single stage migration and you are migrating from IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later, optionally uninstall the current version of the product. Note, that you carry out this step only if you are doing a single stage migration; see “Migrating on Windows: single stage” on page 694.
7. Install the later version of IBM MQ. On Windows, you can do this either by using the Installation Launchpad or by using the **`msiexec`** command. For more information, see:
   - Modifying the installation using IBM MQ Installation Launchpad
   - Silently modifying an IBM MQ server installation using **`msiexec`**
8. Reenter domain, user ID, and password information

   When the installation of the latest version completes, the Prepare IBM MQ Wizard starts automatically.

   Where UAC is enabled: If you rerun the Prepare IBM MQ Wizard, ensure that the wizard is run with Administrator privilege, otherwise the wizard might fail.
9. Start the queue manager.

   ```
   strmqm QmgrName
   ```

   When you first start a queue manager after migration:
   - Any new attributes for existing objects are set to their default values.
   - Any new default objects are created.
   - Queue manager data is migrated.

   Important: Do not use the `-c` option to start the queue manager, unless you explicitly want to reset or re-create the default system objects.

   You must start IBM MQ before you start any listeners.

What to do next

Complete the tasks in your migration plan, such as verifying the new code level and deploying new functions such as automatically restarting client connections.

If you are using publish/subscribe, you must migrate the publish/subscribe broker.

If the queue manager is a member of a queue manager cluster, migrate the other members of the cluster.

Important: You must migrate the publish/subscribe broker state before you migrate your IBM MQ system to IBM MQ Version 8.0, or later, as broker publish/subscribe migration is not supported in IBM MQ Version 8.0, or later.

➡ Fix Central

➡ IBM Passport Advantage

"Migrating a queue manager in a high-availability configuration" on page 814
High-availability configurations of queue managers can increase the availability of IBM MQ applications. If a queue manager, or server fails, it is restarted automatically on another server. You can arrange for IBM MQ MQI client applications to automatically reconnect to the queue manager. Server applications can be configured to start when the queue manager starts.

"Migrating a queue manager cluster" on page 808
You can migrate queue managers in a cluster all at once, or one at a time, which is called a staged migration. Migrate full repository queue managers in a cluster before partial repository queue managers. You must consider what the effect is of migrating some queue managers in a cluster, before all the queue managers are migrated.

"Restoration of a queue manager to an earlier version on all platforms" on page 650
You can remove an upgrade before you have started a queue manager. However, if you remove the upgrade after a queue manager has been started, the queue manager will not work.

➡ IBM MQ - SupportPacs by Product

"Maintaining and migrating IBM MQ" on page 565
Maintenance, upgrade, and migration have three distinct meanings for IBM MQ. The definitions are described here. The following sections describe the various concepts associated with migration, followed by the various tasks needed; these tasks are platform-specific where needed.

"Migrating IBM MQ" on page 625
Migration is the conversion of programs and data to work with a new code level of IBM MQ. Some types of migration are required, and some are optional. Queue manager migration is never required after applying a maintenance level update, that does not change the command level. Some types of migration are automatic, and some are manual. Queue manager migration is typically automatic and required after releases and manual and optional after a maintenance level upgrade that introduces a new function. Application migration is typically manual and optional.

"Applying upgrades and fixes to IBM MQ" on page 618
The term upgrade applies to changing the version `V`, release `R`, or modification `M` of a product. The term fix applies to a change in the `F` digit.

Migrating on Windows: single stage: Windows

Single-stage migration is the term used to describe replacing the only installation of IBM MQ on a server, with a later version of the product. Single stage migration is also known as *upgrading in place* or *in place upgrade*. Until Version 7.0.1, Fix Pack 6, single-stage was the only migration scenario. Single-stage migration preserves existing scripts and procedures for running IBM MQ the most. With other migration scenarios you might change some scripts and procedures, but you can reduce the effect queue manager migration has on users.

Before you begin

These topics guide you in deciding what other tasks you must perform to migrate queue managers and applications to the later version. For the precise sequence of commands to upgrade a queue manager to the later version, do the migration task for the platform you are interested in. All the tasks are listed by platform in the links at the end of this topic. As part of the queue manager migration task, back up your existing queue manager data. Even on a multi-installation server, queue managers cannot be restored to a previous command level after migration.

Attention: V 9.0.0 From IBM MQ Version 9.0, the `ccsid_part2.tbl` file replaces the existing `ccsid.tbl` file, used in previous versions of the product, to supply additional CCSID information.

The `ccsid_part2.tbl` file takes precedence over the `ccsid.tbl` file and:
- Allows you to add or modify CCSID entries
- Specify default data conversion
- Specify data for different command levels

The `ccsid_part2.tbl` is applicable to the following platforms only:
- Linux - all versions
- Solaris
- Windows

If you have added any of your own CCSID information into your existing `ccsid.tbl` file, you should copy this information into the new `ccsid_part2.tbl` file, if you want to take advantage of the new formats in your customizations

You should copy the required information, rather than move the information, so that your existing version of IBM MQ continues to work.

About this task

In the single-stage migration scenario, the installation of the later version of the product replaces an earlier version in the same installation location. It is the same migration process that you might previously have used to upgrade the product prior to IBM WebSphere MQ Version 7.0.1, Fix Pack 6. From Version 7.0.1, Fix Pack 6, this method of migration is termed *single-stage* migration, in contrast to *side-by-side* and *multi-stage* migration.

The advantage of single-stage migration is that it changes the configuration of a queue manager on the earlier version as little as possible. Existing applications switch from loading the libraries from the earlier version, to loading the libraries of the later version, automatically. Queue managers are automatically associated with the installation on the later version. Administrative scripts and procedures are affected as little as possible by setting the installation to be the primary installation. If you set the installation of the later version to be the primary installation, commands such as **`strmqm`** work without providing an explicit path to the command.

When you upgrade the earlier version to the later version, all the objects that you previously created are maintained. The components that were previously installed are preselected in the feature options when you install the new level. If you leave these components selected, you can keep them or reinstall them. If you clear any of these components, the installation process uninstalls them. By default, a typical migration installs only the same features that were installed in the previous version installation.

For example, if IBM MQ Explorer was not installed in an earlier installation, it is not stored in a later installation. If you want IBM MQ Explorer, select a custom installation, and select the IBM MQ Explorer feature on the Features panel. If you do not want IBM MQ Explorer, uninstall the IBM MQ Explorer feature by selecting a custom installation. Then clear the IBM MQ Explorer feature on the Features panel. For more information about how to uninstall features, see Modifying the installation using IBM MQ Installation Launchpad.

You can also migrate a queue manager to a later version of the product on a system where an earlier version has been uninstalled. In this case, the queue manager data must have been retained, or restored from a backup.

Procedure
1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.

3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

      ```
                    ┌─-c─┐
      ►►──endmqm────┼─-w─┼──QmgrName──────────────────────────────────────────────►◄
                    ├─-i─┤
                    └─-p─┘
      ```

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.
   d. Stop any listeners associated with the queue managers, using the command:

      ```
      endmqlsr -m QMgrName
      ```
4. Back up the queue manager. Take copies of all the queue manager's data and log file directories, including all subdirectories, and also the `qm.ini` file and the registry entries. For more information, see Backing up and restoring IBM MQ queue manager data.
5. Stop the IBM WebSphere MQ or IBM MQ Service and exit the Service icon application.
6. Optional: If you are migrating from IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later, optionally uninstall the current version of the product.
7. Upgrade the earlier version of the product to the later version in the same installation directory. A reason for installing into the same location is to simplify application migration. If you change the

installation location, you might remove IBM MQ libraries from an application search path. To migrate an application search path you must modify the application environment, or more rarely, the application itself.

a. Decide on an installation naming convention. Give the installation a name of your choosing, or accept the default installation name. For the first installation, the default name is *Installation1*. For the second installation, the name is *Installation2*, and so on.
b. Upgrade the earlier version of the product to the later version in place, or uninstall the earlier version, without deleting any queue managers, and install the later version in the same default location. On Windows, you can do this either by using the Installation Launchpad or by using the **msiexec** command. For more information, see:
   - Modifying the installation using IBM MQ Installation Launchpad
   - Silently modifying an IBM MQ server installation using **msiexec**

   On Windows, uninstalling the previous version of the product before you install the later version is optional.

8. Reenter domain, user ID, and password information

   When the installation of the latest version completes, the Prepare IBM MQ Wizard starts automatically.

   Where UAC is enabled: If you rerun the Prepare IBM MQ Wizard, ensure that the wizard is run with Administrator privilege, otherwise the wizard might fail.
9. Optional: Make the later version of the installation the primary installation.
   a. Run the **setmqinst** command

   ```
   "Inst_1_INSTALLATION_PATH\bin\setmqinst" -i -n Inst_1
   ```

   Make the installation primary to avoid specifying a search path to run IBM MQ commands
10. Start the queue managers and applications.
    a. Run the **setmqm** command to associate the queue managers with `Inst_1`.

    ```
    setmqm -m QM1 -n Inst_1
    setmqm -m QM2 -n Inst_1
    ```

    Notes:
    - The **setmqm** step is optional only in the case where migration is from IBM WebSphere MQ Version 7.0.1 to a later release. In this case, the **strmqm** command automatically associates the queue manager with its own installation.
    - If you are migrating between any other releases of the product, you must use **setmqm** to associate the queue managers with the new installation manually.

    If you have multiple installations, note that queue managers that were configured to start automatically, and remain after uninstalling IBM WebSphere MQ Version 7.0.1, automatically start under any other existing Version 7.1 (or later) installation when either the machine reboots, or the Service for that installation is restarted. In order to avoid this, ensure that all queue managers have been moved to the required installation before uninstalling IBM WebSphere MQ Version 7.0.1.

    b. Run the **strmqm** command to start the queue managers and migrate them to the later version of the product.

    ```
    strmqm QM1
    strmqm QM2
    ```

    You must start IBM MQ before you start any listeners.

    When you first start a queue manager after migration:
    - Any new attributes for existing objects are set to their default values.
    - Any new default objects are created.
    - Queue manager data is migrated.

At this point, when the queue manager data is migrated, you cannot revert to a previous release.

Important: Do not use the `-c` option to start the queue manager, unless you explicitly want to reset or re-create the default system objects.

- When an application connects to a queue manager, the operating system searches its load path to load the IBM MQ library [4] . A Version 7.1, or later, library contains code that checks that the queue manager is associated with an installation. If a queue manager is associated with a different installation, IBM MQ loads the correct IBM MQ library for the installation the queue manager is associated with.

What to do next

You cannot reinstall an earlier version of the product on a system that has the latest, or any other, version of IBM MQ installed.

Related concepts:

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

4. On Windows, the IBM MQ library is a DLL. A DLL is sometimes called a load library or a shared library. The entry points to a DLL are defined in a link library, with the file extension `.lib32` or `.lib`. The `.lib` library is linked at build-time and the DLL loaded at runtime.

setmqinst

setmqm

Migrating on Windows: side-by-side: Windows

Side-by-side migration is the term used to describe installing a later version of IBM MQ alongside an earlier version on the same server. Queue managers remain running during the installation and verification of the later version of IBM MQ. They remain associated with the older version of IBM MQ. When you decide to migrate queue managers to the later version of IBM MQ, you stop all queue managers, uninstall the earlier version, and migrate them all to the new version of IBM MQ.

Before you begin

If you are using IBM WebSphere MQ Version 7.0.1, you must ensure that you are running IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later before installing the later version of the product on the same server. For more information about Version 7.0.1 fix packs, see Recommended Fixes for IBM MQ.

Attention: V 9.0.0 From IBM MQ Version 9.0, the `ccsid_part2.tbl` file replaces the existing `ccsid.tbl` file, used in previous versions of the product, to supply additional CCSID information.

The `ccsid_part2.tbl` file takes precedence over the `ccsid.tbl` file and:
- Allows you to add or modify CCSID entries
- Specify default data conversion
- Specify data for different command levels

The `ccsid_part2.tbl` is applicable to the following platforms only:
- Linux Linux - all versions
- Solaris Solaris
- Windows Windows

If you have added any of your own CCSID information into your existing `ccsid.tbl` file, you should copy this information into the new `ccsid_part2.tbl` file, if you want to take advantage of the new formats in your customizations

You should copy the required information, rather than move the information, so that your existing version of IBM MQ continues to work.

About this task

In the side-by-side migration scenario, you install the later version of IBM MQ alongside queue managers that continue to be associated with Version 7.0.1, or later.

When you are ready to migrate the queue managers, and applications, to the later version:
1. Stop all the queue managers.
2. Uninstall the earlier version of the product.
3. Migrate all the queue managers and applications to the later version.

Procedure
1. Install the later version in a different installation directory from the earlier version.
   a. Decide on an installation naming convention. Give the installation a name of your choosing, or accept the default installation name. For the first installation, the default name is *Installation1*. For the second installation, the name is *Installation2*, and so on.

   b. Verify the installation.

      Run the installation verification procedures and your own tests.

2. Uninstall the earlier version of the product.

   When uninstalling the earlier product, you must stop all queue managers and applications that have loaded an IBM MQ library on the server. For this reason, you might choose to postpone uninstalling the earlier version of the product until a convenient maintenance window. When an earlier version of the product is not installed on a server, it is sufficient to stop the queue managers and applications that have loaded libraries from the installation that you are uninstalling or updating. It is not necessary to stop applications and queue managers associated with other installations.

   a. Stop all applications that have loaded IBM MQ libraries on the server.
   b. Stop the queue managers and listeners on the server.
   c. Uninstall the earlier version of the product.
      - Stop all local IBM MQ applications
      - If you are migrating from IBM WebSphere MQ Version 7.0.1, stop all your queue managers and listeners, ensuring that you do not delete the queue managers.

        Note: If you are migrating from a release other than IBM WebSphere MQ Version 7.0.1 you do not need to stop all the queue managers at this point.

3. Make the later version of the installation the primary installation.

   a. Run the **setmqinst** command

      ```
      "Inst_1_INSTALLATION_PATH\bin\setmqinst" -i -n Inst_1
      ```

      Make the installation primary to avoid specifying a search path to run IBM MQ commands

   Use the dspmqinst command to discover the *Installation name*, or use the default value `Installation 1`.

   Doing this means that you do not have to specify a search path on IBM MQ commands.

4. Start the queue managers and applications.

   - When an application connects to a queue manager, the operating system searches its load path to load the IBM MQ library [5] . A Version 7.1, or later, library contains code that checks that the queue manager is associated with an installation. If a queue manager is associated with a different installation, IBM MQ loads the correct IBM MQ library for the installation the queue manager is associated with.

   During this process you continue to use queue manager QM2 while you upgrade queue manager QM1 and you use queue manager QM1 while you upgrade QM2.

   Note that each queue manager needs to be stopped in order to be associated with the new installation.

What to do next

You cannot reinstall an earlier version of the product on a system that has the latest, or any other, version of IBM MQ installed.

5. On Windows, the IBM MQ library is a DLL. A DLL is sometimes called a load library or a shared library. The entry points to a DLL are defined in a link library, with the file extension `.lib32` or `.lib`. The `.lib` library is linked at build-time and the DLL loaded at runtime.

Migrating on Windows: multi-stage: Windows

Multi-stage migration is the term used to describe running a later version of IBM MQ alongside an earlier version on the same server. After installing the later version alongside the earlier version, you can create new queue managers to verify the later installation, and develop new applications. At the same time, you can migrate queue managers and their associated applications from the earlier version to the later version. By migrating queue managers and applications one-by-one, you can reduce the peak workload on staff managing the migration.

Before you begin

If you are using IBM WebSphere MQ Version 7.0.1, you must ensure that you are running IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later before installing a later version of the product on the same server. For more information about Version 7.0.1 fix packs, see Recommended Fixes for IBM MQ.

Attention: V 9.0.0 From IBM MQ Version 9.0, the `ccsid_part2.tbl` file replaces the existing `ccsid.tbl` file, used in previous versions of the product, to supply additional CCSID information.

The `ccsid_part2.tbl` file takes precedence over the `ccsid.tbl` file and:
- Allows you to add or modify CCSID entries
- Specify default data conversion
- Specify data for different command levels

The `ccsid_part2.tbl` is applicable to the following platforms only:

- Linux Linux - all versions
- Solaris Solaris
- Windows Windows

If you have added any of your own CCSID information into your existing `ccsid.tbl` file, you should copy this information into the new `ccsid_part2.tbl` file, if you want to take advantage of the new formats in your customizations

You should copy the required information, rather than move the information, so that your existing version of IBM MQ continues to work.

Note:

- If an application uses COM or ActiveX it can connect to any queue manager as long as there is a primary installation and it is Version 7.1 or later.
- If you are running the IBM MQ.NET monitor in transactional mode, the queue manager it connects to must be the primary installation.

You cannot migrate these applications to the later version until you uninstall the earlier version.

About this task

In the multi-stage migration scenario, you install the later version of the product alongside running queue managers that continue to be associated with the earlier version. You can create queue managers and run new applications using the later version installation. When you are ready to start migrating queue managers and applications from the earlier, you can do so, one-by-one. When migration to the later version is complete, you can uninstall the earlier version, and make the later version installation the primary installation.

With the multi-stage approach, until you uninstall the earlier version , you must configure an environment to run applications that connect to a queue manager to the later version. You must also provide a path to run IBM MQ commands. Both these tasks are accomplished with the **`setmqenv`** command.

Note: When you have uninstalled the earlier version, and set the later version as a primary installation, in most circumstances it is not necessary to run the **`setmqenv`** command to run applications. It is still necessary to run **`setmqenv`** to set the environment for commands that connect to a queue manager associated with an installation that is not primary.

Procedure

1. Install the later version in a different installation directory from the earlier version and verify the installation.
   a. Decide on an installation naming convention. Give the installation a name of your choosing, or accept the default installation name. For the first installation, the default name is *Installation1*. For the second installation, the name is *Installation2*, and so on.
   b. Verify the installation.
      Run the installation verification procedures and your own tests.
   - You might create new queue managers running the later version, and start to develop new applications before migrating applications from the earlier version.
2. Configure the operating system so that applications load the libraries for the later version of the product.
   a. Migrate queue managers one at a time.

The first set of applications to load the libraries for the later version of the product are the applications that connect to the first queue manager you are going to migrate.

It does not matter if those applications also connect to other queue managers on the server. If the applications load the later version libraries, IBM MQ automatically loads the libraries for the earlier version for those applications that connect to that version.

You can either migrate the operating system environment of all applications, or just the applications that connect to the first queue manager you are going to migrate.

b. Migrate IBM MQ MQI client applications

   Some of the applications might be running as IBM MQ MQI client applications on another workstation. When you migrate a queue manager, clients connected to it continue to run without loading a client library for the later version.

   You can migrate these clients later, when you need to do so.

   Important: If any IBM MQ MQI client applications are using the library for the earlier version on the server, you must eventually migrate the clients to use the later version of the product before you uninstall the earlier version.

3. Migrate an application to load the new library for the later version:
   - Run **setmqenv** to modify the local path that is searched for IBM MQ libraries.
   - Relink applications with an additional runtime load path.

   Consult operating system documentation about how to modify the global search path, or include a fixed runtime load path in the application load module.

   To run **setmqenv** using the `-s` option:

   ```
   "Inst_1_INSTALLATION_PATH\bin\setmqenv" -s
   ```

   The `-s` option sets up the environment for the installation that runs the **setmqenv** command.
4. Restart the queue manager and the applications that connect to it.
   a. Set up the local environment to the installation `Inst_1`.

      ```
      "Inst_1_INSTALLATION_PATH\bin\setmqenv" -s
      ```

      The `-s` option sets up the environment for the installation that runs the **setmqenv** command.
   b. Run the **setmqm** command to associate `QM1` with `Inst_1`.

      ```
      setmqm -m QM1 -n Inst_1
      setmqm -m QM2 -n Inst_1
      ```

   c. Run the **strmqm** command to start `QM1` and migrate it to the later version.

      ```
      strmqm QM1
      strmqm QM2
      ```

   d. Restart application 1

      The application loads the later version library and connects to `QM1`, which is associated with the later version of the product.
5. Migrate all queue managers and applications to the later version.

   Repeat steps 2 on page 702 and 4, when required, until all the queue managers and applications are migrated to the later version of the product.
6. Uninstall the earlier version of the product.

   When uninstalling the earlier product, you must stop all queue managers and applications that have loaded an IBM MQ library on the server. For this reason, you might choose to postpone uninstalling the earlier version of the product until a convenient maintenance window. When an earlier version of the product is not installed on a server, it is sufficient to stop the queue managers and applications that have loaded libraries from the installation that you are uninstalling or updating. It is not necessary to stop applications and queue managers associated with other installations.
   a. Stop all applications that have loaded IBM MQ libraries on the server.
   b. Stop the queue managers and listeners on the server.

c. Uninstall the earlier version of the product.
   - Stop all local IBM MQ applications
   - If you are migrating from IBM WebSphere MQ Version 7.0.1, stop all your queue managers and listeners, ensuring that you do not delete the queue managers.

     Note: If you are migrating from a release other than IBM WebSphere MQ Version 7.0.1 you do not need to stop all the queue managers at this point.

7. Make `Inst_1` the primary installation.
   a. Run the **`setmqinst`** command

   ```
   "Inst_1_INSTALLATION_PATH\bin\setmqinst" -i -n Inst_1
   ```

   Note: Use the dspmqinst command to discover the *`Installation name`*, or use the default value `Installation 1`.

   You do not have to set up a search path to run IBM MQ commands from the primary installation.

What to do next

You cannot reinstall an earlier version of the product on a system that has the latest, or any other, version of IBM MQ installed.

Now that you have uninstalled the earlier version of the product, and made the later installation primary, you can review how the application runtime environment is set. It is no longer necessary to run **`setmqenv`** to set up the search path to load libraries for the later version. If you have only one installation of the later version of the product installed, it is not necessary to run **`setmqenv`** to run commands.

Reverting a queue manager to an earlier version on Windows:

On Windows platforms, you can revert a queue manager to an earlier version of the product from a later version, if you have made a backup of the system or queue manager. If you have started the queue manager and processed any messages, or changed the configuration, the task cannot give you any guidance on reverting the current state of the queue manager.

Before you begin

1. You must have made a backup of the system or queue manager before you upgraded to the later version. For more information see Backing up and restoring IBM MQ queue manager data
2. If any messages were processed after starting the queue manager, you cannot easily undo the effects of processing the messages. You cannot revert the queue manager to the earlier version of the product in its current state. The task cannot give you any guidance how to deal with subsequent changes that have occurred. For example, messages that were indoubt in a channel, or in a transmission queue on another queue manager, might have been processed. If the queue manager is part of a cluster, then configuration messages and application messages might have been exchanged.
3. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

When you revert to a earlier version of a queue manager, you revert the queue manager to its earlier code level. Queue manager data is reverted to the state it was in when the queue manager was backed up.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **`dspmq`** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:
      ```
      dspmq -o installation -o status
      dspmq -a
      ```
      `dspmq -o installation -o status` displays the installation name and status of queue managers associated with all installations of IBM MQ.

      `dspmq -a` displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **`DISPLAY LSSTATUS`** to list the status of listeners associated with a queue manager, as shown in the following example:
      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **`endmqm`** command to stop each running queue manager associated with this installation.

```
              ┌─-c─┐
►►──endmqm────┼─-w─┼──QmgrName──────────────────────────────────────────────────►◄
              ├─-i─┤
              └─-p─┘
```

The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

Note: The topic, "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577, describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

d. Stop any listeners associated with the queue managers, using the command:

```
endmqlsr -m QMgrName
```

4. Restore the system, or IBM MQ and the queue manager.

   If your backup procedure was to save the queue manager data, you must reinstall IBM MQ:

   a. Uninstall the earlier installation.
   b. Reinstall the product from a manufacturing refresh.
   c. Apply the fix pack and interim fixes that restore IBM MQ to its previous level.
   d. Restore the queue manager data from the backup taken before installing the later version.
5. Restart the earlier version queue manager.

What to do next

You might be reverting to a earlier version on a server with multiple IBM MQ installations. If one of the installations is primary, after reverting the earlier version that installation, by default, becomes the primary installation.

You must review how applications connect to an installation. After reverting to the earlier version, some applications might connect to the wrong installation.

Migrating an IBM MQ MQI client to a later version on Windows: ▶ Windows

Before migrating an IBM MQ MQI client on Windows platforms, create a migration plan. Stop all IBM MQ activity on the client workstation. Upgrade the IBM MQ MQI client installation. Make any essential configuration and application changes.

Before you begin

Before starting to migrate a client, create a migration plan. For guidance on what to include in the plan, see "Planning to migrate to a later version on Windows" on page 685.

About this task

IBM MQ MQI client migration is the process of converting IBM MQ MQI client configurations, and client and server channels from one version to another. Client migration is reversible. It is optional and manual on a client workstation and is required and automatic on the IBM MQ server.

You must upgrade an IBM MQ MQI client before migrating a client workstation to make use of new configuration options. You can make configuration changes to client and server connection channels on the server, but they have no effect on a client workstation until the client is upgraded.

Procedure

1. Review the IBM MQ system requirements for the later version of the product. See System Requirements for IBM MQ.
2. Review all the changes in IBM MQ that affect you. For more information, see "Changes that affect migration" on page 626.
3. End all IBM MQ activity on the workstation.

4. Upgrade the client. Select the appropriate option for your enterprise.
   - For a client installation on a workstation, see Installing an IBM MQ client on Windows.
   - For a client installation on an IBM MQ server, see Installing IBM MQ clients and servers on the same system.

What to do next

After upgrading the IBM MQ MQI client, you must check the client channel configuration, and verify that your IBM MQ MQI client applications work correctly with the later version of the product.

Related concepts:

"IBM MQ MQI client migration" on page 650
IBM MQ MQI client migration is the process of converting IBM MQ MQI client configurations, and client and server channels from one version to another. Client migration can take place after upgrading the IBM MQ MQI client, and is reversible.

Restoring an IBM MQ MQI client to an earlier version on Windows: Windows

If you revert an IBM MQ MQI client from a later version of the product to an earlier version of the product, you must undo the configuration changes manually.

About this task

It is unusual to revert earlier IBM MQ MQI client libraries to a workstation. The principal tasks are listed in the following steps.

Procedure

1. End all IBM MQ activity on the workstation.
2. Uninstall the later version of the IBM MQ MQI client code.
3. Follow the client installation procedure for the platform to install the earlier version of the IBM MQ MQI client code.
4. If you configured a Client Connection Definition Table (CCDT) for a queue manager on a later version of the product, revert to using a table created by a queue manager on the earlier version. The CCDT must always be created by a queue manager on the same, or earlier, release to the client.

Migrating IBM MQ library loading to a later version on Windows

Windows

On Windows, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

Before you begin

To migrate applications from an earlier version of the product to the later version, you must know how the operating system loads a IBM MQ library for an application. Is the load path fixed by the application, and can you set the path in an environment variable? It is not essential to know the name of the IBM MQ library that the application loads. The library name does not change from an earlier version of the product to the later version, although the contents of the library do.

Read “Multi-installation queue manager coexistence on UNIX, Linux, and Windows” on page 668 before starting this task.

Plan and install the later version of IBM MQ, and remember the installation name and whether the installation was set to primary.

About this task

To migrate an application from an earlier version of the product to the later version, you do not have to recompile or relink the application, because the IBM MQ libraries are compatible with later versions; see “Application compatibility and interoperability with later versions of IBM MQ” on page 678.

Windows searches numerous directories for load libraries, called DLLs; see Dynamic-Link Library Search Order. The build procedure for IBM WebSphere MQ Version 7.0.1 or later applications places the IBM MQ libraries to load before any other product libraries in the **cl** command. The IBM MQ .lib libraries must be in the PATH environment variable that you have specified at build time, and the DLL libraries at run time. The PATH variable is used by the application process to find the libraries it must load.

If you have followed this build procedure in the earlier release, then the effect of installing the later version of the product on the libraries that are loaded depends on which migration scenario that you are following:

Single-stage scenario
If you are replacing an earlier version of the product with the later version, based on the single stage scenario described in “Migrating on Windows: single stage” on page 694, you do not, in most cases, need to make any changes to the way IBM MQ libraries are loaded. The possible exception to this is if you changed the location of the libraries from the earlier version, or created symbolic links to the libraries.

Side-by-side and Multi-stage scenarios
If you have chosen a multi-installation approach to installing the later version of the product, based either on the side-by-side scenario described in “Migrating on Windows: side-by-side” on page 699, or the multi-stage migration scenario described in “Migrating on Windows: multi-stage” on page 701, you must investigate whether applications connecting to the later version of the product are linked to, and load libraries from, the correct installation and then modify the environment for the operating system to resolve IBM MQ dependencies for an

application as appropriate. Typically, you can modify the runtime environment, rather than relink the application. You can use the following two commands to assist you in configuring the runtime environment:

- **setmqinst** sets the primary installation; see setmqinst.
- **setmqenv** initializes the command environment by setting environment variables; see setmqenv.

Table 84 summarizes the actions needed for each of these scenarios.

Table 84. Windows configurations

Action / Scenario	**Latest version replaces earlier version in the same location** **Single-stage**	**Latest version replaces earlier version in a different location** **Side-by-side**	**Latest version alongside earlier version** **Multi-stage**
setmqinst	**setmqinst** makes the later version installation primary. The global PATH is changed to point to the later version library and all Windows features work with the later version [See note].		No. The later version installation can be primary, because an earlier version is installed.
No other configuration actions	Library loading works correctly. The global PATH contains the location of the later version libraries. Even if the later version installation is not primary, library loading works correctly. The later version libraries are in the same location as the earlier version libraries were.	Library loading probably works correctly. The library loading might not work, if the application process locally modified the PATH to reference the location of the earlier version libraries. A local setting of PATH might override the global PATH that is set by **setmqinst**.	The library loading continues to work with the earlier version correctly, nothing works with the later version.
setmqenv	Library loading works correctly. **setmqenv** sets the local PATH correctly.		Library loading works correctly, both for the earlier version and the later version. **setmqenv** sets the local PATH correctly for the later version. But the Windows features that depend on the global path do not work correctly with the later version [See note]. The correct earlier version is loaded, because the later version library loads the earlier version library for queue managers that have not been migrated from the earlier version.

Procedure

1. Consider which of the following questions apply to your configuration.
   - Did you follow the build procedure documented in the product documentation for the earlier version of the product? You might be following a different build procedure tailored to your development environment, or adapted from a development tool such as Microsoft Visual Studio.
   - How did you specify the load path for the earlier version?

- Is the application is loaded by another environment, such as Eclipse, or an application server? You must modify the parameters that govern how the parent environment loads applications, not the way the parent environment is loaded.
- Do the functions performed by an application require that the queue manager it connects to is associated with the primary installation?
- What constraints and requirements do you have on how the load path is specified in the later version? Security rules might restrict the use of `LD_LIBRARY_PATH`.
- Is the later version of the product installed alongside the earlier version? If Version 7.0.1 is installed:
  - You cannot make a later installation primary.
  - You cannot install the later version in the default installation path, that was referenced by applications in Version 7.0.1.

2. Identify the installation of the later version of the product, from which the operating system is going to load IBM MQ libraries:
   - If you have a multiple installations of the later versions to load from a server, IBM MQ checks that the installation the library was loaded from is the installation that is associated with any queue manager the application calls. IBM MQ loads the correct library if the wrong library is loaded. It is necessary to configure only one runtime environment for all IBM MQ applications.
   - A typical choice is set the primary installation. Setting an installation to be primary places its library path in the global `PATH` variable.
   - If you upgraded an earlier version installation to the later version, a link path to the earlier version installation now points to an installation containing the later version. Applications that have a fixed linkage path to the earlier version installation now load the libraries for the later installation. They are then switched to the installation that is associated with any queue manager they connect to.
   - If you rebuild an application, it must link to an installation of the later version.
   - If an application uses COM or ActiveX it can connect to any queue manager as long as there is a primary installation and it is Version 7.1 or later.

     Note: If an earlier version of the product is installed, COM or ActiveX server applications connect to queue managers associated only with the earlier installation. COM or ActiveX client applications are not affected by the limitation.
   - If you are running the IBM MQ.NET monitor in transactional mode, the queue manager it connects to must be the primary installation.

What to do next

If you add further installations of the later version of the product, you must decide which installation to make primary, if you have chosen to make any primary. As long as applications load IBM MQ libraries from one of the later version installations, such as the primary installation, they can connect to queue managers associated with any other later version installation.

On Windows, you might build applications with different development tools. You must identify the property of the development tool that sets the `PATH` of the application that is being built, and not the properties of the tool itself. For example, if you are debugging with Microsoft Visual Studio, you can insert a call to **`setmqenv`** in the **`Environment`** property of the debugging section of the **`Configuration`** properties of a project.

A Windows application might call LoadLibrary and specify an explicit load path. You might build a side-by-side assembly and configure an explicit load path. If an application uses either of these mechanisms, and the later version IBM MQ library is not on the same path as the earlier release, you must recompile, or configure and relink your application to load the later version libraries.

Migrating from a single instance to a multi-instance queue manager on Windows

▶ Windows

To migrate a single instance queue manager, to a multi-instance queue manager, on Windows platforms, you must move the queue manager data to a shared directory, and reconfigure the queue manager on two other servers.

Before you begin

You must check the prerequisites for running a multi-instance queue manager as part of this task. For a list of tested environments, see Testing statement for IBM MQ multi-instance queue manager file systems. Other environments might work; a test tool is provided with IBM MQ to assist you in qualifying other environments.

You must have three servers to run a multi-instance queue manager. One server has a shared file system to store the queue manager data and logs. The other servers run the active and standby instances of the queue manager.

About this task

You have a single-instance queue manager that you want to convert to a multi-instance queue manager. The queue manager conversion itself is straightforward, but you must do other tasks to create a fully automated production environment.

You must check the prerequisites for a multi-instance queue manager, set up the environment and check it. You must set up a monitoring and management system to detect if the multi-instance queue manager has failed and been automatically restarted. You can then find out what caused the restart, remedy it, and restart the standby. You must also modify applications, or the way applications are connected to the queue manager, so that they can resume processing after a queue manager restart.

Procedure

1. Check the operating system that you are going to run the queue manager on, and the file system on which the queue manager data and logs are stored on. Check that they can run a multi-instance queue manager.
   a. Consult Testing and support statement for IBM MQ multi-instance queue managers. See whether the combination of operating system and file system is tested and capable of running a multi-instance queue manager. A shared file system must provide lease-based locking to be adequate to run multi-instance queue managers. Lease-based locking is a recent feature of some shared file systems, and in some case fixes are required. The support statement provides you with the essential information.
   b. Run **amqmfsck** to verify that the file system is configured correctly. File systems are sometimes configured with performance at a premium over data integrity. It is important to check the file system configuration. A negative report from the **amqmfsck** tool tells you the settings are not adequate. A positive result is an indication that the file system is adequate, but the result is not a definitive statement that the file system is adequate. It is a good indication.
   c. Run the integrity checking application provided in the technote, Testing a shared file system for compatibility with IBM MQ Multi-instance Queue Managers. The checking application tests that the queue manager is restarting correctly.
2. Configure a user and group to be able to access a share on the networked file system from each server that is running a queue manager instance. On Windows, the security IDs (SIDs) of the `mqm` group can be different; see Windows domains and multi-instance queue managers.
3. Set up a directory for the share on the networked file system with the correct access permissions. A typical configuration is to set up a single shared directory that contains all data and log directories for all queue managers that use the shared disk; see Share named qmgrs and log directories (Version 7.0.1 onwards). For example, create a root directory on the share called `MQHA` that has subdirectories `data` and `logs`. Each queue manager creates its own data and log directories under `data` and `logs`. Create *drive* `\MQHA` on the shared drive. The owner is a member of `mqm`. `mqm` must have full-control authority. Create a share for *drive*`\MQHA`.

   If you are using an NFS v4 file server, add the line `/MQHA * rw,sync,no_wdelay,fsid=0)` to `etc/exports`, and then start the NFS daemon: `/etc/init.d/nfs start`.
4. Copy the queue manager data and the logs to the share. You can choose to copy files manually, by following the procedure to back up the queue manager. On Windows, you can run the **hamvmqm** command to move the queue manager data to the share. The **hamvmqm** command works for queue managers created before Version 7.0.1, and not reconfigured with a datapath, or for queue managers that do not have a **DataPath** configuration attribute. Choose one of these methods:
   - Follow the instructions in Backing up queue manager data, copying the queue manager data to the share. You must use this method if the **DataPath** configuration attribute is specified for this queue manager.
   - Stop the queue manager, and then type the following command:
     ```
     hamvmqm /m /dd share\data /dd share\logs
     ```
     where *share* is to be the location of the data and logs that you created in step 3.
5. Update the queue manager configuration information stored on the current queue manager server.
   - If you moved the queue manager data and logs by running the **hamvmqm** command, the command has already modified the configuration information correctly for you.
   - If you moved the queue manager data and logs manually, you must complete the following steps.
     a. Modify the log registry key:
     ```
     HKEY_LOCAL_MACHINE\SOFTWARE\IBM\WebSphere MQ\Installation\MQ_INSTALLATION_NAME\Configuration\QueueManager\QMgr
     "LogPath"="share\\logs\\QMgrName\\"
     ```
     b. Modify the Prefix registry key:
     ```
     HKEY_LOCAL_MACHINE\SOFTWARE\IBM\WebSphere MQ\Installation\MQ_INSTALLATION_NAME\Configuration\QueueManager\QMgr
     "Prefix"="share\\data"
     ```

where *QMgrName* is the representation of the queue manager name in the existing registry key on Windows. *share* is share where the data and logs are moved to.

6. Add the queue manager configuration information to the new queue manager server.
   a. Run the **dspmqinf** command to display the queue manager information Run the command on the server that ran the queue manager.

      ```
      dspmqinf -o command QMgrName
      ```

      The command output is formatted ready to create a queue manager configuration. `addmqinf -s QueueManager -v Name= QMgrName -v Directory= QMgrName -v Prefix=d:\var\mqm Datapath= \share\data\QMgrName`
   b. Create a queue manager configuration on the other server. Run the **addmqinf** command copied from the previous output.
7. Add the network address of the new server to the connection name in client and channel definitions.
   a. Find all the client, sender, and requester TCPIP settings that refer to the server.
      - Client settings might be in Client Definition Tables (CCDT), in environment variables, in Java properties files, or in client code.
      - Cluster channels automatically discover the connection name of a queue manager from its cluster receiver channel. As long as the cluster receiver channel name is blank or omitted, TCPIP discovers the IP address of the server hosting the queue manager.
   b. Modify the connection name for each of these connections to include the TCPIP addresses of both servers that are hosting the multi-instance queue manager. For example, change the following connection name:

      ```
      echo DISPLAY CHANNEL(ENGLAND) CONNAME | runmqsc QM1
      ```

      ```
      5724-H72 (C) Copyright IBM Corp. 1994, 2009.  ALL RIGHTS RESERVED.
      Starting MQSC for queue manager QM1.
      1: DISPLAY CHANNEL(ENGLAND) CONNAME
      AMQ8414: Display Channel details.
      CHANNEL(ENGLAND) CHLTYPE(SDR)
      CONNAME(LONDON)
      ```

      into:

      ```
      echo ALTER CHANNEL(ENGLAND) CHLTYPE(SDR) CONNAME('LONDON, BRISTOL') | runmqsc QM1
      ```
8. Update your monitoring and management procedures to detect the queue manager restarting.
9. Update client applications to be automatically reconnectable, if appropriate.
10. Update the start procedure for your IBM MQ applications to be started as queue manager services.
11. Start each instance of the queue manager, permitting them to be highly available. The first instance of the queue manager that is started becomes the active instance. Issue the command twice, once on each server.

    ```
    strmqm -x QMgrName
    ```

What to do next

To get the highest availability out of multi-instance queue managers, you must design client applications to be reconnectable and server applications to be restartable; see Application recovery.

Reverting to a single-instance queue manager on Windows

Windows

Revert a multi-instance queue manager to a single instance queue manager, on Windows platforms, by stopping the standby instance. Then restart the active instance and do not set the flag that permits standby instances.

Before you begin

You have at least three servers configured to run a queue manager as a multi-instance queue manager. The queue manager is currently running as a multi-instance queue manager, with one standby instance active.

About this task

The task involves deactivating the active standby so that only the running multi-instance queue manager remains active. To prevent a standby instance being started in the future, you must stop the active instance and restart it. When you restart it, you start it as a single instance queue manager that prevents standby instances being started. The standby instance is stopped as a separate step, to give you the option of restarting the active instance at a later date. You can stop both instances by running the standard `endmqm` *QMgrName* command on the server running the active queue manager.

Procedure

1. Stop the standby queue manager instance. On the server running the standby instance:
   ```
   endmqm -w QMgrName
   ```
2. Stop the active queue manager instance. On the server running the active instance:
   ```
   endmqm -w (QMgrName)
   ```
3. Restart the queue manager, preventing standbys. On the server that is going to run the queue manager:
   ```
   strmqm QMgrName
   ```

What to do next

You might want to run the queue manager as a single instance on the same server as the queue manager data.

When the queue manager is stopped move the queue manager data back to the server that is running the queue manager. Alternatively install IBM MQ, and then move the queue manager configuration definition onto the server with the queue manager data. Both tasks are variations of steps in "Migrating from a single instance to a multi-instance queue manager on Windows" on page 712 to create a multi-instance queue manager.

Migrating MQ Telemetry on Windows

Windows

Follow these instructions to migrate your existing installation of MQ Telemetry to a later version of the product on Windows.

Before you begin

Before proceeding with this task, ensure that you back up your existing IBM MQ installation. You must stop the MQ Telemetry service `SYSTEM.MQXR.SERVICE` before migrating.

About this task

From Version 7.1 onwards, the telemetry server is included in the product as an optional installation.

For Version 7.1 and Version 7.5, the Client Software Development Kit (the telemetry clients) is also included in the optional installation. From Version 8.0 onwards, the Client Software Development Kit is no longer supplied as part of the product. Instead, the current version of the SDK is available as the IBM Messaging Telemetry Clients SupportPac.

Because MQ Telemetry is a component of IBM WebSphere MQ Version 7.1 and later, MQ Telemetry can either be installed with the main product, or installed after the main product has been installed. When you upgrade from a previous version of the product, you must download and use the latest version of the Client Software Development Kit.

After the successful upgrade, Windows systems retain the telemetry data in the installation directory of the product, for example: `C:\Program Files (x86)\IBM\WebSphere MQ`. Telemetry data is migrated to the later version of the product when the queue manager is started again.

Procedure

1. Create a migration plan. See "Planning to migrate to a later version on Windows" on page 685.
2. Migrate your queue managers to the later release.
3. Install MQ Telemetry.
4. Verify that the MQ Telemetry installation was successful. See Verifying the installation of MQ Telemetry.

Results

Message AMQ4616 indicates completion of the task. The existing MQTT channels and previous subscriptions are still present.

Migrating an MSCS configuration on Windows

Windows

Migrate queue managers in a Microsoft Cluster Service (MSCS) configuration one node at a time, following these instructions.

About this task

These steps are required for a rolling upgrade with a minimum amount of downtime. You must always upgrade an offline node with no online IBM MQ resources. In an Active/Passive configuration, if the node is Passive, you must ensure it cannot be switched to Active during the upgrade process.

The example, "Migrating a four-node MSCS cluster from an earlier version of the product to the latest version," shows this procedure applied to a four-node cluster.

Procedure

1. Modify the possible owners of the IBM MQ resource to encompass only the Active node or nodes. With no owners assigned to Passive nodes, the IBM MQ resource that is being migrated cannot be activated.
2. Ensure that the group containing the IBM MQ resource is currently on one of the nodes defined as a possible owner. The group must include any applications connecting to the queue manager resource.
3. Stop the cluster service on the node being migrated. The MSCS cache is cleared of any IBM MQ DLLs that have been registered.
4. Migrate the selected node by following the standard instructions in "Migrating a queue manager to a later version on Windows" on page 691. Apply the required maintenance level.
5. Start the cluster service on the selected node.
6. On the next node to be migrated, ensure that the IBM MQ resources are offline.
7. Remove this node from the list of possible owners. For clusters with more than two nodes, see the Additional considerations later in this topic.
8. Move the group containing the IBM MQ resource to one of the possible owners and bring it online.
9. Repeat steps 3-8 as necessary for any remaining nodes.

Migrating a four-node MSCS cluster from an earlier version of the product to the latest version

The example in Table 85 on page 718 illustrates the steps involved in migrating a four-node MSCS cluster.

In the example IBM MQ resources include queue managers, applications, and dependant MSCS resources, such as an IP address defined an as MSCS resource. In each step, the changes are italicized.

Step 1 Select the node to migrate and prepare it for upgrading from an earlier version of the product to the latest version.

1. Select node 1 to be migrated and convert it into a Passive node with no running IBM MQ resources.

2. Modify the possible owners of the group containing the IBM MQ resources, to encompass only the required online nodes. Failover does not attempt to switch IBM MQ resources to the node that is not a possible owner. It is safe to migrate that node.
3. Move the group containing the IBM MQ resource to one of the nodes that is a possible owner, and bring it online.
4. Stop the cluster service on the node being migrated. Stopping the service clears the MSCS cache of any IBM MQ libraries that have been registered for MSCS. The node goes offline.

Step 2 Migrate IBM MQ from an earlier version of the product to the latest version

Step 3 Start the cluster service on the selected node. The node becomes online, but it is not a possible owner, so no work is switched to it.

Step 4 Repeat steps 1 - 3 for node 2. Nodes 1 and 2 are now online, and you have migrated them to the latest version. They are still doing no work, as they are not possible owners of any of the IBM MQ resource groups.

Step 5 Migrate the cluster from running an earlier version of the product to the latest version. The number of migrated nodes is now greater or equal to the number of unmigrated nodes.

1. Change the set of possible owners from `3,4` to `1,2`.
2. Move the IBM MQ resource groups from nodes `3` and `4` to nodes `1` and `2` and bring online.
3. From this point onward, the list of possible owners must include migrated nodes only. The IBM MQ resource must never failover to a node running a back level version of the product.

Note: If you must revert IBM MQ to an earlier version, the IBM MQ resources must be removed from MSCS control, before performing an uninstallation of IBM MQ

Step 6 Migrate node 3 to the latest version.

1. Follow steps 1 - 3 for node 3.
2. Add node 3 to the list of possible owners.
3. Move the QMC resource group back from node 1 to node 3 and bring online again.

Step 7 Repeat step 6 for node 4.

Table 85. Migrating a four-node MSCS cluster

Steps		**0**	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Node 1	State	Online	*Offline*	Offline	*Online*	Online	Online	Online	Online
	Version	Earlier version	Earlier version	*Latest version*	Latest version	Latest version	Latest version	Latest version	Latest version
	Groups	QMA					*QMC, QMA*	*QMA*	QMA

	Groups	QMC	QMC, QMA	QMC, QMA	QMC, QMA	QMC, QMA		*QMC*	QMC

Table 85. Migrating a four-node MSCS cluster (continued)

Steps		0	1	2	3	4	5	6	7
Node 4	State	Online	Online	Online	Online	Online	Online	Online	Online
	Version	Earlier version	Earlier version	Earlier version	Earlier version	Earlier version	Earlier version	Earlier version	*Latest version*
	Groups	QMD	QMD	QMD	QMD	QMD, QMB			*QMD*
Possible Owners		1,2,3,4	*2,3,4*	2,3,4	2,3,4	*3,4*	*1,2*	*1,2,3*	*1,2,3,4*
Task			Update 1			Update 2	Transfer	Update 3	Update 4

What to do next

Additional considerations in an MSCS setup with more than 2 nodes: A cluster might contain enough nodes for you to form a group of migrated queue managers and a group of unmigrated nodes. Switch to the migrated group when it contains half the number of queue managers. Before you have reached the half way point, the unmigrated group are possible owners. When you reach the half way point, switch the possible owners to the migrated group.

Related tasks:

"Migrating a queue manager in a high-availability configuration" on page 814
High-availability configurations of queue managers can increase the availability of IBM MQ applications. If a queue manager, or server fails, it is restarted automatically on another server. You can arrange for IBM MQ MQI client applications to automatically reconnect to the queue manager. Server applications can be configured to start when the queue manager starts.

Related reference:

"MSCS restriction with multiple installations on Windows" on page 641
When you install or upgrade to Version 7.1 or later, the first installation of the product on the server is the only one that can be used with Microsoft Cluster Server (MSCS). No other installations on the server can be used with MSCS. This restriction limits the use of MSCS with multiple installations of the product.

Migrating logs to an Advanced Format disk on Windows

Windows V 9.0.4

An Advanced Format disk is one that has 4096 bytes per sector. The following is applicable only to the Windows platform as Advanced Format disks can be used on other platforms, without carrying out a migration procedure.

Attention: On Windows prior to Version 9.0.4, IBM MQ does not support Advanced Format disks

Note the following:

- A migrated log can be used on any disk whether or not it is Advanced Format.
- If you are not using an Advanced Format disk, you do not need to migrate the log of your queue manager.
- Queue managers that are created at IBM MQ Version 9.0.4 can be used on an Advanced Format disk without being migrated.
- If you use a queue manager that was created before Version 9.0.4 on a native Advanced Format disk, without migrating the queue manager first, the queue manager will not start
- It is possible to start a queue manager on an Advanced Format disk in emulation mode without migration. However IBM MQ log writes will not be on 4k boundaries and so the queue manager will not have data integrity. Once the logs have been migrated, an Advanced Format disk in emulation mode is reliable.

- If you are not sure whether your disk is Advanced Format or not, use the Windows utility **fsutil** to find out.
- The Advanced Format disks that require you to migrate your log, include 4k native disks and 512-byte Emulation disks.
- Using **migmqlog** to change from linear logging to circular logging, or from circular logging to linear logging, also migrates the log so that the log can be used on an Advanced Format disk.

Related tasks:

"Migrating logs on UNIX, Linux, and Windows" on page 820
From IBM MQ Version 9.0.4 you can migrate a circular log to a linear log, or from a linear log to a circular log.

Migrating IBM MQ on UNIX and Linux

UNIX Linux

Migration tasks associated with UNIX and Linux platforms are grouped in this section.

Windows "Migrating IBM MQ on Windows" on page 684
IBM MQ migration tasks associated with Windows platforms are grouped in this section.

z/OS "Migrating IBM MQ on z/OS" on page 770
Migration tasks associated with z/OS are grouped in this section.

Related reference:

"Changes that affect migration" on page 626
Changes to the product might affect the migration of a queue manager from an earlier release to the current release of IBM MQ, or affect existing applications or configurations. Review these changes before upgrading queue managers to the latest product version and decide whether you must plan to make changes to existing applications, scripts, and procedures before starting to migrate your systems.

Planning to migrate to a later version on UNIX and Linux

Linux UNIX

Before migrating from one version to another on UNIX and Linux, read this topic. Create your own migration plan based on the outline in the planning topic.

If there are concepts about migration you do not understand, read "Migration concepts and methods" on page 645, and the subsections you need, first.

About this task

Use the following steps as a guide to creating a migration plan.

Procedure

1. Review the IBM MQ system requirements for the later version of the product. See System Requirements for IBM MQ.

2. Decide whether to run the earlier version and the later version of the product on the same server, and also which migration method you want to use. See “Migration methods on IBM MQ for Multiplatforms” on page 653.

   Important: Note that if you require a multi-version installation, and you are using a version of the product prior to IBM WebSphere MQ Version 7.0.1, Fix Pack 6, you must install Version 7.0.1, Fix Pack 6 first before installing the later version.
3. Review all the changes in IBM MQ that affect you. For more information, see “Changes that affect migration” on page 626.
4. Review performance changes. See IBM MQ Family - Performance Reports.
5. Review the readme file for the product that you are working with. See IBM MQ, WebSphere MQ, and MQSeries product readmes.
6. Plan the sequence and timing of queue manager upgrades.
   - If the queue manager is part of a queue manager cluster, you must migrate the queue managers that are full repositories first.
   - If the queue manager is part of a high availability cluster, plan the migration to minimize downtime and maximize availability; see “Migrating a queue manager in a high-availability configuration” on page 814.
7. Plan to migrate your queue manager to the later version. See “Migrating a queue manager to a later version on UNIX and Linux” on page 722.

   Backing up queue manager data is part of the queue manager migration task. An alternative approach to backing up queue manager data, is to install and configure a new server. Test the later version with a new queue manager on the new server. When you are ready to go into production on the later version, copy the queue manager configuration and data, to the new server.
8. Plan to update any manual or automated procedures you have written with changes to messages and codes.
9. Decide on what regression tests to perform before putting the queue manager into production on the later version. Include the procedures and applications you identified in steps 6 and 7 in your regression tests.
10. Plan to upgrade your IBM MQ MQI client installations to the later version.
11. Plan to upgrade your client and server applications to use new functions in the later version.

Migrating a queue manager on UNIX and Linux

UNIX Linux

The procedures for migrating a queue manager to a later version of the product, and for restoring a queue manager to an earlier version of the product are detailed in this section.

Related tasks:

IBM i "Migrating a queue manager to a later version on IBM i" on page 751
Follow these instructions to migrate a queue manager from an earlier release to a later release.

Windows "Migrating a queue manager on Windows" on page 691
The procedures for migrating a queue manager to a later version of the product, and for restoring a queue manager to an earlier version of the product are detailed in this section.

z/OS "Migrating IBM MQ on z/OS" on page 770
Migration tasks associated with z/OS are grouped in this section.

Migrating a queue manager to a later version on UNIX and Linux: UNIX Linux

On UNIX and Linux, follow these instructions to migrate a queue manager from an earlier version to a later version of IBM MQ.

Before you begin

If you have installed early support program code on the server, you must delete all the queue managers created with the installation. Uninstall the code before proceeding with installing the production level code.

1. The upgrade from the earlier version to the latesr version of the product requires a full migration of queue managers. Create a migration plan. Use the planning task, "Planning to migrate to a later version on UNIX and Linux" on page 720, as a guide.
2. Review the IBM MQ system requirements for the later version; see System Requirements for IBM MQ.
3. Back up your system before you install a later version of IBM MQ over an earlier version. Once you have started a queue manager you cannot revert to the previous version. If you must restore the system, you cannot recover any work, such as changes to messages and objects, performed by the later version of IBM MQ. For more information about backing up your system, see Backing up and restoring IBM MQ queue manager data.
4. Review any other installed SupportPacs for their applicability to the later version.
5. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

To run a command, the operating system must find the command in an IBM MQ installation. For some commands, you must run the command from the installation that is associated with the correct queue manager. IBM MQ does not switch commands to the correct installation. For other commands, such as **`setmqinst`**, you can run the command from any installation that has the latest version of the product installed.

If an earlier version of the product is installed, the command that is run is the command for that version, unless the search path is overridden by a local setting. You can override the search path by running **`setmqenv`**. If Version 7.0.1 is not installed, you must set the correct path to run a command. If you have set a primary installation, the command that is run is the copy in the primary installation, unless you override the selection with a local search path.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.

3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **dspmq** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:

      ```
      dspmq -o installation -o status
      dspmq -a
      ```

      dspmq -o installation -o status displays the installation name and status of queue managers associated with all installations of IBM MQ.

      dspmq -a displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **DISPLAY LSSTATUS** to list the status of listeners associated with a queue manager, as shown in the following example:

      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **endmqm** command to stop each running queue manager associated with this installation.

      ```
                    ┌─-c─┐
      ►►──endmqm────┼─-w─┼──QmgrName──────────────────────────────────────►◄
                    ├─-i─┤
                    └─-p─┘
      ```

      The **endmqm** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **endmqm** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: "Applying maintenance level updates to multi-instance queue managers on UNIX and Linux" on page 611 describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.
   d. Stop any listeners associated with the queue managers, using the command:

      ```
      endmqlsr -m QMgrName
      ```
4. Back up the queue manager. Take copies of all the queue manager's data and log file directories, including all subdirectories, and also the `qm.ini` file. For more information, see Backing up and restoring IBM MQ queue manager data.
5. Log in as root.
6. If you are running IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later, optionally uninstall the current version of IBM MQ. Note, that you carry out this step only if you are doing a single stage migration; see "Migrating on UNIX and Linux: single-stage" on page 724.
7. If you are running IBM WebSphere MQ Version 7.0.1, Fix Pack 5 or earlier, uninstall the current version of IBM MQ. If you require a side-by-side migration or multistage migration only, you must upgrade to IBM WebSphere MQ Version 7.0.1, Fix Pack 6.
8. Install the later version of the product. See the appropriate topic for the platform that your enterprise uses:

AIX Installing IBM MQ Server on AIX.

HP-UX Installing IBM MQ Server on HP-UX.

Linux Installing IBM MQ Server on Linux.

Solaris Installing IBM MQ Server on Solaris.

9. Move the queue manager to the new IBM MQ installation. You need to carry out this step, only if you are running IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later, and did not uninstall your current version of the product.

   See "Migrating on UNIX and Linux: side-by side" on page 727 or "Migrating on UNIX and Linux: multi-stage" on page 730 for further information.

10. Start the queue manager.

    `strmqm` *`QmgrName`*

    When you first start a queue manager after migration:

    - Any new attributes for existing objects are set to their default values.
    - Any new default objects are created.
    - Queue manager data is migrated.

    Important: Do not use the `-c` option to start the queue manager, unless you explicitly want to reset or re-create the default system objects.

    You must start IBM MQ before you start any listeners.

Backing up and restoring a queue manager

"The version naming scheme for IBM MQ for Multiplatforms" on page 567
From IBM MQ Version 9.0, releases have a three digit Version, Release, and Modification (VRM) code or a four-digit Version, Release, Maintenance, and Fix (VRMF) level code.

Migrating on UNIX and Linux: single-stage: UNIX Linux

Single-stage migration is the term used to describe replacing the only installation of IBM MQ on a server, with a later release. Single stage migration is also known as *upgrading in place* or *in place upgrade*. Until Version 7.0.1, Fix Pack 6, single-stage was the only migration scenario. Single-stage migration preserves existing scripts and procedures for running IBM MQ the most. With other migration scenarios you might change some scripts and procedures, but you can reduce the effect queue manager migration has on users.

Before you begin

Attention: V 9.0.0 From IBM MQ Version 9.0, the `ccsid_part2.tbl` file replaces the existing `ccsid.tbl` file, used in previous versions of the product, to supply additional CCSID information.

The `ccsid_part2.tbl` file takes precedence over the `ccsid.tbl` file and:
- Allows you to add or modify CCSID entries
- Specify default data conversion
- Specify data for different command levels

The `ccsid_part2.tbl` is applicable to the following platforms only:
- Linux Linux - all versions
- Solaris Solaris
- Windows Windows

If you have added any of your own CCSID information into your existing `ccsid.tbl` file, you should copy this information into the new `ccsid_part2.tbl` file, if you want to take advantage of the new formats in your customizations

You should copy the required information, rather than move the information, so that your existing version of IBM MQ continues to work.

About this task

In the single-stage migration scenario, the installation of the later version of the product replaces an earlier version in the same installation location. It is the same migration process that you might have previously used to upgrade the product prior to IBM WebSphere MQ Version 7.0.1, Fix Pack 6. From Version 7.0.1, Fix Pack 6, this method of migration is termed *single-stage* migration, in contrast to *side-by-side* and *multi-stage* migration.

The advantage of single-stage migration is that it changes the configuration of a queue manager on the earlier version as little as possible. Existing applications switch from loading the libraries from the earlier version, to loading the libraries of the later version, automatically. Queue managers are automatically associated with the installation on the later version. Administrative scripts and procedures are affected as little as possible by setting the installation to be the primary installation. If you set the installation of the later version to be the primary installation, commands such as **`strmqm`** work without providing an explicit path to the command.

You can also migrate a queue manager to a later version of the product on a system where an earlier version has been uninstalled. In this case, the queue manager data must have been retained, or restored from a backup.

Procedure

1. Stop local IBM MQ applications.
2. Stop all the queue managers and listeners.
3. Uninstall any fix packs you have installed from the previous IBM MQ version.
4. Upgrade the earlier version of the product to the later version in the same installation directory.
   - A reason for installing into the same location is to simplify application migration. If you change the installation location, you might remove IBM MQ libraries from an application search path. To migrate an application search path you must modify the application environment, or more rarely, the application itself.
   - UNIX Linux The default installation path is specified as a load path in the IBM MQ build scripts for UNIX and Linux. After installation of the later version, the load libraries of the later version of IBM MQ are in the same location as were the libraries of the earlier version. If you built applications by following the examples in the product documentation for the earlier version, the applications load the correct libraries in the later version.

   a. Decide on an installation naming convention. Give the installation a name of your choosing, or accept the default installation name. For the first installation, the default name is *Installation1*. For the second installation, the name is *Installation2*, and so on.

      AIX On AIX there is no option to set the installation name, *Installation1* is set by default.

   b. Upgrade the earlier version of the product to the later version in place, or uninstall the earlier version, without deleting any queue managers, and install the later version in the same default location. Whether you have to uninstall your previous version of the product depends upon your operating system.

      On the following platforms, you do not have to uninstall a previous version of the product:

      - AIX AIX

- IBM i IBM i, where the process is known as a *slip* installation

  AIX If `mqm.xr.clients` and `mqm.txclient.rte` file sets from earlier versions are installed, you must uninstall these file sets from the earlier versions.

  On the following platforms, you must uninstall the previous version of the product:

  - HP-UX HP-UX
  - Linux Linux
  - Solaris Solaris

5. Optional: Make the later version of the installation the primary installation.
   a. Run the **`setmqinst`** command

      ```
      Inst_1_INSTALLATION_PATH/bin/setmqinst -i -n Inst_1
      ```
   - Make the installation primary to avoid specifying a search path to run IBM MQ commands.
   - If there is a primary installation, UNIX and Linux applications that expect to find the IBM MQ library in `/usr/lib`, find a symbolic link to the library in `/usr/lib/32`[6] . `/usr/lib/32` is normally in the default search path. It is also specified as a load path in the IBM MQ build scripts for UNIX and Linux.
   - It is sufficient to link applications only to `/usr/lib`. With a primary installation of the later version of the product defined on the server, an application can connect to any queue manager associated with any installation on the server. IBM MQ loads the correct library for the application.
6. Start the queue managers and applications.
   a. Optional: Run the **`setmqm`** command to associate the queue managers with `Inst_1`.

      ```
      setmqm -m QM1 -n Inst_1
      setmqm -m QM2 -n Inst_1
      ```

      Notes:
      - The **`setmqm`** step is optional only in the case where migration is from IBM WebSphere MQ Version 7.0.1 to a later release. In this case, the **`strmqm`** command automatically associates the queue manager with its own installation.
      - If you are migrating between any other releases of the product, you must use **`setmqm`** to associate the queue managers with the new installation manually.

   b. Run the **`strmqm`** command to start the queue managers and migrate them to the later version of the product.

      ```
      strmqm QM1
      strmqm QM2
      ```

      At this point, queue manager data is migrated and you cannot revert to a previous release.
   - When an application connects to a queue manager, the operating system searches its load path to load the IBM MQ library. A Version 7.1, or later, library contains code that checks that the queue manager is associated with an installation. If a queue manager is associated with a different installation, IBM MQ loads the correct IBM MQ library for the installation the queue manager is associated with.

What to do next

You cannot reinstall an earlier version of the product on a system that has the latest, or any other, version of IBM MQ installed.

6. `/usr/lib` for 64 bit applications.

Related concepts:

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

Related tasks:

"Planning to migrate to a later version on Windows" on page 685
Before migrating from one version of IBM MQ to another on Windows, read this topic, then create your own migration plan based on the outline in this topic.

"Migrating a queue manager to a later version on UNIX and Linux" on page 722
On UNIX and Linux, follow these instructions to migrate a queue manager from an earlier version to a later version of IBM MQ.

"Migrating a queue manager to a later version on Windows" on page 691
On Windows platforms, follow these instructions to migrate a queue manager from an earlier version to a later version of IBM MQ.

"Migrating IBM MQ library loading from an earlier version of the product to the latest version" on page 684
No change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the latest version. You must have followed the instructions on building IBM MQ applications in the earlier version, and you must replace the earlier version with the latest version of the product. If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

Migrating on UNIX and Linux: side-by side: UNIX Linux

Side-by-side migration is the term used to describe installing a later version of IBM MQ alongside an earlier version on the same server. Queue managers remain running during the installation and verification of the later version of IBM MQ. They remain associated with the earlier version of IBM MQ. When you decide to migrate queue managers to the later version of IBM MQ, you stop all queue managers, uninstall the earlier version, and migrate them all to the later version of IBM MQ.

Before you begin

If you are using IBM WebSphere MQ Version 7.0.1, you must ensure that you are running IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later before installing a later version of the product on the same server. For more information about Version 7.0.1 fix packs, see Recommended Fixes for IBM MQ.

Attention: V 9.0.0 From IBM MQ Version 9.0, the `ccsid_part2.tbl` file replaces the existing `ccsid.tbl` file, used in previous versions of the product, to supply additional CCSID information.

The `ccsid_part2.tbl` file takes precedence over the `ccsid.tbl` file and:
- Allows you to add or modify CCSID entries
- Specify default data conversion
- Specify data for different command levels

The `ccsid_part2.tbl` is applicable to the following platforms only:
- Linux Linux - all versions
- Solaris Solaris
- Windows Windows

If you have added any of your own CCSID information into your existing `ccsid.tbl` file, you should copy this information into the new `ccsid_part2.tbl` file, if you want to take advantage of the new formats in your customizations

You should copy the required information, rather than move the information, so that your existing version of IBM MQ continues to work.

About this task

In the side-by-side migration scenario, you install the later version of IBM MQ alongside queue managers that continue to be associated with Version 7.0.1, or later.

When you are ready to migrate the queue managers, and applications, to the later version:
1. Stop all the queue managers.
2. Uninstall the earlier version of the product.
3. Migrate all the queue managers and applications to the later version.

Procedure
1. Install the later version in a different installation directory from the earlier version.
   a. Decide on an installation naming convention. Give the installation a name of your choosing, or accept the default installation name. For the first installation, the default name is *Installation1*. For the second installation, the name is *Installation2*, and so on.

      AIX On AIX there is no option to set the installation name, *Installation1* is set by default.
   b. Verify the installation.

      Run the installation verification procedures and your own tests.
2. Uninstall the earlier version of the product.

   When uninstalling the earlier product, you must stop all queue managers and applications that have loaded an IBM MQ library on the server. For this reason, you might choose to postpone uninstalling the earlier version of the product until a convenient maintenance window. When an earlier version of the product is not installed on a server, it is sufficient to stop the queue managers and applications that have loaded libraries from the installation that you are uninstalling or updating. It is not necessary to stop applications and queue managers associated with other installations.

   a. Stop all applications that have loaded IBM MQ libraries on the server.
   b. Stop the queue managers and listeners on the server.
   c. Uninstall the earlier version of the product.
      - Stop all local IBM MQ applications
      - If you are migrating from IBM WebSphere MQ Version 7.0.1, stop all your queue managers and listeners, ensuring that you do not delete the queue managers.

        Note: If you are migrating from a release other than IBM WebSphere MQ Version 7.0.1 you do not need to stop all the queue managers at this point.

3. Make the later version of the installation the primary installation.
   a. Run the **`setmqinst`** command

      ```
      Inst_1_INSTALLATION_PATH/bin/setmqinst -i -n Inst_1
      ```

   - Make the installation primary to avoid specifying a search path to run IBM MQ commands.
   - If there is a primary installation, UNIX and Linux applications that expect to find the IBM MQ library in `/usr/lib`, find a symbolic link to the library in `/usr/lib/32`[7] . `/usr/lib/32` is normally in the default search path. It is also specified as a load path in the IBM MQ build scripts for UNIX and Linux.
   - It is sufficient to link applications only to `/usr/lib`. With a primary installation of the later version of the product defined on the server, an application can connect to any queue manager associated with any installation on the server. IBM MQ loads the correct library for the application.

   Use the dspmqinst command to discover the *`Installation name`*, or use the default value `Installation 1`.

   Doing this means that you do not have to specify a search path on IBM MQ commands.

4. Start the queue managers and applications.
   - When an application connects to a queue manager, the operating system searches its load path to load the IBM MQ library [8] . A Version 7.1, or later, library contains code that checks that the queue manager is associated with an installation. If a queue manager is associated with a different installation, IBM MQ loads the correct IBM MQ library for the installation the queue manager is associated with.

   During this process you continue to use queue manager QM2 while you upgrade queue manager QM1 and you use queue manager QM1 while you upgrade QM2.

   Note that each queue manager needs to be stopped in order to be associated with the new installation.

What to do next

You cannot reinstall an earlier version of the product on a system that has the latest, or any other, version of IBM MQ installed.

7. `/usr/lib` for 64 bit applications.

8. On Windows, the IBM MQ library is a DLL. A DLL is sometimes called a load library or a shared library. The entry points to a DLL are defined in a link library, with the file extension `.lib32` or `.lib`. The `.lib` library is linked at build-time and the DLL loaded at runtime.

"Planning to migrate to a later version on Windows" on page 685
Before migrating from one version of IBM MQ to another on Windows, read this topic, then create your own migration plan based on the outline in this topic.

Associating a queue manager with an installation

Changing the primary installation

Choosing an installation name

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

"Migrating IBM MQ library loading from an earlier version of the product to the latest version" on page 684
No change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the latest version. You must have followed the instructions on building IBM MQ applications in the earlier version, and you must replace the earlier version with the latest version of the product. If you choose to take advantage of multi-installation in the latest version of the product, based on the side-by-side or multi-stage migration scenarios, you must modify the environment for the operating system to resolve IBM MQ dependencies for an application. Typically, you can modify the runtime environment, rather than relink the application.

"Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668
You can install multiple copies of IBM MQ for UNIX, Linux, and Windows on the same server. The installations must be at Version 7.1 or later, with one exception. One Version 7.0.1 installation, at fix pack level 6, or later, can coexist with multiple Version 7.1, or later installations.

setmqenv

setmqinst

setmqm

Migrating on UNIX and Linux: multi-stage: UNIX Linux

Multi-stage migration is the term used to describe running a later version of IBM MQ alongside an earlier version on the same server. After installing the later version alongside the earlier version, you can create new queue managers to verify the installation of the later version, and develop new applications. At the same time, you can migrate queue managers and their associated applications from the earlier version to the later version. By migrating queue managers and applications one-by-one, you can reduce the peak workload on staff managing the migration.

Before you begin

If you are using IBM WebSphere MQ Version 7.0.1, you must ensure that you are running IBM WebSphere MQ Version 7.0.1, Fix Pack 6 or later before installing a later version of the product on the same server. For more information about Version 7.0.1 fix packs, see Recommended Fixes for IBM MQ.

Attention: V 9.0.0 From IBM MQ Version 9.0, the `ccsid_part2.tbl` file replaces the existing `ccsid.tbl` file, used in previous versions of the product, to supply additional CCSID information.

The `ccsid_part2.tbl` file takes precedence over the `ccsid.tbl` file and:
- Allows you to add or modify CCSID entries
- Specify default data conversion
- Specify data for different command levels

The `ccsid_part2.tbl` is applicable to the following platforms only:
- Linux Linux - all versions
- Solaris Solaris
- Windows Windows

If you have added any of your own CCSID information into your existing `ccsid.tbl` file, you should copy this information into the new `ccsid_part2.tbl` file, if you want to take advantage of the new formats in your customizations

You should copy the required information, rather than move the information, so that your existing version of IBM MQ continues to work.

Note:
- If an application uses COM or ActiveX it can connect to any queue manager as long as there is a primary installation and it is Version 7.1 or later.
- If you are running the IBM MQ.NET monitor in transactional mode, the queue manager it connects to must be the primary installation.

You cannot migrate these applications to the later version until you uninstall the earlier version.

About this task

In the multi-stage migration scenario, you install the later version of the product alongside running queue managers that continue to be associated with the earlier version. You can create queue managers and run new applications using the later version installation. When you are ready to start migrating queue managers and applications from the earlier, you can do so, one-by-one. When migration to the later version is complete, you can uninstall the earlier version, and make the later version installation the primary installation.

With the multi-stage approach, until you uninstall the earlier version , you must configure an environment to run applications that connect to a queue manager to the later version. You must also provide a path to run IBM MQ commands. Both these tasks are accomplished with the **`setmqenv`** command.

Note: When you have uninstalled the earlier version, and set the later version as a primary installation, in most circumstances it is not necessary to run the **`setmqenv`** command to run applications. It is still necessary to run **`setmqenv`** to set the environment for commands that connect to a queue manager associated with an installation that is not primary.

Procedure

1. Install the later version in a different installation directory from the earlier version and verify the installation.
   a. Decide on an installation naming convention. Give the installation a name of your choosing, or accept the default installation name. For the first installation, the default name is *Installation1*. For the second installation, the name is *Installation2*, and so on.

AIX On AIX there is no option to set the installation name, *Installation1* is set by default.

   b. Verify the installation.

      Run the installation verification procedures and your own tests.

- You might create new queue managers running the later version, and start to develop new applications before migrating applications from the earlier version.

2. Configure the operating system so that applications load the libraries for the later version of the product.
   a. Migrate queue managers one at a time.

      The first set of applications to load the libraries for the later version of the product are the applications that connect to the first queue manager you are going to migrate.

      It does not matter if those applications also connect to other queue managers on the server. If the applications load the later version libraries, IBM MQ automatically loads the libraries for the earlier version for those applications that connect to that version.

      You can either migrate the operating system environment of all applications, or just the applications that connect to the first queue manager you are going to migrate.
   b. Migrate IBM MQ MQI client applications

      Some of the applications might be running as IBM MQ MQI client applications on another workstation. When you migrate a queue manager, clients connected to it continue to run without loading a client library for the later version.

      You can migrate these clients later, when you need to do so.

      Important: If any IBM MQ MQI client applications are using the library for the earlier version on the server, you must eventually migrate the clients to use the later version of the product before you uninstall the earlier version.
3. Migrate an application to load the new library for the later version:
   - Run **setmqenv** to modify the local path that is searched for IBM MQ libraries.
   - Modify the global search path that is searched for IBM MQ libraries.
   - Relink applications with an additional runtime load path.

     Consult operating system documentation about how to modify the global search path, or include a fixed runtime load path in the application load module.

   To run **setmqenv** using the `-s` option:

   ```
   .Inst_1_INSTALLATION_PATH/bin/setmqenv -s -k
   ```

   The `-s` option sets up the environment for the installation that runs the **setmqenv** command.

   The `-k` option inserts the path to the IBM MQ load libraries at the start of the `LD_LIBRARY_PATH` environment variable, and adds the variable to the local environment; see “Loading IBM MQ libraries” on page 670.

   Note: On UNIX the leading `"."` is critical. The dot followed by a space instructs the command shell run **setmqenv** in the same command shell and inherit the environment set by **setmqenv**.
4. Restart the queue manager and the applications that connect to it.
   a. Set up the local environment to the installation `Inst_1`.

      ```
      .Inst_1_INSTALLATION_PATH/bin/setmqenv -s
      ```

      The `-s` option sets up the environment for the installation that runs the **setmqenv** command.
   b. Run the **setmqm** command to associate `QM1` with `Inst_1`.

      ```
      setmqm -m QM1 -n Inst_1
      setmqm -m QM2 -n Inst_1
      ```
   c. Run the **strmqm** command to start `QM1` and migrate it to the later version.

      ```
      strmqm QM1
      strmqm QM2
      ```

   d. Restart application 1

      The application loads the later version library and connects to `QM1`, which is associated with the later version of the product.

5. Migrate all queue managers and applications to the later version.

   Repeat steps 2 on page 732 and 4 on page 732, when required, until all the queue managers and applications are migrated to the later version of the product.

6. Uninstall the earlier version of the product.

   When uninstalling the earlier product, you must stop all queue managers and applications that have loaded an IBM MQ library on the server. For this reason, you might choose to postpone uninstalling the earlier version of the product until a convenient maintenance window. When an earlier version of the product is not installed on a server, it is sufficient to stop the queue managers and applications that have loaded libraries from the installation that you are uninstalling or updating. It is not necessary to stop applications and queue managers associated with other installations.

   a. Stop all applications that have loaded IBM MQ libraries on the server.
   b. Stop the queue managers and listeners on the server.
   c. Uninstall the earlier version of the product.
      - Stop all local IBM MQ applications
      - If you are migrating from IBM WebSphere MQ Version 7.0.1, stop all your queue managers and listeners, ensuring that you do not delete the queue managers.

        Note: If you are migrating from a release other than IBM WebSphere MQ Version 7.0.1 you do not need to stop all the queue managers at this point.

7. Make `Inst_1` the primary installation.

   a. Run the **`setmqinst`** command

      ```
      Inst_1_INSTALLATION_PATH/bin/setmqinst -i -n Inst_1
      ```

   - You do not have to set up a search path to run IBM MQ commands from the primary installation.
   - If you set an installation of the later version of the product as primary on UNIX and Linux, you do not have to set up `LD_LIBRARY_PATH` in most cases. You can remove calls to **`setmqenv`** to set `LD_LIBRARY_PATH`.

What to do next

You cannot reinstall an earlier version of the product on a system that has the latest, or any other, version of IBM MQ installed.

Now that you have uninstalled the earlier version of the product, and made the later installation primary, you can review how the application runtime environment is set. It is no longer necessary to run **`setmqenv`** to set up the search path to load libraries for the later version. If you have only one installation of the later version of the product installed, it is not necessary to run **`setmqenv`** to run commands.

Reverting a queue manager to an earlier version on UNIX and Linux: Linux UNIX

On UNIX and Linux, you can revert a queue manager to an earlier version of the product from a later version, if you have made a backup of the system or queue manager. If you have started the queue manager and processed any messages, or changed the configuration, the task cannot give you any guidance on reverting the current state of the queue manager.

Before you begin

1. You must have made a backup of the system or queue manager before you upgraded to the later version. For more information see Backing up and restoring IBM MQ queue manager data
2. If any messages were processed after starting the queue manager, you cannot easily undo the effects of processing the messages. You cannot revert the queue manager to the earlier version of the product in its current state. The task cannot give you any guidance how to deal with subsequent changes that have occurred. For example, messages that were indoubt in a channel, or in a transmission queue on another queue manager, might have been processed. If the queue manager is part of a cluster, then configuration messages and application messages might have been exchanged.

3. If you are running on a server with multiple IBM MQ installations, you must identify the installation. Make sure that the commands you enter run against the correct installation; see setmqenv.

About this task

When you revert to a earlier version of a queue manager, you revert the queue manager to its earlier code level. Queue manager data is reverted to the state it was in when the queue manager was backed up.

Procedure

1. Log in as a user in `group mqm`.
2. Stop all applications using the IBM MQ installation.

   If you use the Managed File Transfer (MFT) component, ensure that any MFT agents have finished all of the file transfers that they were engaged in. There should be no incomplete transfers associated with the agents, and their SYSTEM.FTE.STATE queues should contain no messages.
3. End all the activity of queue managers associated with the IBM MQ installation.
   a. Run the **`dspmq`** command to list the state of all the queue managers on the system.

      Run either of the following commands from the installation that you are updating:
      ```
      dspmq -o installation -o status
      dspmq -a
      ```
      `dspmq -o installation -o status` displays the installation name and status of queue managers associated with all installations of IBM MQ.

      `dspmq -a` displays the status of active queue managers associated with the installation from which the command is run.
   b. Use the MQSC command **`DISPLAY LSSTATUS`** to list the status of listeners associated with a queue manager, as shown in the following example:
      ```
      echo "DISPLAY LSSTATUS(*) STATUS" | runmqsc QmgrName
      ```
   c. Run the **`endmqm`** command to stop each running queue manager associated with this installation.

      ```
                   ┌─-c─┐
      ►►──endmqm───┼─-w─┼──QmgrName──────────────────────────────────────►◄
                   ├─-i─┤
                   └─-p─┘
      ```

      The **`endmqm`** command informs an application that the queue manager it is connected to is stopping; see Stopping a queue manager.

      For the maintenance to proceed, applications must respond to an **`endmqm`** command by disconnecting from the queue manager and releasing any IBM MQ libraries they have loaded. If they do not, you must find another way to force applications to release IBM MQ resources, such as by stopping the applications.

      You must also stop applications that are using the client libraries that are part of the installation. Client applications might be connected to a different queue manager, running a different installation of IBM MQ. The application is not informed about queue managers in the current installation being shut down.

      Any applications that continue to have IBM MQ shared libraries from the installation loaded prevent you applying IBM MQ maintenance. An application might disconnect from a queue manager, or be forcibly disconnected, but keep an IBM MQ shared library loaded.

      Note: The topic, "Applying maintenance level updates to multi-instance queue managers on Windows" on page 577, describes how to apply maintenance to a multi-instance queue manager. A multi-instance queue manager can continue to run on one server, while maintenance is applied to another server.

   d. Stop any listeners associated with the queue managers, using the command:

      ```
      endmqlsr -m QMgrName
      ```
4. Restore the system, or IBM MQ and the queue manager.

   If your backup procedure was to save the queue manager data, you must reinstall IBM MQ:
   a. Uninstall the earlier installation.
   b. Reinstall the product from a manufacturing refresh.
   c. Apply the fix pack and interim fixes that restore IBM MQ to its previous level.
   d. Restore the queue manager data from the backup taken before installing the later version.
5. Restart the earlier version queue manager.

What to do next

You might be reverting to a earlier version on a server with multiple IBM MQ installations. If one of the installations is primary, after reverting the earlier version that installation, by default, becomes the primary installation.

You must review how applications connect to an installation. After reverting to the earlier version, some applications might connect to the wrong installation.

Before migrating an IBM MQ MQI client, create a migration plan. Stop all IBM MQ activity on the client workstation. Upgrade the IBM MQ MQI client installation. Make any essential configuration and application changes.

Migrating an IBM MQ MQI client to a later version on UNIX and Linux: Linux UNIX

To upgrade a client to a later version of the product on UNIX and Linux, you must first stop all IBM MQ activity on the workstation, then uninstall the earlier version and install the later version. After you have upgraded the client, you can then make any essential configuration and application changes.

Before you begin

Before migrating an IBM MQ MQI client on UNIX and Linux, first create a migration plan. For guidance on what to include in the plan, see "Planning to migrate to a later version on UNIX and Linux" on page 720, as a guide.

About this task

IBM MQ MQI client migration is the process of converting IBM MQ MQI client configurations, and client and server channels from one version to another. Client migration is reversible. It is optional and manual on a client workstation and is required and automatic on the IBM MQ server.

You must upgrade an IBM MQ MQI client before migrating a client workstation to make use of new configuration options. You can make configuration changes to client and server connection channels on the server, but they have no effect on a client workstation until the client is upgraded.

Procedure

1. Review the IBM MQ system requirements for the later version of the product. See System Requirements for IBM MQ.
2. Review all the changes in IBM MQ that affect you. For more information, see "Changes that affect migration" on page 626.
3. End all IBM MQ activity on the workstation. You are now ready to upgrade the client. Follow the instructions for the appropriate platform that your enterprise uses.
4. AIX To upgrade the client on AIX:
   a. Uninstall your existing IBM MQ client installation. For more information, see Uninstalling or modifying IBM MQ on AIX.
   b. Follow the client installation procedure to install the upgraded version of the IBM MQ client:
      - For a client installation on a workstation, see Installing an IBM MQ client on AIX
      - For a client installation on an IBM MQ server, see Installing IBM MQ clients and servers on the same system.
5. HP-UX To upgrade the client on HP-UX:
   a. Uninstall your existing IBM MQ client installation. For more information, see Uninstalling or modifying IBM MQ on HP-UX.
   b. Follow the client installation procedure to install the upgraded version of the IBM MQ client:
      - For a client installation on a workstation, see Installing an IBM MQ client on HP-UX.
      - For a client installation on an IBM MQ server, see Installing IBM MQ clients and servers on the same system.
6. Linux To upgrade the client on Linux:
   a. Uninstall your existing IBM MQ client installation. For more information, see Uninstalling or modifying IBM MQ on Linux.
   b. Follow the client installation procedure to install the upgraded version of the IBM MQ client:
      - For a client installation on a workstation, see Installing an IBM MQ client on Linux.
      - For a client installation on an IBM MQ server, see Installing IBM MQ clients and servers on the same system.
7. Solaris To upgrade the client on Solaris:
   a. Uninstall your existing IBM MQ client installation. For more information, see Uninstalling IBM MQ on Solaris.
   b. Follow the client installation procedure to install the upgraded version of the IBM MQ client:
      - For a client installation on a workstation, see Installing an IBM MQ client on Solaris.

- For a client installation on an IBM MQ server, see Installing IBM MQ clients and servers on the same system.

What to do next

After upgrading the IBM MQ MQI client, you must check the client channel configuration, and verify that your IBM MQ MQI client applications work correctly with the later version of the product.

Related concepts:

"IBM MQ MQI client migration" on page 650
IBM MQ MQI client migration is the process of converting IBM MQ MQI client configurations, and client and server channels from one version to another. Client migration can take place after upgrading the IBM MQ MQI client, and is reversible.

Restoring an IBM MQ MQI client to an earlier version on UNIX and Linux: UNIX Linux

To revert a client to an earlier version of the product on UNIX and Linux, you must uninstall the later version, and then install the earlier version.

About this task

If you revert an IBM MQ MQI client and client connection to an earlier code level, you must undo the configuration changes manually.

It is unusual to revert earlier IBM MQ MQI client libraries to a workstation.

Procedure

1. End all IBM MQ activity on the workstation. You are now ready to restore the client to the earlier version. Follow the instructions for the appropriate platform that your enterprise uses.
2. AIX To revert the client to the earlier version on AIX:
   a. Uninstall the IBM MQ MQI client code for the later version. For more information, see Uninstalling or modifying IBM MQ on AIX.
   b. Follow the client installation procedure to install the IBM MQ MQI client for the earlier version. For more information, see the client installation procedure for the earlier version that you want to install.
3. HP-UX To revert the client to the earlier version on HP-UX:
   a. Uninstall the IBM MQ MQI client code for the later version. For more information, see Uninstalling or modifying IBM MQ on HP-UX.
   b. Follow the client installation procedure to install the IBM MQ MQI client for the earlier version: For more information, see the client installation procedure for the earlier version that you want to install.
4. Linux To revert the client to the earlier version on Linux:
   a. Uninstall the IBM MQ MQI client code for the later version. For more information, see Uninstalling or modifying IBM MQ on Linux.
   b. Follow the client installation procedure to install the IBM MQ MQI client for the earlier version: For more information, see the client installation procedure for the earlier version that you want to install.

5. Solaris To revert the client to the earlier version on Solaris:
   a. Uninstall the IBM MQ MQI client code for the later version. For more information, see Uninstalling IBM MQ on Solaris.
   b. Follow the client installation procedure to install the IBM MQ MQI client for the earlier version. For more information, see the client installation procedure for the earlier version that you want to install.
6. If you configured a Client Connection Definition Table (CCDT) for a queue manager using the later version, revert to using a table created by a queue manager for the earlier version. If a client uses CCDT to connect to a queue manager, the CCDT can be at a version greater than, less than, or equal to that of the client. For more information, see MQI client: Client Channel Definition Table (CCDT).

Migrating IBM MQ library loading to a later version on UNIX and Linux

Linux UNIX

On UNIX and Linux, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to a later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

Before you begin

To migrate applications from an earlier version of the product to the later version, you must know how the operating system loads a IBM MQ library for an application. Is the load path fixed by the application, and can you set the path in an environment variable? It is not essential to know the name of the IBM MQ library that the application loads. The library name does not change from an earlier version of the product to the later version, although the contents of the library do.

Read "Multi-installation queue manager coexistence on UNIX, Linux, and Windows" on page 668 before starting this task.

Plan and install the later version of IBM MQ, and remember the installation name and whether the installation was set to primary.

About this task

To migrate an application from an earlier version of the product to the later version, you do not have to recompile or relink the application, because the IBM MQ libraries are compatible with later versions; see "Application compatibility and interoperability with later versions of IBM MQ" on page 678.

In Version 7.0.1 and later, the build procedure for IBM MQ applications is to include an explicit library path to the location of the IBM MQ libraries, and to `/usr/lib`, in the link step of the compiler, as shown in Figure 75 on page 740. The build procedure is the same for the later version of the product.

```
gcc -m32 -o amqsput_32_r amqsput0.c -I/opt/mqm/inc -L/opt/mqm/lib
-Wl,-rpath=/opt/mqm/lib -Wl,-rpath=/usr/lib -lmqm_r -lpthread
```

Figure 75. Linux C server application, 32 bit, threaded compile and link

The example shown in Figure 75 is for Linux, but the build step for UNIX platforms is similar.

If you have followed this build procedure in the earlier release, then the effect of installing the later version of the product on the libraries that are loaded depends on which migration scenario that you are following:

Single-stage scenario
If you are replacing an earlier version of the product with the later version, based on the single stage scenario described in "Migrating on UNIX and Linux: single-stage" on page 724, you do not, in most cases, need to make any changes to the way IBM MQ libraries are loaded. The possible exception to this is if you changed the location of the libraries from the earlier version, or created symbolic links to the libraries.

Side-by-side and Multi-stage scenarios
If you have chosen a multi-installation approach to installing the later version of the product, based either on the side-by-side scenario described in "Migrating on UNIX and Linux: side-by side" on page 727, or the multi-stage migration scenario described in "Migrating on UNIX and Linux: multi-stage" on page 730, you must investigate whether applications connecting to the later version of the product are linked to, and load libraries from, the correct installation and then modify the environment for the operating system to resolve IBM MQ dependencies for an application as appropriate. Typically, you can modify the runtime environment, rather than relink the application. You can use the following two commands to assist you in configuring the runtime environment:

- **`setmqinst`** sets the primary installation; see setmqinst.
- **`setmqenv`** initializes the command environment by setting environment variables; see setmqenv.

Table 86 summarizes the actions needed for each of these scenarios. The examples in Table 86 are all based on Linux, but the actions for UNIX are similar.

Table 86. UNIX and Linuxconfigurations

Action \ Scenario	Latest version replaces earlier version in the same location Single-stage	Latest version replaces earlier version in a different location Side-by-side	Latest version alongside earlier version Multi-stage
`setmqinst`	**`setmqinst`** makes the later version installation primary. Symbolic links to the IBM MQ link libraries are inserted into `/usr/lib`.		No. The later version installation can be primary, because an earlier version is installed.
No other configuration actions	Library loading works correctly. Library loading works, even without the later version installation being made primary, because the libraries are installed in `/opt/mqm/lib` and the application was built with the link option, `-rpath=/opt/mqm/lib`	Library loading works correctly. Library loading works, because the installation is primary, and the application was built with the link option, `-rpath=/usr/lib`.	The library loading continues to work with the earlier version correctly, nothing works with the later version.

Table 86. UNIX and Linuxconfigurations (continued)

Scenario / Action	Latest version replaces earlier version in the same location Single-stage	Latest version replaces earlier version in a different location Side-by-side	Latest version alongside earlier version Multi-stage
setmqenv, without setting the `-k` or `-l` options.	Library loading works correctly. **setmqenv** is unnecessary. Library loading works, because the libraries are installed in `/opt/mqm/lib` and the application was built with the link option, `-rpath=/opt/mqm/lib`.	Library loading works correctly. **setmqenv** is unnecessary. Library loading works, because the installation is primary, and the application was built with the link option, `-rpath=/usr/lib`.	The library loading continues to work with the earlier version correctly, nothing works with the later version.
setmqenv, with the `-k` or `-l` options set.	Library loading works correctly.		Library loading works correctly, both for the earlier version and the later version. The correct earlier version is loaded, because the later version library loads the earlier version library for queue managers that have not been migrated from the earlier version.
	The operating system finds the IBM MQ library location set by **setmqenv**. **setmqenv** adds the location to `LD_LIBRARY_PATH` (`LIBPATH` on AIX. On HP-UX `LD_LIBRARY_PATH` is set, not `SHLIB_PATH`.) . `LD_LIBRARY_PATH` is searched before paths set in the application or paths in the default search path. Not all applications can load a library using `LD_LIBRARY_PATH`. In which case the application works only if the library location is `/opt/mqm/lib` or `/usr/lib`		

Procedure

1. Consider which of the following questions apply to your configuration.
   - Did you follow the build procedure documented in the product documentation for the earlier version of the product? You might be following a different build procedure tailored to your development environment, or adapted from a development tool.
   - How did you specify the load path for the earlier version?
   - Is the application is loaded by another environment, such as Eclipse, or an application server? You must modify the parameters that govern how the parent environment loads applications, not the way the parent environment is loaded.
   - What constraints and requirements do you have on how the load path is specified in the later version? Security rules might restrict the use of `LD_LIBRARY_PATH`.
   - Is the later version of the product installed alongside the earlier version? If Version 7.0.1 is installed:
     - You cannot make a later installation primary.
     - You cannot install the later version in the default installation path, that was referenced by applications in Version 7.0.1.
2. Identify the installation of the later version of the product, from which the operating system is going to load IBM MQ libraries:
   - If you have a multiple installations of the later versions to load from a server, IBM MQ checks that the installation the library was loaded from is the installation that is associated with any queue manager the application calls. IBM MQ loads the correct library if the wrong library is loaded. It is necessary to configure only one runtime environment for all IBM MQ applications.

- A typical choice is to set the primary installation. Setting an installation to be primary places symbolic links to the IBM MQ libraries in `/usr/lib`. Applications built following the Version 7.0 instructions have an explicit link to `/usr/lib`. `/usr/lib` is also normally in the default library search path.
- If you upgraded an earlier version installation to the later version, a link path to the earlier version installation now points to an installation containing the later version. Applications that have a fixed linkage path to the earlier version installation now load the libraries for the later installation. They are then switched to the installation that is associated with any queue manager they connect to.
- If you rebuild an application, it must link to an installation of the later version.
- AIX If you set `LD_LIBRARY_PATH`, or `LIBPATH` on AIX, you must check that the application is able to use `LD_LIBRARY_PATH`. `setuid` or `setgid`, applications, or applications built in other ways, might ignore `LD_LIBRARY_PATH` for security reasons.

What to do next

If you add further installations of the later version of the product, you must decide which installation to make primary, if you have chosen to make any primary. As long as applications load IBM MQ libraries from one of the later version installations, such as the primary installation, they can connect to queue managers associated with any other later version installation.

Related tasks:

"Migrating IBM MQ library loading to a later version on Windows" on page 709
On Windows, no change in the way IBM MQ libraries are loaded is normally required if you upgrade from an earlier version of the product to the later version by replacing an earlier version of the product with the later version, based on the single stage scenario. However, if you choose to take advantage of multi-installation in the later version of the product, based on the side-by-side or multi-stage migration scenarios, you might have to configure the runtime environment differently, for the operating system to load the later version of the IBM MQ library.

Related reference:

"Coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations. In addition to queue managers coexisting on a server, objects, and commands must work correctly with different queue managers running at different command levels.

Loading IBM MQ libraries

Migrating from a single instance to a multi-instance queue manager on UNIX and Linux

Linux UNIX

To migrate a single instance queue manager, to a multi-instance queue manager, on UNIX and Linux, you must move the queue manager data to a shared directory, and reconfigure the queue manager on two other servers.

Before you begin

You must check the prerequisites for running a multi-instance queue manager as part of this task.For a list of tested environments, see Testing statement for IBM MQ multi-instance queue manager file systems. Other environments might work; a test tool is provided with IBM MQ to assist you in qualifying other environments.

You must have three servers to run a multi-instance queue manager. One server has a shared file system to store the queue manager data and logs. The other servers run the active and standby instances of the queue manager.

About this task

You have a single-instance queue manager that you want to convert to a multi-instance queue manager. The queue manager conversion itself is straightforward, but you must do other tasks to create a fully automated production environment.

You must check the prerequisites for a multi-instance queue manager, set up the environment and check it. You must set up a monitoring and management system to detect if the multi-instance queue manager has failed and been automatically restarted. You can then find out what caused the restart, remedy it, and restart the standby. You must also modify applications, or the way applications are connected to the queue manager, so that they can resume processing after a queue manager restart.

Procedure

1. Check the operating system that you are going to run the queue manager on, and the file system on which the queue manager data and logs are stored on. Check that they can run a multi-instance queue manager.
   a. Consult Testing and support statement for IBM MQ multi-instance queue managers. See whether the combination of operating system and file system is tested and capable of running a multi-instance queue manager. A shared file system must provide lease-based locking to be adequate to run multi-instance queue managers. Lease-based locking is a recent feature of some shared file systems, and in some case fixes are required. The support statement provides you with the essential information.
   b. Run **`amqmfsck`** to verify that the file system is configured correctly. File systems are sometimes configured with performance at a premium over data integrity. It is important to check the file system configuration. A negative report from the **`amqmfsck`** tool tells you the settings are not adequate. A positive result is an indication that the file system is adequate, but the result is not a definitive statement that the file system is adequate. It is a good indication.
   c. Run the integrity checking application provided in the technote, Testing a shared file system for compatibility with IBM MQ Multi-instance Queue Managers. The checking application tests that the queue manager is restarting correctly.
2. Configure a user and group to be able to access a share on the networked file system from each server that is running a queue manager instance. On UNIX and Linux, the `uid` and `gid` for `mqm` in `/etc/password` must be the same on each system; see Create a multi-instance queue manager on Linux.
3. Set up a directory for the share on the networked file system with the correct access permissions. A typical configuration is to set up a single shared directory that contains all data and log directories for all queue managers that use the shared disk; see Share named qmgrs and log directories (Version 7.0.1 onwards) in Example directory configurations on UNIX. For example, create a root directory on the share called `MQHA` that has subdirectories `data` and `logs`. Each queue manager creates its own data and log directories under `data` and `logs`. Create `/MQHA` on the shared drive. `/MQHA` is owned by the user and group `mqm` and has the access permissions `rwx`.
4. Copy the queue manager data and the logs to the share. You can choose to copy files manually, by following the procedure to back up the queue manager. Choose one of these methods:

- Follow the instructions in Backing up queue manager data, copying the queue manager data to the share. You must use this method if the **DataPath** configuration attribute is specified for this queue manager.
- Stop the queue manager, and then type the command,

  ```
  hamvmqm /m /dd share\data /dd share\logs
  ```

  Where *share* is to be the location of the data and logs that you created in step 3 on page 743.

5. Update the queue manager configuration information stored on the current queue manager server.
   - If you moved the queue manager data and logs by running the **hamvmqm** command, the command has already modified the configuration information correctly for you.
   - If you moved the queue manager data and logs manually, you must complete the following steps.
     a. Modify the `Log:` stanza in the queue manager `qm.ini` file, which is on the *share*:

        ```
        LogPath= share/logs/QMgrName
        ```

     b. Modify the `QueueManager:` stanza in the IBM MQ `mqs.ini` file, which is typically in the `/var/mqm` directory on UNIX and Linux:

        ```
        DataPath= share/data/QMgrName
        ```

   Where *QMgrName* is the `Directory` name in the `QueueManager:` stanza in the `mqs.ini` file and *share* is share where the data and logs are moved to.
6. Add the queue manager configuration information to the new queue manager server.
   a. Run the **dspmqinf** command to display the queue manager information. Run the command on the server that ran the queue manager.

      ```
      dspmqinf -o command QMgrName
      ```

      The command output is formatted ready to create a queue manager configuration. `addmqinf -s QueueManager -v Name= QMgrName -v Directory= QMgrName -v Prefix=d:\var\mqm Datapath= \share\data\QMgrName`
   b. Create a queue manager configuration on the other server. Run the **addmqinf** command copied from the previous output.
7. Add the network address of the new server to the connection name in client and channel definitions.
   a. Find all the client, sender, and requester TCPIP settings that refer to the server. Client settings might be in Client Definition Tables (CCDT), in environment variables, in Java properties files, or in client code. Cluster channels automatically discover the connection name of a queue manager from its cluster receiver channel. As long as the cluster receiver channel name is blank or omitted, TCPIP discovers the IP address of the server hosting the queue manager.
   b. Modify the connection name for each of these connections to include the TCPIP addresses of both servers that are hosting the multi-instance queue manager. For example, change the following connection name:

      ```
      echo DISPLAY CHANNEL(ENGLAND) CONNAME | runmqsc QM1
      ```

      ```
      5724-H72 (C) Copyright IBM Corp. 1994, 2009.  ALL RIGHTS RESERVED.
      Starting MQSC for queue manager QM1.
      1: DISPLAY CHANNEL(ENGLAND) CONNAME
      AMQ8414: Display Channel details.
      CHANNEL(ENGLAND) CHLTYPE(SDR)
      CONNAME(LONDON)
      ```

      into:

      ```
      echo ALTER CHANNEL(ENGLAND) CHLTYPE(SDR) CONNAME('LONDON, BRISTOL') | runmqsc QM1
      ```

8. Update your monitoring and management procedures to detect the queue manager restarting.
9. Update client applications to be automatically reconnectable, if appropriate.
10. Update the start procedure for your IBM MQ applications to be started as queue manager services.

11. Start each instance of the queue manager, permitting them to be highly available. The first instance of the queue manager that is started becomes the active instance. Issue the command twice, once on each server.

```
strmqm -x QMgrName
```

What to do next

To get the highest availability out of multi-instance queue managers, you must design client applications to be reconnectable and server applications to be restartable; see Application recovery.

Reverting to a single-instance queue manager on UNIX and Linux

Linux UNIX

Revert a multi-instance queue manager to a single instance queue manager, on UNIX and Linux, by stopping the standby instance. Then restart the active instance and do not set the flag that permits standby instances.

Before you begin

You have at least three servers configured to run a queue manager as a multi-instance queue manager. The queue manager is currently running as a multi-instance queue manager, with one standby instance active.

About this task

The task involves deactivating the active standby so that only the running multi-instance queue manager remains active. To prevent a standby instance being started in the future, you must stop the active instance and restart it. When you restart it, you start it as a single instance queue manager that prevents standby instances being started. The standby instance is stopped as a separate step, to give you the option of restarting the active instance at a later date. You can stop both instances by running the standard `endmqm` *QMgrName* command on the server running the active queue manager.

Procedure

1. Stop the standby queue manager instance. On the server running the standby instance:
   ```
   endmqm -w QMgrName
   ```
2. Stop the active queue manager instance. On the server running the active instance:
   ```
   endmqm -w (QMgrName)
   ```
3. Restart the queue manager, preventing standbys. On the server that is going to run the queue manager:
   ```
   strmqm QMgrName
   ```

What to do next

You might want to run the queue manager as a single instance on the same server as the queue manager data.

When the queue manager is stopped move the queue manager data back to the server that is running the queue manager. Alternatively install IBM MQ, and then move the queue manager configuration definition onto the server with the queue manager data. Both tasks are variations of steps in "Migrating from a single instance to a multi-instance queue manager on UNIX and Linux" on page 742 to create a multi-instance queue manager.

Cleaning up after using the `rpm` freshen or upgrade options on Linux

▶ Linux

The use of **rpm** upgrade or freshen options is not supported. If you use the options, follow this cleanup procedure, and then install following the correct steps.

Before you begin

You have attempted to upgrade IBM MQ for Linux using `rpm -U` or `rpm -F`

About this task

By using the freshen or upgrade options, you might have deleted your old IBM MQ package entries from the **rpm** database without removing the product from your system. You might also have partially installed IBM MQ

Procedure

Follow these steps to clean up your system.

1. Find out which IBM MQ MQ packages still have entries in your RPM database.
   ```
   rpm -qa | grep MQSeries
   ```
2. Remove all remaining IBM MQ packages from your system.
   ```
   rpm -e package-name
   ```
3. Remove the `/opt/mqm` directory.
   ```
   rm -rf /opt/mqm
   ```

Rebuilding a C++ application on Linux

Linux

C++ IBM MQ MQI client and server applications on Linux must be recompiled using GNU Compiler Collection (GCC) 4.1.2, or later. Compilers older than GCC 4.1.2 are no longer supported. The C++ GCC 4.1.2 run time libraries, or later, must be installed in `/usr/lib` or `/usr/lib64`

If you are using one of the supported Linux distributions, the libraries are correctly installed; see System Requirements for IBM MQ.

The GCC 4.1.2 libraries support SSL and TLS connections from an IBM MQ MQI client. SSL and TLS use GSKit version 8, which depends on `libstdc++.so.6`. `libstdc++.so.6` is included in GCC 4.1.2.

Before you begin

1. Check the required level of GCC for your distribution of Linux; see System Requirements for IBM MQ.
2. If you are using SSL or TLS, also check the required level of `libstdc++.so`.
3. Check whether the application requires rebuilding. Run the following command to display what version of `libstdc++.so` the application depends upon. If the result is less than `libstdc++.so.6`, you must rebuild your application.
   ```
   ldd ApplicationPath
   ```

About this task

The task describes the steps required to rebuild a Linux C++ IBM MQ application. For more detailed instructions about building Linux applications for IBM MQ ; see Building your procedural application on Linux

Procedure

1. Check that the required GCC library is installed correctly.

   Run one of the following commands:
   - Check the 32 bit library on an x86 Linux system:
     ```
     ls -l /usr/lib/libstdc++.so.6
     ```
   - Check the 64 bit library on any other Linux system.
     ```
     ls -l /usr/lib64/libstdc++.so.6
     ```
2. Check that the GCC compiler is at least at version 4.1.2

   Run the following command to display the version of GCC.
   ```
   gcc -v
   ```
3. Rebuild the application

   The commands to compile and link Linux C++ applications are described in Building 32-bit applications and Building 64-bit applications

What to do next

When you deploy your Linux C++ application, ensure that the same GCC runtime library is correctly installed on the run time system.

Migrating MQ Telemetry on Linux

▶ Linux

Follow these instructions to migrate your existing installation of MQ Telemetry on Linux to the latest version of the product.

Before you begin

Before proceeding with this task, ensure that you back up your existing IBM MQ installation. You must stop the MQ Telemetry service `SYSTEM.MQXR.SERVICE` before migrating.

About this task

From Version 7.1 onwards, the telemetry server is included in the product as an optional installation.

For Version 7.1 and Version 7.5, the Client Software Development Kit (the telemetry clients) is also included in the optional installation. From Version 8.0 onwards, the Client Software Development Kit is no longer supplied as part of the product. Instead, the current version of the SDK is available as the IBM Messaging Telemetry Clients SupportPac.

Because MQ Telemetry is a component of IBM WebSphere MQ Version 7.1 and later, MQ Telemetry can either be installed with the main product, or installed after the main product has been installed. When you upgrade from a previous version of the product, you must download and use the latest version of the Client Software Development Kit.

After the successful upgrade, Linux systems retain all telemetry data kept in `/var/mqm`. Telemetry data is migrated to the later version of the product when the queue manager is started again.

Procedure

1. Create a migration plan. See "Planning to migrate to a later version on UNIX and Linux" on page 720.
2. Migrate your queue managers to the latest release.
3. Install MQ Telemetry.
4. Verify that the MQ Telemetry installation was successful. See Verifying the installation of MQ Telemetry.

Results

Message AMQ4616 indicates completion of the task. The existing MQTT channels and previous subscriptions are still present.

Related information:

Windows "Migrating IBM MQ on Windows" on page 684
IBM MQ migration tasks associated with Windows platforms are grouped in this section.

z/OS "Migrating IBM MQ on z/OS" on page 770
Migration tasks associated with z/OS are grouped in this section.

Related reference:
"Changes that affect migration" on page 626
Changes to the product might affect the migration of a queue manager from an earlier release to the current release of IBM MQ, or affect existing applications or configurations. Review these changes before upgrading queue managers to the latest product version and decide whether you must plan to make changes to existing applications, scripts, and procedures before starting to migrate your systems.

Planning to migrate to the latest version on IBM i

IBM i

Before migrating from one version to another on IBM i, read this planning topic, then create your own migration plan based on the outline in this topic.

Before you begin

If there are concepts about migration you do not understand, read "Migration concepts and methods" on page 645, and the subsections you need, first.

About this task

Use the following steps as a guide to creating a migration plan.

Procedure

1. Review the IBM MQ system requirements for the latest version of the product. See System Requirements for IBM MQ.
2. Decide whether to run the current version of your product and the latest version on the same server.
3. Review all the changes in IBM MQ that affect you. For more information, see "Changes that affect migration" on page 626.
4. Review performance changes. See IBM MQ Family - Performance Reports.
5. Review the latest readme file for the product that you are working with. See IBM MQ, WebSphere MQ, and MQSeries product readmes.
6. Plan the sequence and timing of queue manager upgrades.
   - If the queue manager is part of a queue manager cluster, you must migrate the queue managers that are full repositories first.
   - If the queue manager is part of a high availability cluster, plan the migration to minimize downtime and maximize availability; see "Migrating a queue manager in a high-availability configuration" on page 814.
7. Plan to migrate your queue manager to the latest version. See IBM i - Migrating a queue manager from a previous release to the latest release or Migrating a queue manager from a previous release to the latest release, alternative method

   Backing up queue manager data is part of the queue manager migration task. An alternative approach to backing up queue manager data, is to install and configure a new server. Test the latest version with a new queue manager on the new server. When you are ready to go into production on the latest version, copy the queue manager configuration and data, to the new server.
8. Plan to update any manual or automated procedures you have written with changes to messages and codes.
9. Decide on what regression tests to perform before putting the queue manager into production on the latest version. Include the procedures and applications you identified in steps 6 and 7 in your regression tests.
10. Plan to upgrade your IBM MQ MQI client installations to the latest version.
11. Plan to upgrade your client and server applications to use new functions in the latest version.

Migrating an IBM MQ classes for JMS and Java client on IBM i

IBM i

If you have IBM MQ Java SupportPac MA88 installed, you must uninstall it first.

Before you begin

SupportPac MQ88 is installed.
If you try to install the latest version of IBM MQ classes for Java anyway, the installation fails with a warning requesting you to uninstall the old client. You must follow the steps in this task to uninstall IBM MQ classes for Java and IBM MQ classes for JMS.

A previous version of IBM MQ classes for Java is installed.
Installation of the latest version of IBM MQ classes for Java uninstalls the previous version automatically. Do not follow the steps in this task.

About this task

The steps in this task uninstall the IBM MQ classes for JMS and Java.

Procedure

To uninstall the previous IBM MQ Java client:

1. Delete the `QMQMJAVA` library and the `/QIBM/ProdData/mqm/java` directory, by issuing the command:
   ```
   DLTLICPGM LICPGM(5648C60) OPTION(*ALL)
   ```
2. If the previous step failed to delete the IFS directory `/QIBM/ProdData/mqm/java` and its subdirectories, use the **`EDTF`** command, for example:
   ```
   EDTF STMF('/QIBM/ProdData/mqm')
   ```
   and select option 9 against the `java` directory.

Migrating a queue manager to a later version on IBM i

IBM i

Follow these instructions to migrate a queue manager from an earlier release to a later release.

Before you begin

If you decide to do a side-by-side installation, you must prepare the new server first, installing the prerequisite software.

1. Create a migration plan. Use the planning task, Planning migration to the latest version, as a guide.
2. Review the IBM MQ system requirements for the latest release of the product; see System Requirements for IBM MQ
3. Review any other installed SupportPacs for their applicability to the latest release of IBM MQ.

About this task

There are various types of migration:

- The migration takes place on the same machine, optionally accompanied by a hardware upgrade. This migration is referred to as a *slip installation*. On IBM i, uninstalling the earlier version of the product before you install the later version is optional.
- The migration takes place on a different machine. This migration is referred to as a *side-by-side installation*.

A side-by-side installation gives you the option of preparing the new environment first, without interrupting the queue manager. It also gives you the limited option of reverting to use the earlier release installation, if the migration is unsuccessful. It is limited, because you cannot restore the queue manager data from the later version. You must restart processing with the queue manager data at the point you stopped the queue manager on the earlier release.

If you want to add Advanced Message Security to your system, you must select Option (2) when you install the product; see Installing Advanced Message Security on IBM i for further information.

Migration tasks associated with z/OS are grouped in this section.

Installation methods on IBM i: IBM i

Select a slip installation or a side-by-side installation to upgrade IBM MQ for IBM i.

About this task

A slip installation upgrades IBM MQ for IBM i on a computer with an earlier version is installed.

A side-by-side installation upgrades IBM MQ for IBM i on a different computer. You must save your queue managers before you start.

Follow the steps in the following tasks to carry out an upgrade.

The steps for both forms of upgrade are identical, except that you do not carry out the actions described in "Restore queue managers after upgrading IBM MQ on IBM i" on page 760 for a slip installation.

End IBM MQ activity on IBM i: IBM i

End IBM MQ applications and connections, and remove any unwanted or indoubt messages.

About this task

Before performing a slip installation or side-by-side installation, carry out the following procedure:

Procedure

1. Sign on to the system with a user profile that has *ALLOBJ special authority, for example QSECOFR.
2. Stop all applications that are using the existing version of IBM MQ. Use the command `WRKMQM`, option 22, Work with queue manager jobs, to help find them.
3. End all channels for all queue managers on the system. To do so, use the WRKMQMCHL command and select option 15.
4. On each queue manager, end the command server. To do so, enter the command:
   ```
   ENDMQMCSVR MQMNAME( QMGRNAME ) OPTION(*IMMED)
   ```
   where *QMGRNAME* is the name of the queue manager.

5. Remove any unwanted messages from your queues.
6. Resolve any in-doubt messages that are held by sender or server channels. To do so, use the WRKMQMCHST command and select option 17.
7. On each queue manager, save the latest media recovery checkpoint. To do so, enter the following command:
   ```
   RCDMQMIMG OBJ(*ALL) OBJTYPE(*ALL) MQMNAME( QMGRNAME ) DSPJRNDTA(*YES)
   ```

Quiesce IBM MQ on IBM i: IBM i

Stop all queue managers. If necessary force all queue managers to stop, tidy up shared memory and end all jobs in the QMQM subsystem.

About this task

The orderly shutdown of IBM MQ is called *quiescing*. You need to quiesce IBM MQ to upgrade to a newer version.

To quiesce one or more queue managers:

Procedure
1. Sign on to a new interactive IBM i session, ensuring that you are not accessing any IBM MQ objects.
2. Ensure that you have:
   a. *ALLOBJ authority, or object management authority for the QMQM library.
   b. Sufficient authority to use the ENDSBS command.
3. Warn all users that you are going to stop IBM MQ.
4. Use the ENDMQM command to quiesce all queue managers:
   ```
   ENDMQM MQMNAME(*ALL) OPTION(*CNTRLD) ENDCCTJOB(*YES) RCDMQMIMG(*YES)
   TIMEOUT( 15 )
   ```
   Where *15* is a timeout value in seconds.

   If the ENDMQM command has not completed within a reasonable period (at least 10 minutes), use the WRKMQM command. This command identifies the queue managers that are still ending. Then force each one in turn to stop by issuing:
   ```
   ENDMQM MQMNAME( QMGRNAME ) OPTION(*IMMED)
   ```
   Where *QMGRNAME* is the name of the queue manager.

   Complete the tidying up of shared memory by issuing the command:
   ```
   ENDMQM MQMNAME(*ALL) OPTION(*IMMED) ENDCCTJOB(*YES) RCDMQMIMG(*NO)
   TIMEOUT( 15 )
   ```
5. If the command in the previous step does not complete, end the subsystem immediately by issuing:
   ```
   ENDSBS SBS(QMQM) OPTION(*IMMED)
   ```
6. If this command also fails, use the operating system command ENDJOB to end all jobs in the subsystem QMQM, as described in the following steps.

   Note: Do not use ENDJOBABN unless you intend to perform an IPL on the machine before starting IBM MQ. Ending IBM MQ jobs using ENDJOBABN can lead to damaged semaphores, which in turn can prevent your queue manager from starting.
   a. If a QMGR must be shut down manually, the recommended order of ending jobs (ENDJOB) is shown in the list that follows. Wait a few minutes for AMQA* or AMQZ* jobs to tidy up.
      1) RUNMQLSR - TCP listener (multi-threaded)
      2) AMQCLMAA - TCP listener (single-threaded)
      3) AMQRMPPA - Channel process pooling job

4) `RUNMQCHI` - channel initiator
5) `AMQCRSTA` - receiving MCA jobs
6) `RUNMQCHL` - sending MCA jobs
7) `AMQCRS6B` - LU62 receiver channel
8) `AMQPCSEA` - command server
9) `RUNMQTRM` - Application trigger monitor
10) `RUNMQDLQ` - Dead letter queue handler
11) `AMQFCXBA` - IBM Integration Bus Worker Job
12) `AMQFQPUB` - Queued Publish/Subscribe Daemon
13) `RUNMQBRK` - IBM Integration Bus Control Job
14) `AMQZMUC0` ('0' is a zero) - Utility Manager
15) `AMQZMUF0` ('0' is a zero) - Utility Manager
16) `AMQZMUR0` ('0' is a zero) - Utility Manager
17) `AMQZMGR0` ('0' is a zero) - Process Controller
18) `AMQRRMFA` - cluster repository manager
19) `AMQZDMAA` - deferred message manager
20) `AMQALMPX` - Log Manager
21) `AMQZFUMA` - object authority manager
22) `AMQZLSA0` ('0' is a zero) - LQM agents
23) `AMQZLAA0` ('0' is a zero) - LQM agents
24) `AMQZXMA0` ('0' is a zero) - Execution Controller

b. Issue the following command:

```
ENDMQM MQMNAME( QMGRNAME ) OPTION(*IMMED)
```

c. Issue the following command:

```
ENDMQM MQMNAME(*ALL) OPTION(*CNTRLD) ENDCCTJOB(*YES) RCDMQMIMG(*NO)
TIMEOUT( 05 )
```

Where *05* is a timeout value in seconds.

d. Manually clean up shared memory. Issue the following command:

```
EDTF '/QIBM/UserData/mqm/qmgrs'
```

then:

1) Take option 5 for **&SYSTEM** and check that the following directories are empty: `isem`, `esem`, `msem`, `ssem`, and `shmem`.
2) Take option 5 for **QMGRNAME** and check that the following directories are empty:- `isem`, `esem`, `msem`, `ssem`, and `shmem`.
3) Take option 5 for **&ipcc** in the QMGRNAME directory and check that the following directories are empty:- `isem`, `esem`, `msem`, `ssem`, and `shmem`.
4) Take option 5 for **&qmpersist** in the QMGRNAME directory and check that the following directories are empty:- `isem`, `esem`, `msem`, `ssem`, and `shmem`.
5) Take option 5 for **&app** and check that the following directories are empty: `isem`, `esem`, `msem`, `ssem`, and `shmem`.

Save IBM MQ data on IBM i: IBM i

Save IBM MQ data after removing unwanted FDC, trace, and JOB files.

Before you begin

You need to have completed the tasks to remove unwanted and indoubt messages and quiesced IBM MQ.

About this task

Procedure

1. Create a save file for every queue manager library on your system. To do so, issue the command:
   ```
   CRTSAVF FILE(QGPL/ queue_manager_library )
   ```
   where the *queue_manager_library* name consists of the name of the queue manager preceded by `QM`.
2. Save your queue manager libraries into the save files. To do so, issue the commands:
   ```
   SAVLIB LIB( queue_manager_library ) DEV(*SAVF)
   SAVF(QGPL/ queue_manager_library )
   ```
3. Remove all unwanted FDC data from directory:
   ```
   QIBM/UserData/mqm/errors
   ```
4. Remove old FDC files with the command:
   ```
   RMVLNK OBJLNK('/QIBM/UserData/mqm/errors/*.FDC')
   ```
   This command cleans up all files with an extension of 'FDC' in the IFS.
5. Remove old JOB files with the command:
   ```
   RMVLNK OBJLNK('/QIBM/UserData/mqm/errors/*.JOB')
   ```
   This command cleans up all files with an extension of 'JOB' in the IFS.
6. Remove all unwanted trace data from directory, or remove the whole directory:
   ```
   QIBM/UserData/mqm/trace
   ```
7. Remove all trace files with the command:
   ```
   RMVLNK OBJLNK('/qibm/userdata/mqm/trace/*')
   ```
8. Create a save file for IBM MQ IFS data. To do so, issue the command:
   ```
   CRTSAVF FILE(QGPL/QMUSERDATA)
   ```
9. Save your IBM MQ IFS data, using the command:
   ```
   SAV DEV('/QSYS.LIB/QGPL.LIB/QMUSERDATA.FILE') OBJ('/QIBM/UserData/mqm')
   ```
10. If you are going to run IBM MQ on a new machine, transfer the save files to the new machine.

Install IBM MQ server on IBM i: IBM i

Install the IBM MQ server in its primary language.

Before you begin

You have completed planning the installation, obtained the installation disks, and set the system values; see Setting system values.

About this task

Install the IBM MQ server and force object conversion. Object conversion migrates objects from the older to the newer version. By performing it now, rather than when an object is first used, you avoid slowing down the first use of the upgraded product.

After following the optional step to pre-agree the license, the **RSTLICPGM** command runs without requiring any interactive input. Otherwise the license agreement is displayed for you to accept. See License requirements.

Procedure

1. Sign on to the system with a user profile that has `*ALLOBJ` special authority, for example `QSECOFR`.
2. Optionally pre-agree the license terms and conditions by running the command,
   ```
   CALL PGM (QSYS/QLPACAGR) PARM ('5724H72' 'V8R0M0' '0000' 0)
   ```
   Where the parameters of **PARM** are,

   5724H72
   The product identifier for IBM i.

   V8R0M0
   The version, release, and modification level.

   0000
   The option number for the *BASE IBM MQ product option.

   0 Unused error structure.
3. Install IBM MQ for IBM i, base product, and primary language.
   ```
   RSTLICPGM LICPGM (5724H72) DEV (installation device) OPTION (*BASE) OUTPUT (*PRINT)
   ```
   where the parameters of RSTLICPGM are,

   LICPGM (5724H72)
   The product identifier for IBM i.

   DEV (*installation device*)
   The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`.

   OPTION (*BASE)
   Install the base IBM MQ for IBM i product.

   Unspecified parameters
   Unspecified parameters such as **RSTOBJ** (`*ALL`), revert to defaults. The command installs both IBM MQ and the language files for the primary language of your system. For installing additional languages see Installing translated versions.

What to do next

Install any Progam Temporary Fixes (PTF) that have been issued.

Install samples on IBM i: ▶ IBM i

Install the IBM MQ samples

Before you begin

If you have not already done so, sign on to the system with a user profile that has `*ALLOBJ` special authority, for example `QSECOFR`.

About this task

Install the samples.

After following the optional step to pre-agree the license, the **RSTLICPGM** command runs without requiring any interactive input. Otherwise the license agreement is displayed for you to accept. See License requirements.

Procedure

1. Optionally pre-agree the license terms and conditions by running the command,

   ```
    CALL PGM (QSYS/QLPACAGR) PARM ('5724H72' 'V8R0M0' '0001' 0)
   ```

   Where the parameters of **PARM** are,

   5724H72
   The product identifier for IBM i.

   V8R0M0
   The version, release, and modification level.

   0001
   The option number for the samples.

   0 Unused error structure.

2. Install the samples using the command:

   ```
   RSTLICPGM LICPGM (5724H72) DEV (installation device) OPTION (1) OUTPUT (*PRINT)
   ```

   Where the parameters of RSTLICPGM are,

   LICPGM (5724H72)
   The product identifier for IBM i.

   DEV (*installation device*)
   The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`.

   OPTION (1)
   Install the samples for IBM i.

   OUTPUT (*PRINT
   The output is printed with the spooled output of the job.

Install translated versions on IBM i: IBM i

Install translated versions of IBM MQ from a choice of national-languages.

About this task

The following language versions are available for IBM i:

Table 87. National-language versions of IBM MQ for IBM i

Language ID	Language
2909	Belgian English
2966	Belgian French MNCS (Multi-National Character Set)
2981	Canadian French MNCS
2975	Czech
2950	English uppercase
2924	English uppercase and lowercase
2984	English US DBCS
2938	English US uppercase DBCS
2928	French
2940	French MNCS
2929	German
2939	German MNCS
2976	Hungarian
2932	Italian
2942	Italian MNCS
2962	Japanese
2986	Korean
2978	Polish
2979	Russian
2989	Simplified Chinese
2931	Spanish

IBM MQ for IBM i is installed in the language that is the primary language on your system.

You can install additional versions of the product in any of the languages shown in Table 87. To do so:

Procedure

1. Sign on to the system with a user profile that has *ALLOBJ special authority
2. Issue the following command specifying the appropriate language ID:
   ```
   RSTLICPGM LICPGM(5724H72) DEV( installation device ) RSTOBJ(*LNG) LNG( language ID )
   ```

   This installs the commands, message file, and panel groups into the relevant QSYS library for the language. For example, library QSYS2928 is used for French. If this QSYS29nn library does not exist, it is created by the RSTLICPGM command.

Results

Note:

1. To run the Japanese language version of IBM MQ for IBM i, the CCSID of the job must be 939 (5035) rather than 930 (5026) because IBM MQ uses lowercase English characters.
2. If you are installing IBM MQ for IBM i onto a machine for which the primary language is not on the CD, the installation program prompts you to load a CD containing the product in that language. If, however, you have only one product CD, this means that the IBM MQ product has not been translated into your language. To get around this issue, proceed as follows:
   - Install the product in one of the supplied languages, and then add the corresponding QSYS29nn library into the *system library* list (for example using command CHGSYSLIBL). At the same time, check that there are no IBM MQ *CMD, *MENU, or *MSGF objects in libraries higher up the library list. If some exist, then either delete these objects (because they refer to an earlier version of IBM MQ) or reorder the System Library list (because the product has been installed in more than one of the supplied languages).

Verify the installation on IBM i: IBM i

How to check that your installation has been successful.

Procedure

1. To ensure that the product has loaded correctly, issue the Display Software Resources (DSPSFWRSC) command and check that the licensed program `5724H72` is listed. If you have installed the base and the optional samples, you see:

```
Resource
ID    Option Feature Description
5724H72  *BASE  5050 IBM MQ for IBM i
5724H72  *BASE  2924 IBM MQ for IBM i
5724H72  1    5050 IBM MQ for IBM i - Samples
```

2. Press F11, while viewing the Display Software Resources screen, and you see the library and version number of the products installed:

```
Resource         Feature
ID    Option Feature  Type  Library  Release
5724H72  *BASE  5050   *CODE  QMQM   V9R0M0
5724H72  *BASE  2924   *LNG   QMQM   V9R0M0
5724H72  1    5050   *CODE  QMQMSAMP V9R0M0
```

3. If you have installed additional language versions, you also see entries for these versions. For example, if you have installed the French version, for which the language ID is 2928, you see:
   a.
   ```
   Resource
   ID    Option Feature Description
   5724H72  *BASE  2928 IBM MQ for IBM i
   ```
   b. and when you press F11:
   ```
   Resource          Feature
   ID    Option Feature  Type  Library   Release
   5724H72  *BASE  2928  *LNG  QSYS2928  V9R0M0
   ```

4. Use the command DSPMQMVER to check exactly what version you have installed. For example, for V9R0M0, it reports:

```
Version: 9.0.0.0
```

Verify the upgrade on IBM i: IBM i

After you have verified the installation, start the IBM MQ subsystem, check the queue managers, and take a fresh media recovery checkpoint.

About this task

To verify that you have migrated to the latest version IBM MQ for IBM i, successfully:

Procedure

1. Make QMQMADM either the primary or a secondary group profile for your user profile. To do so, issue one of the following commands:
   ```
   CHGUSRPRF USRPRF( YOUR PROFILE ) GRPPRF(QMQMADM)
   CHGUSRPRF USRPRF( YOUR PROFILE ) SUPGRPPRF(QMQMADM)
   ```
2. Start the IBM MQ subsystem with the command:
   ```
   STRSBS SBSD(QMQM/QMQM)
   ```
   (If it is already running, you get error message `CPF1010` which you can safely ignore).
3. Check that your queue managers are accessible by issuing the command:
   ```
   WRKMQM
   ```
   Use option 14 against each queue manager to start it.

   Use option 5 against each queue manager to check its attributes.
4. You can use the other options to check your queue manager objects. For example, check your queues using option 18, check your channels using option 20, and so on.
5. Take a fresh media recovery checkpoint, using the following command:
   ```
   RCDMQMIMG OBJ(*ALL) OBJTYPE(*ALL) MQMNAME( QMGRNAME ) DSPJRNDTA(*YES)
   ```
   Where *QMGRNAME* is the name of the queue manager.

Restore queue managers after upgrading IBM MQ on IBM i: IBM i

Complete the side-by-side upgrade by restored the saved queue managers onto the server that you have upgraded.

Before you begin

Note: Carry out this task only if you are performing a side-by-side upgrade.

Ensure that you have saved your queue manager data, see "End IBM MQ activity on IBM i" on page 752, and installed and verified the upgrade.

About this task

Transfer the queue manager data, and journal receivers, onto the server that has been upgraded.

Procedure

1. Restore the queue manager libraries for every queue manager, using the command:
   ```
   RSTLIB SAVLIB( queue_manager_library ) DEV(*SAVF) (*PRINT)
   SAVF(QGPL/ queue_manager_library )
   ```

where the *`queue_manager_library`* name consists of the name of the queue manager preceded by `QM`.

2. Restore the IBM MQ IFS data, using the command:
   ```
   RST DEV('/QSYS.LIB/QGPL.LIB/QMUSERDATA.FILE') OBJ('/QIBM/UserData/mqm') (*PRINT)
   ```
3. To associate the journal receivers, issue the command `WRKJRN` on the journal `AMQAJRN` in each queue manager library, by pressing *PF4* and selecting option 9.
4. If you want to set up your work management environment, job descriptions, and pools, see the Administering IBMi for guidance. Otherwise, use the default setup.

After Upgrading on IBM MQ for IBM i: IBM i

Tasks to perform after you have upgraded IBM MQ for IBM i.

About this task

Satisfy yourself the upgrade has completed successfully.

Procedure

Delete the saved data in the save files in QGPL. This data was saved in "Save IBM MQ data on IBM i" on page 755.

Post installation tasks for IBM i: IBM i

Tasks to perform after you have installed IBM MQ for IBM i, and before using it.

About this task

When you have correctly installed IBM MQ for IBM i on your system:

Procedure

1. For the latest product information for IBM i, see System requirements for IBM MQ .
2. To install and apply all fix packs, see "Applying maintenance level updates on IBM i" on page 613.
3. Where you have more than one system and a mixture of releases of OS/400 or IBM i, and IBM MQ, you must take care when compiling CL programs. You must compile CL programs either on the system they are to run on, or on one with an identical combination of releases of OS/400 or IBM i, and IBM MQ. When you install later versions of IBM MQ, delete all IBM MQ commands from previous releases in any QSYSVvRrMm libraries using the QSYS/DLTCMD command.
4. If you have not installed IBM MQ on your system before, you must add user profiles to the `QMQMADM` group profile. Make all user profiles that are to be used for creating and administering queue managers members of the `QMQMADM` group profile, using the command `CHGUSRPRF`.
   a. Start the IBM MQ subsystem, by issuing the command:
      ```
      STRSBS SBSD(QMQM/QMQM)
      ```
      Note: The subsystem must be started after each IPL of the system, so you might choose to start it as part of your system startup process.
5. Create the system-default objects. The system-default objects are created automatically when you issue the CRTMQM command to create a queue manager. For example: `CRTMQM MQMNAME(QMGRNAME) ASP(*SYSTEM)`. You can refresh them using the STRMQM command (Warning: this command will replace any existing default objects). For example: `STRMQM MQMNAME(QMGRNAME) RDEFSYS(*YES)`. Refer to the onscreen help for information about using this command.

   Note: on the command `STRMQM MQMNAME(QMGRNAME) RDEFSYS(*YES)`:

- The command does not re-create the objects, it performs a CRTxxxx REPLACE(*YES) for all of the SYSTEM.* objects.
- This means that it refreshes the parameters on the objects back to their defaults. So if, for example, on the SYSTEM.DEFAULT.LOCAL.QUEUE object, TRGENBL had previously been changed to *YES, then, when the command is run, it is changed back to TRGENBL(*NO).
- If any messages exist on a queue, they are left intact, because the queues are not physically deleted.
- The contents of the SYSTEM.AUTH.DATA.QUEUE are untouched when this command is run.
- So, if the contents of this (or any other significant queue) become corrupt, it must be physically deleted and re-created either from scratch, or from a backup.

Results

You are now ready to start using IBM MQ for IBM i.

Note: When you install IBM MQ for IBM i, two user profiles are created:
- QMQM
- QMQMADM

These two objects are central to the correct running of IBM MQ for IBM i. Do not alter or delete them. If you do, IBM cannot guarantee correct behavior of your product.

If you uninstall IBM MQ and data, these profiles are deleted. If you uninstall IBM MQ only, these profiles are retained.

Migrating a queue manager to a later version on IBM i - alternative method

IBM i

An alternative method of migrating a queue manager from an earlier version to a later version

Before you begin

1. Review the IBM MQ system requirements for the later version of the product; see System Requirements for IBM MQ
2. Review any other installed SupportPacs for their applicability to the later version of IBM MQ.

About this task

There are various parts to this form of migration:
1. As part of upgrading the IBM MQ product, carry out the following tasks:
   a. “Preparing to install IBM MQ on IBM i” on page 763
   b. “Install IBM MQ server on IBM i” on page 763
2. Following the IBM MQ product upgrade, carry out the following task:
   a. “Post installation tasks” on page 764

Preparing to install IBM MQ on IBM i: IBM i

Carry out the following tasks to prepare your system for an upgrade.

Procedure

1. Stop the IBM MQ queue managers by issuing the following command:

   ```
   ENDMQM MQMNAME(*ALL) OPTION(*IMMED) ENDCCTJOB(*YES) RCDMQMIMG(*YES)
   TIMEOUT(30)
   ```

   Ensure that the user profile issuing this command has `*ALLOBJ` authority.
2. Create a save file for every queue manager library on your system. To do so, issue the command:

   ```
   CRTSAVF FILE(QGPL/ queue_manager_library )
   ```

   where the *`queue_manager_library`* name consists of the name of the queue manager preceded by `QM`.
3. Save your queue manager libraries into the save files. To do so, issue the commands:

   ```
   SAVLIB LIB( queue_manager_library ) DEV(*SAVF)
   SAVF(QGPL/ queue_manager_library )
   ```
4. Create a save file for IBM MQ IFS data. To do so, issue the command:

   ```
   CRTSAVF FILE(QGPL/QMUSERDATA)
   ```
5. Save your IBM MQ IFS data, using the command:

   ```
   SAV DEV('/QSYS.LIB/QGPL.LIB/QMUSERDATA.FILE') OBJ('/QIBM/UserData/mqm')
   ```
6. If you are going to run IBM MQ on a new machine, transfer the save files to the new machine.
7. Issue the following command before you upgrade your IBM MQ product, only if the upgrade is required on the same machine.
   a. `DLTMQM` *`QMgrName`*
   b. `ENDSBS SBS(QMQM) OPTION(*IMMED)`
   c. `WRKOBJLCK OBJ(QMQM) OBJTYPE(*LIB)`

   Relinquish any locks on the system.

Install IBM MQ server on IBM i: IBM i

Install the IBM MQ server in its primary language and force object conversion.

Before you begin

In either of the following cases, ensure that you have completed the planning and set the system values; see Setting system values

- If you have obtained the product through IBM passport advantage, follow the instructions in the `EGA.README.txt` file.
- If you have obtained the product on disk, follow the instructions within this topic.

About this task

Install the IBM MQ server and force object conversion. Object conversion migrates objects from the older to the newer version. By performing it now, rather than when an object is first used, you avoid slowing down the first use of the upgraded product.

After following the optional step to pre-agree the license, the **`RSTLICPGM`** command runs without requiring any interactive input. Otherwise the license agreement is displayed for you to accept. See License requirements.

Procedure

1. Sign on to the system with a user profile that has `*ALLOBJ` special authority, for example `QSECOFR`.
2. Optionally pre-agree the license terms and conditions by running the command,

   ```
   CALL PGM (QSYS/QLPACAGR) PARM ('5724H72' 'V8R0M0' '0000' 0)
   ```

   Where the parameters of **PARM** are,

   5724H72
   The product identifier for IBM i.

   V8R0M0
   The version, release, and modification level.

   0000
   The option number for the *BASE IBM MQ product option.

   0 Unused error structure.
3. Install IBM MQ for IBM i, base product, and primary language.

   ```
   RSTLICPGM LICPGM (5724H72) DEV (installation device) OPTION (*BASE) OUTPUT (*PRINT)
   ```

   where the parameters of RSTLICPGM are,

   LICPGM (5724H72)
   The product identifier for IBM i.

   DEV (*installation device*)
   The device from which the product is to be loaded, typically an optical drive, for example, `OPT01`.

   OPTION (*BASE)
   Install the base IBM MQ for IBM i product.

   Unspecified parameters
   Unspecified parameters such as **RSTOBJ** (`*ALL`), revert to defaults. The command installs both IBM MQ and the language files for the primary language of your system. For installing additional languages see Installing translated versions.

What to do next

Install any Progam Temporary Fixes (PTF) that have been issued.

To install the IBM MQ samples, see: "Install samples on IBM i" on page 757.

Post installation tasks:

Actions required after upgrading IBM MQ.

About this task

Install the samples.

Carry out these steps after installing the product.

Procedure

1. Issue the following commands:
   a. `STRSBS SBSD(QMQM/QMQM)`
   b. `CRTMQM MQMNAME(`*`QMgrName`*`) DFTQMGR(*YES)` You receive the message " IBM MQ queue manager created."

   c. `STRMQM MQMNAME(`*`QMgrName`*`)` You receive the message " IBM MQ queue manager '*QMgrName*' started."
2. Issue the following command:
   ```
   STRMQMMQSC SRCMBR(QMgrName) SRCFILE(*CURLIB/QMQSC) OPTION(*RUN)
   MQMNAME(QMgrName)
   ```
3. Reapply IBM MQ Authorities by issuing the command: `CALL PGM(*CURLIB/`*`QMgrName`*`)`
   a. You must compile the CLP as follows:
      ```
      CRTCLPGM PGM(*CURLIB/QMgrName) SRCFILE(*CURLIB/QMAUT) SRCMBR(*PGM)
      ```

Upgrading an entire IBM MQ system on IBM i

IBM i

How to upgrade an IBM MQ system on IBM i

Before you begin

Ensure that you have backed up your entire system.

About this task

To upgrade an IBM MQ system on IBM i you carry out a slip installation.

See “Installation methods on IBM i” on page 752 for further information.

Related tasks:

“Migrating a queue manager on Windows” on page 691
The procedures for migrating a queue manager to a later version of the product, and for restoring a queue manager to an earlier version of the product are detailed in this section.

Migrating an IBM MQ MQI client to the latest version on IBM i

IBM i

Before migrating an IBM MQ MQI client, create a migration plan. Stop all IBM MQ activity on the client workstation. Upgrade the IBM MQ MQI client installation. Make any essential configuration and application changes.

Before you begin

1. Create a migration plan. Use the planning task, “Planning to migrate to the latest version on IBM i” on page 749, as a guide.

Procedure

1. Review the IBM MQ system requirements for the later version of the product. See System Requirements for IBM MQ.
2. Review all the changes in IBM MQ that affect you. For more information, see “Changes that affect migration” on page 626.
3. End all IBM MQ activity on the workstation.
4. Upgrade the client. To upgrade an IBM MQ MQI client for IBM i installation on a workstation; see Client installation procedure on IBM i.

What to do next

Complete the tasks in your migration plan, such as verifying IBM MQ MQI client applications work correctly with the latest version.

Related concepts:

"IBM MQ MQI client migration" on page 650
IBM MQ MQI client migration is the process of converting IBM MQ MQI client configurations, and client and server channels from one version to another. Client migration can take place after upgrading the IBM MQ MQI client, and is reversible.

Migrating from a single instance to a multi-instance queue manager on IBM i

IBM i

To migrate a single instance queue manager to a multi-instance queue manager, on IBM i, you must move the queue manager data to a shared directory, and reconfigure the queue manager on two other servers.

Before you begin

You must check the prerequisites for running a multi-instance queue manager as part of this task. Some environments have been tested with multi-instance queue managers, and are known to work. IBM i has been tested with multi-instance queue managers and is known to work See Testing and support statement for IBM MQ multi-instance queue managers for the latest list of tested environments. The support statement has detailed version and prerequisite information for each environment it lists. Other environments might work; a test tool is provided with IBM MQ to assist you in qualifying other environments.

You must have three servers to run a multi-instance queue manager. One server has a shared file system to store the queue manager data and logs. The other servers run the active and standby instances of the queue manager.

About this task

You have a single-instance queue manager that you want to convert to a multi-instance queue manager. The queue manager conversion itself is straightforward, but you must do other tasks to create a fully automated production environment.

You must check the prerequisites for a multi-instance queue manager, set up the environment and check it. You must set up a monitoring and management system to detect if the multi-instance queue manager has failed and been automatically restarted. You can then find out what caused the restart, remedy it, and restart the standby. You must also modify applications, or the way applications are connected to the queue manager, so that they can resume processing after a queue manager restart.

Procedure

1. Check the operating system that you are going to run the queue manager on, and the file system on which the queue manager data and logs are stored on. Check that they can run a multi-instance queue manager.
   a. Consult Testing and support statement for IBM MQ multi-instance queue managers. See whether the combination of operating system and file system is tested and capable of running a multi-instance queue manager.

      A shared file system must provide lease-based locking to be adequate to run multi-instance queue managers. Lease-based locking is a recent feature of some shared file systems, and in some case fixes are required. The support statement provides you with the essential information.
   b. Run **amqmfsck** to verify that the file system is configured correctly.

      File systems are sometimes configured with performance at a premium over data integrity. It is important to check the file system configuration. A negative report from the **amqmfsck** tool tells you the settings are not adequate. A positive result is an indication that the file system is adequate, but the result is not a definitive statement that the file system is adequate. It is a good indication.
   c. Run the integrity checking application provided in the technote, Testing a shared file system for compatibility with IBM MQ Multi-instance Queue Managers.

      The checking application tests that the queue manager is restarting correctly.
2. Configure a user and group to be able to access a share on the networked file system from each server that is running a queue manager instance. On IBM i, `QMQM`, `QMQMADM`, and any other user profiles that are granted access to the share must have the same passwords on all the servers
3. Set up a directory for the share on the networked file system with the correct access permissions.

   A typical configuration is to set up a single shared directory that contains all data and log directories for all queue managers that use the shared disk; see Share named qmgrs and log directories (Version 7.0.1 onwards) in Example directory configurations on UNIX.

   For example, create a root directory on the share called `MQHA` that has subdirectories `data` and `logs`. Each queue manager creates its own data and log directories under `data` and `logs`. Create `MQHA` with the following properties:

   On IBM i, follow the instructions to create a network share using NetServer.
4. Copy the queue manager data and the logs to the share.

   You can choose to copy files manually, by following the procedure to back up the queue manager. elect one of these methods:
   - Follow the instructions in Backups of IBM MQ for IBM i data, copying the queue manager data to the share. You must use this method if the **DataPath** configuration attribute is specified for this queue manager.
   - Stop the queue manager, and then type the command,
     ```
     hamvmqm /m /dd share\data /dd share\logs
     ```
     Where *share* is to be the location of the data and logs that you created in step 3.
5. Update the queue manager configuration information stored on the current queue manager server.

   If you moved the queue manager data and logs by running the **hamvmqm** command, the command has already modified the configuration information correctly for you.

   If you moved the queue manager data and logs manually, you must complete the following steps.
   - On IBM i,
     a. Modify the `Log:` stanza in the queue manager `qm.ini` file, which is on the *share*:
        ```
        LogPath= share/logs/QMgrName
        ```

   b. Modify the `QueueManager:` stanza in the IBM MQ `mqs.ini` file, which is typically in the `/QIBM/UserData/mqm` directory on IBM i:

      ```
      DataPath= share/data/QMgrName
      ```

   Where, *QMgrName* is the `Directory` name in the `QueueManager:` stanza in the `mqs.ini` file on IBM i. *share* is share where the data and logs are moved to.
6. Add the queue manager configuration information to the new queue manager server.
   a. Run the **dspmqinf** command to display the queue manager information

      Run the command on the server that ran the queue manager in Version 6.0.

      ```
      dspmqinf -o command QMgrName
      ```

      The command output is formatted ready to create a queue manager configuration. `addmqinf -s QueueManager -v Name= QMgrName -v Directory= QMgrName -v Prefix=d:\var\mqm Datapath= \share\data\QMgrName`
   b. Create a queue manager configuration on the other server.

      Run the **addmqinf** command copied from the previous output
7. Add the network address of the new server to the connection name in client and channel definitions.
   a. Find all the client, sender, and requester TCPIP settings that refer to the server.

      Client settings might be in Client Definition Tables (CCDT), in environment variables, in Java properties files, or in client code.

      Cluster channels automatically discover the connection name of a queue manager from its cluster receiver channel. As long as the cluster receiver channel name is blank or omitted, TCPIP discovers the IP address of the server hosting the queue manager.
   b. Modify the connection name for each of these connections to include the TCPIP addresses of both servers that are hosting the multi-instance queue manager.

      For example, change:

      ```
      echo DISPLAY CHANNEL(ENGLAND) CONNAME | runmqsc QM1
      5724-H72 (C) Copyright IBM Corp. 1994, 2009.  ALL RIGHTS RESERVED.

      Starting MQSC for queue manager QM1.

      1: DISPLAY CHANNEL(ENGLAND) CONNAME

      AMQ8414: Display Channel details.

      CHANNEL(ENGLAND) CHLTYPE(SDR)

      CONNAME(LONDON)
      ```

      Into:

      ```
      echo ALTER CHANNEL(ENGLAND) CHLTYPE(SDR) CONNAME('LONDON, BRISTOL') | runmqsc QM1
      ```
8. Update your monitoring and management procedures to detect the queue manager restarting.
9. Update client applications to be automatically reconnectable, if appropriate.
10. Update the start procedure for your IBM MQ applications to be started as queue manager services.
11. Start each instance of the queue manager, permitting them to be highly available.

    The first instance of the queue manager that is started becomes the active instance.

    Issue the command twice, once on each server.

    ```
    strmqm -x QMgrName
    ```

What to do next

To get the highest availability out of multi-instance queue managers, you must design client applications to be reconnectable and server applications to be restartable; see Application recovery.

IBM i The IBM MQ configuration file mqs.ini - IBM i

Verifying shared file system locking

Reverting to a single-instance queue manager on IBM i

IBM i

Revert a multi-instance queue manager to a single instance queue manager, on IBM i, by stopping the standby instance. Then restart the active instance and do not set the flag that permits standby instances.

Before you begin

You have at least three servers configured to run a queue manager as a multi-instance queue manager. The queue manager is currently running as a multi-instance queue manager, with one standby instance active.

About this task

The task involves deactivating the active standby so that only the running multi-instance queue manager remains active. To prevent a standby instance being started in the future, you must stop the active instance and restart it. When you restart it, you start it as a single instance queue manager that prevents standby instances being started. The standby instance is stopped as a separate step, to give you the option of restarting the active instance at a later date. You can stop both instances by running the standard `endmqm` *`QMgrName`* command on the server running the active queue manager.

Procedure

1. Stop the standby queue manager instance.

   On the server running the standby instance:
   ```
   ENDMQM MQMNAME (QMgrName) *WAIT
   ```
2. Stop the active queue manager instance.

   On the server running the active instance:
   ```
   ENDMQM MQMNAME (QMgrName) *WAIT
   ```
3. Restart the queue manager, preventing standbys.

   On the server that is going to run the queue manager:

```
STRMQM MQMNAME (QMgrName)
```

What to do next

You might want to run the queue manager as a single instance on the same server as the queue manager data.

When the queue manager is stopped move the queue manager data back to the server that is running the queue manager. Alternatively install IBM MQ, and then move the queue manager configuration definition onto the server with the queue manager data. Both tasks are variations of steps in "Migrating from a single instance to a multi-instance queue manager on IBM i" on page 766 to create a multi-instance queue manager.

"Changes that affect migration" on page 626
Changes to the product might affect the migration of a queue manager from an earlier release to the current release of IBM MQ, or affect existing applications or configurations. Review these changes before upgrading queue managers to the latest product version and decide whether you must plan to make changes to existing applications, scripts, and procedures before starting to migrate your systems.

Migrating IBM MQ for z/OS - order of tasks

z/OS

Perform these instructions, in the order shown, to migrate a single IBM MQ for z/OS queue manager.

About this task

The tables within this topic show the tasks required in each part of the process to migrate IBM MQ for z/OS, and the order in which these tasks must be done.

Notes:

- You must perform the tasks in the following order:
  1. Before migration
  2. Migrating to the next release
  3. Post-migration tasks

and the order of tasks within each table.

Table 88. Before migration

Task	For your own use
1. Make your configuration ready for migration	
2. Install the new version code	
3. Perform backup	
4. Restart IBM MQ systems	
5. Review pageset 0 usage	
6. Migrate Db2 tables - for each QSG	
7. Add new CF structure definition - for each QSG	
8. Server application migration	
9. Preparing to migrate Advanced Message Security	

Table 89. Migrating to the next release

Task	For your own use
10. Stop or disconnect all your applications	
11. Stop the queue manager	
12. Update STEPLIB for MSTR and channel initiator	
13. Update the initialization input data sets	
CD 14. Update the target version system parameter module	
15. Migrating Advanced Message Security	
16. Review the security control of your system	
17. Start the queue manager	
18. Optionally, revert the queue manager to a previous version	

Table 90. Post migration tasks

Task	For your own use
19. Check the changes in behavior	
20. Modify the backup jobs	
21. Post migration tasks for Advanced Message Security	
22. Perform a full regression test	
23. Update the ZPARM module, if not already done	
24. Set OPMODE to NEWFUNC	
25. Exploit the new function	
26. Consider client application migration	

Planning to migrate to the latest release on z/OS: z/OS

Create a migration plan for IBM MQ for z/OS to upgrade to the latest release.

About this task

The goal of this task is for you to create your own plan to migrate your queue managers to the latest release. Incorporate the task to migrate a queue manager, "Migrating IBM MQ for z/OS - order of tasks" on page 770, into your plan.

Migration plan overview for your enterprise

Migration phase	Required tasks
Phase I, before migration. See "Preparing to migrate a single IBM MQ for z/OS queue manager" on page 791 for further information.	Preparing each queue manager in your enterprise for migration.
Phase II, migrate each single queue manager in the order listed. See "Migrating a single IBM MQ z/OS queue manager to the next release of the product" on page 796 for further information.	Carry out this process for each queue manager in the order shown: 1. z/OS queue managers in a queue-sharing group (QSG). 2. z/OS queue managers not in a queue-sharing group (if any). 3. Queue managers in a full repository on platforms other than z/OS. See "Migrating a queue manager on Windows" on page 691 for further information. 4. z/OS partial repository queue managers in a QSG. 5. z/OS partial repository queue managers not in a QSG . 6. z/OS queue managers not in a queue-sharing group or cluster. 7. Partial repository queue managers on platforms other than z/OS. 8. Queue managers not in a cluster on platforms other than z/OS.
Phase III, post migration. See "Post migration tasks" on page 803 for further information.	Carry out a full regression test, and then explore the new function available to you. Optionally, at any time in the process, upgrade your client libraries if necessary, recompile your clients using the additional features provided by the new version, and deploy the clients.

Procedure

1. Review the IBM MQ system requirements for the latest version.

   See System requirements for IBM MQ.
2. Review all the changes in the product that affect you. For further information, see:
   - LTS What's new and changed in IBM MQ Version 9.0
   - CD What's new and changed in Version 9.0.x Continuous Delivery
3. Review performance changes. See IBM MQ Family - Performance Reports.
4. Review the backward and coexistence (or migration and toleration) PTFs for your current version of the product. See IBM MQ Support, Migration PTFs.

These PTFs must be applied to your current version of the product to enable you to revert your queue managers to the current version, after the queue managers have been started at the target version.

Note, that you can have different versions of queue managers coexisting in the same queue-sharing group.

If you are unsure which migration PTFs you require, run the following command SMP/E:

CD

```
REPORT MISSINGFIX ZONES(mqtgtzone) FIXCAT(IBM.Coexistence.MQ.V9R0M0)
```

See FIXCAT and IBM MQ Migration Installation for further information.

Attention: If a PTF requires a rebind of Db2 plans, the PTF is shipped with ++HOLD(ACTION), indicating the need for this process. In such a case, see Migrating Db2 tables to bind the plans before starting migration.

Other FIXCAT categories are listed in IBM Fix Category Values and Descriptions.

5. Plan to install the latest version early code, and activate for all queue managers on the LPAR. See Installing early code for more information.

   Note that:

      Before migration, all systems that are running queue managers that you plan to migrate to the latest version must have the early code for that version installed and running. Queue managers in queue-sharing groups that contain queue managers that are to be migrated, must also be running the early code.

      A queue manager must use the early code from the same release level, or a later release level.

   If you need to rebind the plans or packages, see Step 1 on page 806 in Migrating queue-sharing groups from a previous release for further information.

6. Consider using aliases for the IBM MQ libraries.

   For example, use the IDCAMS utility with the DEFINE command:

   ```
   DEFINE ALIAS(NAME(MQM.SCSQANLE)RELATE(MQM.V710.SCSQANLE))
   ```

   You can use `MQM.SCSQANLE`, where applicable, in your STEPLIB, and it resolves to the actual data set.

   When you migrate to a new release, change the alias definition, rather than changing all the places in your JCL where the library is referenced.

   This process has the most benefit for your server application programs, because you can get all of the programs to refer to the new libraries at the same time.

7. Plan the sequence and timing of queue manager upgrades.
   - You must install the backward and coexistence (or migration and toleration) PTF to bring the previous version queue managers up to the latest maintenance level for that version.
   - You must install the PTF on all members of a queue-sharing group, before you migrate any queue managers to the latest version. You can install the PTF one member at a time, leaving the other members running.
   - If the queue manager is a member of a queue manager cluster, you must consider the order of migration of queue managers in the cluster; see “Migrating a queue manager cluster” on page 808.
   - Check that any products that require the previous version of the product also support the new version.

8. Plan to update any manual or automated procedures you have written with changes to messages and codes.

9. Plan to update applications that might be affected by changes. Update the IBM MQ library in the application STEPLIB concatenations to the latest version.

   Consider whether the application must be able to run on both the previous version and the latest version. You might be able to change the application to be compatible with both code levels. If you cannot, you can query the queue manager command level, and make the code conditional on the command level. Call MQINQ setting the `MQIA_COMMAND_LEVEL` selector.

10. LTS If you are migrating to a Long Term Support (LTS) release, decide on what regression tests to perform before enabling the new function in the latest version. The **OPMODE** parameter controls a staged migration from the previous version to the latest version.

    LTS Do not change **OPMODE** initially, when migrating to an LTS release, to make sure that you can go back to using an earlier version of the product, and that all the functions that were available before migration will still be available after migration.

    If you are migrating from IBM WebSphere MQ Version 7.1 to IBM MQ Version 9.0, once you are satisfied with the stability of the latest version, you can start to use the new functions. To use the new functions, you must set **OPMODE** to `(NEWFUNC,900)`.

    There are no new functions in IBM MQ Version 9.0 that are controlled by **OPMODE**, therefore if you are migrating from IBM MQ Version 8.0 to IBM MQ Version 9.0, setting **OPMODE** to `(NEWFUNC,900)` does not enable any new functions.

    CD Backwards migration from a Continuous Delivery release CD release is not possible. If you are migrating to a CD release for the first time, you must set **OPMODE** to `(NEWFUNC,90x)` as part of the migration procedure, where `x` is the modification number.

    Include the procedures and applications you identified in steps 8 on page 773 and 9 on page 773 in your regression tests.
11. Review the tasks to customize z/OS, and the queue manager. Plan how to change the queue manager definitions and started task JCL to migrate your queue managers to the latest versions. The customization steps for migration are described in "Reviewing and modifying queue manager customizations from the previous release on z/OS" on page 775.
12. Review the usage of page set 0. Issue the operator command **cpf**, `/cpf DISPLAY USAGE PSID(0)` to obtain a report on pageset 0 usage.

    The size of queue definitions increased in IBM WebSphere MQ Version 7.1. During migration queue definitions stored on pageset 0 are rewritten if you are migrating from a previous release. The rewrite is carried out as a single transaction when the queue manager is first migrated to IBM WebSphere MQ Version 7.1.

    Ensure that there is enough space available on pageset 0 to create a copy of the queue definitions while migration is taking place. Typically, 60% free space on pageset 0 before migration is sufficient. However, the use of `EXPAND(SYSTEM)` on the pageset definition allows for automatic expansion as required. If there is insufficient space on pageset 0 during migration, the queue manager abends with completion code `X'5C6'` and reason code `X'00C91900'`.
13. Check that you are using a supported level of assembler or compiler. You can write IBM MQ applications using any compiler capable of generating standard OS linkage to the IBM MQ stub routines.

    Some of the data types used by IBM MQ API calls are not supported on some older compilers. You might require a more recent compiler. The following limitations are known:
    a. Assembler copy books contain blank lines, which are not tolerated by assemblers earlier than **HLASM**.
    b. Some older releases of PL/I do not support fixed `bin(63)` type. A macro defines such fields as `char(8)` when an earlier compiler is detected.
    c. Some older releases of COBOL do not support function-pointers, which are used by the MQCB API.
14. Plan any changes to libraries required by your applications and channel exits.
15. Plan to upgrade your IBM MQ MQI client installations to the latest version.
16. Plan to upgrade your client and server applications to use new functions in the latest version.

17. Plan to migrate other vendor software, such as WebSphere Application Server, or CICS to use the latest version. Update the IBM MQ libraries in the `STEPLIB` and `DFHRPL` concatenations of your CICS region JCL and restart CICS.

    Note:
    - CICS

      Update the IBM MQ libraries in the `STEPLIB` and `DFHRPL` concatenations of your CICS region JCL and restart CICS.

      Up to, and including CICS 3.2, the connection between IBM MQ and CICS is provided by IBM MQ. You must change the `SCSQCICS` and `SCSQAUTH` libraries in the `DFHRPL` concatenation provided by IBM MQ.

      After CICS 3.2, the connection between IBM MQ and CICS is provided by CICS libraries. Update the libraries, if you are using CICS Transaction Server for z/OS Version 3.2 or later. Without this change, you are not able to use the most recent IBM MQ features. You must change the `SCSQCICS` library in the `DFHRPL` concatenation provided by IBM MQ, and also the `STEPLIB` concatenation.

      Create separate CICS started procedure JCL. For each CICS region that is connected to an IBM MQ queue manager, ensure that there is a separate CICS started procedure JCL.

      This ensures that the modification of reference to a certain version of IBM MQ libraries in the CICS started procedure JCL only has impact for that single CICS region. In this way you can migrate one queue manager, and only the CICS region or regions connected to it, which makes staged migration possible.

      CICS `STEPLIB` has `thlqual.SCSQAUTH`, and `DFHRPL` has `thlqual.SCSQCICS`, `thlqual.SCSQLOAD`, and `thlqual.SCSQAUTH`. For more information, see Setting up the CICS- IBM MQ adapter.
18. Review any other installed SupportPacs for their applicability to the latest version.

What to do next

Do the task, "Reviewing and modifying queue manager customizations from the previous release on z/OS" to migrate a queue manager. If you must restore a queue manager to the previous version, see "Reverting a queue manager to a previous release on z/OS" on page 801.

When you are confident existing applications are running without migration problems on the latest version, plan to update **`OPMODE`** to `(NEWFUNC,900)` to enable new function, if you migrated from IBM WebSphere MQ Version 7.1 to IBM MQ Version 9.0.0 LTS release.

CICS Transaction Server for z/OS, Version 3 Release 2 product documentation

The CICS-IBM MQ adapter

IBM MQ Support, Migration PTFs

IBM MQ - SupportPacs by Product

Reviewing and modifying queue manager customizations from the previous release on z/OS: z/OS

Review the z/OS and IBM MQ customization steps, and change any customizations before starting any queue managers with the libraries of the latest version.

Before you begin

You must change the JCL and configuration definitions for the queue manager when you migrate to the latest version. Make copies of the JCL libraries, configuration definitions, and the started task JCL. Modify the copied files to customize the queue manager definitions and JCL for the latest version.

1. Copy the JCL libraries containing the configuration definitions for your queue manager. You must change some of the members, for example to reference the libraries of the new version.
2. Copy the started task JCL for the queue manager and the channel initiator. You might change these members.

You can continue to run the queue manager on the previous version until it is ready to switch to the latest version. Preparing for the switch is a long process. Switching from the earlier version to the latest version is a quick process. The switch to the latest version occurs when you restart the queue manager:

- Switch to using your customized copies of the configuration definitions and started task JCL for the queue manager.

  Create data set aliases, such as `MQM.MQP1.SCSLOAD`, and reference them in JCL. Map the aliases to the real data sets, such as `MQM.MQV71.SCSLOAD` or `MQM.MQV80.SCSLOAD`.

  Change the aliases to switch between the two sets of target libraries. With the aliases, you can start applications or the queue manager when moving to a new release of IBM MQ without changing the `STEPLIB` JCL; switch the aliases from referring to the earlier version of the product to refer to the latest version of the product.
- Until you have verified the startup, start the queue manager, channel initiator, and listener separately, checking for errors on the console after each component is started. If the startup runs cleanly, combine the startup of all three components in the production environment.

Tip: Create data set aliases such as `MQM.MQP1.SCSLOAD`, and reference them in JCL. Map the aliases to the real data sets, such as `MQM.MQV71.SCSLOAD` or `MQM.MQV80.SCSLOAD`. Change the aliases to switch between the two sets of target libraries. With the aliases, you can start applications or the queue manager when moving to a new release of IBM MQ without changing the `STEPLIB` JCL.

Tip: You can use the z/OS command `D GrS,system,RES=(*,MQM.V701.SCSQLOAD)` to display which jobs are using the specified data set, and so identify which jobs and JCL need to be changed.

About this task

The steps in this task can be performed by restarting a queue manager once. You must restart the queue manager to apply essential maintenance, and to install early code before proceeding with migration.

The steps are based on the setup procedure for new queue managers; see Customizing your queue managers.

Procedure

Steps 1 to 10 on page 778 are z/OS customization tasks.
Steps 11 on page 778 to 16 on page 779 are IBM MQ customization tasks.

1. Review that all the load libraries that must be APF authorized are authorized.

   See Task 2: APF authorize the IBM MQ load libraries.
2. Update the LPA libraries with the new version of early code libraries.

   See Task 3: Update the z/OS link list and LPA.

   This step is unnecessary if you update the IBM MQ early code in all the LPARs as part of bringing your previous version IBM MQ libraries up to the latest maintenance level; see step 3 on page 777.

   You must activate the early code with an IPL, or restart the queue manager after issuing the following command.

```
REFRESH QMGR TYPE(EARLY)
```

Note: As part of the update you are asked to stop the queue manager. While the queue manager is stopped, you must check the *qmgr*.REFRESH.QMGR security profile is set up, refresh the queue manager and restart it.

3. Make your configuration of the previous version ready for migration.
   a. Apply current maintenance to the current version libraries.

      Refer to the Preventive Service Planning (PSP) bucket for the current version of your product; see PSP Buckets - How to find them on Web.
   b. Apply the latest version migration and toleration [9] PTFs to the previous version code; see IBM MQ Support, Migration PTFs.
   c. If required by any of the PTFs, make Db2 configuration changes and rebind Db2.

      See the appropriate section in Task 9: Select and set up your coupling facility offload storage environment.
   d. Install the early code for the latest version.

      Replace the early code.
   e. Make the latest version early code and earlier version target libraries available on all the LPARs that are running queue managers.

      If the queue manager is a member of a queue-sharing group, update all the systems in the group.
   f. Restart IBM MQ systems.

      The early code is activated by an IPL, or a by issuing the command `REFRESH QMGR TYPE(EARLY)`, and restarting the queue manager.
   g. Verify correct function before proceeding and review any special actions detailed in the PTFs.

   If you require fall back at this stage, use normal maintenance procedures to revert to the code for the previous version before PTF application.
4. Update your procedure to start the queue manager.

   Change the `STEPLIB` for the queue manager to reference the libraries of the new version of the product.

   See Task 6: Create procedures for the IBM MQ queue manager.

   IBM MQ uses z/OS memory objects above the bar for some functions. You must allow the queue manager to access storage above the bar.

   Your installation might have customized the `SMFPRMxx` member of `SYS1.PARMLIB`, or the **`IEFUSI`** exit to provide a default limit for jobs using virtual storage above the 2 GB bar. Check these limits give sufficient memory for a queue manager. A reasonable starting allocation is 2GB. The message CSQY220I displays the amount of virtual storage currently used and available.

   If your installation does not have a default limit for storage above the bar, or if you want to use a different limit for your queue manager, you can provide a queue manager-specific restriction on the amount of virtual storage available above the bar for memory objects by coding a **`MEMLIMIT`** parameter on the JCL of the queue manager stored procedure, `xxxxMSTR`, for example:

```
//PROCSTEP EXEC PGM=CSQYASCP,REGION=0M,MEMLIMIT=2G
```

   `MEMLIMIT` defines memory available above the bar; see Address space storage for more information.

   For specific information on setting `MEMLIMIT`, when using the accounting and statistics changes in IBM MQ Version 8.0, see Channel initiator storage usage.
5. Update your procedures for the channel initiator.

   Change the `STEPLIB` for the channel initiator to reference the libraries of the new version of the product.

   See Task 7: Create procedures for the channel initiator.

9. The “migration and toleration” PTFs are also known as the “backward migration and coexistence” PTFs. They are the same PTFs.

6. Review any automated alerts when queue manager and channel initiator messages, and errors, are detected. New messages might have been added that cause automated alerts, and some messages might have changed.
7. Review C language channel exits

   Ensure your C language channel exits are using the following statement:

```
#pragma environment(function-name)
```

   as defined in the C systems programming environment for system exits, described in the z/OS C/C++ Programming Guide.
8. Update the IBM MQ Db2 configuration.

   If you are using queue-sharing groups, you must update the procedures.

   If all queue managers in the Db2 tables are at IBM WebSphere MQ Version 7.1 or earlier, customize and run the CSQ4570T and CSQ4571T sample JCL in hlq.SCSQPROC.

   Customize and run the `CSQ45BPL` and `CSQ45GEX` samples in `hlq.SCSQPROC`. Tailor these members to your environment, using your Db2 subsystem names and data set names.

   `CSQ45BPL` of `hlq.SCSQPROC` contains the plan names required for the latest version of IBM MQ. `CSQ45GEX` of `hlq.SCSQPROC` contains the authorities required.

   See steps 5 and 6 of Task 9: Select and set up your coupling facility offload storage environment.
9. Review your security controls for queue-sharing groups, the channel initiator, and all queue managers accessing the coupling facility list structures.

   See Task 11: Implement your ESM security controls.

   You must ensure that you have addressed the following points when you migrate your security profiles to the latest version of IBM MQ.

   - The External Security Manager software is at the correct version and level and that all of your prerequisite software is installed.
   - IBM MQ security classes have been updated to include the mixed case classes.
   - Enterprise has migrated to mixed case security; see "z/OS Migrating a queue manager to mixed case security" on page 799.
10. Change `SYS1.PARMLIB` to ensure that any changes you made dynamically remain in effect after an IPL.

    `SYS1.PARMLIB` must reference the initialization input data sets that you customize in step 11.

    See Task 12: Update SYS1.PARMLIB members.
11. Update the initialization input data sets.

    Each IBM MQ queue manager gets its initial definitions from a series of commands contained in the IBM MQ initialization input data sets. These data sets are referenced by the Data Definition (DD) names `CSQINP1` and `CSQINP2` defined in the queue manager started task procedure.

    See Task 13: Customize the initialization input data sets.

    The `CSQINP1` and `CSQINP2` initialization input data sets include more samples and the contents of some samples have been moved to other samples. Particular changes to take note of are the commands to define queues to hold publish/subscribe state information. The commands must be in the right order.

    You must review the customization you have made previously to `CSQINP1` and `CSQINP2`, and merge them into the initial definitions provided with the latest version of the product.

    Secure the server-connection channels used by clients; see Securing remote connectivity to the queue manager.

    DEFINE SUB for SYSTEM.DEFAULT.SUB is no longer permitted in the CSQINP2 input data set. DEFINE SUB commands can instead be issued from the CSQINPT input data set. The CSQINPT input data set is processed each time the publish/subscribe engine is started, either during queue manager startup, or when the publish/subscribe engine is started with the **`ALTER QMGR PSMODE(ENABLED)`** command. See Issuing commands to IBM MQ for z/OS for more information on using the CSQINPT input data set.

12. Update your system parameter module.

    Your system parameter module is based on the default module, `CSQZPARM` and `CSQ4ZPRM`.

    See Task 17: Tailor your system parameter module.

13. Update the libraries you added to STEPLIB concatenations to make Batch, TSO, and RRS adapters available to applications.

    Change the `STEPLIB` for the Batch, TSO, and RRS adapters to reference the libraries of the new version of the product.

    See Task 19: Set up Batch, TSO, and RRS adapters.

    Note: You can connect applications that reference the latest version `STEPLIB` to a queue manager that is running on the latest version, or an earlier version. You must not connect applications that reference a `STEPLIB` from an earlier version to a queue manager running on a later version.

14. Update the libraries you added to connect CICS to the queue manager.

    You must update the IBM MQ libraries in the STEPLIB and DFHRPL concatenations of your CICS region JCL and restart CICS. You are then able to use the most recent IBM MQ features.

    Note:

    - CICS

      Update the IBM MQ libraries in the `STEPLIB` and `DFHRPL` concatenations of your CICS region JCL and restart CICS.

      Up to, and including CICS 3.2, the connection between IBM MQ and CICS is provided by IBM MQ. You must change the `SCSQCICS` and `SCSQAUTH` libraries in the `DFHRPL` concatenation provided by IBM MQ.

      After CICS 3.2, the connection between IBM MQ and CICS is provided by CICS libraries. Update the libraries, if you are using CICS Transaction Server for z/OS Version 3.2 or later. Without this change, you are not able to use the most recent IBM MQ features. You must change the `SCSQCICS` library in the `DFHRPL` concatenation provided by IBM MQ, and also the `STEPLIB` concatenation.

      Create separate CICS started procedure JCL. For each CICS region that is connected to an IBM MQ queue manager, ensure that there is a separate CICS started procedure JCL.

      This ensures that the modification of reference to a certain version of IBM MQ libraries in the CICS started procedure JCL only has impact for that single CICS region. In this way you can migrate one queue manager, and only the CICS region or regions connected to it, which makes staged migration possible.

      CICS `STEPLIB` has `thlqual.SCSQAUTH`, and `DFHRPL` has `thlqual.SCSQCICS`, `thlqual.SCSQLOAD`, and `thlqual.SCSQAUTH`. For more information, see Setting up the CICS- IBM MQ adapter.

15. Update the libraries you use to set up the operations and control panels.

    Change the `STEPLIB` for the operations and control panel.

    See Task 20: Set up the operations and control panels.

    Note: You can connect the operations and control panel that references the latest version `STEPLIB` to the queue manager that is running on the latest version, or an earlier version. You must not connect the operations and control panel that references a `STEPLIB` from an earlier version to a queue manager running on a later version.

16. Update system libraries to format IBM MQ dumps using the Interactive Problem Control System (IPCS).

    See Task 21: Include the WebSphere(r) MQ dump formatting member.

What to do next

Carry out the instructions in this topic to migrate a single IBM MQ queue manager on z/OS,

IBM MQ Version 9.0 JCL changes on z/OS: z/OS

Table showing changed members between IBM MQ Version 8.0 hlq.SCSQPROC and the IBM MQ Version 9.0 hlq.SCSQPROC PDS libraries at general availability time.

Notes:

1. Nearly all of the members do show changes between releases, but the majority of those changes are what are termed cosmetic. They are often simply changes to reflect the modification to the release number.
2. Any changes to the samples libraries since general availability are not included.
3. This information can be useful to your administrators when migrating existing queue managers, to make sure that new features are picked up correctly.

Modified members on z/OS

Table 91. IBM MQ for z/OS changed members on z/OS

Member name	Description
CSQ4BSDS	Recommended number of records in BSDS increased to support BSDS version 2. This change was delivered in IBM MQ Version 8.0 in a program temporary fix. Naming convention for active log data sets changed to allow up to 310 active log data sets to be defined.
CSQ4CHIN	Changed to add the following parameters to the JCL JOB statement: • MEMLIMIT=256M, to support the gathering of channel initiator statistics. This change was delivered in IBM MQ Version 8.0 in a program temporary fix. • TIME=NOLIMIT, to indicate that the channel initiator can use the processor for an unlimited amount of time.
CSQ4LREC	Naming convention for active log data sets changed to allow up to 310 active log data sets to be defined.
CSQ4SMFJ	Changed to add a DD statement to describe the output file for formatted data manager page set statistics.
CD CSQ4ZPRM	OPMODE default value updated: • OPMODE=(COMPAT,900), IBM MQ Version 9.0.0 LTS release default value • OPMODE=(NEWFUNC,901), IBM MQ Version 9.0.1 CD release default value ACELIM=0 parameter added. This specifies that the maximum size of the ACE storage pool is unlimited.
CSQ4570T and CSQ4571T	Sample jobs to migrate Db2 resources from IBM WebSphere MQ Version 7.0 and IBM WebSphere MQ Version 7.1 to IBM MQ Version 9.0, updated with IBM MQ Version 9.0 names.
CSQ45BPK and CSQ45BPL	Sample jobs to bind Db2 packages updated to use the IBM MQ Version 9.0 names

Table 91. IBM MQ for z/OS changed members on z/OS (continued)

Member name	Description
CSQ4DTB	Statements added to delete the following Db2 tables used by IBM MQ CSQ.ADMIN_MSGS_BAUX4 CSQ.ADMIN_MSGS_BAUX3 CSQ.ADMIN_MSGS_BAUX2 CSQ.ADMIN_MSGS_BAUX1 CSQ.EXTEND_B_QMGR This change was delivered in IBM MQ Version 8.0 in a program temporary fix
CSQ45GEX	Sample Db2 GRANT job updated to use the IBM MQ Version 9.0 names.

OPMODE on z/OS: z/OS

The availability of new functions and backward migration for IBM MQ for z/OS is controlled by the **OPMODE** parameter in the **CSQ6SYSP** macro. IBM MQ Version 8.0 new functions that are restricted by **OPMODE** are not available at Version 9.0 unless enabled with **OPMODE**. There are no new functions in Version 9.0 that are restricted by **OPMODE**.

Important: CD Backwards migration is not supported for a Continuous Delivery (CD) release. Queue managers running a CD release of IBM MQ must be started with (`OPMODE=(NEWFUNC,90`*x*`)`. For example, a Version 9.0.1 queue manager must be started with `OPMODE=(NEWFUNC,901)`.

Once a queue manager has been started at a CD release of IBM MQ with `OPMODE=(NEWFUNC,901)` or higher, there is no need to change OPMODE every time the queue manager is migrated to a later CD release.

LTS The default setting of OPMODE at Version 9.0.0 is `OPMODE=(COMPAT,900)`, which restricts the set of new functions available. Functions added in IBM MQ Version 8.0 and IBM MQ Version 9.0 that are restricted by **OPMODE** are not available. This makes it possible to revert a queue manager to its earlier release level, if you must do so.

LTS To access all capabilities on a Long Term Support (LTS) release queue manager, change the value of **OPMODE** to `OPMODE=(NEWFUNC,900)`. This prevents the queue manager from being started at an earlier version. Plan to do this in order to exploit all new functions as soon as you are confident that you will not need to revert the queue manager to its earlier release.

LTS

Important: When migrating a queue manager to IBM MQ Version 9.0 LTS, do not recompile the system parameter (ZPARM) module with `OPMODE=(COMPAT,900)`. Doing so stops function working, restricted by **OPMODE** in IBM MQ Version 8.0, that might have been in use before the migration.

This is a change from the migration procedure to previous versions of IBM MQ. Leaving **OPMODE** at its current value retains the ability to revert the queue manager to its earlier release, while also keeping the same set of functions enabled.

If you query the value of **OPMODE** with the command DISPLAY SYSTEM, the result is *compatibility mode, compatibility VRM, function VRM*, where *VRM* is a release level.

The value of compatibility *VRM* is the release level you can revert the queue manager back to. If the queue manager is newly created at Version 9.0.0, then `VRM=900`. If the queue manager was previously run at Version 7.1.0, then `VRM=710`.

The value of *function VRM* is the release level of the new functions that are available. In a queue-sharing group, this depends on the **OPMODE** of the other queue managers in the queue-sharing group as well.

Each queue manager in a queue-sharing group must have **OPMODE** set to **OPMODE**=(NEWFUNC,*vrm*), where *vrm* is 800, 900, or 901, and be restarted in order for any queue manager in the queue-sharing group to use Version 8.0 function.

This means that there are effectively two phases to enabling Version 8.0 new function in a queue-sharing group:

1. The first restart with **OPMODE** set to **OPMODE**=(NEWFUNC,800), or higher, prevents the queue manager from being reverted to run on an earlier release level.

   Queue managers migrated from Version 8.0 to Version 9.0.0 can be restarted with **OPMODE** set to `OPMODE=(NEWFUNC,800)` without being prevented from reverting to run at Version 8.0.
2. The second restart, when all other queue-sharing group members have already been restarted with **OPMODE** set to `OPMODE=(NEWFUNC,800)`, or `OPMODE=(NEWFUNC,900)` on an LTSR queue manager, and therefore cannot revert to run on a release level earlier than Version 8.0, allows Version 8.0 new function to be used.

For example, in a queue-sharing group containing three queue managers, there will be a total of five queue manager restarts required to enable Version 8.0 new function on all queue-sharing group members.

You can reset **OPMODE** to `OPMODE=(COMPAT,900)`, after setting `OPMODE=(NEWFUNC,900)` on an LTS release queue manager, to prevent new functions being used. If you do so, DISPLAY SYSTEM shows `OPMODE(COMPAT,900,710`, indicating that you cannot revert the queue manager to a version prior to Version 9.0.0, and that only Version 7.1.0 new functions are available.

The syntax of **OPMODE** is as follows:

OPMODE=(Mode,*VerificationLevel*)

OPMODE specifies the operation mode of the queue manager.

LTS The default setting of **OPMODE** for IBM MQ Version 9.0.0 is `OPMODE=(COMPAT,900)` .

CD The only valid setting of **OPMODE**, for a Continuous Delivery (CD) release of IBM MQ, is `OPMODE=(NEWFUNC,90x)`. For example, at IBM MQ Version 9.0.1, you must specify `OPMODE=(NEWFUNC,901)`.

Mode

Specifies the requested operation mode. The values are as follows:

COMPAT

The queue manager runs in compatibility mode. Certain new functions are not available. The queue manager can be migrated back to an earlier release.

LTS

Important: This value is valid only for a Long Term Support (LTS) release of IBM MQ.

NEWFUNC

All new functions provided in this level of code are available. The queue manager cannot be migrated back to an earlier release.

VerificationLevel

VerificationLevel is a Version.Release.Modification (VRM) code, without punctuation; 900, for example.

The value of *VerificationLevel* ensures that the **CSQ6SYSP** parameters are coded for use with the level of **CSQ6SYSP** macro being compiled. If *VerificationLevel* does not match the VRM level of SCSQMACS used for **CSQ6SYSP**, then a compile-time error is reported. The *VerificationLevel* is compiled into the parameter module.

LTS At queue manager start up, if the *VerificationLevel* does not match the release level of the queue manager, for an LTS release, then COMPAT mode is forced.

CD For a queue manager started at a CD release, if *VerificationLevel* refers to a CD release, but does not match the release level of the queue manager, OPMODE=(NEWFUNC,*vrm*) takes effect, where *vrm* is the CD release level of the queue manager.

For example, a Version 9.0.2 queue manager started with OPMODE=(NEWFUNC,901), behaves as if OPMODE=(NEWFUNC,902) had been specified.

If *VerificationLevel* refers to an LTS release, the queue manager will not start at a CD release.

The intent of the *VerificationLevel* parameter is to avoid inadvertent and irreversible setting of OPMODE to NEWFUNC. The mistake might occur when migrating to a newer version of IBM MQ using **CSQ6SYSP** statements prepared for an older version of the queue manager. It might also occur using a **CSQ6SYSP** parameter module built with an older version of the SCSQMACS macros.

If you need assistance to revert to an earlier version of IBM MQ, contact your IBM support center.

z/OS: Switching from new function mode to compatibility mode
The availability of new functions and backward migration for IBM MQ for z/OS is controlled by the **OPMODE** parameter in the **CSQ6SYSP** macro. You should be aware of the implications of switching from new function mode to compatibility mode, that is, switching from OPMODE=(NEWFUNC,800) or OPMODE=(NEWFUNC,900) to OPMODE=(COMPAT,800) or OPMODE=(COMPAT,900).

Using CSQ6SYSP

OPMODE restrictions by version on z/OS: z/OS

The availability of some new functions and backward migration for IBM MQ for z/OS is controlled by the **OPMODE** parameter in the **CSQ6SYSP** macro. The **OPMODE** parameter determines whether you can use selected new functions, before you commit to staying at a given release. The functions and capabilities that are restricted in the different versions of the product are listed here.

IBM WebSphere MQ Version 7.1 on z/OS

Table 92. Functions and capabilities in Version 7.1 on z/OS

Function	Reference
CFLEVEL(5) which is a prerequisite for Shared Message Data Sets (SMDS) and custom offload rules	DEFINE CFSTRUCT Planning your coupling facility and offload storag
Support for the X'3C' OTMA protocol messages, which report IMS health status	The IMS bridge
Resilience to coupling facility connectivity failures	Shared queue recovery

IBM MQ Version 8.0 on z/OS

Table 93. Functions and capabilities in Version 8.0 on z/OS

Function	**Reference**
Buffer pools can be located above the bar	DEFINE BUFFPOOL
Multiple cluster transmission queues	Clustering: Planning how to configure cluster transmission queues Working with cluster transmission queues and cluster-sender channels Planning how you use multiple cluster transmission queues
Increased maximum addressable log range	Larger log Relative Byte Address
Configurable certificates for individual channels using CERTLABL	Certificate label (CERTLABL)
Using host names, restricting the certificate issuer, and checking client credentials in CHLAUTH rules	SET CHLAUTH

Note: CD These functions are also restricted by OPMODE in IBM MQ Version 9.0

Related information:

Using CSQ6SYSP

Switching from new function mode to compatibility mode on z/OS: z/OS

The availability of new functions and backward migration for IBM MQ for z/OS is controlled by the **OPMODE** parameter in the **CSQ6SYSP** macro. You should be aware of the implications of switching from new function mode to compatibility mode, that is, switching from `OPMODE=(NEWFUNC,800)` or `OPMODE=(NEWFUNC,900)` to `OPMODE=(COMPAT,800)` or `OPMODE=(COMPAT,900)`.

CD

Note: Backwards migration is not supported for a Continuous Delivery (CD) release. Queue managers running a CD release of IBM MQ must be started with **OPMODE**=(`NEWFUNC,90x`) where `x` is the modification level.

Switching from OPMODE=(NEWFUNC,800) or OPMODE=(NEWFUNC,900) to OPMODE=(COMPAT,800) or OPMODE=(COMPAT,900)

When you switch from `OPMODE=(NEWFUNC,800)` or `OPMODE=(NEWFUNC,900)` to `OPMODE=(COMPAT,800)` or `OPMODE=(COMPAT,900)`, certain new Version 8.0 functions will no longer be available. This will cause the following conditions to occur:

- If the BSDS has been converted to version 2, the queue manager will not be able to access the BSDS when it is started in compatibility mode. This means that the queue manager fails to start and terminates with reason code 00D10120.
  - You can find the BSDS version by running the print log map utility (**CSQJU004**).
- Any buffer pools with an ID greater than 15 are marked as suspended. This means that these buffer pools cannot be used, deleted, or altered until the queue manager starts in new function mode again. Information about the buffer pools is kept in checkpoint log records until the queue manager starts in new function mode again.
  - Any page set that uses a suspended buffer pool is also suspended. Information about the suspended page set is also kept in checkpoint records.
  - While a page set is suspended, any messages in the page set are unavailable. An attempt to use a queue or topic which uses the suspended page set results in an `MQRC_PAGESET_ERROR` message.

- While it is suspended, a page set can be associated with a different buffer pool by using the FORMAT function of the utility program CSQUTIL, specifying `TYPE(REPLACE)`. You can then issue a **`DEFINE PSID`** command to bring the page set back into use with a different buffer pool.
  -

    Note: All units of recovery that involved the suspended page set, except units that are indoubt, will have been backed out by the queue manager when the page set was last used. Indoubt units of recovery can be resolved when the page set is again in use by the queue manager.
- Any buffer pools with an ID of 15 or less that have their **`LOCATION`** attribute set to `ABOVE`, have the **`LOCATION`** attribute switched to `BELOW` and their **`PAGECLAS`** attribute set to 4KB and the buffer pool size is set to 1000 pages.
- Any cluster-sender channels that have been configured to use a transmission queue other than SYSTEM.CLUSTER.TRANSMIT.QUEUE fail to start with message CSQX295E. To allow these channels to start, you need to perform the following actions:
  - Change the default cluster transmission queue configuration of the queue manager, so that all cluster-sender channels default to use the transmission queue SYSTEM.CLUSTER.TRANSMIT.QUEUE. You can do this by changing the value of the **`DEFCLXQ`** queue manager attribute to `SCTQ`.
  - Identify any manually defined transmission queues that have a non blank cluster channel name attribute value, by using the following command:
    ```
    DISPLAY QLOCAL(*) WHERE(CLCHNAME NE ' ')
    ```
    Change the cluster channel-name attribute value of these queues to blank.
- No inbound channels will be allowed to start if any channel authentication records have been created with a host name specified in their **`ADDRESS`** attribute. Message CSQY344E is issued for each channel authentication rule that uses restricted function, if this condition occurs.
- Defining channel authentication (**`CHLAUTH`**) with the *CHKCLNT* attribute, requires the queue manager to be running in `NEWFUNC` mode.

If you need assistance to revert to an earlier version of IBM MQ, contact your IBM support center.

Using CSQ6SYSP

DISPLAY SYSTEM

Upgrade and migration of IBM MQ on z/OS: z/OS

You can install new releases of IBM MQ to upgrade IBM MQ to a new release, or version level. Multiple installations at the same or different levels can coexist on the same z/OS instance. Running a queue manager at a higher level requires migration.

From IBM MQ for z/OS Version 9.0, the way you upgrade the systems in your enterprise has changed. See IBM MQ Release Types for more information.

Important: LTS Backwards migration is possible only from a Long Term Support (LTS) release.

When you install a new VRM level of IBM MQ on z/OS using SMP/E, it creates a set of IBM MQ libraries. The libraries for different VRM levels of IBM MQ can coexist on the same instance of z/OS. You can then run different queue managers against different release levels of IBM MQ on the same z/OS instance.

If you start a queue manager running on a later release level, then migration of the queue manager to that release level is required. Even if the difference is only in the modification level, some migration might be required. The migration tasks that you must perform to migrate from one version to another are documented in “Planning to migrate to the latest release on z/OS” on page 772; see also “Changes that affect migration” on page 626.

From Version 7.0.1, after you have fully migrated a queue manager to a new version or release, reverse migration is not possible. For Version 7.0.1 and later versions, you have control over when migration takes place, using a new **CSQ6SYSP** parameter, **OPMODE**; see “OPMODE on z/OS” on page 781. If your queue manager is on Version 7.0 or earlier, you can revert to an earlier release. You might have to contact your IBM support center for a backward migration PTF.

Using **OPMODE**, you can migrate all your existing applications to the new release level, and still be able to revert to the previous release level. Once you start changing applications, or adding applications that use new function, you cannot revert to the previous level of the product. **OPMODE** applies to migration from Version 6.0 to Version 7.0.1 onwards.

OPMODE gives you the option of enforcing a two-stage migration process:
1. Regression test your existing applications.
2. Develop new applications, and change existing applications, to use the new function in the release.

The strategy for upgrading queue managers at Version 6.0 or later is as follows:
1. Apply the coexistence and backward migration PTFs to all the queue managers you are going to upgrade. After applying the PTFs, you can run queue managers of different levels in the same queue-sharing groups. You can also reverse the migration of a queue manager back to your current level.
2. Upgrade the first queue manager.
3. Check all your existing applications run correctly on this queue manager.
4. Bring all the queue managers in a queue-sharing group up to the new level, and check that existing applications continue to work correctly.
5. Change the setting of **OPMODE** so that applications can use new function on all the queue managers in the queue-sharing group.

   Note: Step 5 is the point of no return. You can no longer run that queue manager at the previous level of the product.
6. To enable new Version 7.1 or later, function, restart all queue managers within the queue-sharing group.

The coexistence and backward migration PTFs have two distinct purposes:[10]
1. To allow queue managers at the earlier release level to coexist with ones at the later release level. In particular for queue managers to coexist in the same queue-sharing group.
2. To handle queue manager data and logs formatted using the data definitions of the later release.

Characteristics of different types of upgrade on z/OS

When you upgrade from one release to another on z/OS, the impact of the change depends on the extent of the change in VRM level. The VRM codes are explained in “The version naming scheme for IBM MQ for z/OS” on page 569.

Note that migration is required if the version, release, or modification number changes.

LTS From Version 7.0.1, all upgrades from Version 6.0 or later to a Version 9.0 Long Term Support (LTS) release are reversible if the **OPMODE** has not been set to NEWFUNC.

10. Coexistence and backward migration changes might be shipped as a single or multiple fixes.

CD Upgrades to a Continuous Delivery (CD) release are not reversible.

Related concepts:

"The version naming scheme for IBM MQ for z/OS" on page 569
On IBM MQ for z/OS, releases have a three digit Version, Release, and Modification (VRM) code. To run a queue manager at a different VRM level, you must migrate the queue manager, its applications, and the environment in which it runs. Depending on the migration path, the migration might require more or less effort.

"Queue manager coexistence" on page 664
Queue managers, with different names, can coexist on any server as long as they use the same IBM MQ installation. On z/OS, UNIX, Linux, and Windows, different queue managers can coexist on the same server and be associated with different installations.

"Backward migration to earlier supported releases of IBM MQ for z/OS" on page 789
After installation of a new release of IBM MQ for z/OS, you carry out queue manager migration by stopping the queue manager, which is running with the prior release of code, and restarting the queue manager using the new release of code.

"Migration methods on IBM MQ for Multiplatforms" on page 653
There are three main methods of migrating from one release to another: Single-stage migration (called a slip installation on IBM i), side-by-side migration, and multi-stage migration. Multi-stage migration is not an option for IBM i.

Order of migration tasks on z/OS: z/OS

Read this information that shows an overall migration plan for your system, together with the order in which you must undertake the tasks.

Before you begin

Read the information in Clustering: Best practices and Clustering: Topology design considerations to understand repositories.

About this task

The tables within this topic show the tasks required in each part of the process to migrate an overall system, and the order in which these tasks must be done.

Notes:

- You must perform the tasks in the following order:
  1. Overview of migration
  2. Migrating your system to the next release

Queue managers in a queue-sharing group (QSG) and queue managers in a cluster can be migrated in parallel, but at any time there should be enough queue managers working in the QSG, and cluster, to ensure that your business can operate satisfactorily while a staged migration takes place.

If there are queue managers in clusters, ensure that you migrate the full repository queue managers before migrating any partial repository queue managers, so that the cluster always has a full picture of the current cluster architecture.

Table 94. Overview of migration on z/OS

Task	For your own use
1. Make your configuration ready for migration	
2. Install the new code	
3. Server application migration	

Table 95. Migrating your system to the next release on z/OS

Task	For your own use
Full repositories	
Overview - Migrate one full repository on IBM MQ for z/OS in a QSG	
4. Migrate DB/2 tables and New CF structure definitions	
5. Migrate the queue manager	
6. Migrate other full repositories on IBM MQ for z/OS, if any	
7. Full repositories not in a QSG	
8. Full repositories on other platforms	
Other queue managers	
Overview - Migrate partial repositories on IBM MQ for z/OS, in a QSG	
9. Migrate DB/2 tables and New CF structure definitions if not yet done	
10. Migrate one queue manager	
11. Test the migration and upgrade the other queue managers	
12. Migrate the partial repositories not in a QSG	
Migrate queue managers not in a queue-sharing group or cluster on IBM MQ for z/OS	
13. Migrate partial repositories on other platforms	
14. Migrate queue managers not in a cluster on other platforms	
Testing and using new function; see “Post migration tasks” on page 803	
15. Regression tests	
16. Use the new function available to you	

You can upgrade the client libraries at any time during the process. As a final task, recompile the clients using new functions and deploy.

Results

You have migrated your system to another release.

Migrating from earlier unsupported releases of IBM WebSphere MQ for z/OS: z/OS

You must take into consideration whether you are upgrading a production system, or a test system, before you undertake the migration process.

Production systems

For production systems you must, firstly, migrate the unsupported release of IBM MQ to IBM WebSphere MQ Version 7.1, following the instructions given in the documentation for that release. For more information about where to find the documentation for older versions of the product, see Documentation for older versions of IBM MQ

You can then migrate to IBM MQ Version 9.0 following the instructions in this section.

Important: Ensure that your system is stable at Version 7.1, before migrating to Version 9.0, so that you have a system to revert to, if necessary.

Test systems

For a test system, it might be appropriate to migrate directly to IBM MQ Version 9.0 instead.

Before you begin the migration, take complete backups of your system, to ensure that you can restart from backups if you need to use the old release again.

IBM MQ Version 9.0 migrates IBM MQ objects and messages during the first startup at Version 9.0.

New attributes added to objects in IBM WebSphere MQ Version 7.0 and IBM MQ Version 9.0 releases are set to their default values.

Important: After you have migrated to IBM MQ Version 9.0 using this method, you cannot revert to the original version.

You can restart a queue manager, at the original version, using the full set of backups taken before migration. However, note that any changes you make to the system after the backups were taken, or while running at Version 9.0, will be lost.

Backward migration to earlier supported releases of IBM MQ for z/OS: z/OS

After installation of a new release of IBM MQ for z/OS, you carry out queue manager migration by stopping the queue manager, which is running with the prior release of code, and restarting the queue manager using the new release of code.

Maintenance in a queue-sharing group

In a queue-sharing group, individual queue managers can be migrated forwards to IBM MQ Version 9.0, while those that remain at either IBM WebSphere MQ Version 7.1.0 or IBM MQ Version 8.0.0 can continue to function. This allows you to upgrade queue-sharing group queue managers to Version 9.0 at different times, maintaining the high availability of the queue-sharing group.

The function required to enable lower level queue managers to tolerate Version 9.0 additions to QSGDISP(GROUP) and QSGDISP(SHARED) objects is incorporated in the same authorized program analysis reports (APARs) which provide backward migration capability.

Code levels supported

Migration support is provided from both IBM WebSphere MQ Version 7.1.0 and IBM MQ Version 8.0.0 to IBM MQ for z/OS Version 9.0.

The backward migration APARs are PI64465 for IBM WebSphere MQ Version 7.1.0, and PI64466 for IBM MQ Version 8.0.0.

Important: LTS PTFs for these APARs must be applied on IBM WebSphere MQ Version 7.1.0 or IBM MQ Version 8.0.0 prior to attempting to fall back from IBM MQ for z/OS Version 9.0.0 Long Term Support (LTS) release.

CD Backwards migration is not supported for a Continuous Delivery (CD) release.

PTFs for these APARs are the *Migration and Toleration PTFs for Version 9.0* described in Planning for migration to the latest release.

Service has been discontinued for versions of the product prior to IBM WebSphere MQ Version 7.1.0. No backward migration capability is available for these versions.

CD The IBM MQ for z/OS Version 9.0.0 and IBM MQ for z/OS Version 9.0.1 early code installed in the link pack area (LPA) is downward compatible. The code supports queue managers running at IBM WebSphere MQ Version 7.1.0 and IBM MQ Version 8.0.0.

Once updated to the Version 9.0 level, and the queue manager subsystem refreshed using the REFRESH QMGR TYPE(EARLY) command, the early code need not be changed for any subsequent forward or backward migration activity

Message

```
CSQ3111I <cpf> CSQYSCMD - EARLY PROCESSING PROGRAM IS V9.0 LEVEL 008-000
```

is displayed during startup in the queue manager joblog and indicates that the queue manager is using the correct level of early code.

Limitations and restrictions

IBM MQ for z/OS Version 9.0 uses a migration switch to support backward migration by preventing use of certain new functions, that cannot be backward migrated, until the installation confirms that backward migration is no longer required.

The migration switch is configured through a change to ZPARM using the OPMODE parameter of CSQ6SYSP.

LTS While **OPMODE** is set to COMPAT, it is possible to backward migrate from a Long Term Support (LTS) release, although certain new functions are not available. Once **OPMODE** is set to NEWFUNC, all new functions are available, but it is no longer possible to perform backward migration.

CD Backwards migration is not supported for a Continuous Delivery (CD) release. Queue managers running a CD release of IBM MQ must be started with **OPMODE**=(NEWFUNC,90x). For example, a Version 9.0.1 queue manager must be started with **OPMODE**=(NEWFUNC,901).

The MQSC command DISPLAY SYSTEM command displays three values, the operation mode, either COMPAT or NEWFUNC, and two version numbers. The first version number indicates to which version of IBM MQ for z/OS you can fall back to. The second version number indicates level of new functions that are available

When the operation mode is COMPAT, then the version number indicates to which version of IBM MQ for z/OS you can fall back.

The value of OPMODE displayed during startup in message CSQY101I reflects the operation mode requested using ZPARM. Queue manager initialization evaluates the requested operation mode in combination with local state and other members of the queue-sharing group, to determine the actual operation mode displayed with DISPLAY SYSTEM.

You cannot backward migrate a queue manager, newly created at Version 9.0, to a prior release. A queue manager migrated forward to Version 9.0 *remembers* where it was migrated from, and it is only possible to fall back to that *remembered* prior version.

Certain connection types (IMS, BATCH and RRSBATCH used by WAS and Db2 stored procedures) allow an application to connect to multiple queue managers concurrently. If required, these queue managers can be running different levels of IBM MQ code. In such a scenario, the adapter code (usually referenced through a STEPLIB DD statement or environment variable) must be loaded from libraries corresponding with the highest level of the queue managers connected. This ability for the adapter code to support connections to older queue managers means that in a backward migration scenario it is possible to just restart the MSTR and CHIN procedures with the back level code, and not change connecting jobs.

The operations and controls ISPF panels, CSQOREXX, from IBM MQ for z/OS Version 9.0, are able to connect to and administer queue managers from a prior release. However, the ISPF panels from lower releases are not able to connect to IBM MQ for z/OS Version 9.0. When migrating, or during fall back, either use the same version ISPF panels as the level of code the queue manager is running, or use CSQOREXX from the higher release of code. In a mixed level queue-sharing group, the IBM MQ for z/OS Version 9.0 panels must be used to administer Version 8.0.0 or Version 7.1 queue managers, as ISPF panels from earlier releases do not tolerate responses from any Version 9.0 queue managers.

Related reference:

"Switching from new function mode to compatibility mode on z/OS" on page 784
The availability of new functions and backward migration for IBM MQ for z/OS is controlled by the **`OPMODE`** parameter in the **`CSQ6SYSP`** macro. You should be aware of the implications of switching from new function mode to compatibility mode, that is, switching from `OPMODE=(NEWFUNC,800)` or `OPMODE=(NEWFUNC,900)` to `OPMODE=(COMPAT,800)` or `OPMODE=(COMPAT,900)`.

Preparing to migrate a single IBM MQ for z/OS queue manager: z/OS

Follow the steps to prepare a single IBM MQ queue manager on z/OS for migration.

About this task

To prepare to migrate an IBM MQ queue manager on z/OS, you need to carry out the detailed steps in this topic, using the links within this overview.

1. Make your existing queue manager ready for migration; see Step 1
2. Install the new code and make target libraries available to all MVS systems that are running queue managers, and grant access; see Step 2.
3. Perform a back up operation of each queue manager in your enterprise; see Step 3.
4. Review definitions of the user IDs for the queue manager(MSTR) and channel initiator (CHIN) address spaces; see Step 4
5. Restart your IBM MQ systems; see Step 5.

6. Review pageset zero usage before migration; see Step 6.
7. Migrate your Db2 tables, and repeat this step for each queue-sharing group (QSG), if your enterprise uses QSGs; see Step 7
8. Add a new coupling facility (CF) structure definition and repeat this step for each QSG, if your enterprise uses QSGs; see Step 8.
9. Consider the migration of your server applications; see Step 9
10. Configure Advanced Message Security (AMS); see Step 10

.

Procedure

1. Make your IBM MQ configuration ready for migration.
   a. Refer to the Preventive Service Planning (PSP) bucket for your version of IBM MQ; see PSP Buckets - How to find them on Web.
   b. Apply the migration and toleration PTFs to the version of the IBM MQ code that your enterprise uses; see IBM MQ Support, Migration PTFs.

      Note that the “migration and toleration” PTFs are also known as the “backward migration and coexistence” PTFs; they are the same PTFs.

      If you are unsure which migration PTFs you require, run the following command SMP/E:

      CD

      ```
      REPORT MISSINGFIX ZONES(mqtgtzone) FIXCAT(IBM.Coexistence.MQ.V9R0M0)
      ```

      See FIXCAT and IBM MQ Migration Installation for further information.

      Attention: If a PTF requires a rebind of Db2 plans, the PTF is shipped with ++HOLD(ACTION), indicating the need for this process. In such a case, see Migrating Db2 tables to bind the plans before starting migration.

      Other FIXCAT categories are listed in IBM Fix Category Values and Descriptions.

      There is an additional category of `TargetSystem-RequiredService.MQ.V9R0M0` enabling other products to run with IBM MQ Version 9.0.
2. Install the new code and make target libraries available to all MVS systems that are running queue managers, and grant access. You must carry out the following procedure for each MVS system.
   a. Copy the IBM MQ target libraries to the system, and install the early code for the new version (once for each MVS system). Activate the code for all of the queue managers on each MVS system that is running queue managers.

      This updates the LPA. See Update the z/OS link list and LPA for more information.
   b. APF authorize the load libraries and grant access to the data sets using your external security system. See APF authorize the IBM MQ load libraries for more information.
   c. Copy the file system zFS and mount it read only.

      You only need zFS, or older HFS, if the IBM MQ for z/OS Unix System Services Component is installed. See the Program Directory for further information.

   Refresh all the queue managers so that they use the new early code using the command REFRESH QMGR TYPE(EARLY). See REFRESH QMGR for more information.
3. Perform a back up operation for each queue manager in your enterprise, so that you have a `before` copy of all objects and JCL before you make any changes. This makes rolling back to the current system easier, if you require to do so.
   a. Back up your IBM MQ defined objects, for example using CSQUTIL COMMAND MAKEDEF(..) See Using the COMMAND function of CSQUTIL for more information.
   b. Back up:
      - The MSTR and CHINIT started procedure jobs

- The Initialization input data sets used in the CSQINP1 and CSQINP2 concatenations
- The system parameter module (ZPARM) libraries
- Other tasks as necessary.

Note: You might also make a back up of page sets, BSDSs, and active logs as a fallback option. See How to back up and recover pagesets for more information on backing up IBM MQ resources.

4. Check that MSTR and CHIN address spaces run under user IDs that have OMVS segments defined, with a valid UID, to enable calling Unix System Services (USS).
5. Restart your IBM MQ system to run with the migration and toleration PTFs.
   a. Restart the queue managers and monitor the whole system in your enterprise closely to ensure that there are no issues. Depending on the size and complexity of your enterprise this can take a considerable length of time, so you must plan for this in your migration schedule.
6. Review the usage of pageset 0. Note that you can ignore this step if your enterprise is already using IBM WebSphere MQ Version 7.1. Issue the operator command `/cpf DISPLAY USAGE PSID(0)`, where **`cpf`** is the command prefix for the subsystem of the queue manager, to get a report on pageset 0 usage.

   The size of queue definitions increased in IBM WebSphere MQ Version 7.1. During migration to this version, or later versions of the product from an earlier version of the product, queue definitions stored on pageset 0 are rewritten.

   The rewrite is carried out as a single transaction when the queue manager is first migrated to IBM WebSphere MQ Version 7.1, or later.

   Ensure that there is enough space available on pageset 0 to create a copy of the queue definitions while migration is taking place. Typically, 60% free space on pageset 0 before migration is sufficient. However, the use of `EXPAND(SYSTEM)` on the pageset definition allows for automatic expansion as required.

   If there is insufficient space on pageset 0 during migration, the queue manager abends with completion code `X'5C6'` and reason code `X'00C91900'`.
7. Migrate your Db2 tables for each Db2 data sharing group.

   You must do this for each Db2 data sharing group, as multiple QSGs can use the same Db2 tables.

   You can use IBM provided samples shipped in the new version of the product to perform this task. Some Db2 table definitions are updated, and some new Db2 tables are created for the migrated version of the queue manager.

   Notes:

   a. You must have applied the migration and toleration PTFs to all the queue managers, before migrating the Db2 tables.
   b. Every queue manager in the queue-sharing group needs to be restarted at the current release, with the PTFs applied.
   c. At no stage is an outage of the entire queue-sharing group required.
   d. Migrate your Db2 tables.

      If the jobs described fail because of a Db2 locking problem, it might be due to contention for a Db2 resource. Locking is more likely, if the system is being heavily used. Resubmit the job later, preferably when the system is lightly used or quiesced.

      See steps 5 and 6 of Set up the Db2 environment.
   e. Use the `CSQ45*` jobs in the newest *`thlqual`*`.SCSQPROC` supplied with the version of the product to which you are migrating.

      Note that the JCL to use depends on the highest version of IBM MQ in the Db2 tables.

Attention: CD If the Db2 tables have IBM MQ Version 9.0 queue managers, ignore the preceding steps, b and c.

1) If the Db2 tables have IBM WebSphere MQ Version 7.1 queue managers, use `CSQ4571T`. If the Db2 tables have IBM WebSphere MQ Version 7.0 queue managers, use `CSQ4570T`.
2) Customize the `CSQ45*` sample.

   The header information in `CSQ45*` describes how to customize the sample.
3) Run the customized `CSQ45*` job.
4) Customize the `CSQ45BPL` and `CSQ45GEX` samples, in *`thlqual`*`.SCSQPROC`

   The header information in `CSQ45BPL` and `CSQ45GEX` describes how to customize the samples.
5) Run the customized jobs, `CSQ45BPL` and `CSQ45GEX`.

   If you need to rebind the plans or packages, see Step 1 on page 806 in Migrating queue-sharing groups from a previous release for further information.

f. If you have multiple QSGs in the same data sharing group (DSG) you need to check each queue-sharing group to see if each member meets its migration criteria. Use sample JCL `CSQ45MQS` in conjunction with `CSQ4571T`.

   See the JCL header description for further information.

8. Add the new coupling facility (CF) definition. Repeat this step for each QSG. Note that you can ignore this step if your enterprise is already using IBM WebSphere MQ Version 7.1.

   Starting with IBM WebSphere MQ Version 7.0.1, a new CF structure is required; see Set up the coupling facility for information on how to add such a definition.

   The correct process to migrate SYSTEM.QSG.CHANNEL.SYNCQ, from a normal application CF structure, to system CF structure CSQSYSAPPL structure is:

   a. Stop the channel initiator (CHINIT) on all queue-sharing group queue managers, so that no channels are running.
   b. Copy the messages in SYSTEM.QSG.CHANNEL.SYNCQ to a temporary data set, using CSQUTIL COPY.
   c. Delete SYSTEM.QSG.CHANNEL.SYNCQ from the repository.
   d. Define SYSTEM.QSG.CHANNEL.SYNCQ with CFSTRUCT(CSQSYSAPPL). As this is a shared queue, it only needs to be defined once per QSG. Note that you can define this queue from any queue manager within the QSG.
   e. Reload the SYNCQ messages from the temporary data set, back to the newly defined shared queue, using CSQUTIL LOAD.
   f. Perform the other migration steps, and then restart CHINIT to make the changes taking effect.

9. Migrate server applications.

   Java or JMS applications running on the same host with IBM MQ connect to queue managers in bindings mode. This is a cross-memory connection. In this mode, applications need to update their STEPLIB concatenations, so that they can always load the highest version IBM MQ library in the system.

   Note, that if a z/OS Java or JMS application is running under WebSphere Application Server, the application can use client mode as an alternative to bindings mode.

   IBM MQ libraries include:

   thlqual.SCSQANLx
   This library contains error message information for your national language. The letter 'x' represents the letter for your national language.

   thlqual.SCSQAUTH
   This library contains the code that the applications use.

   Server applications for IBM MQ can include:

   - Batch applications

- Control panels in ISPF
- IMS
- Interactive problem control system (IPCS)
- RRS adapter, including Db2 stored procedures.
- TSO
- Additionally, WebSphere Application Server for z/OS, IBM Integration Bus, and CICS.

a. You can use the "TSO ISRDDN ENQ ' `thlqual`.SCSQANLE'" command, replacing `thlqual` with the High Level Qualifier for your installation, to check which jobs are running with the specified library. You can then modify them accordingly.

b. Update STEPLIB in the application JCL, and refer to the new IBM MQ libraries.

c. Restart these applications. For further information, see:
   - Set up Batch, TSO, and RRS adapters
   - Setting up the IMS adapter
   - Set up the operations and control panels
   - Include the IBM MQ dump formatting member

d. Migrate other software, such as WebSphere Application Server, IBM Integration Bus, or CICS to use the version of IBM MQ that you need.
   - CICS

     Update the IBM MQ libraries in the `STEPLIB` and `DFHRPL` concatenations of your CICS region JCL and restart CICS.

     Up to, and including CICS 3.2, the connection between IBM MQ and CICS is provided by IBM MQ. You must change the `SCSQCICS` and `SCSQAUTH` libraries in the `DFHRPL` concatenation provided by IBM MQ.
