Communications Server for Windows, Version 6.1 Personal Communications for Windows, Version 5.9

# System Management Programming

Communications Server for Windows, Version 6.1 Personal Communications for Windows, Version 5.9

# System Management Programming

Note

Before using this information and the product it supports, read the information in Appendix B, "Notices," on page 633.

Ninth Edition (July 2006)

This edition applies to Version 6.1 of IBM Communications Server for Windows, Version 5.9 of Personal Communications for Windows (program number: 5639–I70), and to all subsequent releases and modifications until otherwise indicated in new editions.

Chapter 2. Overview of the Verbs in This Book

verb Summary	•	•	•	•	•	•	•	•	•	. 0
Node Configuration .										. 8
Activation and Deacti	vati	on								. 9
Querying the Node.										. 10
Session Limit Verbs.										. 12
Unsolicited Indication	S									. 12
Security Verbs										. 13
APING Verbs										. 14
CPI-C Verbs										. 14
Attach Manager Verbs	5.									. 14
DLC Processes, Ports,	and	1 L	ink	: St	atio	ons				. 14

## Chapter 3. Node Operator Facility Entry

Points	•	•		•	. 17
WinNOF()					. 18
WinAsyncNOF()					. 19
WinAsyncNOFEx()					. 20
WinNOFCancelAsyncRequest() .					. 21
WinNOFCleanup()					. 22
WinNOFStartup()					. 23
WinNOFRegisterIndicationSink() .					. 24
WinNOFUnregisterIndicationSink()					. 25
WinNOFGetIndication()					. 26

Chapter 4. Node DEFINE_ADJACENT	Со	nf	ig	ur	ati	ior	ו ו	/er	bs			27

## **About This Book**

This book describes how to develop programs that use IBM<sup>®</sup> Communications Server for Windows<sup>®</sup> and IBM Personal Communications for Windows.

IBM Communications Server for Windows (referred to as *Communications Server*) is a communications services platform. This platform provides a wide range of services for workstations that communicate with host computers and with other workstations. Communications Server users can choose from among a variety of remote connectivity options.

IBM Personal Communications for Windows (referred to as *Personal Communications*) is a full-function emulator. In addition to host terminal emulation, it provides these useful features:

- File transfer
- Dynamic configuration
- An easy-to-use graphical interface
- APIs for SNA-based client applications
- An API allowing TCP/IP-based applications to communicate over an SNA-based network.

While in most instances, developing programs for Personal Communications and Communications Server is very similar in that they each support many of the same verbs, there are some differences. These differences are denoted through the use of icons. See "Icons" on page x for specific details. Throughout this book, *the Program* refers to both Personal Communications and Communications Server. When only the Personal Communications program or only the Communications Server program applies, then that specific program name is used.

In this book, *Windows* refers to Windows 2000, Windows Server 2003, and Windows XP. Throughout this book, *workstation* refers to all supported personal computers. When only one model or architecture of the personal computer is referred to, only that type is specified.

## Who Should Read This Book

This book is intended for programmers and developers who plan to use Node Operator Facility (NOF) API messages to manage and query the operation of Personal Communications or Communications Server, or plan to use ASCII Configuration files or both.

This book is also intended for developers who are writing network management applications that use the underlying management services support provided by Personal Communications and Communications Server to communicate with remote (host focal point) network management applications.

## How to Use This Book

This book is organized into two parts. Part 1, "Personal Communications and Communications Server Node Operator Facility," on page 1 contains the following chapters:

- Chapter 1, "Introduction," on page 3 describes the purpose of this book.
- Chapter 2, "Overview of the Verbs in This Book," on page 7 describes the Node Operator Facility API structure and the verbs it supports. The chapter outlines the categories of the verbs implemented and the additional signals provided by Personal Communications and Communications Server.
- Chapter 3, "Node Operator Facility Entry Points," on page 17 describes the entry point extensions.
- Chapters 4 through 12 describe the syntax of each verb. A copy of the structure that holds the information for each verb is included and each entry described, followed by a list of possible return codes.

Part 2, "Personal Communications and Communications Server Management Services API," on page 599 contains the following chapters:

- Chapter 13, "Introduction to Management Services API," on page 601 describes the management services API.
- Chapter 14, "Management Services Entry Points," on page 605 describes the entry points for the management services verbs.
- Chapter 15, "Management Services Verbs," on page 615 describes the syntax of each verb. A copy of the structure that holds the information for each verb is included and each entry described, followed by a list of possible return codes.

#### Icons

In this book, when it is necessary to communicate special information, the following icons appear:

This icon represents a note, important information that can affect the operation of Personal Communications or Communications Server or the completion of a task.

This icon appears when the information applies only to the Personal Communications program.

This icon appears when the information applies only to the Communications Server program.

## **Number Conventions**

Binary numbers	Represented as BX'xxxx xxxx' or BX'x' except in certain instances where they are represented with text ("A value of binary xxxx xxxx is").
Bit positions	Start with 0 at the rightmost position (least significant bit).
Decimal numbers	Decimal numbers over 4 digits are represented in metric style. A space is used rather than a comma to separate groups of 3 digits. For example, the number sixteen thousand, one hundred forty-seven is written 16 147.

HexadecimalRepresented in text as hex xxxx or X'xxxx' ("The address of the adjacentnumbersnode is hex 5D, which is specified as X'5d'.")

## Where to Find More Information

For more information, refer to *Quick Beginnings*, which contains a complete description of both the Communications Server library and related publications.

To view a specific book after Communications Server has been installed, use the following path from your desktop:

- 1. Programs
- 2. IBM Communications Server
- 3. Documentation
- 4. Choose from the list of books

The Communications Server books are in Portable Document Format (PDF), which is viewable with the Adobe Acrobat Reader. If you do not have a copy of this program on your machine, you can install it from the Documentation list.

The Communications Server home page on the Internet has general product information as well as service information about APARs and fixes. To get the home page, using an Internet browser, go to the following URL:

#### http://www.ibm.com/software/network/commserver/

For more information, refer to *Quick Beginnings*, which contains a complete description of both the Personal Communications library and related publications.

The Personal Communications books are included on the CD-ROM in portable document format (pdf). Books can be accessed directly from the root directory of the Personal Communications CD-ROM or from the Install Manager welcome panel.

To view the Personal Communications documentation using Install Manager, select **View Documentation** from the main panel of the Install Manager on the CD-ROM. Clicking **View Documentation** invokes Adobe Acrobat Reader from your system to view the books. If Acrobat Reader is not detected on your system, you are given the opportunity to install it at this time. After installation of Acrobat Reader is complete, a window opens displaying the books available on the CD-ROM.

#### Notes:

- 1. You can copy the book files from the CD-ROM to a local or network drive to view at a later time.
- **2**. *Quick Beginnings* in HTML format is installed during installation of Personal Communications.

The Personal Communications home page on the Internet has general product information as well as service information about APARs and fixes. To get the home page, using an Internet browser such as IBM Web Explorer, go to the following URL:

#### http://www.ibm.com/software/network/pcomm/

The complete *IBM Dictionary of Computing* is available on the World Wide Web at http://www.ibm.com/networking/nsg/nsgmain.htm.

Part 1. Personal Communications and Communications Server Node Operator Facility

## **Chapter 1. Introduction**

This part describes the Node Operator Facility (NOF) API provided by Personal Communications and Communications Server.

#### Purpose of the Document

The intent of this book is to:

- Provide a brief overview of the structure of the Node Operator Facility API
- Define the syntax of the signals that flow across the interface.

## Personal Communications and Communications Server Node Operator Facility

The Personal Communications and Communications Server Node Operator Facility enables communication between the node operator, and the control point (CP) and logical units (LUs). The Node Operator Facility receives node configuration information from the operator, which it uses to initialize the control point when the node is started. The Node Operator Facility also receives requests to query and display node configuration information. The node operator is able to:

- Define and delete LUs, DLCs, ports, and links
- Activate and deactivate links and sessions
- Query the control point and LUs for database and status information

The node operator can be a human operator working with an interactive display, a command file accessed by a file interface, or a transaction program. The Node Operator Facility communicates with the node operator by using a verb interface.

## **Entry Points**

Personal Communications and Communications Server provide a library file that handles Node Operator Facility verbs.

Node Operator Facility verbs have a straightforward language interface. Your program fills in fields in a block of memory called a *verb control block*. Then your program calls the entry point and passes a pointer to the verb control block. When its operation is complete, Node Operator Facility returns, having used and then modified the fields in the verb control block. Your program can then read the returned parameters from the verb control block.

Following is a list of entry points for Node Operator Facility verbs:

- WinNOF()
- WinAsyncNOF()
- WinAsyncNOFEx()
- WinNOFCancelAsyncRequest()
- WinNOFCleanup()
- WinNOFStartup()
- WinNOFRegisterIndicationSink()
- WinNOFUnregisterIndicationSink()
- WinNOFGetIndication()

See Chapter 3, "Node Operator Facility Entry Points," on page 17 for detailed descriptions of the entry points.

## Verb Control Blocks (VCBs)

*Programming Note:* The base operating system optimizes performance by executing some subsystems in the calling application's address space. This means that incorrect use of local descriptor table (LDT) selectors by application programs can cause improper operation, or perhaps system failures. Accordingly, application programs should not perform pointer arithmetic operations that involve changing the LDT selector field of a pointer.

The segment used for the verb control block (VCB) must be a read/write data segment. Your program can either declare the VCB as a variable in your program, allocate it, or suballocate it from a larger segment. It must be sufficiently large to contain all the fields for the verb your program is issuing.

An application program should not change any part of the verb control block after it has been issued until the verb completes. When Node Operator Facility finishes the execution of a verb, it copies a complete, modified VCB back onto the original block. Therefore, if your program declares a verb control block as a variable, consider declaring it in static storage rather than on the stack of an internal procedure.

Fill all reserved and unused fields in each VCB with zeros (X'00'). In fact, it might be more time-efficient to set the entire verb control block to zeros before your program assigns the values to the parameters. Setting reserved fields to zeros is particularly important.

**Note:** If the VCB is not read/write, or if it is not at least 10 bytes (that is, large enough to hold the Node Operator Facility primary and secondary return codes), Node Operator Facility cannot access it, and the base operating system abnormally ends the process. This termination is recognized as a *general protection fault*, processor exception trap D.

Node Operator Facility returns the INVALID\_VERB\_SEGMENT primary return code when the VCB is too short or the incorrect type of segment is used.

## Writing Node Operator Facility (NOF) Programs

Personal Communications and Communications Server provide a dynamic link library (DLL) file, that handles NOF verbs.

The DLL is reentrant; multiple application processes and threads can call the DLL concurrently.

NOF verbs have a straightforward language interface. Your program fills in fields in a block of memory called a *verb control block* (VCB). Then it calls the NOF DLL and passes a pointer to the verb control block. When its operation is complete, NOF returns, having used and then modified the fields in the VCB. Your program can then read the returned parameters from the verb control block.

Table 1 on page 5 shows source module usage of supplied header files and libraries needed to compile and link NOF programs. Some of the header files may include other required header files.

Table 1. Header Files and Libraries for NOF

Operating System	Header File	Library	DLL Name
WINNT	WINNOF.H	WINNOF32.LIB	WINNOF32.DLL

## **Communications Server SNA API Client Support**

This information applies only to Communications Server.

Included with Communications Server are a set of clients for the Windows 2000, Windows Server 2003, and Windows XP operating systems. These clients are referred to as SNA API clients in this book and only support a subset of the full node operator facility. Specifically, **WINNOF** is the only API supported on the Windows 2000, Windows Server 2003, and Windows XP clients. The following is a list of the NOF verbs supported:

- QUERY\_LOCAL\_LU
- QUERY\_LU\_0\_TO\_3
- QUERY\_LU\_POOL
- QUERY\_MODE
- QUERY\_MODE\_DEFINITION
- QUERY\_PARTNER\_LU
- QUERY\_PARTNER\_LU\_DEFINITION
- QUERY\_PU
- QUERY\_SESSION
- QUERY\_TP
- QUERY\_TP\_DEFINITION

# Verbs Supported by Communications Server and Not by Personal Communications

This information applies only to Communications Server.

The following list of verbs are supported by Communications Server and not by Personal Communications.

- DEFINE\_DOWNSTREAM\_LU
- DEFINE\_DOWNSTREAM\_LU\_RANGE
- DEFINE\_DSPU\_TEMPLATE
- DELETE\_DOWNSTREAM\_LU
- DELETE\_DOWNSTREAM\_LU\_RANGE
- DELETE\_DSPU\_TEMPLATE
- QUERY\_ADJACENT\_NN
- QUERY\_DIRECTORY\_STATS
- QUERY\_DOWNSTREAM\_LU

- QUERY\_DOWNSTREAM\_PU
- QUERY\_DSPU\_TEMPLATE
- QUERY\_HPR\_STATS
- QUERY\_ISR\_SESSION
- QUERY\_NN\_TOPOLOGY\_NODE
- QUERY\_NN\_TOPOLOGY\_STATS
- QUERY\_NN\_TOPOLOGY\_TG
- DOWNSTREAM\_LU\_INDICATION
- DOWNSTREAM\_PU\_INDICATION
- ISR\_INDICATION
- NN\_TOPOLOGY\_NODE\_INDICATION
- NN\_TOPOLOGY\_TG\_INDICATION

## Chapter 2. Overview of the Verbs in This Book

The verb interface described in this book allows your programs to perform most of the configuration, system management, and node definition functions associated with a Personal Communications or Communications Server network environment. This chapter provides an overview of each of these functions and the associated verbs.

#### How to Read Verb Descriptions

Chapters 4 through 12 describe the configuration, system management, and attach manager verbs.

#### **Supplied Parameters**

Each verb description has a section that provides a detailed description of the parameters and any associated parameter values supplied by the program.

In some cases, you must supply a variable value for a parameter.

#### **Returned Parameters**

Each verb description has a section that provides a detailed description of the parameters and any associated parameter values returned to the program.

#### **Return Codes**

The configuration, system management, and attach manager verbs described in this book have return codes associated with them that supply information about the success of verb execution or that provide error information. These codes are listed in the "Returned Parameters" section for each verb.

#### Additional Information

Many of the verb descriptions also contain a section titled "Additional Information." This section provides additional useful information about the verb.

#### **Common VCB Fields**

This chapter documents the syntax of each verb passed across the Node Operator Facility API. It also describes the parameters passed in and returned for each verb.

typedef struct nof\_hdr
{

```
unsigned short opcode;
unsigned char reserv2;  /* reserved */
unsigned char format;
unsigned short primary_rc;
unsigned long secondary_rc;
} NOF HDR;
```

Each VCB has a number of common fields. These are listed and described below.

#### opcode

Verb operation code. This field identifies the verb.

#### format

Identifies the format of the VCB. The value that this field must be set to in order to specify the current version of the VCB is documented individually under each verb.

#### primary\_rc

Primary return code. Possible values for each verb are listed in each verb section.

#### secondary\_rc

Secondary return code. This supplements the information provided by the primary return code.

#### Verb Summary

The Node Operator Facility API is composed of verbs that can be used to do the following things:

- Configure node resources
- Activate and deactivate links and sessions
- Query information held by the node
- Change the number of sessions
- Handle unsolicited indications
- Provide password support
- "ping" a remote LU
- Define, query, and delete CPI-C side information

## Node Configuration

The following verbs can be used to define resources:

- DEFINE\_ADJACENT\_NODE
- DEFINE\_CN
- DEFINE\_COS
- DEFINE\_DEFAULT\_PU
- DEFINE\_DLC
- DEFINE\_DLUR\_DEFAULTS
- DEFINE\_DOWNSTREAM\_LU

DEFINE\_DOWNSTREAM\_LU is Communications Server only.

DEFINE\_DOWNSTREAM\_LU\_RANGE

DEFINE\_DOWNSTREAM\_LU\_RANGE is Communications Server only.

- DEFINE\_DSPU\_TEMPLATE
- DEFINE\_FOCAL\_POINT
- DEFINE\_INTERNAL\_PU
- DEFINE\_LOCAL\_LU
- DEFINE\_LS
- DEFINE\_LU62\_TIMEOUT
- DEFINE\_LU\_0\_TO\_3
- DEFINE\_LU\_0\_TO\_3\_RANGE

- DEFINE\_LU\_POOL
- DEFINE\_MODE
- DEFINE\_PARTNER\_LU
- DEFINE\_PORT
- DEFINE\_TP

The following verbs can be used to delete resources:

- DELETE\_ADJACENT\_NODE
- DELETE\_CN
- DELETE\_COS
- DELETE\_DLC
- DELETE\_DOWNSTREAM\_LU

DELETE\_DOWNSTREAM\_LU is Communications Server only.

• DELETE\_DOWNSTREAM\_LU\_RANGE

DELETE\_DOWNSTREAM\_LU\_RANGE is Communications Server only.

- DELETE\_DSPU\_TEMPLATE
- DELETE\_FOCAL\_POINT
- DELETE\_INTERNAL\_PU
- DELETE\_LOCAL\_LU
- DELETE\_LS
- DELETE\_LU62\_TIMEOUT
- DELETE\_LU\_0\_TO\_3
- DELETE\_LU\_0\_TO\_3\_RANGE
- DELETE\_LU\_POOL
- DELETE\_MODE
- DELETE\_PARTNER\_LU
- DELETE\_PORT
- DELETE\_TP

## **Activation and Deactivation**

The following verbs are used at link level:

- START\_DLC
- START\_LS
- START\_PORT
- STOP\_DLC
- STOP\_LS
- STOP\_PORT

The following verbs are used for dependent LU requestor function:

- START\_INTERNAL\_PU
- STOP\_INTERNAL\_PU

The following verbs are used at session level:

- ACTIVATE\_SESSION
- DEACTIVATE\_CONV\_GROUP
- DEACTIVATE\_SESSION

The following verb is used to force a high performance routing (HPR) RTP connection to switch paths: PATH\_SWITCH

## **Querying the Node**

These verbs return node information in named fields:

- QUERY\_DEFAULT\_PU
- QUERY\_DLUR\_DEFAULTS
- QUERY\_MDS\_STATISTICS
- QUERY\_NN\_TOPOLOGY\_STATS

QUERY\_NN\_TOPOLOGY\_STATS is Communications Server only.

- QUERY\_NODE
- QUERY\_STATISTICS

The following verbs can return one or more units of information:

- QUERY\_ADJACENT\_NN
- QUERY\_ADJACENT\_NODE
- QUERY\_CN
- QUERY\_CN\_PORT
- QUERY\_COS
- QUERY\_DEFAULTS
- QUERY\_DLUS
- QUERY\_DOWNSTREAM\_PU

QUERY\_DOWNSTREAM\_PU is Communications Server only.

- QUERY\_DSPU\_TEMPLATE
- QUERY\_FOCAL\_POINT
- QUERY\_LU\_POOL
- QUERY\_LU62\_TIMEOUT
- QUERY\_MDS\_APPLICATION
- QUERY\_MODE\_TO\_COS\_MAPPING
- QUERY\_NMVT\_APPLICATION
- QUERY\_PU
- QUERY\_TP

This information can be thought of as being stored in the form of a list. The verb can specify a named entry in the list, which is then considered to be a place

marker (or index value) in the list. The **list\_options** field on these verbs specifies from which point in the list information will be returned.

- If **list\_options** is set to AP\_FIRST\_IN\_LIST, then the fields specifying the index value will be ignored, and the returned list will start at the beginning.
- If **list\_options** is set to AP\_LIST\_INCLUSIVE, then the returned list will start from the specified index value.
- If **list\_options** is set to AP\_LIST\_FROM\_NEXT, then the returned list will start from the entry after the specified index value.

The index value specifies the starting point for returned information. Once this has been determined, some of the query verbs also provide additional filtering options for the returned list. These are specified independently of the index value. Note that unless specified otherwise, the returned list will be ordered according to IBM's 6611 APPN<sup>®</sup> MIB. (See Appendix A, "IBM APPN MIB Tables," on page 631 for information on how verb parameters map to MIB table entries.)

The number of entries to be returned or the buffer size to be filled is set. (If both are set, then the verb is returned with the lower of the two specified quantities of information.) Because the application buffer size typically limits the amount of information that can be returned, the Node Operator Facility returns additional information indicating the total amount of buffer space required to return the requested information, and the total number of entries this represents.

In addition to returning one or more units of information, the following verbs are also able to return different levels of information. The **list\_options** field specifies whether summary or detailed information will be returned by including either AP\_DETAIL or AP\_SUMMARY in the **list\_options** field. These options are specified by **ORing** one of the previous **list\_options**, for example: AP\_DETAIL | AP\_FIRST\_IN\_LIST.

- QUERY\_DIRECTORY\_LU
- QUERY\_DLC
- QUERY\_DLUR\_LU
- QUERY\_DLUR\_PU
- QUERY\_DOWNSTREAM\_LU

QUERY\_DOWNSTREAM\_LU is Communications Server only.

• QUERY\_ISR\_SESSION

QUERY\_ISR\_SESSION is Communications Server only.

- QUERY\_LOCAL\_LU
- QUERY\_LOCAL\_TOPOLOGY
- QUERY\_LS
- QUERY\_LU\_0\_TO\_3
- QUERY\_MODE
- QUERY\_MODE\_DEFINITION
- QUERY\_NN\_TOPOLOGY\_NODE

QUERY\_NN\_TOPOLOGY\_NODE is Communications Server only.

• QUERY\_NN\_TOPOLOGY\_TG

QUERY\_NN\_TOPOLOGY\_TG is Communications Server only.

- QUERY\_PARTNER\_LU
- QUERY\_PARTNER\_LU\_DEFINITION
- QUERY\_PORT
- QUERY\_RTP\_CONNECTION
- QUERY\_SESSION
- QUERY\_TP\_DEFINITION

## **Session Limit Verbs**

- CHANGE\_SESSION\_LIMIT
- INITIALIZE\_SESSION\_LIMIT
- RESET\_SESSION\_LIMIT

## **Unsolicited Indications**

Applications displaying node information can use these indications (which are issued when a change occurs and return summary information only) to trigger the query verbs (returning detailed information). The node only produces the signals listed below as unsolicited indications of the named events if there are any applications registered to receive the information. Applications should therefore unregister if they no longer require the information.

- DLC\_INDICATION
- DLUR\_LU\_INDICATION
- DLUS\_INDICATION
- DOWNSTREAM\_LU\_INDICATION

DOWNSTREAM\_LU\_INDICATION is Communications Server only.

DOWNSTREAM\_PU\_INDICATION

DOWNSTREAM\_PU\_INDICATION is Communications Server only.

- FOCAL\_POINT\_INDICATION
- ISR\_INDICATION

ISR\_INDICATION is Communications Server only.

- LOCAL\_LU\_INDICATION
- LOCAL\_TOPOLOGY\_INDICATION

- LS\_INDICATION
- LU\_0\_TO\_3\_INDICATION
- MODE\_INDICATION
- NN\_TOPOLOGY\_NODE\_INDICATION

NN\_TOPOLOGY\_NODE\_INDICATION is Communications Server only.

• NN\_TOPOLOGY\_TG\_INDICATION

NN\_TOPOLOGY\_TG\_INDICATION is Communications Server only.

- PLU\_INDICATION
- PORT\_INDICATION
- PU\_INDICATION
- REGISTRATION\_FAILURE
- RTP\_INDICATION
- SESSION\_INDICATION
- SESSION\_FAILURE\_INDICATION

The entry points used for indications are:

#### WinNOFRegisterIndicationSink

Register to receive an indication

WinNOFUnregisterIndicationSink Unregister from receiving an indication

#### WinNOFGetIndication

Receive an indication

These indications are passed to any indication sinks that have registered with the Node Operator Facility. If the component generating the indication is unable to send it, then it sets the **data\_lost** indicator on the next indication it issues. If the **data\_lost** flag has been set to AP\_YES on an indication, then subsequent data fields can be set to null. This flag is used to notify the application that a change has occurred whose details have been lost, indicating that the application should respond by issuing the appropriate query verb.

Note that the signal LULU\_EVENT is also classified as an indication as it is sent unsolicited by the node to a process registered using the verbs REGISTER\_LULU\_EVENT and UNREGISTER\_LULU\_EVENT. It is not listed above, since its behavior is significantly different: registration is for an LU-Partner LU pair, and there is no equivalent of **data\_lost** — these LULU event indications are generated without fail.

#### Security Verbs

The following security verbs allow management of passwords for LU\_LU verification or conversation security.

- DEFINE\_LU\_LU\_PASSWORD
- DEFINE\_USERID\_PASSWORD
- DELETE\_LU\_LU\_PASSWORD

DELETE\_USERID\_PASSWORD

## **APING Verbs**

The APING verb allows a management application to ping a remote LU in the network.

#### **CPI-C** Verbs

The following verbs allow CPI-C side information to be defined, queried, and deleted.

- DEFINE\_CPIC\_SIDE\_INFO
- DELETE\_CPIC\_SIDE\_INFO
- QUERY\_CPIC\_SIDE\_INFO

Refer to *CPI-C Reference* for more information about the CPI-C support provided by Personal Communications and Communications Server.

#### Attach Manager Verbs

The following verbs can be used to control the attach manager:

- DISABLE\_ATTACH\_MANAGER
- ENABLE\_ATTACH\_MANAGER
- QUERY\_ATTACH\_MANAGER

## **DLC Processes, Ports, and Link Stations**

#### **DLC Processes**

Personal Communications or Communications Server can create multiple DLC processes. Each DLC process is created by Personal Communications or Communications Server in response to a START\_DLC verb issued at the Node Operator Facility API. Each DLC is responsible for communication over a link, or set of links, using a specific data link protocol (such as SDLC or Token Ring).

Each DLC process can manage one or more ports. Ports are described below.

#### Ports

A port represents a unique access point (such as a MAC/SAP address pair) in the local machine and is associated with a DLC process. Each DLC can have one or more ports. A port can be one of the following types:

#### Switched port

Can have one or more adjacent link stations that are active at any one time. (Note that this differs from the definition in *SNA APPN Architecture Reference*.)

#### Nonswitched port

Can have both point-to-point and multipoint link connections. Adjacent link stations on a nonswitched link connection must be defined by a Node Operator Facility component. Multipoint nonswitched links require primary/secondary relationships to be defined properly on all nodes to avoid unpredictable results.

#### **SATF** port

Uses a shared-access transport facility such as token ring. It allows connectivity between any pair of link stations attaching to the facility. The

initial role for all link stations being activated on a token ring must always be defined as negotiable, so that link activation can be initiated through any link station.

**Note:** SATF ports can also be associated with Connection Networks. In this case, topology updates are used to broadcast the address of the unique access point.

#### Link Stations

A link station is associated with a port and represents a connection to an adjacent node. A port can have multiple link stations. Link stations can be categorized in the following way:

#### Defined link station

A link station that has been defined explicitly (using a DEFINE\_LS verb).

#### Dynamic link station

A link station that has been created as a result of activating a dynamic connection through a connection network. This is also known as a virtual routing node (VRN).

#### Implicit link station

A link station that has been created as a result of a call received from a previously unknown partner node on a switched or SATF port. This type of port is not defined in *SNA APPN Architecture Reference*.

#### Temporary link station

A link station that is created when a CONNECT\_IN is received over the DLC interface on a switched or SATF port. It is either deleted, or becomes dynamic or implicit, when the remote node identity is determined.

# **Chapter 3. Node Operator Facility Entry Points**

This chapter describes the entry points for Node Operator Facility verbs.

## WinNOF()

This function provides a synchronous entry point for all of the Node Operator Facility verbs.

## **Syntax**

void WINAPI WinNOF(long vcb,unsigned short vcb\_size)

#### Parameters

vcb Pointer to verb control block.

#### vcb\_size

Number of bytes in the verb control block.

#### Returns

No return value. The **primary\_rc** and **secondary\_rc** fields in the verb control block indicate any error.

#### Remarks

This is the main synchronous entry point for the Node Operator Facility API. This call blocks until the verb completes.

## WinAsyncNOF()

This function provides an asynchronous entry point for all of the Node Operator Facility verbs.

## **Syntax**

HANDLE WINAPI WinAsyncNOF(HWND hWnd, long vcb, unsigned short vcb\_size)

#### Parameters

hWnd Window handle to receive completion message.

vcb Pointer to verb control block.

vcb\_size

Number of bytes in the verb control block.

#### Returns

The return value specifies whether the asynchronous request was successful. If the function was successful, the actual return value is a handle. If the function was not successful, a zero is returned.

#### Remarks

Each application thread can only have one outstanding request at a time when using this entry point.

When the asynchronous operation is complete, the application's window *hWnd* receives the message returned **RegisterWindowMessage** with **"WinAsyncNOF"** as the input string. The *wParam* argument contains the asynchronous task handle returned by the original function call.

If the function returns successfully, a **WinAsyncNOF()** message will be posted to the application when the operation completes or the conversation is canceled.

Note: See also WinNOFCancelAsyncRequest() on page 21.

## WinAsyncNOFEx()

This function provides an asynchronous entry point for all of the Node Operator Facility verbs. Use this entry point instead of the blocking calls to allow multiple verbs to be handled on the same thread.

## **Syntax**

HANDLE WINAPI WinAsyncNOFEx(HANDLE handle, long vcb, unsigned short vcb\_size);

#### Parameters

#### handle

Handle of the event that the application will wait on.

vcb Pointer to verb control block.

#### vcb\_size

Number of bytes in the verb control block.

#### Returns

The return value specifies whether the asynchronous request was successful. If the function was successful, the actual return value is a handle.

#### Remarks

This entry point is intended for use with WaitForMultipleObjects in the Win32 API. For more information about this function, see the programming documentation for the Win32 API.

When the asynchronous operation is complete, the application is notified by way of the signaling of the event. Upon signaling of the event, examine the primary return code and secondary return code for any error conditions.

Note: See also WinNOFCancelAsyncRequest() on page 21.

## WinNOFCancelAsyncRequest()

This function cancels an outstanding WinAsyncNOF based request.

## **Syntax**

int WINAPI WinNOFCancelAsyncRequest(HANDLE handle);

#### Parameters

#### handle

Supplied parameter; specifies the handle of the request to be canceled.

## Returns

The return value specifies whether the asynchronous request was canceled. If the value is zero, the request was canceled. Otherwise the value is:

#### WNOFALREADY

An error code indicating that the asynchronous request being canceled has already completed, or the handle was not valid.

## Remarks

An asynchronous request previously issued by one of the **WinAsyncNOF** functions can be canceled prior to completion by issuing the **WinNOFCancelAsyncRequest()** call, specifying the handle returned by the initial function in *handle*.

Canceling an asynchronous request stops any update to the application verb control block and stops the application being notified that the verb has completed (either by way of the window message or event). It does not cancel the underlying request. To actually cancel the underlying request, the application must issue the appropriate NOF verb (that is, STOP\_LS to cancel START\_LS).

Should an attempt to cancel an existing asynchronous **WinAsyncNOF** routine fail with an error code of WNOFALREADY, one of two things has occurred. Either the original routine has already completed and the application has dealt with the resulting notification, or the original routine has already completed but the application has not dealt with the completion notification.

Note: See also WinAsyncNOF() on page 19.

#### WinNOFCleanup()

This function terminates and unregisters an application from the Node Operator Facility API.

#### **Syntax**

BOOL WINAPI WinNOFCleanup(void);

#### Returns

The return value specifies whether the unregistration was successful. If the value is not zero, the application was successfully unregistered. The application was not unregistered if a value of zero is returned.

#### **Remarks**

Use **WinNOFCleanup()** to indicate unregistration of a Node Operator Facility application from the Node Operator Facility API.

**WinNOFCleanup** unblocks any thread waiting in **WinNOFGetIndication**. These return with WNOFNOTREG, (the application is not registered to receive indication). **WinNOFCleanup** unregisters the application for all indications. **WinNOFCleanup** returns any outstanding verb (synchronous or asynchronous) with the error AP\_CANCELLED. However, the verb completes inside the node.

It is not a requirement to use **WinNOFStartup** and **WinNOFCleanup**. However, an application must be consistent in its use of these calls. You should use both of them or never use either of them.

Note: See also WinNOFStartup() on page 23.

# WinNOFStartup()

This function allows an application to specify the version of Node Operator Facility API required and to retrieve the version of the API supported by the product. This function can be called by an application before issuing any further Node Operator Facility API calls to register itself.

# Syntax

# Parameters

# wVersionRequired

Specifies the version of Node Operator Facility API support required. The high-order byte specifies the minor version (revision) number; the low-order byte specifies the major version number.

# nofdata

Returns the version of Node Operator Facility API and a description of API implementation.

# Returns

The return value specifies whether the application was registered successfully and whether the Node Operator Facility API implementation can support the specified version number. If the value is zero, it was registered successfully and the specified version can be supported. Otherwise, the return value is one of the following values:

# WNOFSYSERROR

The underlying network subsystem is not ready for network communication.

# WNOFVERNOTSUPPORTED

The version of Node Operator Facility API support requested is not provided by this particular implementation.

# WNOFBADPOINTER

Incorrect nofdata parameter.

# Remarks

This call is intended to help with compatibility of future releases of the API. The current version is 1.0.

It is not a requirement to use **WinNOFStartup** and **WinNOFCleanup**. However, an application must be consistent in its use of these calls. You should use both of them or never use either of them.

Note: See also WinNOFCleanup() on page 22.

# WinNOFRegisterIndicationSink()

This allows the application to register to receive unsolicited indications.

# **Syntax**

BOOL WINAPI WinNOFRegisterIndicationSink(unsigned short indication\_opcode, unsigned short queue\_size, unsigned short \*primary\_rc, unsigned long \*secondary rc);

# Parameters

# indication\_opcode

The indication to register for.

# queue\_size

Number of unreceived indications to queue. Zero means use the current value (the initial default value is set to 10). There is only one queue for all indications registered by application.

### primary\_rc

Returned: primary return code

### secondary\_rc

Returned: secondary return code

# Returns

The function returns a value indicating whether the registration was successful. If the value is not zero, the registration was successful. If the value is zero, the registration was not successful.

# Remarks

Use **WinNOFRegisterIndicationSink** to register to receive unsolicited indications of type **indication\_opcode**.

An application must issue a **WinNOFRegisterIndicationSink** for each type of indication it wants to receive.

Note: See also WinNOFUnregisterIndicationSink() on page 25 and WinNOFGetIndication() on page 26.

# WinNOFUnregisterIndicationSink()

This allows the application to stop receiving unsolicited indications.

# **Syntax**

BOOL WINAPI WinNOFUnregisterIndicationSink(unsigned short indication\_opcode, unsigned short \*primary\_rc, unsigned long \*secondary\_rc);

# Parameters

indication\_opcode The indication to unregister from.

# primary\_rc

Returned: primary return code.

# secondary\_rc

Returned: secondary return code.

# Returns

The function returns a value indicating whether the unregistration was successful. If the value is not zero, the unregistration was successful. If the value is zero, the unregistration was not successful.

# Remarks

Use **WinNOFUnregisterIndicationSink** to stop receiving unsolicited indications of type **indication\_opcode**.

An application must issue a **WinNOFUnregisterIndicationSink** for each type of indication it wants to stop receiving.

Note: See also WinNOFRegisterIndicationSink() on page 24 and WinNOFGetIndication() on page 26.

# WinNOFGetIndication()

This allows the application to received unsolicited indications.

# Syntax

### Parameters

**buffer** Pointer to a buffer to receive indication.

## buffer\_size

Size of buffer. Returned: the size of the indication.

#### timeout

Time to wait for indication in milliseconds.

# **Returns**

The function returns a value indicating whether an indication was received.

0 Indication returned.

### WNOFTIMEOUT

Timeout waiting for indication.

# WNOFSYSNOTREADY

The underlying network subsystem is not ready for network communication.

#### WNOFNOTREG

The application is not registered to receive indications.

#### WNOFBADSIZE

The buffer is too small to receive the indication. Reissue the **WinNOFGetIndication** call with a large enough buffer. The size of the indication is returned in the **buffer\_size** parameter.

### **WNOFBADPOINTER**

Either the buffer or **buffer\_size** parameter is not valid.

### WNOFSYSERROR

An unexpected system error has occurred.

# Remarks

This is a blocking call, it returns in one of the following circumstances:

- An indication is returned
- The timeout expires
- The application issues a WinNOFCleanup call
- The product is stopped
- A system error occurs

Note: See also WinNOFRegisterIndicationSink() on page 24 and WinNOFUnregisterIndicationSink() on page 25.

# Chapter 4. Node Configuration Verbs

The verbs in this chapter are used to define and delete node configuration information.

# DEFINE\_ADJACENT\_NODE

DEFINE\_ADJACENT\_NODE adds entries to the node directory database for the resources on an adjacent node.

**Note:** This verb is not required, and should not be issued, if there is an active path to the adjacent node using CP-CP sessions.

This verb can be issued on an end node, in which case the node's control point is added to the root of the directory.

To define the node's control point LU, set the following fields:

- Specify the node's control point name in the cp\_name field
- Add an ADJACENT\_NODE\_LU structure, specifying the control point name in the fqlu\_name field.

Any additional LUs on the node are added to the directory as children of the node's control point.DEFINE\_ADJACENT\_NODE can also be used to add LU definitions to an existing node definition. LUs can be removed in the same way by issuing the DELETE\_ADJACENT\_NODE verb. If the verb fails part way through processing, all new directory entries are removed, leaving the directory as it was before the verb was issued.

# VCB Structure

The DEFINE\_ADJACENT\_NODE verb contains a variable number of ADJACENT\_NODE\_LU overlays. The ADJACENT\_NODE\_LU structures are concatenated onto the end of DEFINE\_ADJACENT\_NODE structure.

typedef struct define\_adjacent\_node

unsigned short unsigned char unsigned char	opcode; reserv2; format;	/* /*	verb operation code reserved format	*/ */ */		
unsigned short	primary_rc;		primary return code	*/		
unsigned long unsigned char	<pre>secondary_rc; cp name[17];</pre>		secondary return code CP name	*/ */		
unsigned char			resource description	*/		
unsigned char	reserv3[19];	/*	reserved	*/		
unsigned short } DEFINE_ADJACENT_NODE;	num_of_lus;	/*	number of LUs	*/		
typedef struct adjacent_node_lu {						
unsigned char	wildcard_lu;		wildcard LU name indicator	*/ */		
unsigned char unsigned char	fqlu_name[17]; reserv1[6];		fully qualified LU name reserved	*/ */		
<pre>} ADJACENT_NODE_LU;</pre>						

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DEFINE\_ADJACENT\_NODE

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### cp\_name

The fully qualified name of the control point in the adjacent end node. This should match the name the node sends on its XIDs (if it supports them), and the adjacent control point name specified on the DEFINE\_LS for the link to the node. The name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### description

Resource description (returned on QUERY\_DIRECTORY\_LU). This is a 16-byte (nonzero) string in a locally displayable character set. All 16 bytes are significant.

### num\_of\_lus

The number of adjacent LU overlays that follow the DEFINE\_ADJACENT\_NODE VCB.

#### adjacent\_node\_lu.wildcard\_lu

Indicates whether the specified LU name is a wildcard name (AP\_YES or AP\_NO).

### adjacent\_node\_lu.fqlu\_name

The LU name to be defined. If this name is not fully qualified the network ID of the CP name is assumed. The name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of either one or two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

When **wildcard\_lu** is TRUE, a dot (.) followed by EBCDIC spaces means a Full Wildcard (that will match anything). All EBCDIC spaces will match anything beginning with the Net id of the CP Name.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_CP\_NAME

AP\_INVALID\_LU\_NAME AP\_INVALID\_WILDCARD\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc

AP\_STATE\_CHECK

secondary\_rc AP\_INVALID\_CP\_NAME

### AP\_INVALID\_LU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameters:

### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

#### secondary\_rc

AP\_MEMORY\_SHORTAGE

AP\_DIRECTORY\_FULL

# **DEFINE\_CN**

DEFINE\_CN defines a connection network (also known as a virtual routing node or VRN). The verb provides the network-qualified name of the connection network along with its transmission group (TG) characteristics. It also provides a list of the names of the local ports that can access this connection network.

DEFINE\_CN can be used to redefine an existing connection network. In particular, new ports can be added to the list of ports that access the connection network by issuing another DEFINE\_CN. (Ports can be removed in the same way by issuing the DELETE\_CN verb.)

# **VCB** Structure

typedef struct define_cn					
ι	unsigned short unsigned char unsigned char unsigned char unsigned short unsigned long unsigned char CN_DEF_DATA unsigned char	<pre>opcode; attributes; reserv2; format; primary_rc; secondary_rc; fqcn_name[17]; def_data; port_name[8][8];</pre>	/* /* /* /* /* /* /*	verb operation code verb attributes reserved format primary return code secondary return code name of connection network CN defined data	*/
} DEFIN	E CN;		/*	port names	*/
	struct cn_def_da	ata			
t	unsigned char	description[RD_LI	EN]	;	
} CN_DEI	unsigned char unsigned char TG_DEFINED_CHAR F_DATA;	reserv1[16];	/* /*	resource description number of ports on CN reserved TG characteristics	*/ */ */
· ·	<pre>struct tg_define</pre>	ed_chars			
{	unsigned char unsigned char	<pre>reserve1[5]; connect_cost; byte_cost; reserve2; security; prop_delay; modem_class; user_def_parm_1; user_def_parm_2;</pre>	/* /* /* /* /* /*	effective capacity reserved connection cost byte cost reserved security propagation delay modem class user-defined parameter 1 user-defined parameter 2 user-defined parameter 3	*//////////////////////////////////////

```
} TG_DEFINED_CHARS;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_CN

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

#### AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### fqcn\_name

Fully qualified name (17 bytes long) of connection network being defined. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### def\_data.description

Resource description (returned on QUERY\_CN). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### def\_data.num\_ports

Number of ports associated with this connection network. There can be as many as eight ports per DEFINE\_CN verb, and up to and including 239 ports in total per CN.

### def\_data.tg\_chars.effect\_cap

Actual units of effective capacity. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemm. Each unit of effective capacity is equal to 300 bits per second.

### def\_data.tg\_chars.connect\_cost

Cost per connect time. Valid values are integer values in the range 0–255, where 0 is the lowest cost per connect time and 255 is the highest.

#### def\_data.tg\_chars.byte\_cost

Cost per byte. Valid values are integer values in the range 0–255, where 0 is the lowest cost per byte and 255 is the highest.

#### def\_data.tg\_chars.security

Security values as described in the list below:

# AP\_SEC\_NONSECURE

No security exists.

#### AP\_SEC\_PUBLIC\_SWITCHED\_NETWORK

Data transmitted over this connection network will flow over a public switched network.

#### AP\_SEC\_UNDERGROUND\_CABLE

Data transmitted over secure underground cable.

#### AP SEC SECURE CONDUIT

The line is a secure conduit that is not guarded.

# AP\_SEC\_GUARDED\_CONDUIT

Conduit is protected against physical tapping.

#### AP\_SEC\_ENCRYPTED

Encryption over the line.

### AP\_SEC\_GUARDED\_RADIATION

Line is protected against physical and radiation tapping.

#### def\_data.tg\_chars.prop\_delay

Propagation delay representing the time it takes for a signal to travel the

length of the link, in microseconds. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemm. Default values are listed below:

## AP\_PROP\_DELAY\_MINIMUM

No propagation delay.

### AP\_PROP\_DELAY\_LAN

Less than 480 microseconds delay.

AP\_PROP\_DELAY\_TELEPHONE Between 480 and 49 512 microseconds delay.

### AP\_PROP\_DELAY\_PKT\_SWITCHED\_NET Between 49 512 and 245 760 microseconds delay.

AP\_PROP\_DELAY\_SATELLITE Longer than 245 760 microseconds delay.

#### AP\_PROP\_DELAY\_MAXIMUM Maximum propagation delay.

# def\_data.tg\_chars.modem\_class

Reserved. This field should always be set to zero.

# def\_data.tg\_chars.user\_def\_parm\_1

User defined parameter in the range 0–255.

def\_data.tg\_chars.user\_def\_parm\_2 User defined parameter in the range 0–255.

# def\_data.tg\_chars.user\_def\_parm\_3

User defined parameter in the range 0–255.

#### port\_name

Array of up to eight port names defined on the connection network. Each named port must have already been defined by a DEFINE\_PORT verb. Each port name is an 8-byte string in a locally displayable character set and must match that on the associated DEFINE\_PORT verb. Additional ports can be defined on the connection network by issuing another DEFINE\_CN specifying the new port names.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_CN\_NAME

AP\_INVALID\_NUM\_PORTS\_SPECIFIED AP\_INVALID\_PORT\_NAME

# AP\_INVALID\_PORT\_TYPE AP\_DEF\_LINK\_INVALID\_SECURITY AP\_EXCEEDS\_MAX\_ALLOWED

If the verb does not execute because of a state error, the Program returns the following parameters:

# primary\_rc AP\_STATE\_CHECK

secondary\_rc AP\_PORT\_ACTIVE

# AP\_CANT\_MODIFY\_VISIBILITY

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_COS

DEFINE\_COS adds a class-of-service definition. The DEFINE\_COS verb can also be used to modify any fields in a previously defined COS.

The definition provides node and TG rows. These rows associate a range of node and TG characteristics with weights that are used for route calculation. The lower the weight the more favorable the route.

# VCB Structure

The DEFINE\_COS verb contains a variable number of **cos\_tg\_row** and **cos\_node\_row** overlays. The **cos\_tg\_row** structures are concatenated onto the end of DEFINE\_COS (and ordered in ascending weight) and are followed by the **cos\_node\_row** structures (also ordered in ascending weight).

```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_COS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### cos\_name

Class-of-service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### description

Resource description (returned on QUERY\_COS). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### transmission\_priority

Transmission priority. This is set to one of the following values:

AP\_LOW AP\_MEDIUM AP\_HIGH AP\_NETWORK

#### num\_of\_node\_rows

Number of node row overlays that follow the DEFINE\_COS VCB. The maximum is 8. Each node row contains a set of minimum node characteristics, a set of maximum node characteristics, and a weight. When computing the weights for a node, its characteristics are checked against the minimum and maximum characteristics defined for each node row. The node is then assigned the weight of the first node row, which confines all the node's characteristics within the limits specified. If the node characteristics do not satisfy any of the listed node rows, the node is considered unsuitable for this COS, and is assigned an infinite weight. Note that the node rows must be concatenated in ascending order of weight.

#### num\_of\_tg\_rows

Number of TG row overlays that follow the node row overlays. The maximum is 8. Each TG row contains a set of minimum TG characteristics, a set of maximum TG characteristics, and a weight. When computing the weights for a TG, its characteristics are checked against the minimum and maximum characteristics defined for each TG row. The TG is then assigned the weight of the first TG row, which confines all the TG's characteristics within the limits specified. If the TG characteristics do not satisfy any of the listed TG rows, the TG is considered unsuitable for this COS, and is assigned an infinite weight. Note that the TG rows must be concatenated in ascending order of weight.

#### cos\_node\_row.minimum.rar

Route additional resistance minimum. Values must be in the range 0–255.

#### cos\_node\_row.minimum.status

Specifies the minimum congestion status of the node. This can be one of the following values:

### AP\_UNCONGESTED

The node is not congested.

#### AP\_CONGESTED

The number of ISR sessions is greater than the **isr\_sessions\_upper\_threshold**.

#### cos\_node\_row.maximum.rar

Route additional resistance maximum. Values must be in the range 0–255.

### cos\_node\_row.maximum.status

Specifies the maximum congestion status of the node. This can be one of the following values:

#### AP\_UNCONGESTED

The node is not congested.

### AP\_CONGESTED

The number of ISR sessions is greater than the **isr\_sessions\_upper\_threshold**.

### cos\_node\_row.weight

Weight associated with this node row. Values must be in the range 0–255.

### cos\_tg\_row.minimum.effect\_cap

Minimum limit for actual units of effective capacity. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemm. Each unit of effective capacity is equal to 300 bits per second.

### cos\_tg\_row.minimum.connect\_cost

Minimum limit for cost per connect time. Valid values are integer values in the range 0–255, where 0 is the lowest cost per connect time and 255 is the highest.

#### cos\_tg\_row.minimum.byte\_cost

Minimum limit for cost per byte. Valid values are integer values in the range 0–255, where 0 is the lowest cost per byte and 255 is the highest.

#### cos\_tg\_row.minimum.security

Minimum limits for security values as described in the list below:

#### AP\_SEC\_NONSECURE

No security exists.

#### AP\_SEC\_PUBLIC\_SWITCHED\_NETWORK

Data transmitted over this connection network will flow over a public switched network.

#### AP\_SEC\_UNDERGROUND\_CABLE

Data transmitted over secure underground cable.

#### AP\_SEC\_SECURE\_CONDUIT

The line is a secure conduit that is not guarded.

#### AP\_SEC\_GUARDED\_CONDUIT

Conduit is protected against physical tapping.

#### AP\_SEC\_ENCRYPTED

Encryption over the line.

### AP\_SEC\_GUARDED\_RADIATION

Line is protected against physical and radiation tapping.

### cos\_tg\_row.minimum.prop\_delay

Minimum limits for propagation delay representing the time it takes for a signal to travel the length of the link, in microseconds. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemm. Default values are listed below:

## AP\_PROP\_DELAY\_MINIMUM

No propagation delay.

### AP\_PROP\_DELAY\_LAN

Less than 480 microseconds delay.

#### AP\_PROP\_DELAY\_TELEPHONE

Between 480 and 49 512 microseconds delay.

#### AP\_PROP\_DELAY\_PKT\_SWITCHED\_NET Between 49 512 and 245 760 microseconds delay.

# AP\_PROP\_DELAY\_SATELLITE

Longer than 245 760 microseconds delay.

# AP\_PROP\_DELAY\_MAXIMUM

Maximum propagation delay.

### cos\_tg\_row.minimum.modem\_class

Reserved. This field should always be set to zero.

#### cos\_tg\_row.minimum.user\_def\_parm\_1 Minimum limit for user-defined parameter in the range 0–255.

# cos\_tg\_row.minimum.user\_def\_parm\_2

Minimum limit for user-defined parameter in the range 0–255.

# cos\_tg\_row.minimum.user\_def\_parm\_3

Minimum limit for user-defined parameter in the range 0–255.

### cos\_tg\_row.maximum.effect\_cap

Maximum limit for actual units of effective capacity. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemm. Each unit of effective capacity is equal to 300 bits per second.

#### cos\_tg\_row.maximum.connect\_cost

Maximum limit for cost per connect time. Valid values are integer values in the range 0–255, where 0 is the lowest cost per connect time and 255 is the highest.

#### cos\_tg\_row.maximum.byte\_cost

Maximum limit for cost per byte. Valid values are integer values in the range 0–255, where 0 is the lowest cost per byte and 255 is the highest.

#### cos\_tg\_row.maximum.security

Maximum limits for security values as described in the list below:

# AP\_SEC\_NONSECURE

No security exists.

## AP\_SEC\_PUBLIC\_SWITCHED\_NETWORK

Data transmitted over this connection network will flow over a public switched network.

#### AP\_SEC\_UNDERGROUND\_CABLE

Data transmitted over secure underground cable.

### AP\_SEC\_SECURE\_CONDUIT

The line is a secure conduit that is not guarded.

#### AP\_SEC\_GUARDED\_CONDUIT

Conduit that is protected against physical tapping.

#### AP\_SEC\_ENCRYPTED

Encryption over the line.

#### AP\_SEC\_GUARDED\_RADIATION

Line is protected against physical and radiation tapping.

## cos\_tg\_row.maximum.prop\_delay

Maximum limits for propagation delay representing the time it takes for a signal to travel the length of the link, in microseconds. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemm. Default values are listed below:

#### AP\_PROP\_DELAY\_MINIMUM

No propagation delay.

AP\_PROP\_DELAY\_LAN Less than 480 microseconds delay.

AP\_PROP\_DELAY\_TELEPHONE

Between 480 and 49 512 microseconds delay.

#### AP\_PROP\_DELAY\_PKT\_SWITCHED\_NET Between 49 512 and 245 760 microseconds delay.

AP\_PROP\_DELAY\_SATELLITE Longer than 245 760 microseconds delay.

AP\_PROP\_DELAY\_MAXIMUM

Maximum propagation delay.

# cos\_tg\_row.maximum.modem\_class

Reserved. This field should always be set to zero.

## cos\_tg\_row.maximum.user\_def\_parm\_1 Maximum limit for user-defined parameter in the range 0–255.

cos\_tg\_row.maximum.user\_def\_parm\_2 Maximum limit for user-defined parameter in the range 0–255.

### cos\_tg\_row.maximum.user\_def\_parm\_3 Maximum limit for user-defined parameter in the range 0–255.

#### cos\_tg\_row.weight

Weight associated with this TG row.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_COS\_NAME

AP\_INVALID\_NUMBER\_OF\_NODE\_ROWS AP\_INVALID\_NUMBER\_OF\_TG\_ROWS AP\_NODE\_ROW\_WGT\_LESS\_THAN\_LAST AP\_TG\_ROW\_WGT\_LESS\_THAN\_LAST

If the verb does not execute because of a state error, the Program returns the following parameters:

# primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_COS\_TABLE\_FULL

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_DEFAULT\_PU

DEFINE\_DEFAULT\_PU allows the user to define, redefine, or modify any field of a default PU. It also allows the user to delete the default PU, by specifying a null PU name. If a PU name is not specified explicitly on a TRANSFER\_MS\_DATA verb, then the management services information carried on the TRANSFER\_MS\_DATA is sent on the default PU's session with the host SSCP. For more information about this see Chapter 15, "Management Services Verbs," on page 615.

# **VCB** Structure

typedef {	struct de	efine_de	efault_pu			
	unsigned	short	opcode;	/*	verb operation code	*/
	unsigned	char	reserv2;	/*	reserved	*/
	unsigned	char	format;	/*	format	*/
	unsigned	short	primary rc;	/*	primary return code	*/
	unsigned	long	secondary rc;		secondary return code	*/
	unsigned	char	pu name[8];	/*	PU name	*/
	unsigned	char	description[RD	LEN]	•	
				/*	resource description	*/
	unsigned	char	reserv3[16];	/*	reserved	*/
} DEFIN	E_DEFAULT_	PU;				

# **Supplied Parameters**

The application supplies the following parameters:

# opcode

AP\_DEFINE\_DEFAULT\_PU

# format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### pu\_name

Name of local PU that will serve as the default. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### description

Resource description (returned on QUERY\_DEFAULT\_PU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# **DEFINE\_DEFAULTS**

DEFINE\_DEFAULTS allows the user to define or redefine default actions of the node.

# VCB Structure

```
typedef struct define defaults
          unsigned short opcode; /* verb operation code */
unsigned char reserv2; /* reserved */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
DEFAULT_CHARS default_chars; /* default information */
} DEFINE DEFAULTS;
typedef struct default chars
           unsigned char
                                 description[RD LEN];
                                                         /* resource description
                                                                                            */
                                                       /* default mode name
           unsigned char
                                 mode name[8];
                                                                                             */
           unsigned char
                                implicit plu forbidden;
                                                         /* disallow implicit
                                                                                             */
                                                         /* PLUs?
                                                                                             */
           unsigned char
                                  specific security codes;
                                                         /* generiuc security
                                                                                             */
                                                         /* sense codes
                                                                                             */
           unsigned short limited timeout;/* timeout for limited
                                                                                            */
                                                        /* sessions
                                                                                             */
                                 reserv[244];
           unsigned char
                                                        /* reserved
                                                                                             */
} DEFAULT CHARS;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_DEFAULTS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### default\_chars.description

Resource description (returned on QUERY\_DEFAULTS). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### default\_chars.mode\_name

Name of the mode that will serve as the default. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

# default\_chars.implicit\_plu\_forbidden

Controls whether the Program puts implicit definitions in place for unknown Partner LUs (AP\_YES or AP\_NO).

#### default\_chars.specific\_security\_codes

Controls whether the Program uses specific sense codes on a security authentication or authorization failure (AP\_YES or AP\_NO). Note, specific sense codes will only be returned to those partner LUs that have reported support for them on the session.

#### default\_chars.limited\_timeout

Specifies the timeout after which free limited-resource convinner sessions will be deactivated. Range 0 to 65535 seconds.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb specifies a default mode that is not valid (for example, not EBCDIC A), or is valid but has not been defined, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_MODE\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

The effect of redefinition of each field is as follows:

#### description

The redefinition takes effect immediately. The updated description is returned on subsequent QUERY\_DEFAULT verbs.

#### mode\_name

The effect of a redefinition applies to all subsequent implicit mode definitions, for example, the updated mode serves as the default mode. The effect of a redefinition on a previously unknown mode (for example, one that had inherited the previous default mode characteristics) is identical to a redefinition of the unknown mode. For example, if the default mode is #INTER, and the Program receives a bIND for (an unknown) MODE1, the effect on MODE1 of the default mode subsequently being redefined to #BATCH should be identical to the effect of a DEFINE\_MODE(MODE1) specifying the mode characteristics of #BATCH.

#### implicit\_plu\_forbidden

The redefinition takes effect immediately. All subsequent implicit PLU definitions succeed or fail depending on the updated value of this field.

# specific\_security\_codes

The redefinition takes effect immediately.

# limited\_timeout

The updated value is used for all new session established after the redefinition. The old value is used for existing sessions.

# DEFINE\_DLC

DEFINE\_DLC defines a new DLC or modifies an existing DLC. This verb defines the DLC name, which is unique throughout the node, and some DLC-specific data, which is concatenated to the basic structure. This data is used during initialization of the DLC, and the format is specific to the DLC type (such as Token Ring). Only the DLC-specific data appended to the verb can be modified using the DEFINE\_DLC verb. To do this, a STOP\_DLC verb must first be issued so that the DLC is in a reset state.

See "DLC Processes, Ports, and Link Stations" on page 14 for more information about the relationship between DLCs, ports and link stations.

# **VCB** Structure

typedef struct define_d	edef struct define_dlc					
unsigned short		<pre>/* verb operation code</pre>	*/			
unsigned char	attributes;	/* verb attributes	*/			
unsigned char	reserv2;	/* reserved	*/			
unsigned char		/* format	*/			
unsigned short		/* primary return code	*/			
unsigned long		/* secondary return code	*/			
unsigned char			*/			
DLC_DEF_DATA	def_data;	/* DLC defined data	*/			
<pre>} DEFINE_DLC;</pre>						
typedef struct dlc_def_	data					
{		,	,			
DESCRIPTION		/* resource description	*/			
unsigned char	dlc_type;	/* DLC type	*/			
unsigned char	<pre>neg_ls_supp;</pre>	/* negotiable LS support	*/			
unsigned char	port_types;	/* allowable port types	*/			
unsigned char		/* DLC only supports HPR links:				
unsigned char	,	/* reserved	*/

		/* delay between automatic	*/			
unsigned shan	$max a m \sqrt{1}$	/* retries	*/ */			
unsigned char		/* reserved	'			
unsigned short } DLC_DEF_DATA;	uic_spec_data_len;	/* Length of DLC specific data	*/			

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_DLC

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### dlc\_name

Name of the DLC. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. For OEM devices, this name is manufacturer-specific. Valid values are LAN, SDLC, AnyNet<sup>®</sup>, X25 or TWINAX (padded to 8 chars with spaces).

#### def\_data.description

Resource description (returned on QUERY\_DLC). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

### def\_data.dlc\_type

Type of the DLC.Personal Communications and Communications Server support the following types:

AP\_ANYNET AP\_LLC2 AP\_OEM\_DLC AP\_SDLC AP\_TWINAX AP\_X25

For EEDLC, use AP\_OEM\_DLC.

# def\_data.neg\_ls\_supp

Specifies whether the DLC supports negotiable link stations (AP\_YES or AP\_NO). If the **dlc\_type** is AP\_TWINAX, then only AP\_NO is supported. If the **dlc\_type** is AP\_ANYNET, then only AP\_YES is supported.

#### def\_data.port\_types

Specifies the allowable port types for the supplied **dlc\_type**. The value corresponds to one or more of the following values ORed together.

AP\_PORT\_NONSWITCHED AP\_PORT\_SWITCHED AP\_PORT\_SATF

Use the following table to set the fields for the corresponding DLC type.

Table 2. Port Types for DLC Types

DLC Type	Port Type
AP_ANYNET	AP_PORT_SATF
AP_LLC2	AP_PORT_SATF
AP_OEM_DLC	AP_PORT_SWITCHED or AP_PORT_NONSWITCHED
AP_SDLC	AP_PORT_SWITCHED or AP_PORT_NONSWITCHED
AP_TWINAX	AP_PORT_NONSWITCHED
AP_X25	AP_PORT_SWITCHED or AP_PORT_NONSWITCHED

#### def\_data.hpr\_only

This field specifies whether the DLC only supports HPR links. This must be set to AP\_YES for HPR over IP links.

AP\_YES AP\_NO

#### def\_data.retry\_flags

This field specifies the conditions under which link stations are subject to automatic retry. It is a bit field, and may take any of the following values bit-wise ORed together.

### AP\_RETRY\_ON\_START

Link activation will be retried if no response is received from the remote node when activation is attempted. If the underlying port is inactive when activation is attempted, the Program will attempt to activate it.

#### AP\_RETRY\_ON\_FAILURE

Link activation will be retried if the link fails while active or pending active. If the underlying port has failed when activation is attempted, the Program attempts to activate it.

### AP\_RETRY\_ON\_DISCONNECT

Link activation will be retried if the link is stopped normally by the remote node.

## AP\_DELAY\_APPLICATION\_RETRIES

Link activation retries, initiated by applications (using START\_LS or on-demand link activation) will be paced using the **activation\_delay\_timer**.

### AP\_INHERIT\_RETRY

This flag has no effect.

# def\_data.max\_activation\_attempts

This field has no effect unless at least one flag is set in DEFINE\_LS in **def\_data.retry\_flags**, **def\_data.max\_activation\_attempts** on DEFINE\_LS is set to AP\_USE\_DEFAULTS, and **def\_data.max\_activation\_attempts** on DEFINE\_PORT is set to AP\_USE\_DEFAULTS.

This field specifies the number of retry attempts the Program allows when the remote node is not responding, or the underlying port is inactive. This includes both automatic retries and application-driven activation attempts.

If this limit is ever reached, no further attempts are made to automatically retry. This condition is reset by STOP\_LS, STOP\_PORT, STOP\_DLC or a successful activation. START\_LS or OPEN\_LU\_SSCP\_SEC\_RQ results in a single activation attempt, with no retry if activation fails.

Zero means no limit. The value AP\_USE\_DEFAULTS means no limit.

# def\_data.activation\_delay\_timer

This field has no effect unless at least one flag is set in DEFINE\_LS in **def\_data.retry\_flags**, **def\_data.max\_activation\_attempts** on DEFINE\_LS is set to AP\_USE\_DEFAULTS, and **def\_data.max\_activation\_attempts** on DEFINE\_PORT is set to AP\_USE\_DEFAULTS.

This field specifies the number of seconds that the Program waits between automatic retry attempts, and between application-driven activation attempts if the AP\_DELAY\_APPLICATION\_RETRIES bit is set in **def\_data.retry\_flags**.

The value of zero or AP\_USE\_DEFAULTS results in the use of default timer duration of thirty seconds.

### def\_data.dlc\_spec\_data\_len

This field should always be set to zero.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_DLC\_NAME

AP\_INVALID\_DLC\_TYPE AP\_INVALID\_RETRY\_FLAGS AP\_INVALID\_PORT\_TYPE AP\_HPR\_NOT\_SUPPORTED

If the verb does not execute because of a state error, the Program returns the following parameters:

# primary\_rc

AP\_STATE\_CHECK

# secondary\_rc

AP\_DLC\_ACTIVE

AP\_INVALID\_DLC\_TYPE AP\_CANT\_MODIFY\_VISIBILITY

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_DLUR\_DEFAULTS

DEFINE\_DLUR\_DEFAULTS allows the user to define, redefine, or revoke a default dependent LU server (DLUS) and a backup default DLUS. The default DLUS name is used by DLUR when it initiates SSCP-PU activation for PUs that do not have an explicitly specified associated DLUS. If a DLUS name is not specified explicitly on the DEFINE\_DLUR\_DEFAULTS verb then the current default (or backup DLUS) is revoked.

# VCB Structure

typedef struct define\_dlur\_defaults

```
/* verb operation code
        unsigned short opcode;
                                                                         */
        unsigned char reserv2;
                                             /* reserved

        unsigned short dlus retry timeout; /* DLUS Retry Timeout
                                                                         */
        unsigned short dlus_retry_limit; /* DLUS Retry Limit
                                                                         */
        unsigned char reserv4[16];
                                              /* reserved
                                                                         */
} DEFINE DLUR DEFAULTS;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_DLUR\_DEFAULTS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### description

Resource description. This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### dlus\_name

Name of the DLUS node that will serve as the default. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If this field is set to all zeros, the current default DLUS is revoked.

#### bkup\_dlus\_name

Name of the DLUS node that will serve as the backup default. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If this field is set to all zeros, the current backup default DLUS is revoked.

#### dlus\_retry\_timeout

Interval in seconds between second and subsequent attempts to contact a

DLUS. The interval between the initial attempt and the first retry is always one second. If zero is specified, the default value of 5 seconds is used.

#### dlus\_retry\_limit

Maximum number of retries after an initial failure to contact a DLUS. If zero is specified, the default value of 3 is used. If X'FFFF' is specified, Personal Communications or Communications Server will retry indefinitely.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_INVALID\_DLUS\_NAME

AP\_INVALID\_BKUP\_DLUS\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_DOWNSTREAM\_LU

This verb applies only to Communications Server.

The DEFINE\_DOWNSTREAM\_LU verb is used for PU concentration. When PU concentration is used, downstream LUs are able to communicate with an upstream host. To do this, Communications Server maps each downstream LU to a dependent local LU, referred to as the *host LU*.

DEFINE\_DOWNSTREAM\_LU defines a new downstream LU and cannot be used to modify an existing definition. The downstream LU is mapped to the specified host LU (defined using the DEFINE\_LU\_0\_TO\_3 verb). The host LU can also be specified in terms of an LU pool.

When DEFINE\_DOWNSTREAM\_LU is issued for an existing downstream LU definition, the definition must be identical. If the downstream link is active and the downstream LU is inactive, the verb will be returned as successful and a reactivation attempt is made (although this may not be successful). If the downstream is not active or the downstream LU is already active, the verb failed. The processing of the reactivation attempt depends on the state of the specified host LU.

- If the host LU is active, then the ACTLU is resent to the downstream LU immediately.
- If the host LU is inactive, the node waits for the host LU to become active before sending the ACTLU to the downstream LU. The node attempts to activate the link to the host if it is not active (this will not be successful if the host link cannot be activated automatically).

# VCB Structure

```
typedef struct define downstream lu
        unsigned short opcode;
                                           /* verb operation code

                        reserv2[6];
                                                                           */
        unsigned char
} DOWNSTREAM LU_DEF_DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_DOWNSTREAM\_LU

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### dslu\_name

Name of the downstream LU that is being defined. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

# def\_data.description

Resource description (returned on QUERY\_DOWNSTREAM\_LU). The length of this field should be a multiple of four bytes, and not zero.

### def\_data.nau\_address

Network addressable unit address of the DOWNSTREAM LU. This must be in the range 1–255.

#### def\_data.dspu\_name

Name of the DOWNSTREAM PU (as specified on the DEFINE\_LS). This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### def\_data.host\_lu\_name

Name of the host LU or host LU pool that the downstream LU is mapped to. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### def\_data.allow\_timeout

Specifies whether the Program is allowed to time-out host LUs used by this dowstream LU if the session is left inactive for the **timeout** period specified on the host LU definition (AP\_YES or AP\_NO).

# def\_data.delayed\_logon

Specifies whether the Program should delay connecting the downstream LU to the host LU until the first data is received from the dowstream LU. Instead, a simulated logon screen is sent to the downstream LU (AP\_YES or AP\_NO).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_DNST\_LU\_NAME

#### AP\_INVALID\_NAU\_ADDRESS

If the verb does not execute because of a state error, the Program returns the following parameters:

### primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_PU\_TYPE AP\_PU\_NOT\_DEFINED AP\_LU\_ALREADY\_DEFINED AP\_LU\_NAU\_ADDR\_ALREADY\_DEFD AP\_INVALID\_HOST\_LU\_NAME AP\_LU\_NAME\_POOL\_NAME\_CLASH AP\_PU\_NOT\_ACTIVE AP\_LU\_ALREADY\_ACTIVATING AP\_LU\_ALREADY\_ACTIVE AP\_LU\_ALREADY\_ACTIVE AP\_CANT\_MODIFY\_VISIBILITY AP\_INVALID\_ALLOW\_TIMEOUT AP\_INVALID\_DELAYED\_LOGON AP\_DELAYED\_VERB\_PENDING

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameters:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_DOWNSTREAM\_LU\_RANGE

This verb applies only to Communications Server.

The DEFINE\_DOWNSTREAM\_LU\_RANGE verb is used for PU concentration. When PU concentration is used, downstream LUs are able to communicate with an upstream host. To do this, Communications Server maps each downstream LU to a dependent local LU, referred to as the *host LU*.

DEFINE\_DOWNSTREAM\_LU\_RANGE allows the definition of multiple downstream LUs within a specified NAU range (but cannot be used to modify an existing definition). The node operator provides a base name and an NAU range. The LU names are generated by combining the base name with the NAU addresses.

For example, a base name of LUNME combined with an NAU range of 1 to 4 would define the LUs LUNME001, LUNME002, LUNME003, and LUNME004. A base name of less than five non-pad characters results in LU names of less than eight non-pad characters. Communications Server then right-pads these to eight characters.

Each downstream LU is mapped to the specified host LU (defined using the DEFINE\_LU\_0\_TO\_3 verb).

# VCB Structure

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DEFINE\_DOWNSTREAM\_LU\_RANGE

# attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### dslu\_base\_name

Base name for downstream LU name range. This is a 5-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This base name is appended with three type-A EBCDIC numeric characters, representing the decimal value of the NAU address, for each LU in the NAU range.

#### description

Resource description (returned on QUERY\_DOWNSTREAM\_LU). The length of this field should be a multiple of four bytes, and not zero.

#### min\_nau

Minimum NAU address in the range. This can be from 1 to 255 inclusive.

#### max\_nau

Maximum NAU address in the range. This can be from 1 to 255 inclusive.

#### dspu\_name

Name of the DOWNSTREAM PU (as specified on the DEFINE\_LS). This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### host\_lu\_name

Name of the host LU or host LU pool that all the downstream LUs within the range are mapped to. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

# allow\_timeout

Specifies whether the Program is allowed to time-out host LUs used by this downstream LU if the session is left inactive for the **timeout** period specified on the host LU definition (AP\_YES or AP\_NO).

#### delayed\_logon

Specifies whether the Program should delay connection of the downstream LU to the host LU until the first data is received from the downstream LU. Instead, a simulated logon screen will be sent to the downstream LU (AP\_YES or AP\_NO).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_DNST\_LU\_NAME

AP\_INVALID\_NAU\_ADDRESS AP\_INVALID\_ALLOW\_TIMEOUT AP\_INVALID\_DELAYED\_LOGON

If the verb does not execute because of a state error, the Program returns the following parameters:

# primary\_rc

AP\_STATE\_CHECK

secondary\_rc

AP\_LU\_NAME\_POOL\_NAME\_CLASH

AP\_LU\_ALREADY\_DEFINED AP\_INVALID\_HOST\_LU\_NAME AP\_PU\_NOT\_DEFINED AP\_INVALID\_PU\_NAME AP\_INVALID\_PU\_TYPE AP\_LU\_NAU\_ADDR\_ALREADY\_DEFD AP\_CANT\_MODIFY\_VISIBILITY AP\_DELAYED\_VERB\_PENDING

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameters:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_DSPU\_TEMPLATE

This verb applies only to Communications Server.

This verb is used for PU concentration. When PU concentration is used, downstream LUs are able to communicate with an upstream host. To do this, Communications Server maps each downstream LU to a dependent local LU, referred to as the host LU. DEFINE\_DSPU\_TEMPLATE defines a template for the downstream LUs which are present on a group of downstream workstations. This template is used to put in place definitions for the downstream LUs when a workstation connects into Communications Server over an implicit link (one not previously defined). These templates are referred to by the **implicit\_dspu\_template** field on the DEFINE\_PORT verb. DEFINE\_DSPU\_TEMPLATE can either be used to define a new template or to modify an existing template (although the existing instances of the modified template is not affected).

# VCB Structure

typedef struct define dspu template /\* verb operation code unsigned short opcode; unsigned char attributes; /\* verb attributes \*/ unsigned char format; unsigned short primary\_rc; unsigned long secondary\_rc; unsigned char template\_name[8]; /\* format \*/ /\* primary return code \*/ /\* secondary return code \*/ /\* name of template \*/ unsigned char description; unsigned char modify\_template; /\* resource description \*/ /\* Modify existing template? \*/ unsigned char reserv1[11]; /\* reserved \*/ /\* Max active template unsigned short max instance; \*/ /\* instances \*/ unsigned short num of dslu templates; /\* number of DSLU templates \*/ } DEFINE DSPU TEMPLATE; typedef struct dslu template /\* min NAU address in range \*/ unsigned char min nau; /\* max NAU address in range \*/ unsigned char max nau; /\* Allow timeout of host LU? \*/ unsigned char allow timeout; delayed logon; /\* Allow delayed logon to unsigned char \*/ /\* host LU \*/ reserv1[8]; /\* reserved unsigned char \*/ /\* host LU or pool name host\_lu[8]; unsigned char \*/ } DSLU TEMPLATE;

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_DSPU\_TEMPLATE

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### template\_name

Name of the DSPU template. (This corresponds to the name specified in the **implicit\_dspu\_template** field on PORT\_DEF\_DATA). This is an 8\_byte string in a locally-displayable character set. All 8 bytes are significant and must be set.

#### description

Resource description (returned on QUERY\_DSPU\_TEMPLATE). The length of this should be a multiple of four bytes, and nonzero.

#### modify\_template

Specifies whether this verb should add additional DSLU templates to an existing DSPU template or should replace an existing DSPU template (AP\_MODIFY\_DSPU\_TEMPLATE or AP\_REPLACE\_DSPU\_TEMPLATE).

If modify template is set to AP\_MODIFY\_DSPU\_TEMPLATE and the named DSPU template does not exist, then it will be created.

If **modify\_template** is set to AP\_MODIFY\_DSPU\_TEMPLATE and the named DSPU template does not exist, then appended DSLU templates are added to the existing DSPU template.

If **modify\_template** is set to AP\_REPLACE\_DSPU\_TEMPLATE, then a new template is created. This can be from 0 to 65535 inclusive, where 0 means no limit.

#### max\_instance

This is the maximum number of instances of the template which can be active concurrently. While this limit is reached, no new instances can be created. This can be from 0 to 65535 inclusive, where 0 means no limit.

#### num\_of\_dslu\_templates

The number of DSLU template overlays which follow the DEFINE\_DSPU\_TEMPLATE VCB. This can be from 0 to 255 inclusive.

#### dslu\_template.min\_nau

Minimum NAU address in the range. This can be from 1 to 255 inclusive.

#### dslu\_template.max\_nau

Maximum NAU address in the range. This can be from 1 to 255 inclusive.

#### dslu\_template.allow\_timeout

Specifies whether the Program is allowed to time-out host LUs used by this downstream LU if the session is left inactive for the **timeout** period specified on the host LU definition (AP\_YES or AP\_NO).

#### dslu\_template.delayed\_logon

Specifies whether the Program should delay connecting the downstream LU to the host LU until the first data is received from the downstream LU. Instead, a simulated logon screen is sent to the downstream LU (AP\_YES or AP\_NO).

#### dslu\_template.host\_lu

Name of the host LU or host LU pool that all the downstream LUs within the range will be mapped onto. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC Spaces.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_TEMPLATE\_NAME

AP\_INVALID\_NAU\_ADDRESS AP\_INVALID\_NAU\_RANGE AP\_CLASHING\_NAU\_RANGE AP\_INVALID\_NUM\_DSPU\_TEMPLATES AP\_INVALID\_ALLOW\_TIMEOUT AP\_INVALID\_DELAYED\_LOGON AP\_INVALID\_MODIFY\_TEMPLATE

If the verb does not execute because of a state error, the Program returns the following parameters:

# primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_INVALID\_HOST\_LU\_NAME

#### AP\_CANT\_MODIFY\_VISIBILITY

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameter:

#### primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameters:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_FOCAL\_POINT

Personal Communications or Communications Server can have a number of types of relationships with different focal points. The DEFINE\_FOCAL\_POINT verb defines a focal point with which Personal Communications or Communications Server has an implicit relationship (which can be of type primary or backup). These relationships, and the ways in which they can be established, are described below. Relationships between a management services focal point (FP) and a management services entry point (EP) for a given category are established when they exchange Management Services Capabilities messages. The following types of FP-EP relationships can be established.

• Explicit

This relationship is established by an operator at the focal point assigning the entry point to its sphere of control. The focal point initiates exchange of Management Services Capabilities.

• Implicit (primary)

The relationship is established when an operator at an entry point assigns the entry point to a specified focal point (for example, when the operator issues a DEFINE\_FOCAL\_POINT verb). The entry point initiates the Management Services Capabilities exchange.

• Implicit (backup)

This relationship is established when an entry point loses either an explicit or implicit primary focal point. The entry point initiates Management Services Capabilities exchange. The identity of the backup focal point can be defined (using the DEFINE\_FOCAL\_POINT verb) or can be acquired via Management Services Capabilities exchange.

• Default

This relationship is established when an FP acquires an EP without operator intervention. The FP initiates the MS Capabilities exchange. This relationship only applies to EPs that are NNs.

• Domain

This relationship is established when a serving network node (NN) informs the end node entry point of the identity of the focal point. Domain relationships are only valid in end nodes.

• Host

This relationship does not involve Management Services Capabilities exchange and is established by the configuration of an SSCP-PU session from the entry point node to a host. It is the lowest precedence focal point relationship.

Each DEFINE\_FOCAL\_POINT verb can only be used to define an implicit focal point (which can be of type primary or backup). Each DEFINE\_FOCAL\_POINT verb is issued for a specific management services category. Within this category the DEFINE\_FOCAL\_POINT verb can be used to do the following:

- Define a focal point
- Replace a focal point (or backup focal point)
- Revoke the currently active focal point

The fields on a DEFINE\_FOCAL\_POINT verb are used as follows.

The **ms\_category** must always be filled in. The combination of the **fp\_fqcp\_name** and **ms\_appl\_name fields** specify the focal point (or backup focal point if the **backup** field is set to AP\_YES) for the specified category.

If the verb is being issued to revoke the currently active focal point without providing a new one, the **fp\_fqcp\_name** and **ms\_appl\_name** fields should be set to all zeros. When a DEFINE\_FOCAL\_POINT verb defining or replacing a focal point is received, Personal Communications or Communications Server attempts to establish an implicit primary focal point relationship with the specified focal point by sending a Management Services Capabilities request. When Personal Communications or Communications or Communications or Communications or Communications or Communications Server receives a DEFINE\_FOCAL\_POINT verb revoking the currently active focal point. It is recommended that the DELETE\_FOCAL\_POINT verb (specifying AP\_ACTIVE) be used to revoke the currently active focal point.

# **VCB** Structure

typedef struct define\_focal\_point

{

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_FOCAL\_POINT

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### ms\_category

Management services category. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services categories as described in SNA management services, or an 8-byte type 1134 EBCDIC installation-defined name.

#### fp\_fqcp\_name

Focal point's fully qualified control point name. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the focal point is being revoked, this field should be set to all zeros.

#### ms\_appl\_name

Focal point application name. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services applications as described in SNA Management Services, or an 8-byte type 1134 EBCDIC installation-defined name. If the focal point is being revoked, this field should be set to all zeros.

#### description

Resource description (returned on QUERY\_FOCAL\_POINT). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# backup

Specifies whether a backup focal point is being defined (AP\_YES or AP\_NO). This field is reserved if the currently active focal point is being revoked. It is recommended that the DELETE\_FOCAL\_POINT verb (specifying AP\_ACTIVE) be used to revoke the currently active focal point.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_INVALID\_FP\_NAME

#### AP\_INVALID\_CATEGORY\_NAME

If the verb does not execute successfully, the Program returns the following parameters:

# primary\_rc

AP\_REPLACED

AP\_UNSUCCESSFUL

#### secondary\_rc

AP\_IMPLICIT\_REQUEST\_REJECTED

AP\_IMPLICIT\_REQUEST\_FAILED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

The Program returns the following parameter if the verb does not execute because of a system error or because the Program failed to contact the focal point successfully: primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_INTERNAL\_PU

The DEFINE\_INTERNAL\_PU verb defines a DLUR-served local PU. This verb is not used to define a local PU which is directly attached to the host. See "DEFINE\_LS" on page 74 for this purpose.

Note: The DEFINE\_LS verb should be used to define the following:

- A downstream PU served by:
  - DLUR
  - PU concentration
- A local PU that is directly attached to the host

# VCB Structure

typedef struct define\_internal\_pu

```
unsigned short opcode;

                                                                    */
} INTERNAL PU DEF DATA;
```

# Supplied Parameters

The application supplies the following parameters:

```
opcode
```

AP\_DEFINE\_INTERNAL\_PU

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### pu\_name

Name of the internal PU that is being defined. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## def\_data.description

Resource description (returned on QUERY\_DLUR\_PU and QUERY\_PU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## def\_data.dlus\_name

Name of the DLUS node that DLUR will use when it initiates SSCP-PU activation. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the field is set to all zeros, the global default DLUS (if it has been defined, using the DEFINE\_DLUR\_DEFAULTS verb) is used in DLUR-initiated SSCP-PU activation.

# def\_data.bkup\_dlus\_name

Name of the DLUS node that will serve as the backup DLUS for this PU. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the field is set to all zeros, the global backup default DLUS (if it has been defined by the DEFINE\_DLUR\_DEFAULTS verb) is used as the backup for this PU.

#### def\_data.pu\_id

PU identifier. This a 4-byte hexadecimal string. Bits 0–11 are set to the Block number and bits 12–31 to the ID number that uniquely identifies the PU. This must match the **pu\_id** configured at the host.

#### def\_data.dlus\_retry\_timeout

Interval in seconds between second and subsequent attempts to contact the DLUS specified in the **def\_data.dlus\_name** and **def\_data.bkup\_dlus\_name** fields. The interval between the initial attempt and the first retry is always one second. If zero is specified, the default value configured through DEFINE\_DLUR\_DEFAULTS is used. This field is ignored if **def\_data.dspu\_services** is not set to AP\_DLUR.

## def\_data.dlus\_retry\_limit

Maximum number of retries after an initial failure to contact the DLUS specified in the **def\_data.dlus\_name** and **def\_data.bkup\_dlus\_name** fields. If zero is specified, the default value configured through DEFINE\_DLUR\_DEFAULTS is used. If X'FFFF' is specified, the Program retries indefinitely. This field is ignored if **def\_data.dspu\_services** is not set to AP\_DLUR.

#### def\_data.conventional\_lu\_compression

Specifies whether data compression is requested for conventional LU sessions dependent on this PU.

# AP\_NO

The local node should not be compressing or decompressing data flowing on conventional LU sessions using this PU.

# AP\_YES

Data compression should be enabled for conventional LU sessions dependent on this PU if the host requests compression. If this value is set, but the node does not support compression (defined on the START\_NODE verb) then the INTERNAL\_PU is successfully defined but without compression support.

#### def\_data.conventional\_lu\_cryptography

Note: This function applies only to Communications Server.

Specifies whether session level encryption is required for conventional LU sessions dependent on this PU.

#### AP\_NONE

The local node should not be compressing or decompressing data flowing on conventional LU sessions using this PU.

# **AP\_MANDATORY**

Mandatory session level encryption is performed by APPN if an import key is available to the LU. Otherwise, it must be performed by the application that uses the LU (if this is PU Concentration, then it is performed by a downstream LU).

#### AP\_OPTIONAL

This value allows the cryptography used to be driven by the host application on a per session basis. If the host request cryptography for a session is dependent on this PU, then the behaviour of the Program is the same for AP\_MANDATORY. If the host does not request cryptography, then the behaviour is the same as AP\_NONE.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_PU\_ID AP\_INVALID\_DLUS\_NAME AP\_INVALID\_BKUP\_DLUS\_NAME AP\_INVALID\_CLU\_CRYPTOGRAPHY

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK

# secondary\_rc

AP\_PU\_ALREADY\_DEFINED

# AP\_CANT\_MODIFY\_VISIBILITY

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_LOCAL\_LU

The DEFINE\_LOCAL\_LU verb requests the definition of a local LU with the specified characteristics, or, if the LU already exists, the modification of the **attach\_routing\_data** characteristic of the LU. Note that if a DEFINE\_LOCAL\_LU is used to modify an existing definition then any parameter other than the **attach\_routing\_data** field will be ignored.

} LOCAL_LU_DEF_DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_LOCAL\_LU

#### format

Identifies the format of the VCB. Set this field to zero or one to specify either format 0 or format 1 of the VCB listed above.

#### lu\_name

Name of the local LU that is being defined. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### def\_data.description

Resource description (returned on QUERY\_LOCAL\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### def\_data.lu\_alias

Alias of the local LU to define. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

#### def\_data.nau\_address

Network addressable unit address of the LU, which must be in the range 0–255. A nonzero value implies the LU is a dependent LU. Zero implies the LU is an independent LU.

#### def\_data.syncpt\_support

This field should always be set to AP\_NO unless a sync point manager is available for this LU.

#### def\_data.lu\_session\_limit

Maximum number of sessions supported by the LU. Zero means no limit. If the LU is independent then this can be set to any value. If the LU is dependent then this must be set to 1.

#### def\_data.default\_pool

Set to AP\_YES if the LU is a member of the dependent LU 6.2 default pool, or if it is to be used as the default Local LU for independent LU 6.2 sessions.

#### def\_data.pu\_name

Name of the PU that this LU will use. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is only used by dependent LUs, and should be set to all binary zeros for independent LUs.

# def\_data.lu\_attributes

Specifies further information about the LU. This field either takes the value AP\_NONE, or one or more following options ORed together.

#### AP\_DISABLE\_PWSUB

Disable password substitution support for the local LU.

#### def\_data.sscp\_id

This specifies the ID of the SSCP permitted to activate this LU. It is a 6-byte binary field. This field is only used by dependent LUs, and should be set to all binary zeros for independent LUs or if the LU may be activated by any SSCP.

#### def\_data.disable

Indicates whether the LOCAL LU should be disabled or enabled. The LU can be dynamically enabled or disabled by reissuing the DEFINE\_LOCAL\_LU with this parameter set as appropriate (AP\_YES or AP\_NO). When a disabled LU is enabled, the Program issues a NOTIFY (on-line). When an enabled LU is disabled, the Program issues a NOTIFY (off-line). If the LU is bound when it is disabled, then the Program issues an UNBIND followed by a NOTIFY (off-line).

#### def\_data.attach\_routing\_data

Type of attach routing data.

# AP\_REGISTERED\_OR\_DEFAULT\_ATTACH\_MGR

Specifies that a DYNAMIC\_LOAD\_INDICATION resulting from an attach arriving for the transaction program (TP) at this local LU is sent to the attach manager that has registered to receive DLIs for this LU, or to the default attach manager if no attach manager has registered for this LU.

#### AP\_REGISTERED\_ATTACH\_MGR\_ONLY

Specifies that a DYNAMIC\_LOAD\_INDICATION resulting from an attach arriving for the transaction program (TP) at this local LU is sent only to the attach manager that has registered to receive DLIs for this LU. If no attach manager has registered for this LU, the attach is rejected.

# def\_data.lu\_model

Model type and number of the LU. This field is only used by dependent LUs and should be set to AP\_UNKNOWN for independent LUs. For dependent LUs, this is set to one of the following values:

AP\_3270\_DISPLAY\_MODEL\_2 AP\_3270\_DISPLAY\_MODEL\_3 AP\_3270\_DISPLAY\_MODEL\_4 AP\_3270\_DISPLAY\_MODEL\_5 AP\_RJE\_WKSTN AP\_PRINTER AP\_SCS\_PRINTER AP\_UNKNOWN

For dependent LUs, if **model\_name** is not set to all binary zeros, then this field is ignored. If a value other than AP\_UNKNOWN is specified and the host system supports SDDLU (Self-Defining Dependent LU), the node will generate an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. The PSID subvector will contain the machine type and model number corresponding to the value of this field. This field may

be changed dynamically by reissuing the verb. Changes will not come into effect until after the LU is closed and deactivated.

#### def\_data.model\_name

Model name of the LU. This field is only used by dependent LUs and should be set to binary zeros for independent LUs. APPN checks that this field consists of the EBCDIC characters A–Z, 0–9 and @, #, and \$.

If this field is not set to binary zeros and the host system supports SDDLU, the node generates an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. The PSID subvector contains the name supplied in this field. The **def\_data.model\_name** can be changed dynamically by reissuing the verb. Changes will not come into effect until after the LU is closed and deactivated.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_LU\_MODEL

AP\_INVALID\_LU\_NAME AP\_INVALID\_NAU\_ADDRESS AP\_INVALID\_SESSION\_LIMIT AP\_INVALID\_DISABLE

If the verb does not execute because of a state error, the Program returns the following parameters:

# primary\_rc

AP\_STATE\_CHECK

## secondary\_rc

AP\_PU\_NOT\_DEFINED

AP\_INVALID\_LU\_NAME AP\_LU\_ALREADY\_DEFINED AP\_ALLOCATE\_NOT\_PENDING AP\_LU\_ALIAS\_ALREADY\_USED AP\_PLU\_ALIAS\_ALREADY\_USED AP\_PLU\_ALIAS\_CANT\_BE\_CHANGED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

primary\_rc AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameters:

primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

secondary\_rc

AP\_MEMORY\_SHORTAGE

# DEFINE\_LS

DEFINE\_LS is used to define a new link station (LS) or modify an existing one. This verb provides the LS name, which is unique throughout the node, and the name of the port this LS should use. This port must already have been defined using a DEFINE\_PORT verb. Link-specific data is concatenated to the basic structure. DEFINE\_LS can only be used to modify one or more fields of an existing link station if the link station is in a reset state (after a STOP\_LS has been issued), and the **port\_name** specified on the DEFINE\_LS has not changed since the previous definition of the LS.

See "DLC Processes, Ports, and Link Stations" on page 14 for more information about the relationship between DLCs, ports, and link stations.

The setting of a large number of the fields in LS\_DEF\_DATA depends on the value of the **adj\_cp\_type** field. There are eight values that **adj\_cp\_type** can take (which are described further in "def\_data.adj\_cp\_type" on page 78), four of which are used for links to adjacent Type 2.1 (APPN) nodes:

- AP\_NETWORK\_NODE
- AP\_END\_NODE
- AP\_APPN\_NODE
- AP\_BACK\_LEVEL\_LEN\_NODE

and four of which are used for links carrying PU Type 2.0 traffic only:

- AP\_HOST\_XID3
- AP\_HOST\_XID0
- AP\_DSPU\_XID
- AP\_DSPU\_NOXID.

There are four types of APPN nodes, which are distinguished as follows

- An APPN network node includes the Network Name Control Vector (CV) in its XID3, supports parallel TGs, sets the networking capabilities bit in its XID3, and can support CP-CP sessions on a link.
- An APPN end node includes the Network Name CV in its XID3, supports parallel TGs, does not set the networking capabilities bit in its XID3, and can support CP-CP sessions on a link.
- An up-level node includes the Network Name CV in its XID3, can support parallel TGs, does not set the networking capabilities bit in its XID3, and does not support CP-CP sessions.
- A back-level node does not include the Network Name CV in its XID3, does not support parallel TGs, does not set the networking capabilities bit in its XID3, and does not support CP-CP sessions.

The following fields must be set for all links:

port\_name adj\_cp\_type dest\_address auto\_act\_supp disable\_remote\_act limited\_resource link\_deact\_timer ls\_attributes adj\_node\_id local\_node\_id target\_pacing\_count max\_send\_btu\_size link\_spec\_data\_len ls\_role

Other fields must be set as follows:

- If adj\_cp\_type is set to AP\_NETWORK\_NODE, AP\_END\_NODE, or
  - AP\_APPN\_NODE the following fields must be set: adj\_cp\_name tg\_number solicit\_sscp\_sessions dspu\_services hpr\_supported hpr\_link\_lvl\_error default\_nn\_server cp\_cp\_sess\_support use\_default\_tg\_chars tg\_chars
- If **adj\_cp\_type** is set to AP\_BACK\_LEVEL\_LEN\_NODE the following fields must be set:
  - adj\_cp\_name solicit\_sscp\_sessions dspu\_services use\_default\_tg\_chars tg\_chars
- If a local PU is to use the link (**adj\_cp\_type** is set to AP\_HOST\_XID3 or AP\_HOST\_XID0, or **solicit\_sscp\_sessions** is set to AP\_YES on a link to an APPN node) the following field must be set:

pu\_name

• If a downstream PU is to use the link and will be served by PU Concentration (**dspu\_services** is set to AP\_PU\_CONCENTRATION) the following field must be set:

dspu\_name

 If a downstream PU is to use the link and will be served by DLUR (dspu\_services is set to AP\_DLUR) the following fields must be set: dspu\_name dlus\_name bkup\_dlus\_name

# **VCB** Structure

```

                         user_def_parm_1;
                                               /* user-defined parameter 1
                                                                                    */
                         user_def_parm_1;
user_def_parm_2;
user_def_parm_3;
        unsigned char
                                              /* user-defined parameter 2
                                                                                    */
        unsigned char
                                               /* user-defined parameter 3
                                                                                    */
} TG DEFINED_CHARS;
typedef struct link address
        unsigned short length;
                                               /* length
                                                                                    */
                                               /* reserved
        unsigned short reservel;
                                                                                    */
        unsigned char address[MAX LINK ADDR LEN];
                                               /* address
                                                                                    */
} LINK ADDRESS;
typedef struct link spec data
       unsigned char link_data[SIZEOF_LINK_SPEC_DATA];
```

```
} LINK SPEC DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_DEFINE\_LS

## attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP INTERNALLY VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### ls\_name

Name of link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

Setting the field **ls\_name** to the special value "\$ANYNET\$" (an ASCII string) has the effect of informing the Node Operator Facility that this is the link station to which independent LU session traffic that is to be routed by the AnyNet DLC should be sent. A link station of this name must be defined on a port over the AnyNet DLC if AnyNet routing is required.

# def\_data.description

Resource description (returned on QUERY\_LS, QUERY\_PU ). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# def\_data.port\_name

Name of port associated with this link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. This named port must have already been defined by a DEFINE\_PORT verb.

# def\_data.adj\_cp\_name

Fully qualified 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. For links to APPN nodes it can be set to all zeros unless the field **tg\_number** is set to a number in the range one to 20 or the field **adj\_cp\_type** is set to

AP\_BACK\_LEVEL\_LEN\_NODE. If it is set to all zeros, it is not checked against the name received from the adjacent node during XID exchange.If it is not set to all zeros, it is checked against the name received from the adjacent node during XID exchange unless **adj\_cp\_type** is set to AP\_BACK\_LEVEL\_LEN\_NODE (in which case it is used to identify the adjacent node).

# def\_data.adj\_cp\_type

Adjacent node type.

## AP\_NETWORK\_NODE

Specifies that the node is an APPN network node.

## AP\_END\_NODE

Specifies that the node is an APPN end node or an up-level node.

#### AP\_APPN\_NODE

Specifies that the node is an APPN network node, an APPN end node, or an up-level node. The node type will be learned during XID exchange.

# AP\_BACK\_LEVEL\_LEN\_NODE

Specifies that the node is a back\_level\_len node; that is, it does not send the control point name in the XID. For a link using the AnyNet DLC supporting independent LU sessions, you must specify AP\_BACK\_LEVEL\_LEN\_NODE.

# AP\_HOST\_XID3

Specifies that the node is a host and that Personal Communications or Communications Server responds to a polling XID from the node with a format 3 XID.

# AP\_HOST\_XID0

Specifies that the node is a host and that Personal Communications or Communications Server responds to a polling XID from the node with a format 0 XID. For a link using the AnyNet DLC supporting dependent LU sessions, you must specify AP\_HOST\_XID0.

# AP\_DSPU\_XID

Specifies that the node is a downstream PU and that Personal Communications or Communications Server includes XID exchange in link activation.

# AP\_DSPU\_NOXID

Specifies that the node is a downstream PU and that Personal Communications or Communications Server does not include XID exchange in link activation.

**Note:** A link station to a VRN is always dynamic and is therefore not defined.

#### def\_data.dest\_address.length

Length of destination link station's address on adjacent node.

If **def\_data.dest\_address.length** is set to zero and this LS is associated with a port of type SATF, then the Program considers this link station to be a

wild card link station. This will cause the Program to match LS to any incoming connection that is not matched by another defined link station.

#### def\_data.dest\_address.address

Link station's destination address on adjacent node. For a link using the AnyNet DLC, the <b>dest\_address</b> specifies the adjacent node ID or adjacent control point name. If an adjacent node ID is specified, the length must be 4 and the address must contain the 4-byte hexadecimal node ID (1-byte block ID, 3-byte PU ID). If an adjacent control point name is specified, the length must be 17 and the address must contain the control point name in EBCDIC, padded with EBCDIC blanks.

#### def\_data.auto\_act\_supp

Specifies whether the link can be activated automatically when required by a session. (AP\_YES or AP\_NO). If the link is not to an APPN node then this field can always be set to AP\_YES and has no requirements on other parameters. If the link is to an APPN node, then this field cannot be set to AP\_YES if the link also supports CP-CP sessions; and can only be set to AP\_YES if a preassigned TG number is also defined for the link **tg\_number** and is set to a value between one and 20). These requirements will always be met if **adj\_cp\_type** is set to AP\_BACK\_LEVEL\_LEN\_NODE because **cp\_cp\_sess\_support** and **tg\_number** are ignored in this case).

## def\_data.tg\_number

Preassigned TG number. This field is only relevant if the link is to an adjacent APPN node and is otherwise ignored. If **adj\_cp\_type** is set to AP\_BACK\_LEVEL\_LEN\_NODE then it is also ignored and is assumed to be set to one. For links to adjacent APPN nodes this must be set in the range one to 20. This number is used to represent the link when the link is activated. Personal Communications or Communications Server will not accept any other number from the adjacent node during activation of this link. To avoid link-activation failure because of a mismatch of preassigned TG numbers, the same TG number must be defined by the adjacent node on the adjacent link station (if using preassigned TG numbers). If a preassigned TG number is defined then the **adj\_cp\_name** must also be defined (and cannot be set to all zeros) and the **adj\_cp\_type** must be set to AP\_NETWORK\_NODE or AP\_END\_NODE. If zero is entered the TG number is not preassigned and is negotiated when the link is activated.

# def\_data.limited\_resource

Specifies whether this link station is to be deactivated when there are no sessions using the link. This is set to one of the following values:

#### AP\_NO

The link is not a limited resource and will not be deactivated automatically.

# AP\_YES or AP\_NO\_SESSIONS

The link is a limited resource and will be deactivated automatically when no active sessions are using it. A limited resource link station can be configured for CP-CP session support. (This is done by setting this field to AP\_YES and **cp\_cp\_sess\_support** to AP\_YES.) In this case, if CP-CP sessions are brought up over the link, Personal Communications or Communications Server will not treat the link as a limited resource (and will not bring the link down).

## **AP\_INACTIVITY**

The link is a limited resource and will be deactivated automatically when no active sessions are using it, or when no data has flowed on the link for the time period specified by the **link\_deact\_timer** field. Note that link stations on a nonswitched port cannot be configured as limited resource.

Note that link stations on a nonswitched port cannot be configured as limited resource.

A limited resource link station may be configured for CP-CP session support. (This is done by setting this field to AP\_YES and **cp\_cp\_sess\_support** to AP\_YES.) In this case, if CP-CP sessions are brought up over the link, Personal Communications or Communications Server will not retreat the link as a limited resource (and will not bring the link down). Note, this does not apply if this field is set to AP\_INACTIVITY.

## def\_data.solicit\_sscp\_sessions

AP\_YES requests the adjacent node to initiate sessions between the SSCP and the local control point and dependent LUs. (In this case the **pu\_name** must be set.) AP\_NO requests no sessions with the SSCP on this link. This field is only relevant if the link is to an APPN node and is otherwise ignored. If the adjacent node is defined to be a host (**adj\_cp\_type** is set to AP\_HOST\_XID3 or AP\_HOST\_XID0), then Personal Communications or Communications Server always requests the host to initiate sessions between the SSCP and the local control point and dependent LUs (and again the **pu\_name** must be set).

This field can only be set to AP\_YES on a link to an adjacent APPN node if **dspu\_services** is set to AP\_NONE. If this field is set to AP\_YES and the DCL used by this LS is defined as hpr\_only, then the DEFINE\_LS is rejected with a parameter check and secondary return code of AP\_INVALID\_SOLICIT\_SSCP\_SESS.

# def\_data.pu\_name

Name of local PU that will use this link if the adjacent node is defined to be a host or **solicit\_sscp\_sessions** is set to AP\_YES on a link to an APPN node. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If the adjacent node is not defined to be a host, and is not defined as an APPN node with **solicit\_sscp\_sessions** set to AP\_YES, this field is ignored.

#### def\_data.disable\_remote\_act

Specifies whether remote activation of this link is supported (AP\_YES or AP\_NO).

#### def\_data.dspu\_services

Specifies the services that the local node provides to the downstream PU across this link. This is set to one of the following:

## AP\_PU\_CONCENTRATION

Local node will provide PU concentration for the downstream PU.

#### AP\_DLUR

Local node will provide DLUR services for the downstream PU. This setting is only valid if the local node is a Network Node.

# AP\_NONE

Local node will provide no services for this downstream PU.

The **dspu\_name** must also be set if this field is set to AP\_PU\_CONCENTRATION or AP\_DLUR.

This field must be set to AP\_PU\_CONCENTRATION or AP\_DLUR if the adjacent node is defined as a downstream PU (that is,

**adj\_cp\_type** is set to AP\_DSPU\_XID or AP\_DSPU\_NOXID). It can be set to AP\_PU\_CONCENTRATION or AP\_DLUR on a link to an APPN node if **solicit\_sscp\_sessions** is set to AP\_NO. This field is ignored if the adjacent node is defined as a host.

If this field is not set to AP\_NONE and the DLC used by this LS is defined as hpr\_only, then the DEFINE\_LS is rejected with a parameter check and secondary return code of SP\_INVALID\_DSPU\_SERVICES.

## def\_data.dspu\_name

Name of the downstream PU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

This field must be set if **dspu\_services** is set to AP\_PU\_CONCENTRATION or AP\_DLUR and is otherwise ignored.

# def\_data.dlus\_name

Name of DLUS node which DLUR solicits SSCP services from when the link to the downstream node is activated. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the field is set to all zeros, then the global default DLUS (if it has been defined using the DEFINE\_DLUR\_DEFAULTS verb) is solicited when the link is activated. If the **dlus\_name** is set to zeros and there is no global default DLUS, then DLUR will not initiate SSCP contact when the link is activated. This field is ignored if **dspu\_services** is not set to AP\_DLUR.

# def\_data.bkup\_dlus\_name

Name of DLUS node which serves as the backup for the downstream PU. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the field is set to all zeros, then the global backup default DLUS (if it has been defined by the DEFINE\_DLUR\_DEFAULTS verb) is used as the backup for this PU. This field is ignored if **dspu\_services** is not set to AP\_DLUR.

# def\_data.hpr\_supported

Specifies whether HPR is supported on this link (AP\_YES or AP\_NO). This field is only relevant if the link is to an APPN node and is otherwise ignored. If it is not, setting this field to AP\_YES results in the verb being rejected with a parameter check and a secondary return code of INVALID\_NODE\_TYPE\_FOR\_HPR.

# def\_data.hpr\_link\_lvl\_error

Specifies whether HPR traffic should be sent on this link using link-level error recovery (AP\_YES or AP\_NO). This parameter is ignored if **hpr\_supported** is set to AP\_NO.

# def\_data.link\_deact\_timer

Limited resource link deactivation timer (in seconds).

If **limited\_resource** is set to AP\_INACTIVITY, then a link is automatically deactivated if no data traverses the link for the duration of this timer.

If zero is specified, the default value of 30 is used. Otherwise, the minimum value is 5. (If it is set any lower, the specified value will be ignored and 5 will be used.) This parameter is reserved if **limited\_resource** is set to AP\_NO.

#### def\_data.default\_nn\_server

Specifies whether a link can be automatically activated by an end node to support CP-CP sessions to a network node server. (AP\_YES or AP\_NO). Note that the link must be defined to support CP-CP sessions for this field to take effect.

#### def\_data.ls\_attributes

Specifies further information about the adjacent node.

## def\_data.ls\_attributes[0]

Host type.

#### AP\_SNA

Standard SNA host.

# AP\_FNA

FNA (VTAM-F) host.

#### AP\_HNA

HNA host.

#### def\_data.ls\_attributes[1]

This is a bit field. It may take the value AP\_NO, or any of the following values bit-wise ORed together.

# AP\_SUPPRESS\_CP\_NAME

Network Name CV suppression option for a link to a back-level LEN node. If this bit is set, no Network Name CV is included in XID exchanges with the adjacent node. (This bit is ignored unless **adj\_cp\_type** is set to AP\_BACK\_LEVEL\_LEN\_NODE or AP\_HOST\_XID3.)

# AP\_REACTIVATE\_ON\_FAILURE

If the link is active and then fails, Personal Communications or Communications Server will attempt to reactivate the link. If the reactivation attempt fails, the link will remain inactive.

## AP\_USE\_PU\_NAME\_IN\_XID\_CVS

If the adjacent node is defined to be a host or **solicit\_sscp\_sessions** is set to AP\_YES on a link to an APPN node, and the AP\_SUPPRESS\_CP\_NAME bit is not set, then the fully qualified CP name in Network Name CVs sent on Format 3 XIDs is replaced by the name supplied in **def\_data.pu\_name**, fully qualified with the network ID of the CP.

#### def\_data.adj\_node\_id

Node ID of adjacent node. This a 4-byte hexadecimal string. If **adj\_cp\_type** indicates the adjacent node is a T2.1 node, this field is ignored unless it is nonzero, and either the **adj\_cp\_type** is set to

AP\_BACK\_LEVEL\_LEN\_NODE or the adjacent node does not send a Network Name CV in its XID3. If **adj\_cp\_type** is set to AP\_HOST\_XID3 or AP\_HOST\_XID0, this field is always ignored. If **adj\_cp\_type** is set to AP\_DSPU\_XID and this field is nonzero, it is used to check the identity of the downstream PU. If **adj\_cp\_type** is set to AP\_DSPU\_NOXID, this field is either ignored (if **dspu\_services** is AP\_PU\_CONCENTRATION) or used to identify the downstream PU to DLUS (if **dspu\_services** is AP\_DLUR).

# def\_data.local\_node\_id

Node ID sent in XIDs on this link station. This a 4-byte hexadecimal string. If this field is set to zero, the **node\_id** will be used in XID exchanges. If this field is nonzero, it replaces the value for XID exchanges on this LS.

#### def\_data.cp\_cp\_sess\_support

Specifies whether CP-CP sessions are supported (AP\_YES or AP\_NO). This field is only relevant if the link is to an APPN node and is otherwise ignored. If **adj\_cp\_type** is set to AP\_BACK\_LEVEL\_LEN\_NODE then it is also ignored and is assumed to be set to AP\_NO.

#### def\_data.use\_default\_tg\_chars

Specifies whether the default TG characteristics supplied on the DEFINE\_PORT verb should be used (AP\_YES or AP\_NO). If this is set to AP\_YES then the **tg\_chars** field will be ignored. This field is only relevant if the link is to an APPN node and is otherwise ignored.

#### def\_data.tg\_chars

TG characteristics (See "DEFINE\_CN" on page 31). This field is only relevant if the link is to an APPN node and is otherwise ignored.

#### def\_data.target\_pacing\_count

Numeric value between 1 and 32 767, inclusive, indicating the desired pacing window size for BINDs on this TG. The number is only significant when fixed bind pacing is being performed. Personal Communications or Communications Server does not currently use this value.

#### def\_data.max\_send\_btu\_size

Maximum BTU size that can be sent from this link station. This value is used to negotiate the maximum BTU size than can be transmitted between a link station pair. If the link is not HPR-capable then this must be set to a value greater than or equal to 99. If the link is HPR-capable then this must be set to a value greater than or equal to 768.

#### def\_data.ls\_role

The link station role that this link station should assume. This can be any one of AP\_LS\_NEG, AP\_LS\_PRI or AP\_LS\_SEC to select a role of negotiable, primary or secondary. The field can also be set to AP\_USE\_PORT\_DEFAULTS to select the value configured on the DEFINE\_PORT verb. If the **dlc\_type** is AP\_TWINAX, then only AP\_LS\_SEC is supported. If **dlc\_type** is AP\_ANYNET (and **ls\_name** is "\$ANYNET\$"), then AP\_LS\_PRI is not supported.

#### def\_data.max\_ifrm\_rcvd

The maximum number of I-frames that can be received by the XID sender before acknowledgment.

#### Range: 0-127

If zero is specified, the value of **max\_ifrm\_rcvd** from DEFINE\_PORT is used as the default.

#### def\_data.dlus\_retry\_timeout

Interval in seconds between second and subsequent attempts to contact the DLUS specified in the **def\_data.dlus\_name** and **def\_data.bkup\_dlus\_name** fields. The interval between the initial attempt and the first retry is always one second. If zero is specified, the default value configured through DEFINE\_DLUR\_DEFAULTS is used. This field is ignored if **def\_data.dspu\_services** is not set to AP\_DLUR.

## def\_data.dlus\_retry\_limit

Maximum number of retries after an initial failure to contact the DLUS specified in the **def\_data.dlus\_name** and **def\_data.bkup\_dlus\_name** fields. If zero is specified, the default value configured through DEFINE\_DLUR\_DEFAULTS is used. If X'FFFF' is specified, APPN retries indefinitely. This field is ignored if **def\_data.dspu\_services** is not set to AP\_DLUR.

# def\_data.conventional\_lu\_compression

Specifies whether data compression is requested for conventional LU sessions dependent on this PU. Note that this field is only valid for links carrying LU 0 to 3 traffic.

# AP\_NO

The local node should not be compressing or decompressing data flowing on conventional LU sessions using this PU.

#### AP\_YES

Data compression should be enabled for conventional LU sessions dependent on this PU if the host requests compression. If this value is set, but the node does not support compression (defined on the START\_NODE verb) then the link station is successfully defined but without compression support.

## def\_data.conventional\_lu\_cryptography

Specifies whether session level encryption is required for conventional LU sessions. This field only applies to links carrying conventional LU traffic.

#### AP\_NONE

Session level encryption is not performed by the Program.

#### AP\_MANDATORY

Mandatory session level encryption is performed by the Program if an import key is available to the LU. Otherwise, it must be performed by the application that uses the LU (if this is PU Concentration, then it is performed by a downstream LU).

# AP\_OPTIONAL

This value allows the cryptography used to be driven by the host application on a per session basis. If the host requests cryptography for a session on this LS, then the behavior of the Program is the same as AP\_MANDATORY. If the host does not request cryptography, then the behaviour is as for AP\_NONE.

#### def\_data.retry\_flags

This field specifies the conditions under which activation of this link station is subject to automatic retry. It is a bit field, and may take any of the following values bit-wise ORed together.

#### AP\_RETRY\_ON\_START

Link activation will be retried if no response is received from the remote node when activation is attempted. If the underlying port is inactive when activation is attempted, the Program will attempt to activate it.

# AP\_RETRY\_ON\_FAILURE

Link activation will be retried if the link fails while active or pending active. If the underlying port has failed when activation is attempted, the Program attempts to activate it.

#### AP\_RETRY\_ON\_DISCONNECT

Link activation will be retried if the link is stopped normally by the remote node.

## AP\_DELAY\_APPLICATION\_RETRIES

Link activation retries, initiated by applications (using START\_LS or on-demand link activation) will be paced using the **activation\_delay\_timer**.

# AP\_INHERIT\_RETRY

In addition to the retry conditions specified by flags in this field, those specified in the **retry\_flags** field of the underlying port definition will also be used.

# def\_data.max\_activation\_attempts

This field has no effect unless at least one flag is set in retry\_flags.

This field specifies the number of retry attempts the Program allows when the remote node is not responding, or the underlying port is inactive. This includes both automatic retries and application-driven activation attempts.

If this limit is ever reached, no further attempts are made to automatically retry. This condition is reset by STOP\_LS, STOP\_PORT, STOP\_DLC or a successful activation. START\_LS or OPEN\_LU\_SSCP\_SEC\_RQ results in a single activation attempt, with no retry if activation fails.

Zero means no limit. The value AP\_USE\_DEFAULTS results in the use of **max\_activiation\_attempts** supplied on DEFINE\_PORT.

#### def\_data.activation\_delay\_timer

This field has no effect unless at least one flag is set in retry\_flags.

This field specifies the number of seconds that the Program waits between automatic retry attempts, and between application-driven activation attempts if the AP\_DELAY\_APPLICATION\_RETRIES bit is set in **def\_data.retry\_flags**.

The value AP\_USE\_DEFAULTS results in the use of **activiation\_delay\_timer** supplied on DEFINE\_PORT.

If zero is specified, the Program uses a default timer duration of thirty seconds.

#### def\_data.branch\_link\_type

BrNN only. This specifies whether a link is an uplink or a downlink. This field only applies if the **def\_data.adj\_cp\_type** is set to AP\_NETWORK\_NODE, AP\_END\_NODE, AP\_APPN\_NODE, or AP\_BACK\_LEVEL\_LEN\_NODE.

#### AP\_UPLINK

This link is an uplink.

#### **AP\_DOWNLINK**

The link is a downlink.

If the field **adj\_cp\_type** is set to AP\_NETWORK\_NODE, then this field must be set to AP\_UPLINK.

Other node types: This field is ignored.

# def\_data.adj\_brnn\_cp\_support

BrNN only. This specifies whether the adjacent CP is allowable, is a requirement, or prohibited from being an NN(BrNN); for example, a BrNN showing an NN face. This field only applies if the field **adj\_cp\_type** is set

to AP\_NETWORK\_NODE or AP\_APPN\_NODE (and the node type learned during XID exchange is network node).

# AP\_BRNN\_ALLOWED

The adjacent CP is allowed (but not required) to be an NN(BrNN).

#### The adjacent er

AP\_BRNN\_REQUIRED The adjacent CP is required to be an NN(BrNN).

## AP\_BRNN\_PROHIBITED

The adjacent CP is not allowed to be an NN(BrNN).

If the field **adj\_cp\_type** is set to AP\_NETWORK\_NODE and the field **auto\_act\_supp** is set to AP\_YES, then this field must be set to AP\_BRNN\_REQUIRED or AP\_BRNN\_PROHIBITED.

Other node types: This field is ignored.

#### def\_data.link\_spec\_data\_len

This field should always be set to zero.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_DEF\_LINK\_INVALID\_SECURITY

AP\_INVALID\_CP\_NAME AP\_INVALID\_LIMITED\_RESOURCE AP\_INVALID\_LINK\_NAME AP\_INVALID\_LS\_ROLE AP\_INVALID\_NODE\_TYPE AP\_INVALID\_PORT\_NAME AP\_INVALID\_AUTO\_ACT\_SUPP AP\_INVALID\_PU\_NAME AP\_INVALID\_SOLICIT\_SSCP\_SESS AP\_INVALID\_DLUS\_NAME AP\_INVALID\_BKUP\_DLUS\_NAME AP\_INVALID\_NODE\_TYPE\_FOR\_HPR AP INVALID TARGET PACING COUNT AP\_INVALID\_BTU\_SIZE AP HPR NOT SUPPORTED AP\_INVALID\_TG\_NUMBER AP\_MISSING\_CP\_NAME AP MISSING CP TYPE AP MISSING TG NUMBER AP\_PARALLEL\_TGS\_NOT\_SUPPORTED AP\_INVALID\_DLUS\_RETRY\_TIMEOUT AP\_INVALID\_DLUS\_RETRY\_LIMIT AP INVALID CLU CRYPTOGRAPHY AP\_INVALID\_RETRY\_FLAGS

AP\_BRNN\_SUPPORT\_MISSING AP\_INVALID\_BRANCH\_LINK\_TYPE AP\_INVALID\_BRNN\_SUPPORT

If the verb does not execute because of a state error, the Program returns the following parameters:

# primary\_rc

AP\_STATE\_CHECK

secondary\_rc

AP\_LOCAL\_CP\_NAME

AP\_DEPENDENT\_LU\_SUPPORTED AP\_DUPLICATE\_DEST\_ADDR AP\_INVALID\_NUM\_LS\_SPECIFIED AP\_LS\_ACTIVE AP\_PU\_ALREADY\_DEFINED AP\_DSPU\_SERVICES\_NOT\_SUPPORTED AP\_DUPLICATE\_TG\_NUMBER AP\_TG\_NUMBER\_IN\_USE AP\_CANT\_MODIFY\_VISIBILITY AP\_INVALID\_UPLINK AP\_INVALID\_DPWNLINK

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE LU 0 TO 3

This verb defines an LU of type 0, 1, 2 or 3. It allows the LU to be added to an LU pool. If the pool does not already exist, it is added. This verb cannot be used to modify the lu\_model, model\_name, priority, description, and appc\_spec\_def\_data of an existing definition, but no other fields may be modified.

Personal Communications or Communications Server supports implicit LU type 0, 1, 2 or 3 definition by ACTLU. Implicit definitions cannot be deleted, but are removed when the LU becomes inactive. To obtain information about implicit definitions, use QUERY\_LU\_0\_TO\_3 or register for LU\_0\_TO\_3\_INDICATIONs. An implicit LU definition can be redefined using DEFINE\_LU\_0\_TO\_3, provided lu name, pu name, and nau address are correct, and pool name is all zeros (the LU is then treated as if it had been configured by the operator in the first place).

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DEFINE\_LU\_0\_TO\_3

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero or one to specify one of the versions of the VCB listed above.

#### lu\_name

Name of the local LU that is being defined. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## def\_data.description

Resource description (returned on QUERY\_LU\_0\_TO\_3). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### def\_data.nau\_address

Network addressable unit address of the LU, which must be in the range 1–255.

#### def\_data.pool\_name

Name of LU pool to which this LU belongs. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If the LU does not belong to a pool, this field is set to all binary zeros. If the pool does not currently exist, it is created.

#### def\_data.pu\_name

Name of the PU (as specified on the DEFINE\_LS verb) that this LU will use. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### def\_data.priority

LU priority when sending to the host. This is set to one of the following values:

AP\_NETWORK AP\_HIGH AP\_MEDIUM AP\_LOW

## def\_data.lu\_model

Model type and number of the LU. This is set to one of the following values:

AP\_3270\_DISPLAY\_MODEL\_2 AP\_3270\_DISPLAY\_MODEL\_3 AP\_3270\_DISPLAY\_MODEL\_4 AP\_3270\_DISPLAY\_MODEL\_5 AP\_RJE\_WKSTN AP\_PRINTER AP\_SCS\_PRINTER AP\_UNKNOWN

Format 1 only, if **model\_name** is not set to all binary zeros, then this field is ignored.

If a value other than AP\_UNKNOWN is specified and the host system supports DDDLU (Dynamic Definition of Dependent LUs), the node will generate an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. For format 1 only, the PSID subvector contains the machine type and model number corresponding to the value of this field. This field may be changed dynamically by reissuing the verb. Changes will not come into effect until the LU is next closed and deactivated.

#### def\_data.sscp\_id

This field specifies the ID of the SSCP permitted to activate this LU. It is a 6-byte binary field. If the field is set to binary zeros, then the LU may be activated by any SSCP.

#### def\_data.timeout

Timeout for LU specified in seconds. If a timeout is supplied and the user of the LU specified **allow\_timeout** on the OPEN\_LU\_SSCP\_SEC\_RQ (or, in the case of PU concentration, on the Downstream LU definition), then the LU will be deactivated after the PLU-SLU session is left inactive for this period and one of the following conditions holds:

- The session passes over a limited resource link
- Another application wishes to use the LU before the session is used again

If the timeout is set to zero, the LU will not be deactivated.

#### def\_data.app\_spec\_def\_data

Application specified defined data. This field is not interpreted by Personal Communications or Communications Server, but is stored and subsequently returned on the QUERY\_LU\_0\_TO\_3 verb.

#### def\_data.model\_name

Personal Communications or Communications Server checks that this field consists of the EBCDIC characters A–Z, 0–9 and @, #, and \$. If this field is not set to all binary zeros and the host system supports DDDLU (Dynamic Definition of Dependent LUs), the node will generate an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. The PSID subvector will contain the name supplied in this field. This field may be changed dynamically by reissuing the verb. Changes will not come into effect until the LU is closed and deactivated.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_LU\_NAME

AP\_INVALID\_PU\_NAME AP\_INVALID\_PU\_TYPE AP\_PU\_NOT\_DEFINED AP\_LU\_ALREADY\_DEFINED AP\_LU\_NAU\_ADDR\_ALREADY\_DEFD AP\_CANT\_MODIFY\_VISIBILITY

If the verb does not execute because of a state error, the Program returns the following parameters:

#### primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_PU\_TYPE AP\_PU\_NOT\_DEFINED AP\_LU\_NAME\_POOL\_NAME\_CLASH AP\_LU\_ALREADY\_DEFINED AP\_LU\_NAU\_ADDR\_ALREADY\_DEFD

If the verb does not execute because the system has not been built with Dependent LU support, the Program returns the following parameter:

#### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE LU 0 TO 3 RANGE

This verb allows the definition of multiple LUs within a specified NAU range. The node operator provides a base name and an NAU range. The LU names are generated by combining the base name with the NAU addresses. This verb cannot be used to modify existing definitions.

For example, a base name of LUNME combined with an NAU range of 1 to 4 would define the LUs LUNME001, LUNME002, LUNME003, and LUNME004. A base name of less than five non-pad characters results in LU names of less than eight non-pad characters. Personal Communications or Communications Server then right-pads these to eight characters.

```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_LU\_0\_TO\_3\_RANGE

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero or one to specify one of the versions of the VCB listed above.

#### base\_name

Base LU name. This is an 5-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This base name is appended with three type-A EBCDIC numeric characters, representing the decimal value of the NAU address, for each LU in the NAU range.

This is the field with no bits set in the field **name\_attributes**. Setting bits changes the meaning of this field.

# description

Resource description (returned on QUERY\_LU\_0\_TO\_3). The length of this field should be a multiple of four bytes, and not zero.

#### min\_nau

Minimum NAU address in the range. This can be from 1 to 255 inclusive.

#### max\_nau

Maximum NAU address in the range. This can be from 1 to 255 inclusive.

#### pool\_name

Name of LU pool to which this LU belongs. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If the LU does not belong to a pool, this field is set to all binary zeros.

#### pu\_name

Name of the PU (as specified on the DEFINE\_LS verb) that this LU uses. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## priority

LU priority when sending to the host. This is set to one of the following values:

AP\_NETWORK AP\_HIGH AP\_MEDIUM AP\_LOW

#### lu\_model

Model type and number of the LU. This is set to one of the following values:

AP\_3270\_DISPLAY\_MODEL\_2 AP\_3270\_DISPLAY\_MODEL\_3 AP\_3270\_DISPLAY\_MODEL\_4 AP\_3270\_DISPLAY\_MODEL\_5 AP\_RJE\_WKSTN AP\_PRINTER AP\_SCS\_PRINTER AP\_UNKNOWN

Format 1 only, if **model\_name** is not set to all binary zeros, then this field is ignored.

If a value other than AP\_UNKNOWN is specified and the host system supports DDDLU (Dynamic Definition of Dependent LUs), the node will generate an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. For format 1 only, the PSID subvector contains the machine type and model number corresponding to the value of this field. This field may be changed dynamically by reissuing the verb. Changes will not come into effect until the LU is next closed and deactivated.

#### sscp\_id

This field specifies the ID of the SSCP permitted to activate this LU. It is a 6-byte binary field. If the field is set to binary zeros, then the LU may be activated by any SSCP.

#### timeout

Timeout for LU specified in seconds. If a timeout is supplied and the user of the LU specified **allow\_timeout** on the OPEN\_LU\_SSCP\_SEC\_RQ (or, in the case of PU concentration, on the Downstream LU definition), then the LU will be deactivated after the PLU-SLU session is left inactive for this period and one of the following conditions holds:

- The session passes over a limited resource link
- Another application wishes to use the LU before the session is used again

If the timeout is set to zero, the LU will not be deactivated.

#### model\_name

Personal Communications or Communications Server checks that this field consists of the EBCDIC characters A–Z, 0–9 and @, #, and \$. If this field is not set to all binary zeros and the host system supports SDDLU (Self-Defining Dependent LU), the node will generate an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. The PSID subvector will contain the name supplied in this field.

#### name\_attributes

This bit field modifies the interpretation and usage of the supplied **base\_name**. This field may take the value of zero, or any or all of the following values bit-wise ORed together.

#### AP\_USE\_HEX\_IN\_NAME

If this bit is set, the interpretation of the **base\_name** is modified as follows:

This is an 6-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. The base name is appended with two EBCDIC characters, representing the hexadecimal value of the NAU address, for each LU in the NAU range.

## AP\_USE\_BASE\_NUMBER

If this bit is set, the interpretation **base\_name** is modified as follows:

This is an 5-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This base name is appended with three EBCDIC numeric characters, representing the decimal index of the LU in the range, starting with **base\_number** and ending with (**base\_name + max\_nau — min\_nau**).

#### base\_number

If the AP\_USE\_BASE\_NUMBER bit is not set in **name\_attributes**, this field is ignored. Otherwise, this field modifies the interpretation of **base\_name** described previously. Legal values are from zero to (255 – **max\_nau + min\_nau**).

#### app\_spec\_def\_data

Application specified defined data. This field is not interpreted by Personal Communications or Communications Server, but is stored and subsequently returned on the QUERY\_LU\_0\_TO\_3 verb (the same data is returned for each LU in the range).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_BASE\_NUMBER

AP\_INVALID\_LU\_MODEL AP\_INVALID\_LU\_NAME AP\_INVALID\_NAME\_ATTRIBUTES AP\_INVALID\_NAU\_ADDRESS AP\_INVALID\_PRIORITY

If the verb does not execute because of a state error, the Program returns the following parameters:

## primary\_rc AP\_STATE\_CHECK secondary\_rc AP\_PU\_NOT\_DEFINED

AP\_INVALID\_PU\_NAME AP\_INVALID\_PU\_TYPE AP\_LU\_NAME\_POOL\_NAME\_CLASH AP\_LU\_ALREADY\_DEFINED AP\_LU\_NAU\_ADDR\_ALREADY\_DEFD AP\_IMPLICIT\_LU\_DEFINED AP\_CANT\_MODIFY\_VISIBILITY

If the verb does not execute because the system has not been built with dependent LU support, the Program returns the following parameter:

#### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_LU\_POOL

This verb is used to define an LU pool or to add LUs to an existing pool. The LUs that are to be added must already have been defined using either a DEFINE\_LU\_0\_TO\_3 verb or a DEFINE\_LU\_0\_TO\_3\_RANGE verb. LUs can only belong to one LU pool at a time. If the specified LUs already belong to a pool, they are removed from the existing pool into the pool being defined. Up to 10 LUs can be added to a pool at a time, although there is no limit to the total number of LUs in a pool.

# VCB Structure

typedef struct define\_lu\_pool

l			
unsigned short	opcode;	<pre>/* verb operation code</pre>	*/
unsigned char	attributes;	/* verb attributes	*/
unsigned char	format;	/* format	*/
unsigned short	primary rc;	/* primary return code	*/
unsigned long	secondary rc;	/* secondary return code	*/
unsigned char	pool name[8];	/* LU pool name	*/
unsigned char	description[RD LEN];	<pre>/* resource description</pre>	*/
unsigned char	reserv3[4];	/* reserved	*/
unsigned short	num lus;	/* number of LUs to add	*/
unsigned char	lu names[10][8];	/* LU names	*/
<pre>} DEFINE_LU_POOL;</pre>	—		

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_DEFINE\_LU\_POOL

## attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP INTERNALLY VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### pool\_name

Name of pool to which these LUs belong. This name is an 8-byte string, padded to the right with spaces. This can be either an EBCDIC string or a string in a locally displayable character set.

## description

Resource description (returned on QUERY\_LU\_POOL). The length of this field should be a multiple of four bytes, and not zero.

### num\_lus

Number of LUs to add, in the range 0–10.

#### lu\_names

Names of the LUs that are being added to the pool. Each name is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_LU\_NAME

AP\_INVALID\_NUM\_LUS AP\_INVALID\_POOL\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

#### primary\_rc

AP\_STATE\_CHECK

```
secondary_rc
```

AP\_LU\_NAME\_POOL\_NAME\_CLASH

AP\_INVALID\_POOL\_NAME

If the verb does not execute because the system has not been built with dependent LU support, the Program returns the following parameter:

#### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_LU62\_TIMEOUT

The DEFINE\_LU62\_TIMEOUT verb defines a timeout period for unused LU 6.2 sessions. Each timeout is for a specific resource type (global, mode, local LU, or partner LU) and resource name.

If a define is issued for a resource type/name pair that is already defined, it will overwrite the previous definition. New timeout periods will only take effect for sessions activated after the definition. If more than one relevant timeout period has been defined for a session, the shortest period will apply.

# VCB Structure

typedef struct define\_lu62\_timeout

ι					
	NB USHORT	opcode;	/*	verb operation code	*/
	NBBYTE	reserv2;	/*	reserved	*/
	NBBYTE	format;	/*	format	*/
	NBUSHORT	primary rc;	/*	primary return code	*/
	NBULONG	secondary rc;	/*	secondary return code	*/
	NBBYTE	resource type;	/*	type of resource	*/
	NBBYTE	resource name[17];	/*	name of resource	*/
	NBUSHORT	timeout;	/*	timeout period (s)	*/
}	DEFINE_LU62_TIME0	UT;			

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

NAP\_DEFINE\_LU62\_TIMEOUT

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### resource\_type

Specifies the type of the timeout being defined

## NAP\_GLOBAL\_TIMEOUT

Timeout applies to all LU 6.2 sessions for the local node. The resource name should be set to all zeros.

## NAP\_LOCAL\_LU\_TIMEOUT

Timeout applies to all LU 6.2 sessions for the local LU specified in **resource\_name**. Only the first 8 bytes of **resource\_name** are valid and should be set to the name of the local LU. This is an 8-byte alphanumeric type EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## NAP\_PARTNER\_LU\_TIMEOUT

Timeout applies to all LU 6.2 sessions to the partner LU specified in **resource\_name**. All 17 bytes of **resource\_name** are valid and should be set to the fully qualified name of the partner LU, which is padded to the right with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## NAP\_MODE\_TIMEOUT

Timeout applies to all LU 6.2 sessions on the mode specified in the **resource\_name**. Only the first 8 bytes of **resource\_name** are valid

and should be set to the name of the mode. This is an 8-byte alphanumeric type EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### resource\_name

Name of the resource that is being defined. See the description of the **resource\_type** parameter for the format of this field.

#### timeout

Timeout period in seconds. If the value is set to zero, the session becomes free immediately.

# **Returned Parameters**

If the verb executes successfully, SNAP APPN returns the following parameter:

#### primary\_rc

NAP\_OK

If the verb does not execute because of a parameter error, SNAP APPN returns the following parameters:

#### primary\_rc

NAP\_PARAMETER\_CHECK

#### secondary\_rc

NAP\_INVALID\_RESOURCE\_TYPE NAP\_INVALID\_LU\_NAME NAP\_INVALID\_PARTNER\_LU NAP\_INVALID\_MODE\_NAME

If the verb does not execute because the node has not yet been started, SNAP APPN returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because a STOP\_NODE verb has been issued, SNAP APPN returns the following parameter:

#### primary\_rc

NAP\_NODE\_STOPPING

If the verb does not execute because of a system error, SNAP APPN returns the following parameter:

#### primary\_rc

NAP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_MODE

The DEFINE\_MODE verb defines a set of networking characteristics to assign to a particular mode (or group of sessions). This verb can also be used to modify any fields on a previously defined mode. If the SNASVCMG mode is redefined, its **mode\_name** and **cos\_name** cannot be modified. The CPSVCMG mode cannot be redefined.

The DEFINE\_MODE verb can also be used to define the default COS, which unknown modes will be mapped to. This is done by setting **mode\_name** to all zeros. The default COS is initially #CONNECT.

**Note:** It is not necessary to define all the modes you want to use locally, though they must be defined at your network node and potentially, the partner node. If an ALLOCATE is issued specifying a mode that has not been defined, the node uses the characteristics for the model default mode specified on the DEFINE\_DEFAULTS verb. If no such model has been specified, the characteristics of the blank mode are used for the model.

# VCB Structure

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_MODE

#### format

Identifies the format of the VCB. Set this field to zero or one to specify the version of the VCB listed above.

#### mode\_name

Name of the mode. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this is set to all zeros, the default COS is set to **mode\_chars.cos\_name**, and all other **mode\_chars** fields are ignored.

#### mode\_chars.description

Resource description (returned on QUERY\_MODE\_DEFINITION and QUERY\_MODE). The length of this field should be a multiple of four bytes, and nonzero.

#### mode\_chars.max\_ru\_size\_upp

Upper bound for the maximum size of RUs sent and received on sessions in this mode. The value is used when the maximum RU size is negotiated during session activation. The range is 256–61440. This field is ignored if **default\_ru\_size** is set to AP\_YES.

## mode\_chars.receive\_pacing\_win

Session pacing window for sessions in this mode. For fixed pacing, this value specifies the receive pacing window. For adaptive pacing, this value is used as a preferred minimum window size. Note that Personal Communications or Communications Server will always use adaptive pacing unless the adjacent node specifies that it does not support it. The range is 1–63. The value zero is not allowed.

#### mode\_chars.default\_ru\_size

Specifies whether a default upper bound for the maximum RU size will be used. If this parameter specifies AP\_YES, **max\_ru\_size\_upp** is ignored, and the upper bound for the maximum RU size is set to the link BTU size minus the size of the TH and the RH.

AP\_YES AP\_NO

#### mode\_chars.max\_neg\_sess\_lim

Maximum number of sessions allowed on this mode between any local LU and partner LU. If a value of zero is specified then there will be no implicit CNOS exchange. The range is 0–32 767.

#### mode\_chars.plu\_mode\_session\_limit

Default session limit for this mode. This limits the number of sessions on this mode between any one local LU and partner LU pair. This value is used when CNOS (Change Number of Sessions) exchange is initiated implicitly. If a value of zero is specified then there will be no implicit CNOS exchange. The range is 0–32 767.

#### mode\_chars.min\_conwin\_src

Minimum number of contention winner sessions that can be activated by any one local LU using this mode. This value is used when CNOS (Change Number of Sessions) exchange is initiated implicitly. If a value of zero is specified then there will be no implicit CNOS exchange. The range is 0-32767.

#### mode\_chars.cos\_name

Name of the class of service to request when activating sessions on this mode. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### mode\_chars.cryptography

Specifies whether session-level cryptography must be used (AP\_NONE or AP\_MANDATORY).

## mode\_chars.compression

Specifies the use of compression for sessions activated using this mode.

#### AP\_COMP\_PROHIBITED

Compression is not supported on sessions for this mode.

#### AP\_COMP\_REQUESTED

Compression is supported and requested (but not mandated) on sessions for this mode.

If the **format** field is set to 0, then the compression and decompression levels are set to the maximum supported by the node.

If the **format** field is set to 1, then the maximum levels of compression and decompression are defined by the **max\_compress\_lvl** and **max\_decompress\_lvl** fields.

#### mode\_chars.auto\_act

Specifies how many sessions are automatically activated for this mode. This value is used when Change Number of Sessions (CNOS) exchange is initiated implicitly.

The range is 0-32767.

## mode\_chars.min\_consloser\_src

Specifies the minimum number of contention loser sessions to be activated by any one local LU for this mode. This value is used when CNOS (change number of sessions) exchange is initiated implicitly. The range is 0–32767.

#### mode\_chars.max\_ru\_size\_low

Specifies the lower bound for the maximum size of RUs sent and received on sessions in this mode. This value is used when the maximum RU size is negotiated during session activation. The range is 256–61140.

The value zero means that there is no lower bound.

The field is ignored if **default\_ru\_size** is set to AP\_YES.

## mode\_chars.max\_receive\_pacing\_win

Specifies the maximum pacing window for sessions in this mode. For adaptive pacing, this value is used to limit the receive pacing window it grants. For fixed pacing, this field is not used. Note, the Program always uses adaptive pacing unless the adjacent node specifies that it does not support it. The range is 0–32767.

The value of zero means that there is no upper bound.

#### mode\_chars.max\_compress\_lvl

The maximum compression level that the Program attempts to negotiate for data flowing supported by the node.

AP\_NONE AP\_RLE\_COMPRESSION AP\_LZ9\_COMPRESSION AP\_LZ10\_COMPRESSION AP\_LZ12\_COMPRESSION

The level of compression configured cannot be greater than that supported by the node (specified in the field **max\_compress\_lvl** on START\_NODE). Note, if compression is negotiated using a non-extended BIND, then the compression level is set to RLE compression.

#### mode\_chars.max\_decompress\_lvl

The maximum decompression level that the Program attempts to negotiate for data flowing supported by the node.

AP\_NONE AP\_RLE\_COMPRESSION AP\_LZ9\_COMPRESSION AP\_LZ10\_COMPRESSION AP\_LZ12\_COMPRESSION

The level of compression configured cannot be greater than that supported by the node (specified in the field **max\_compress\_lvl** on START\_NODE). Note, if compression is negotiated using a non-extended BIND, then the decompression level is set to LZ9 compression.

## mode\_chars.comp\_in\_series

Specifies whether the use of LZ compression preceded by RLE compression is allowed. If this field is set to AP\_YES, then **max\_compress\_lvl** must be set to AP\_LZ9\_COMPRESSION, AP\_LZ10\_COMPRESSION, or AP\_LZ12\_COMPRESSION.

AP\_YES

AP\_NO

This field cannot be set to AP\_YES if the node is configured as not supporting RLE and LZ compression (specified in the field **comp\_in\_series** on START\_NODE).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_COS\_NAME

AP\_CPSVCMG\_ALREADY\_DEFD AP\_INVALID\_CNOS\_SLIM AP\_INVALID\_COS\_SNASVCMG\_MODE AP\_INVALID\_DEFAULT\_RU\_SIZE AP\_INVALID\_MAX\_NEGOT\_SESS\_LIM AP\_INVALID\_MAX\_RU\_SIZE\_UPPER

AP\_INVALID\_MAX\_RU\_SIZE\_LOW AP RU SIZE LOW UPPER MISMATCH AP\_INVALID\_COMPRESSION AP\_INVALID\_MIN\_CONWINNERS AP\_INVALID\_MIN\_CONLOSERS AP\_INVALID\_MIN\_CONTENTION\_SUM AP\_INVALID\_MODE\_NAME AP\_INVALID\_RECV\_PACING\_WINDOW AP\_INVALID\_MAX\_RECV\_PACING\_WIN AP\_INVALID\_DEFAULT\_RU\_SIZES AP\_INVALID\_SNASVCMG\_MODE\_LIMIT AP\_MODE\_SESS\_LIM\_EXCEEDS\_NEG AP\_INVALID\_CRYPTOGRAPHY AP\_INVALID\_MAX\_COMPRESS\_LVL AP\_INVALID\_MAX\_DECOMPRESS\_LVL AP\_INVALID\_COMP\_IN\_SERIES

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## **Effects of Redefinition**

Following is the effect of redefinition of each field:

#### description

The updated **description** is returned on subsequent QUERY\_MODE verbs.

#### compression

max\_compress\_lvl

max\_decompress\_lvl

comp\_in\_series

cryptography

max\_ru\_size\_upp

receive\_pacing\_win

default\_ru\_size

#### max\_ru\_size\_low

## max\_receive\_pacing\_win

The updated values are used for all subsequent session activation attempts

for this mode and are returned on all subsequent QUERY\_MODE verbs. The change does not effect any existing active sessions.

#### max\_neg\_sess\_lim

plu\_mode\_session\_limit

min\_conwin\_src

## auto\_act

#### min\_conloser\_src

The updated values are not used for a particular local LU or partner LU pair until the next CNOS command (either locally initiated or remotely initiated). The old value is returned in QUERY\_MODE verbs until the next CNOS command.

#### cos\_name

The updated values are used for all subsequent session activation attempts for this mode and are returned on all subsequent QUERY\_MODE verbs. The change does not effect any existing active sessions. The updated value is also used for any subsequent mode to COS mapping operation (for example, if this node is a network node and provides mode to COS mapping services or its served end nodes), and is returned on all subsequent QUERY\_MODE\_TO\_COS\_MAPPING verbs.

**Note:** An implicit mode definition can be made explicit by a DEFINE\_MODE. This is reflected by subsequent QUERY\_MODE verbs returning with **implicit set** to AP\_NO.

# DEFINE\_PARTNER\_LU

The DEFINE\_PARTNER\_LU verb defines the parameters of a partner LU for LU-LU sessions between a local LU and the partner LU. Alternatively, DEFINE\_PARTNER\_LU can be used to modify all parameters already defined for the partner LU, other than the **fqplu\_name** and **plu\_alias**.

# VCB Structure

typedef	<pre>struct define_p</pre>	artner_lu			
ι	unsigned short	opcode;	/*	verb operation code	*/
	unsigned char	reserv2;	/*	reserved	*/
	unsigned char	format;		format	*/
	unsigned short	primary_rc;		primary return code	*/
	unsigned long	<pre>secondary_rc;</pre>		secondary return code	*/
) ====	PLU_CHARS	plu_chars;	/*	partner LU characteristics	*/

	unsigned char	<pre>plu_un_name[8];</pre>		partner LU uninterpreted name	*/
	unsigned char	preference		routing preference	*/
	unsigned short unsigned char	<pre>max_mc_ll_send_size;</pre>			*/ */
	unsigned char	parallel_sess_supp;		already_verified accepted? parallel sessions supported?	*/
	unsigned char	reserv2[8];		reserved	*/
} PLU_C			7		~ /

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_DEFINE\_PARTNER\_LU

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## plu\_chars.fqplu\_name

Fully qualified name of the partner LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## plu\_chars.plu\_alias

Alias of the partner LU. This is an 8-byte string in a locally displayable character set. This field may be set to all zeros for a partner LU with no alias associated to it.

## plu\_chars.description

Resource description (returned on QUERY\_PARTNER\_LU and QUERY\_PARTNER\_LU\_DEFINITION). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## plu\_chars.plu\_un\_name

Uninterpreted name of the partner LU. This is an 8-byte type-A EBCDIC character string.

#### plu\_chars.max\_mc\_ll\_send\_size

Maximum size of LL records sent by and received by mapped conversation services at the partner LU. Range: 1–32 767 (32 767 is specified by setting this field to 0)

#### plu\_chars.preference

The preferred routing protocol to be used for session activation to this partner LU. This field can take the following values:

#### AP\_NATIVE

Use native (APPN) routing protocols only.

## AP\_NONNATIVE

Use nonnative (AnyNet) protocols only.

#### AP\_NATIVE\_THEN\_NONNATIVE

Try native (APPN) protocols, and if the partner LU cannot be located then retry session activation using nonnative (AnyNet) protocols.

#### AP\_NONNATIVE\_THEN\_NATIVE

Try nonnative (AnyNet) protocols, and if the partner LU cannot be located then retry session activation using native (APPN) protocols.

#### AP\_USE\_DEFAULT\_PREFERENCE

Use the default preference defined when the node was started. (This can be recalled by QUERY\_NODE.)

**Note:** Nonnative routing is only meaningful when an AnyNet DLC is available to the Node Operator Facility, and there is an AnyNet link station defined (see "DEFINE\_LS" on page 74).

## plu\_chars.conv\_security\_ver

Specifies whether the partner LU is authorized to validate **user\_ids** on behalf of local LUs, that is whether the partner LU can set the already verified indicator in an Attach request (AP\_YES or AP\_NO).

#### plu\_chars.parallel\_sess\_supp

Specifies whether the partner LU supports parallel sessions (AP\_YES or AP\_NO).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_ANYNET\_NOT\_SUPPORTED AP\_DEF\_PLU\_INVALID\_FQ\_NAME AP\_INVALID\_UNINT\_PLU\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK

## secondary\_rc

AP\_PLU\_ALIAS\_CANT\_BE\_CHANGED

AP\_PLU\_ALIAS\_ALREADY\_USED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## **Effects of Redefinition**

Following is the effect of redefinition of each field:

## fqplu\_name

Cannot be changed.

#### plu\_alias

If a previous DEFINE\_PARTNER\_LU has been issued with a different **plu\_alias**, the DEFINE\_PARTNER\_LU fails. If a previous DEFINE\_PARTNER\_LU has been issued with an all zero **plu\_alias**, the redefinition is accepted and will effect all existing PLU records. If no previous DEFINE\_PARTNER\_LU has been issued, the specified **plu\_alias** is copied into all correspondig implicitly defined partner LU records, unless all zeros are specified, in which case the implicit **plu\_aliases** are left uchanged.

**Note:** Issuing DEFINE\_PARTNER\_LU with a nonzero **plu\_alias** can cause some running applications to fail, if the application has already obtained the implicit **plu\_alias** from an earlier APPC verb and uses it on a subsequent ALLOCATE.

## description

The updated **description** is returned on subsequent QUERY\_PARTNER\_LU verbs.

## plu\_un\_name

The updated **plu\_un\_name** is used for all subsequent session activation requests to this partner LU, and is returned on all subsequent QUERY\_PARTNER\_LU verbs.

## preference

The updated **preference** is used for all subsequent session activation requests to this partner LU, and is returned on all subsequent QUERY\_PARTNER\_LU verbs.

#### max\_mc\_ll\_send\_size

The updated **preference** is used for all subsequent session activation requests to this partner LU (even on existing sessions). The change does not effect existing conversations. The updated value is returned on all subsequent QUERY\_PARTNER\_LU verbs.

#### conv\_security\_ver

The updated value is not used for a particular local LU until the number of sessions between that local LU and the partner LU drops to zero. BINDs and RSP(BIND)s will flow using the old setting, and the old value will be returned in QUERY\_PARTNER\_LU requests until the number of sessions drops to zero. This is because the partner LU can reject subsequent session activation attempts if the security support is different than that of existing active sessions.

## parallel\_sess\_supp

As with **conv\_security\_ver**, the updated value is not used for a particular local LU until the number of sessions between that local LU and the specified partner LU drops to zero. This is to avoid problems with the architected LU 6.2 session consistency check.

**Note:** An implicit mode definition can be made explicit by a DEFINE\_PARTNER\_LU. This is reflected by subsequent QUERY\_PARTNER\_LU verbs returning with **implicit set** to AP\_NO.

# **DEFINE\_PORT**

DEFINE\_PORT defines a new port or modifies an existing one. This port belongs to a specified DLC, which must already have been defined using a DEFINE\_DLC verb. The DEFINE\_PORT verb provides the port name, which is unique throughout the node, along with port specific parameters and default LS characteristics for use with dynamic link stations. The port specific parameters are concatenated to the basic structure. The default LS characteristics are concatenated immediately following the port specific parameters.

DEFINE\_PORT can be used to modify one or more fields on an existing port if the port is in a reset state (after STOP\_PORT has been issued) and the **dlc\_name** specified on the DEFINE\_PORT has not changed since the previous definition of the port.

If the port is active, only the following fields can be modified:

description implicit\_dspu\_services implicit\_deact\_timer implicit\_cp\_cp\_sess\_support implicit\_link\_lvl\_error default\_tg\_chars implicit\_dspu\_template implicit\_ls\_limit link\_spec\_data\_len link\_spec\_data

If the port spec data is changed while the port is active, the verb will not be rejected but the modifications will be ignored.

See "DLC Processes, Ports, and Link Stations" on page 14 for more information about the relationship between DLCs, ports, and link stations.

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_DEFINE\_PORT

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### port\_name

Name of port being defined. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

## port\_def\_data.description

Resource description (returned on QUERY\_PORT). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## port\_def\_data.dlc\_name

Name of the associated DLC, which is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. This named DLC must have already been defined by a DEFINE\_DLC verb.

#### port\_def\_data.port\_type

Specifies the type of line used by the port. The value corresponds to one of the following line types:

AP\_PORT\_NONSWITCHED AP\_PORT\_SWITCHED AP\_PORT\_SATF

Note that if this field is set to AP\_PORT\_SATF then the **ls\_role** must be set to AP\_LS\_NEG.

#### port\_def\_data.port\_attributes[0]

This is the bit field. It may take the value AP\_NO, or the following:

## AP\_RESOLVE\_BY\_LINK\_ADDRESS

This specifies that an attempt is made to resolve incoming calls by using the link address on CONNECT\_IN before using the CP name (or node ID) carried on the received XID3 to resolve them. This bit is ignored unless the field **port\_type** is set to AP\_PORT\_SWITCHED.

## port\_def\_data.implicit\_uplink\_to\_en

BrNN only: Specifies whether implicit link stations off this port are uplink or downlink if the adjacent node is an end node. The value of this field will only be considered if there are no existing links to the same partner, as such links are used first to determine the link type.

#### AP\_NO

Implicit links are downlink.

#### AP\_YES

Implicit links are uplink.

Other node types: This field is ignored.

## port\_def\_data.port\_number

Port number.

## port\_def\_data.max\_rcv\_btu\_size

Maximum BTU size that can be received. If implicit HPR-capable links are not supported on the port, then this must be set to a value greater than or equal to 99. If implicit HPR-capable links are supported on the port, then this must be set to a value greater than or equal to 768.

## port\_def\_data.tot\_link\_act\_lim

Total link activation limit. This specifies the maximum number of link stations that can be active concurrently. This must be greater than or equal to the sum of the **inb\_link\_act\_lim** and **out\_link\_act\_lim** fields. If the **port\_type** is set to AP\_PORT\_NONSWITCHED and the **ls\_role** is set to AP\_LS\_SEC then this field must be set to one. If the **ls\_role** is set to AP\_LS\_PRI then this field must be in the range greater than or equal to one to 256. If this port is for the AnyNet DLC, you must use 65535.

## port\_def\_data.inb\_link\_act\_lim

Inbound link activation limit. This specifies the number of link stations reserved for inbound activation on this port. The maximum number of outbound link stations that can be active concurrently is therefore **port\_def\_data.tot\_link\_act\_lim - port\_def\_data.inb\_link\_act\_lim**. If the **port\_type** is set to AP\_PORT\_NONSWITCHED and the **ls\_role** is set to AP\_LS\_NEG or AP\_LS\_PRI then this field must be set to zero. If the **port\_type** is set to AP\_PORT\_NONSWITCHED and the **ls\_role** is set to AP\_LS\_SEC then this field must be set to zero or one. If this port is for the AnyNet DLC, you must use zero.

## port\_def\_data.out\_link\_act\_lim

Outbound link activation limit. This specifies the number of link stations reserved for outbound activation on this port. The maximum number of inbound link stations that can be active concurrently is therefore **port\_def\_data.tot\_link\_act\_lim - port\_def\_data.out\_link\_act\_lim**. If the **port\_type** is set to AP\_PORT\_NONSWITCHED and the **ls\_role** is set to AP\_LS\_NEG then this field must be set to zero. If the **ls\_role** is set to AP\_LS\_PRI then this field must be equal to **tot\_link\_act\_lim**. If the **port\_type** is set to AP\_PORT\_NONSWITCHED and the **ls\_role** is set to AP\_LS\_PRI then this field must be equal to **tot\_link\_act\_lim**. If the **port\_type** is set to AP\_PORT\_NONSWITCHED and the **ls\_role** is set to AP\_LS\_SEC then this field must be set to zero or one. If this port is for the AnyNet DLC, you must use zero.

## port\_def\_data.ls\_role

Link station role. This can be negotiable (AP\_LS\_NEG), primary (AP\_LS\_PRI), or secondary (AP\_LS\_SEC). The link station role determines the relationship between the values specified by the **tot\_act\_lim**, **inb\_link\_act\_lim**, and **out\_link\_act\_lim** fields as described above. Note that if the **port\_type** is set to AP\_PORT\_SATF then the **ls\_role** must be set to AP\_LS\_NEG.

## port\_def\_data.retry\_flags

This field specifies the conditions under which activation of this link station is subject to automatic retry if the flag AP\_INHERIT\_RETRY is set on DEFINE\_LS in **port\_def\_data.retry\_flags**. It is a bit field, and may take any of the following values bit-wise ORed together.

## AP\_RETRY\_ON\_START

Link activation will be retried if no response is received from the remote node when activation is attempted. If the underlying port is inactive when activation is attempted, APPN will attempt to activate it.

## AP\_RETRY\_ON\_FAILURE

Link activation will be retried if the link fails while active or pending active. If the underlying port has failed when activation is attempted, APPN attempts to activate it.

## AP\_RETRY\_ON\_DISCONNECT

Link activation will be retried if the link is stopped normally by the remote node.

## AP\_DELAY\_APPLICATION\_RETRIES

Link activation retries, initiated by applications (using START\_LS or on-demand link activation) will be paced using the **activation\_delay\_timer**.

## **AP\_INHERIT\_RETRY**

In addition to the retry conditions specified by flags in this field, those specified in the **retry\_flags** field of the underlying port definition will also be used.

## port\_def\_data.max\_activation\_attempts

This field has no effect unless at least one flag is set in DEFINE\_LS in **port\_def\_data.retry\_flags** and **port\_def\_data.max\_activation\_attempts** on DEFINE\_LS is set to AP\_USE\_DEFAULTS.

This field specifies the number of retry attempts the Program allows when the remote node is not responding, or the underlying port is inactive. This includes both automatic retries and application-driven activation attempts.

If this limit is ever reached, no further attempts are made to automatically retry. This condition is reset by STOP\_LS, STOP\_PORT, STOP\_DLC or a successful activation. START\_LS or OPEN\_LU\_SSCP\_SEC\_RQ results in a single activation attempt, with no retry if activation fails.

Zero means no limit. The value AP\_USE\_DEFAULTS results in the use of **max\_activiation\_attempts** supplied on DEFINE\_DLC.

#### port\_def\_data.activation\_delay\_timer

This field has no effect unless at least one flag is set in DEFINE\_LS in **port\_def\_data.retry\_flags** and **activiation\_delay\_timer** on DEFINE\_LS is set to AP\_USE\_DEFAULTS.

This field specifies the number of seconds that the Program waits between automatic retry attempts, and between application-driven activation attempts if the AP\_DELAY\_APPLICATION\_RETRIES bit is set in **port\_def\_data.retry\_flags**.

The value AP\_USE\_DEFAULTS results in the use of **activiation\_delay\_timer** supplied on DEFINE\_DLC.

If zero is specified, the Program uses a default timer duration of thirty seconds.

#### port\_def\_data.implicit\_dspu\_template

Specifies the DSPU template, defined with the DEFINE\_DSPU\_TEMPLATE verb, that is used for definitions if the local node is to provide PU Concentration for an implicit link activated on this port. If the template specified does not exist (or is already at its instance limit) when the link is activated, activation fails. This is an 8-byte string in a locally-displayable character set. All 8 bytes are significant and must be set.

If the **port\_def\_data.implicit\_dspu\_services** field is not set to AP\_PU\_CONCENTRATION, then this field is reserved.

#### port\_def\_data.implicit\_ls\_limit

Specifies the maximum number of implicit link stations that can be active on this port simultaneously, including dynamic links and links activated for Discovery. A value of 0 means that there is no limit, a value of AP\_NO\_IMPLICIT\_LINKS means that no implicit links are allowed.

## port\_def\_data.implicit.dspu\_services

Specifies the services that the local node will provide to the downstream PU across implicit links activated on this port. This is set to one of the following values:

#### AP\_DLUR

Local node will provide DLUR services for the downstream PU (using the default DLUS configured through the DEFINE\_DLUR\_DEFAULTS verb). This setting is only valid if the local node is a network node.

#### AP\_PU\_CONCENTRATION

Local node will provide PU Concentration for the downstream PU (and will put in place definitions as specified by the DSPU template specified in the field **port\_def\_data.implicit\_dspu\_template**).

#### **AP\_NONE**

Local node will provide no services for this downstream PU.

## port\_def\_data.implicit\_deact\_timer

Limited resource link deactivation timer (in seconds). If

**implicit\_limited\_resource** is set to AP\_YES or AP\_NO\_SESSIONS, then an HPR-capable implicit link is automatically deactivated if no data traverses the link for the duration of this timer, and no sessions are using the link.

If **implicit\_limited\_resource** is set to AP\_INACTIVITY then an implicit link is automatically deactivated if no data traverses the link for the duration of this timer.

The value is an integer in the range of 0–1000 seconds. The default is 10 seconds.

If zero is specified, the default value of 30 is used. Otherwise the minimum value is 5. (If it is set any lower, the specified value will be ignored and 5 will be used.) Note that this parameter is reserved unless **implicit\_limited\_resource** is set to AP\_NO.

#### port\_def\_data.act\_xid\_exchange\_limit

Activation XID exchange limit.

## port\_def\_data.nonact\_xid\_exchange\_limit

Non-activation XID exchange limit.

#### port\_def\_data.ls\_xmit\_rcv\_cap

Specifies the link station transmit/receive capability. This is either two-way simultaneous (AP\_LS\_TWS) (also known as duplex or full-duplex) or two way alternating (AP\_LS\_TWA) (also know as half-duplex).

## port\_def\_data.max\_ifrm\_rcvd

Maximum number of I-frames that can be received by the local link stations before an acknowledgment is sent. The range is 1–127.

## port\_def\_data.target\_pacing\_count

Numeric value between 1 and 32 767 inclusive indicating the desired pacing window size for BINDs on this TG. The number is only significant

when fixed bind pacing is being performed. Note that Personal Communications or Communications Server does not currently use this value.

## port\_def\_data.max\_send\_btu\_size

Maximum BTU size that can be sent from this link station. This value is used to negotiate the maximum BTU size than can be transmitted between a link station pair. If implicit HPR-capable links are not supported on the port then this must be set to a value greater than or equal to 99. If implicit HPR-capable links are supported on the port then this must be set to a value greater than or equal to 768.

#### port\_def\_data.dlc\_data.length

Port address length.

# port\_def\_data.dlc\_data.address

Port address.

# port\_def\_data.hpr\_dlc\_data.length

HPR Port address length.

## port\_def\_data.hpr\_dlc\_data.address

HPR Port address. This is currently used when supporting HPR links. The field specifies the information sent by Personal Communications or Communications Server in the X'80' subfield of the X'61' control vector on XID3s exchanged on link stations using this port. It is passed on the ACTIVATE\_PORT issued to the DLC by Personal Communications or Communications Server. Some DLCs can require this information to be filled in for ports supporting HPR links.

## port\_def\_data.implicit\_cp\_cp\_sess\_support

Specifies whether CP-CP sessions are permitted for implicit link stations off this port (AP\_YES or AP\_NO).

#### port\_def\_data.implicit\_limited\_resource

Specifies whether implicit link stations off this port should be deactivated when there are no sessions using the link. This is set to one of the following values:

#### AP\_NO

Implicit links are not limited resources and will not be deactivated automatically.

## AP\_YES or AP\_NO\_SESSIONS

Implicit links are a limited resource and will be deactivated automatically when no active sessions are using them.

## AP\_INACTIVITY

Implicit links are a limited resource and will be deactivated automatically when no active sessions are using them, or when no data has followed on the link for the time period specified by the **implicit\_deact\_timer** field.

#### port\_def\_data.implicit\_hpr\_support

Specifies whether HPR should be supported on implicit links (AP\_YES or AP\_NO).

## port\_def\_data.implicit\_link\_lvl\_error

Specifies whether HPR traffic should be sent on implicit links using link-level error recovery (AP\_YES or AP\_NO). Note that the parameter is reserved if **implicit\_hpr\_support** is set to AP\_NO.

#### port\_def\_data.default\_tg\_chars

TG characteristics (See "DEFINE\_COS" on page 35). These are used for implicit link stations off this port and also for defined link stations that specify **use\_default\_tg\_chars**.

#### port\_def\_data.discovery\_supported

Specifies whether Discovery functions are to be performed on this port (AP\_YES or AP\_NO).

## port\_def\_data.port\_spec\_data\_len

Length of data to be passed unchanged to port on ACTIVATE\_PORT signal. The data should be concatenated to the basic structure.

## port\_def\_data.link\_spec\_data\_len

This field should always be set to zero.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_PORT\_NAME

AP\_INVALID\_DLC\_NAME AP\_INVALID\_PORT\_TYPE AP\_INVALID\_BTU\_SIZE AP\_INVALID\_LS\_ROLE AP\_INVALID\_LINK\_ACTIVE\_LIMIT AP\_INVALID\_MAX\_IFRM\_RCVD AP\_INVALID\_DSPU\_SERVICES AP\_HPR\_NOT\_SUPPORTED AP\_DLUR\_NOT\_SUPPORTED AP\_PU\_CONC\_NOT\_SUPPORTED AP\_INVALID\_TEMPLATE\_NAME AP\_INVALID\_RETRY\_FLAGS AP\_INVALID\_IMPLICIT\_UPLINK

If the verb does not execute because of a state error, the Program returns the following parameters:

#### primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_PORT\_ACTIVE

AP\_DUPLICATE\_PORT\_NUMBER AP\_CANT\_MODIFY\_WHEN\_ACTIVE AP\_CANT\_MODIFY\_VISIBILITY AP\_INVALID\_IMPLICIT\_UPLINK If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DEFINE\_RTP\_TUNING

DEFINE\_RTP\_TUNING specifies parameters to be used when setting up RTP connections. After you issue this verb, the parameters that you specify will be used for all future RTP connections, until you modify them by issuing a new DEFINE\_RTP\_TUNING verb.

# VCB Structure

typedef struct define\_rtp\_tuning

l					
	AP_UINT16	opcode;	/*	verb operation code	*/
	unsigned char	reserv2;	/*	reserved	*/
	unsigned char	format;	/*	reserved	*/
	AP_UINT16	primary_rc;	/*	primary return code	*/
	AP UINT32	secondary rc;	/*	secondary return code	*/
	unsigned char	<pre>path_switch_attempts;</pre>	/*	number of path switch attempts	*/
	unsigned char	short req retry limit;	/*	short request timer retry limit	*/
	AP_UINT16	<pre>path_switch_times[4];</pre>	/*	path switch times	*/
	AP UINT32	refifo cap;	/*	maximum for refifo timer	*/
	AP UINT32	<pre>srt_cap;</pre>	/*	maximum for short request timer	*/
	unsigned char	reserved[82];	/*	reserved	*/
}	<pre>DEFINE_RTP_TUNING;</pre>				

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_DEFINE\_RTP\_TUNING

#### path\_switch\_attempts

Number of path switch attempts for new RTP connections. Specify a value in the range 1–255.

Specify a value in the range 1–255. If you specify 0 (zero), Personal Communications or Communications Server uses the default value of 6.

#### short\_req\_retry\_limit

Number of times a Status Request is sent before Personal Communications or Communications Server determines that an RTP connection is disconnected and starts Path Switch processing.

Specify a value in the range 1–255. If you specify 0 (zero), Personal Communications or Communications Server uses the default value of 6.

## path\_switch\_times

Length of time in seconds for which Personal Communications or Communications Server attempts to path switch a disconnected RTP connection.

This parameter is specified as four separate time limits for each of the valid transmission priorities in order:

- 1. AP\_LOW
- 2. AP\_MEDIUM
- 3. AP\_HIGH
- 4. AP\_NETWORK

Each of these parameters should be in the range 1–65535. The value that you specify for each transmission priority must not exceed the value for any lower transmission priority.

If you specify 0 (zero) for any of the time limits, Personal Communications or Communications Server uses the corresponding default values:

- AP\_LOW: 480 seconds
- AP\_MEDIUM: 240 seconds
- AP\_HIGH: 120 seconds
- AP\_NETWORK : 60 seconds

## refifo\_cap

The RTP protocol uses the Re-FIFO Timer. The value of this timer is calculated as part of the protocol, but this parameter specifies a maximum value (in milliseconds). In some situations, setting this maximum value can improve performance.

Setting a value of 0 (zero) means that the timer is not limited and can take any value calculated by the protocol. The default value for this parameter is 4000 milliseconds, with a range of 250–12000 milliseconds.

## srt\_cap

The RTP protocol uses the Short Request Timer. The value of this timer is calculated as part of the protocol, but this parameter specifies a maximum value (in milliseconds). In some situations, setting this maximum value can improve performance.

Setting a value of 0 (zero) means that the timer is not limited and can take any value calculated by the protocol. The default value for this parameter is 8000 milliseconds, with a range of 500–24000 milliseconds.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

Values are as follows:

## AP\_INVALID\_PATH\_SWITCH\_TIMES

The path\_switch\_times parameter was not valid. For example, you might have specified a value for one transmission priority that exceeds the value specified for a lower transmission priority.

# DEFINE\_TP

The DEFINE\_TP verb defines transaction program (TP) information for use by the Node Operator Facility TP Attach Manager when it processes incoming attaches from partner LUs. This verb can also be used to modify one or more fields on a previously defined transaction program (but cannot be used to modify Personal Communications or Communications Server defined transaction programs).

# VCB Structure

typedef struct define\_tp

} DEFIN	unsigned sh unsigned ch unsigned ch unsigned ch unsigned sh unsigned lo unsigned ch TP_CHARS E_TP;	nar nar nar nort ong nar	<pre>opcode; attributes; reserv2; format; primary_rc; secondary_rc; tp_name[64]; tp_chars;</pre>	/* /* /* /* /*	verb operation code verb attributes reserved format primary return code secondary return code TP name TP characteristics	*/ */ */ */ */

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_TP

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

## AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### tp\_name

Name of the transaction program (TP) being defined. This is a 64-byte EBCDIC string padded to the right with EBCDIC spaces. Note that Personal Communications or Communications Server does not check the character set of this field.

#### tp\_chars.description

Resource description (returned on QUERY\_TP\_DEFINITION and QUERY\_TP). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### tp\_chars.conv\_type

Specifies the types of conversation supported by this transaction program.

AP\_BASIC AP\_MAPPED AP\_EITHER

#### tp\_chars.security\_rqd

Specifies whether conversation security information is required to start the transaction program (AP\_NO or AP\_YES).

## tp\_chars.sync\_level

Specifies the synchronization levels supported by the transaction program.

## AP\_NONE

The transaction program supports a synchronization level of None.

#### AP\_CONFIRM\_SYNC\_LEVEL

The transaction program supports a synchronization level of Confirm.

#### **AP\_EITHER**

The transaction program supports a synchronization level of None or Confirm.

#### AP\_SYNCPT\_REQUIRED

The transaction program supports a synchronization level of Sync-point.

### AP\_SYNCPT\_NEGOTIABLE

The transaction program supports a synchronization level of None, Confirm or Sync-point.

## tp\_chars.dynamic\_load

Specifies whether the transaction program can be dynamically loaded (AP\_YES or AP\_NO).

## tp\_chars.enabled

Specifies whether the transaction program can be attached successfully (AP\_YES or AP\_NO). The default is AP\_NO.

#### tp\_chars.pip\_allowed

Specifies whether the transaction program can receive program initialization (PIP) parameters (AP\_YES or AP\_NO).

## tp\_chars.duplex\_support

Indicates whether the transaction program is full or half duplex.

#### AP\_FULL\_DUPLEX

Specifies that the transaction program is full duplex.

# AP HALF DUPLEX

Specifies that the transaction program is half duplex.

#### AP\_EITHER\_DUPLEX

Specifies that the transaction program can be either half or full duplex.

#### tp\_chars.tp\_instance\_limit

Limit on the number of concurrently active transaction program instances. A value of zero means no limit.

## tp\_chars.incoming\_alloc\_timeout

Specifies the number of seconds that an incoming attach will be queued waiting for a RECEIVE\_ALLOCATE. Zero implies no timeout, and so it will be held indefinitely.

## tp\_chars.rcv\_alloc\_timeout

Specifies the number of seconds that a RECEIVE\_ALLOCATE verb will be queued while waiting for an Attach. Zero implies no timeout, and so it will be held indefinitely.

## tp\_chars.tp\_data\_len

Length of the implementation-dependent transaction program data.

#### tp\_spec\_data

Information used by the Attach Manager when launching the transaction program. Refer to the information about Attach Manager in *Client/Server Communications Programming* for further details of how this is used.

#### tp\_spec\_data.pathname

Specifies the path and transaction program name.

#### tp\_spec\_data.parameters

Specifies the parameters for the transaction program.

## tp\_spec\_data.queued

Specifies whether the transaction program will be queued.

#### tp\_spec\_data.load\_type

Specifies whether type of load is either AP\_AM\_CONSOLE, AP\_AM\_DETACHED or AP\_AM\_WINDOW.

#### tp\_spec\_data.dynamic\_load

Specifies how the transaction program will be loaded.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_SYSTEM\_TP\_CANT\_BE\_CHANGED

AP\_INVALID\_CONV\_TYPE AP\_INVALID\_SYNC\_LEVEL AP\_INVALID\_DYNAMIC\_LOAD AP\_INVALID\_ENABLED AP\_INVALID\_PIP\_ALLOWED AP\_INVALID\_DUPLEX\_SUPPORT

If the verb does not execute because of a state error, the Program returns the following parameters:

#### primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_CANT\_MODIFY\_VISIBILITY

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

**Effects Of Redefinition**: The redefinition of each field takes effect immediately (for example, when the next instance of the transaction program is started). However, changes to the fields **incoming\_alloc\_timeout** and **rcv\_alloc\_timeout** will not effect any attaches or RECEIVE\_ALLOCATES that are already queued.

# DELETE\_ADJACENT\_NODE

DELETE\_ADJACENT\_NODE removes entries in the node directory database that are associated with the resources on an adjacent node.

To remove the node's control point from the directory along with its LUs, set **num\_of\_lus** to zero. If **num\_of\_lus** is nonzero, this verb is used to remove node LUs from the directory, leaving the control point definition intact.

If the verb fails for any reason, no directory entries will be deleted.

# **VCB** Structure

The DELETE\_ADJACENT\_NODE verb contains a variable number of ADJACENT\_NODE\_LU overlays. The ADJACENT\_NODE\_LU structures are concatenated onto the end of DELETE\_ADJACENT\_NODE structure.

```
typedef struct delete_adjacent_node
```

ι				
} DELET	unsigned short unsigned char unsigned char unsigned short unsigned long unsigned char unsigned short E ADJACENT NODE;	<pre>opcode; reserv2; format; primary_rc; secondary_rc; cp_name[17]; num_of_lus;</pre>	<pre>/* verb operation code /* reserved /* format /* primary return code /* secondary return code /* CP name /* number of LUs</pre>	*/ */ */ */
typedef {	struct adjacent	_node_lu		
ADJAC	unsigned char unsigned char unsigned char ENT NODE LU;	<pre>wildcard_lu; fqlu_name[17]; reserv1[6];</pre>	/* wildcard LU name indicator /* fully qualified LU name /* reserved	*/ */ */

# Supplied Parameters

The application supplies the following parameters:

## opcode

AP\_DELETE\_ADJACENT\_NODE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### cp\_name

The fully qualified name of the control point in the adjacent LEN end node. The name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## num\_of\_lus

The number of LUs to be deleted. Set this to zero if the entire node definition is to be deleted. This number represents the number of adjacent LU overlays that follow the DELETE\_ADJACENT\_NODE VCB.

## adjacent\_node\_lu.wildcard\_lu

Indicates whether the specified LU name is a wildcard name (AP\_YES or AP\_NO).

## adjacent\_node\_lu.fqlu\_name

The LU name to be deleted. If this name is not fully qualified, the network ID of the CP name is assumed. The name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of one or two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_CP\_NAME

AP\_INVALID\_LU\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

## primary\_rc

AP\_STATE\_CHECK

secondary\_rc AP\_INVALID\_CP\_NAME

\_ \_ \_ \_

## AP\_INVALID\_LU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## DELETE\_CN

DELETE\_CN deletes and frees the memory for a connection network control block if all the associated ports are reset. DELETE\_CN can also be used to delete selected ports from a connection network. To do this, the user should set the **num\_ports** field to a nonzero value and supply the port names of the ports to be deleted.

# VCB Structure

typedef struct delete\_cn

```
unsigned short opcode; /* verb operation code */
unsigned char attributes; /* verb attributes */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
unsigned char fqcn_name[17]; /* name of connection network */
unsigned char reserv1; /* reserved */
unsigned short num_ports; /* number of ports to delete */
unsigned char port_name[8] [8];
/* names of ports to delete */
```

} DELETE\_CN;

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DELETE\_CN

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### fqcn\_name

Name of connection network (17 bytes long) to be deleted. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### num\_ports

The number of ports to delete on the connection network. This should be set to zero if the entire connection network is to be deleted.

#### port\_name

Names of the ports to be deleted if the **num\_ports** is nonzero. Each port name is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If the **num\_ports** field is zero this field is reserved.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

primary\_rc AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_CN\_NAME

AP\_INVALID\_NUM\_PORTS\_SPECIFIED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# DELETE\_COS

DELETE\_COS deletes a class-of-service entry unless it is one of the default classes of service defined by SNA.

# VCB Structure

```
typedef struct delete_cos
{
    unsigned short opcode; /* verb operation code */
    unsigned char reserv2; /* reserved */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char cos_name[8]; /* class-of-service name */
} DELETE_COS;
```

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DELETE\_COS

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### cos\_name

Class-of-service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_COS\_NAME\_NOT\_DEFD

AP\_SNA\_DEFD\_COS\_CANT\_BE\_DELETE

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

### DELETE\_DLC

DELETE\_DLC deletes all ports, link stations, and connection network transmission groups (TGs) associated with the DLC if it is reset. All DLC control blocks are deleted and the memory freed. The Node Operator Facility returns a response specifying whether the DLC was deleted successfully.

Note that if a link station, which has a PU associated with it, is deleted (because it is associated with the DLC) then any LUs defined on this PU will also be deleted.

## VCB Structure

```
typedef struct delete_dlc
{
    unsigned short opcode; /* verb operation code */
    unsigned char attributes; /* verb attributes */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char dlc_name[8]; /* name of DLC */
```

} DELETE DLC;

## **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_DELETE\_DLC

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### dlc\_name

Name of DLC to be deleted. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_DLC\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK secondary\_rc AP\_DLC\_ACTIVE

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

### DELETE\_DOWNSTREAM\_LU

This verb applies only to Communications Server.

## VCB Structure

typedef struct delete downstream lu

```
unsigned short opcode; /* verb operation code */
unsigned char attributes; /* verb attributes */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
unsigned char dslu_name[8]; /* Downstream LU name */
} DELETE_DOWNSTREAM_LU;
```

## **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_DELETE\_DOWNSTREAM\_LU

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

The other values that can be bit-wise ORed into this field are as follows:

### AP\_DELAY\_IF\_REQUIRED

This specifies that the downstream LU specified by **dslu\_name** is currently active, this verb should be queued inside the Program until the LU becomes inactive. In this case, the verb is processed to completion when the LU becomes inactive.

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### dslu\_name

Name of the downstream LU that is being deleted. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_LU\_NAME

AP\_DSLU\_ACTIVE AP\_DELAYED\_VERB\_PENDING

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc

AP\_STATE\_CHECK

### secondary\_rc

AP\_INVALID\_LU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

### DELETE\_DOWNSTREAM\_LU\_RANGE

This verb applies only to Communications Server.

For example, a base name of LUNME combined with an NAU range of 1 to 4 deletes the LUs LUNME001, LUNME002, LUNME003, and LUNME004. A base name of less than five non-pad characters results in LU names of less than eight non-pad characters.

This verb deletes all LUs in the range. If an LU in the range does not exist, then the verb continues with the next one that does exist. The verb only fails if no LUs exist in the specified range.

### VCB Structure

```
typedef struct delete_downstream lu range
       unsigned short opcode;
                                       /* verb operation code
                                                                     */
                                      /* verb attributes
       unsigned char attributes;
                                                                     */
       unsigned char format;
                                      /* format
                                                                     */
       unsigned short primary_rc;
       unsigned short primary_rc;  /* primary return code
unsigned long secondary_rc;  /* secondary return code
                                                                     */
                                                                     */
       unsigned char dslu base name[5];/* Downstream LU base name
                                                                    */
       unsigned char
                      */
       unsigned char max_nau;
                                      /* max NAU address in range
                                                                    */
```

```
} DELETE DOWNSTREAM LU RANGE;
```

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DELETE\_DOWNSTREAM\_LU\_RANGE

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### dslu\_base\_name

Base name for downstream LU name range. This is a 5-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This base name is appended with three type-A EBCDIC numeric characters, representing the decimal value of the NAU address, for each LU in the NAU range.

### min\_nau

Minimum NAU address in the range. This can be from 1 to 255 inclusive.

#### max\_nau

Maximum NAU address in the range. This can be from 1 to 255 inclusive.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_INVALID\_NAU\_ADDRESS

### AP\_INVALID\_LU\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

### primary\_rc

AP\_STATE\_CHECK

AP\_INVALID\_LU\_NAME AP\_DSLU\_ACTIVE AP\_DELAYED\_VERB\_PENDING

### secondary\_rc

AP\_INVALID\_LU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameters:

### primary\_rc

### DELETE\_DSPU\_TEMPLATE

This verb applies only to Communications Server.

## VCB Structure

### Format 1

```
typedef struct delete_dspu_template
                                                         /* verb operation code
          unsigned short opcode;
                                                                                               */
         unsigned char attributes; /* verb attributes
unsigned char format; /* format
unsigned short primary_rc; /* primary return coc
unsigned long secondary_rc; /* secondary return co
unsigned char template_name[8]; /* name of template

          unsigned char
                                                                                               */
} DSLU TEMPLATE;
```

## VCB Structure

### Format 0

typedef struct delete\_dspu\_template
{
 unsigned short opcode; /\* verb operation code \*/
 unsigned char attributes; /\* verb attributes \*/
 unsigned char format; /\* format \*/
 unsigned short primary\_rc; /\* primary return code \*/
 unsigned long secondary\_rc; /\* secondary return code \*/
 unsigned char template\_name[8]; /\* name of template \*/
} DELETE DSPU TEMPLATE;

## **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_DELETE\_DSPU\_TEMPLATE

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### template\_name

Name of the DSPU template. (This corresponds to the name specified in the **implicit\_dspu\_template** field on PORT\_DEF\_DATA). This is an 8-byte string in a locally-displayable character set. All 8 bytes are significant and must be set.

### num\_of\_dslu\_templates

The number of DSLU template overlays which follow the DEFINE\_DSPU\_TEMPLATE VCB. This can be from 0 to 255 inclusive. The DSLU templates are appended as overlays to the end of the DELETE\_DSPU\_TEMPLATE VCB.

### dslu\_template.min\_nau

Minimum NAU address in the range. This can be from 1 to 255 inclusive.

#### dslu\_template.max\_nau

Maximum NAU address in the range. This can be from 1 to 255 inclusive.

### def\_data.allow\_timeout

This field is reserved.

### def\_data.delayed\_logon

This field is reserved.

### dslu\_template.host\_lu

This field is reserved.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_TEMPLATE\_NAME

### AP\_INVALID\_NAU\_RANGE

If the verb does not execute because one or more relevant START\_NODE parameters were not set, the Program returns the following parameter:

#### primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

### DELETE\_DSPU\_TEMPLATE

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameters:

### primary\_rc

## DELETE\_FOCAL\_POINT

The DELETE\_FOCAL\_POINT verb can be used to delete focal points of a specified type and category. For more information about focal point types, see "DEFINE\_FOCAL\_POINT" on page 61. If an active focal point is deleted it will be revoked. To revoke the active focal point (of any type) specify a type of AP\_ACTIVE. If a backup or implicit focal point is deleted (by specifying AP\_BACKUP or AP\_IMPLICIT) when it is not currently active, any information stored about it will simply be removed.

Note that the DEFINE\_FOCAL\_POINT verb can also be used to revoke currently active focal points. This duplicated function is retained for back compatibility.

### VCB Structure

typedef struct delete\_focal\_point

```
unsigned short opcode; /* verb operation code */
unsigned char reserv2; /* reserved */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
unsigned char reserved; /* reserved */
unsigned char ms_category[8]; /* management services category */
unsigned char type; /* type of focal point */
} DELETE FOCAL POINT;
```

## **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_DELETE\_FOCAL\_POINT

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### ms\_category

Management services category. This cab either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services categories as described in SNA management services, or an 8-byte type 1134 EBCDIC installation-defined name.

**type** Specifies the type of the focal point that is being deleted. Possible types are:

### AP\_ACTIVE

The currently active focal point (which can be of any type) is revoked.

### AP\_IMPLICIT

The implicit definition is removed. If the currently active focal point is an implicit focal point, then it is revoked.

### AP\_BACKUP

The backup definition is removed. If the currently active focal point is a backup focal point, then it is revoked.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

primary\_rc AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc AP\_INVALID\_TYPE

\_ \_

AP\_INVALID\_CATEGORY\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DELETE\_INTERNAL\_PU

The DELETE\_INTERNAL\_PU verb requests the deletion of a DLUR-served local PU. The verb will only succeed if the PU does not have an active SSCP-PU session.

Any LUs associated with the PU will be deleted.

## **VCB** Structure

typedef struct delete\_internal\_pu
{
 unsigned short opcode; /\* verb operation code \*/
 unsigned char attributes; /\* verb attributes \*/
 unsigned char format; /\* format \*/
 unsigned short primary\_rc; /\* primary return code \*/
 unsigned long secondary\_rc; /\* secondary return code \*/
 unsigned char pu\_name[8]; /\* internal PU name \*/
} DELETE\_INTERNAL\_PU;

## **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_DELETE\_INTERNAL\_PU

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### pu\_name

Name of the internal PU that is being deleted. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_PU\_TYPE

### DELETE\_INTERNAL\_PU

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK secondary\_rc AP\_PU\_NOT\_RESET

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DELETE\_LOCAL\_LU

The DELETE\_LOCAL\_LU verb requests deletion of the local LU definition.

## **VCB** Structure

```
typedef struct delete_local_lu
{
    unsigned short opcode; /* verb operation code */
    unsigned char reserv2; /* reserved */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char lu_name[8]; /* local LU name */
} DELETE LOCAL LU;
```

## **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_DELETE\_LOCAL\_LU

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### lu\_name

Name of the local LU that is being defined. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_LU\_NAME

AP\_CANT\_DELETE\_CP\_LU

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

### DELETE\_LOCAL\_LU

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc

## DELETE\_LS

DELETE\_LS checks that the link station has been previously defined and reset. It removes the link station control block and returns a response from the Node Operator Facility specifying whether the link station has been deleted successfully. Note that any LUs defined on the PU using this link station will also be deleted.

## VCB Structure

```
typedef struct delete_ls
{
    unsigned short opcode; /* verb operation code */
    unsigned char attributes; /* verb attributes */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char ls_name[8]; /* name of link station */
} DELETE_LS;
```

## **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_DELETE\_LS

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### ls\_name

Name of link station being deleted. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

```
primary_rc
```

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_LINK\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK

secondary\_rc AP\_LS\_ACTIVE

AP\_INVALID\_LINK\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DELETE\_LU\_0\_TO\_3

This verb is used to delete a specific LU.

## **VCB** Structure

```
typedef struct delete_lu_0_to_3
{
    unsigned short opcode; /* verb operation code */
    unsigned char attributes; /* verb attributes */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char lu_name[8]; /* LU name */
} DELETE LU 0 TO 3;
```

## **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_DELETE\_LU\_0\_TO\_3

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### lu\_name

Name of the LU to be deleted. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_INVALID\_LU\_NAME

### AP\_CANT\_DELETE\_IMPLICIT\_LU

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK

### $secondary\_rc$

AP\_INVALID\_LU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

\*/

\*/

\*/

\*/

\*/

## DELETE\_LU\_0\_TO\_3\_RANGE

This verb is used to delete a range of LUs. The node operator provides a base name and an NAU range. The LU names are generated by combining the base name with the NAU addresses.

For example, a base name of LUNME combined with an NAU range of 1 to 4 would delete the LUs LUNME001, LUNME002, LUNME003, and LUNME004. A base name of less than five non-pad characters results in LU names of less than eight non-pad characters.

All LUs in the range are deleted. If an LU in the range does not exist, then the verb continues with the next one that does exist. The verb fails if no LUs exist in the specified range.

### VCB Structure

```
Format 1
```

```
typedef struct delete lu 0 to 3 range
        unsigned short opcode;
                                                 /* verb operation code
        unsigned char attributes;
                                                /* verb attributes
        unsigned char format;
                                                /* format
                                                /* primary return code
        unsigned short primary rc;
                        secondary_rc; /* secondary return code
base_name[6]; /* base name
min_nau; /* minimum NAU address
        unsigned long secondary_rc;
        unsigned char
        unsigned char
                                                /* maximum NAU address
/* Attributes of base_name
        unsigned char
                         max nau;
        unsigned char
                         name attributes;
                         base number;
                                                /* Base number for LU names
        unsigned char
                         reserv5[16];
                                                /* reserved
        unsigned char
} DELETE LU 0 TO 3 RANGE;
```

## VCB Structure

Format 0

```
typedef struct delete lu 0 to 3 range
       unsigned short opcode;
                                         /* verb operation code
                                                                      */
       unsigned char attributes;
                                        /* verb attributes
                                                                      */
       unsigned char format;
                                         /* format
                                                                       */
                                         /* primary return code
       unsigned short primary rc;
                                                                      */
                                         /* secondary return code
       unsigned long secondary rc;
                                                                      */
                                         /* base name
       unsigned char base_name[5];
                                                                      */
                                          /* minimum NAU address
                     min_nau;
       unsigned char
                                                                      */
       unsigned char
                     max nau;
                                          /* maximum NAU address
                                                                      */
                                          /* reserved
       unsigned char
                     reserv3;
} DELETE LU 0 TO 3 RANGE;
```

## **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DELETE\_LU\_0\_TO\_3\_RANGE

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### base\_name

Base LU name. This is an 5-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This base name is appended with three type-A EBCDIC numeric characters, representing the decimal value of the NAU address, for each LU in the NAU range.

#### min\_nau

Minimum NAU address in the range. This can be from 1 to 255 inclusive.

### max\_nau

Maximum NAU address in the range. This can be from 1 to 255 inclusive.

### name\_attributes

This bit field modifies the interpretation and usage of the supplied **base\_name**. This field may take the value of zero, or any or all of the following values bit-wise ORed together.

### AP\_USE\_HEX\_IN\_NAME

If this bit is set, the interpretation of the **base\_name** is modified as follows:

This is a 6-byte alphanumeric types A EBCDID string (starting with a letter), padded to the right with EBCDID spaces. This base name is appended with two EBCDID characters, representing the hexadecimal values of the NAU address, for each LU in the NAU range.

### AP\_USE\_BASE\_NUMBER

If this bit is set, the interpretation of the **base\_name** is modified as follows:

This is a 5-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This base name is appended with three EBCDIC numeric characters, representing the decimal index of the LU in the range, starting with **base\_number** and ending with (**base\_number** + **max\_nau** + **min\_nau**).

### base\_number

If the AP\_USE\_BASE\_NUMBER bit is not set in **name\_attributes** this field is ignored. Otherwise, this field modifies the interpretation of **base\_name** as described above. Legal values are from zero to (255 – **max\_nau** + **min\_nau**).

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_NAU\_ADDRESS

AP\_INVALID\_LU\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK

```
secondary_rc
```

AP\_INVALID\_LU\_NAME

### AP\_CANT\_DELETE\_IMPLICIT\_LU

If the verb does not execute because the system has not been built with dependent LU support, the Program returns the following parameter:

### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

### DELETE\_LU\_POOL

This verb is used to delete an LU pool or to remove LUs from a pool. If no LU names are specified, the entire pool is removed. This verb completes successfully when the specified LUs within the LU pool, or the LU pool itself, no longer exist. The verb only fails if none of the specified LUs exist, or if there are no LUs in the specified pool.

### VCB Structure

### Supplied Parameters

The application supplies the following parameters:

```
opcode
```

AP\_DELETE\_LU\_POOL

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### pool\_name

Name of the LU pool. All 8 bytes are significant and must be set. This name is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### num\_lus

Number of LUs specified in the lu\_names list.

#### lu\_names

Names of the LUs to be removed. Each name is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_POOL\_NAME

AP\_INVALID\_LU\_NAME AP\_INVALID\_NUM\_LUS

If the verb does not execute because the system has not been built with dependent LU support, the Program returns the following parameter:

### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

### DELETE\_MODE

The DELETE\_MODE verb requests deletion of a mode definition. Default definitions for CPSVCMG, SNASVCMG, and other standard SNA modes will not be deleted.

## VCB Structure

typedef struct delete\_mode

```
unsigned short opcode; /* verb operation code */
unsigned char reserv2; /* reserved */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
unsigned char mode_name[8]; /* mode name */
} DELETE MODE;
```

### **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DELETE\_MODE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### mode\_name

Name of the mode. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_CP\_OR\_SNA\_SVCMG\_UNDELETABLE

AP\_MODE\_UNDELETABLE AP\_DEL\_MODE\_DEFAULT\_SPCD AP\_MODE\_NAME\_NOT\_DEFD

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

primary\_rc AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc

### DELETE\_PARTNER\_LU

The DELETE\_PARTNER\_LU requests the deletion of a partner LU definition.

### VCB Structure

```
} DELETE_PARTNER_LU;
```

## **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DELETE\_PARTNER\_LU

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### fqplu\_name

Fully qualified name of the partner LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_PLU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

```
primary_rc
```

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

### DELETE\_PORT

DELETE\_PORT deletes all link stations and connection network transmission groups (TGs) associated with the port if it is reset. It then deletes the port's control block, frees the memory, and returns a response from the Node Operator Facility indicating whether the port has been deleted successfully.

Note that if a link station, which has a PU associated with it, is deleted (because it is associated with the port) then any LUs defined on this PU will also be deleted.

## VCB Structure

### Supplied Parameters

The application supplies the following parameters:

#### opcode

AP\_DELETE\_PORT

### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### port\_name

Name of port being deleted. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_PORT\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK secondary\_rc AP\_PORT\_ACTIVE

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

### DELETE\_TP

The DELETE\_TP requests the deletion of a transaction program (TP) definition.

### VCB Structure

```
typedef struct delete_tp
{
    unsigned short opcode; /* verb operation code */
    unsigned char attributes; /* verb attributes */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char tp_name[64]; /* TP name */
} DELETE TP;
```

### Supplied Parameters

The application supplies the following parameters:

#### opcode

AP\_DELETE\_TP

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### tp\_name

Name of the transaction program. The Program does not check the character set of this field.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_TP\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

primary\_rc AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DELETE\_TP

# **Chapter 5. Activation and Deactivation Verbs**

This chapter describes verbs that are used to activate and deactivate:

- Data link controls (DLCs)
- Internal PUs
- Ports
- Link stations
- Sessions
- Conversation groups

This chapter also describes a verb used to request a path switch to a connection that supports High-Performance Routing (HPR).

## START\_DLC

START\_DLC requests the activation of a data link control (DLC). It is subsequently returned indicating whether the activation of the DLC was successful. Note that the DLC can be started even if no ports have been defined for it. See "DLC Processes, Ports, and Link Stations" on page 14 for more information about the relationship between DLCs, ports, and link stations.

### VCB Structure

typedef struct start\_dlc

```
unsigned short opcode; /* verb operation code */
unsigned char reserv2; /* reserved */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
unsigned char dlc_name[8]; /* name of DLC */
} START_DLC;
```

## **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_START\_DLC

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### dlc\_name

Name of Data Link Control instance that is to be started. This is an 8-byte string in a locally displayable character set, which must have already been defined by a DEFINE\_DLC verb.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

```
secondary_rc
AP_INVALID_DLC
```

If the verb does not execute because the DLC is deactivating, the Program returns the following parameters:

```
primary_rc
AP_STATE_CHECK
```

secondary\_rc AP\_DLC\_DEACTIVATING If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# START\_INTERNAL\_PU

The START\_INTERNAL\_PU verb requests the dependent LU requester (DLUR) to initiate SSCP-PU session activation for a previously defined local PU that is served by DLUR.

## VCB Structure

```
typedef struct start internal pu
                                                /* verb operation code
        unsigned short opcode;
                                                                            */
        unsigned char reserv2;
                                               /* reserved
                                                                            */
        unsigned char format; /* primary return code
unsigned short primary_rc; /* primary return code
/* secondary return cod
                                                                            */
                                                                            */
                                               /* secondary return code */
        unsigned long secondary_rc;
                         pu name[8];
                                                /* internal PU name
        unsigned char
                                                                            */
                         dlus name[17]; /* DLUS name
        unsigned char
                                                                            */
                         bkup dlus name[17]; /* Backup DLUS name
        unsigned char
                                                                            */
} START INTERNAL PU;
```

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_START\_INTERNAL\_PU

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### pu\_name

Name of the internal PU for which the SSCP-PU session activation flows will be solicited. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## dlus\_name

Name of the dependent LU server (DLUS) node that DLUR will contact to solicit SSCP-PU session activation for the given PU. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This value overrides the value specified in the DEFINE\_INTERNAL\_PU verb. If the field is set to all zeros, the DLUS specified in the DEFINE\_INTERNAL\_PU verb will be used. If no DLUS has been specified in the DEFINE\_INTERNAL\_PU verb will be used. If no DLUS has been specified by a DEFINE\_DLUR\_DEFAULTS verb) will be used.

## bkup\_dlus\_name

Name of the DLUS node that DLUR will store as the backup DLUS for the given PU. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This value overrides the value specified in the DEFINE\_INTERNAL\_PU verb. If the field is set to all zeros, the backup DLUS name specified by a DEFINE\_INTERNAL\_PU verb will be retained as the backup DLUS for this PU. If no backup DLUS was specified by the DEFINE\_INTERNAL\_PU verb, the global backup default DLUS (if defined by the DEFINE\_DLUR\_DEFAULTS verb) is retained as the backup default for this PU.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_INVALID\_DLUS\_NAME

## AP\_INVALID\_BKUP\_DLUS\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

## primary\_rc

AP\_STATE\_CHECK

## secondary\_rc

AP\_NO\_DEFAULT\_DLUS\_DEFINED

AP\_PU\_NOT\_DEFINED AP\_PU\_ALREADY\_ACTIVATING AP\_PU\_ALREADY\_ACTIVE

If the verb does not execute successfully, the Program returns the following parameters:

# primary\_rc

AP\_UNSUCCESSFUL

## secondary\_rc

AP\_DLUS\_REJECTED

AP\_DLUS\_CAPS\_MISMATCH AP\_PU\_FAILED\_ACTPU

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# START\_LS

START\_LS requests activation of a link. It is returned as a response specifying whether the link was successfully activated.

See "DLC Processes, Ports, and Link Stations" on page 14 for more information about the relationship between DLCs, ports and link stations.

## VCB Structure

```
typedef struct start_ls
{
    unsigned short opcode; /* verb operation code */
    unsigned char reserv2; /* reserved */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char ls_name[8]; /* name of link station */
    unsigned char enable; /* whether the link is enabled*/
    unsigned char reserv3[3]; /* reserved */
} START_LS;
```

## Supplied Parameters

The application supplies the following parameters:

#### opcode

AP\_START\_LS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### ls\_name

Name of link station to be started. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. The value of **ls\_name** must match that on the DEFINE\_LS verb.

#### enable

Set this field to start the link. If this field is set to AP\_ACTIVATE, then the link is started. Otherwise, the link is not started, and the following values are possible. These values can be ORed together.

#### AP\_AUTO\_ACT

The link can subsequently be activated on demand by the local node. This value is only valid if **auto\_act\_supp** was set to AP\_YES on the DEFINE\_LS verb.

## AP\_REMOTE\_ACT

The link can subsequently be activated by the remote node. This does not alter the defined value of **disable\_remote\_act**.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_LINK\_NAME\_SPECIFIED

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK

secondary\_rc

AP\_PORT\_INACTIVE

AP\_ACTIVATION\_LIMITS\_REACHED AP\_PARALLEL\_TGS\_NOT\_SUPPORTED AP\_ALREADY\_STARTING AP\_LINK\_DEACT\_IN\_PROGRESS

If the verb does not execute because it was canceled by a subsequent STOP\_LS or STOP\_PORT before the link became active, the Program returns the following parameters:

```
primary_rc
```

AP\_CANCELLED

secondary\_rc

AP\_LINK\_DEACTIVATED

If the verb does not execute because the partner could not be found by the link software, the Program returns the following parameters:

primary\_rc

AP\_LS\_FAILURE

secondary\_rc

AP\_PARTNER\_NOT\_FOUND

If the verb does not execute because a link error occurred while the link was being established, the Program returns the following parameters:

## primary\_rc

AP\_LS\_FAILURE

secondary\_rc AP\_ERROR

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc

# START\_PORT

START\_PORT requests the activation of a port. It is returned indicating whether the port was successfully activated. The port can be started even if no link stations have been defined for it, but it will not be started if its parent DLC is inactive.

See "DLC Processes, Ports, and Link Stations" on page 14 for more information about the relationship between DLCs, ports and link stations.

# VCB Structure

```
typedef struct start_port
{
    unsigned short opcode;    /* verb operation code */
    unsigned char reserv2;    /* reserved */
    unsigned char format;    /* format */
    unsigned short primary_rc;    /* primary return code */
    unsigned long secondary_rc;    /* secondary return code */
    unsigned char port_name[8];    /* name of port */
} START_PORT;
```

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_START\_PORT

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## port\_name

Name of port to be started. This is an 8-byte string in a locally displayable character set and must match that on the DEFINE\_PORT verb.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_INVALID\_PORT\_NAME

If the verb does not execute because of a state error, the Program returns the following parameters:

```
primary_rc
AP_STATE_CHECK
secondary_rc
AP_DLC_INACTIVE
```

## AP\_STOP\_PORT\_PENDING AP\_DUPLICATE\_PORT

If the verb does not execute because it was canceled, the Program returns the following parameter:

## primary\_rc

AP\_CANCELLED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# STOP\_DLC

STOP\_DLC requests that a DLC be stopped. It is returned indicating whether the DLC was successfully stopped. STOP\_DLC is also used to instruct the Program to stop automatically retrying the activation of any link stations on ports over this DLC.

# VCB Structure

typedef struct stop\_dlc
{
 unsigned short opcode; /\* verb operation code \*/
 unsigned char reserv2; /\* reserved \*/
 unsigned char format; /\* format \*/
 unsigned short primary\_rc; /\* primary return code \*/
 unsigned long secondary\_rc; /\* secondary return code \*/
 unsigned char stop\_type; /\* stop type \*/
 unsigned char dlc\_name[8]; /\* name of DLC \*/
} STOP\_DLC;

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_STOP\_DLC

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## stop\_type

Manner in which DLC should be stopped.

## AP\_ORDERLY\_STOP

Node should perform cleanup operations before stopping DLC.

## AP\_IMMEDIATE\_STOP

Node should stop DLC immediately.

## dlc\_name

Name of DLC to be stopped. This is an 8-byte string in a locally displayable character set, which must match that on the DEFINE\_DLC verb.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_DLC

AP\_UNRECOGNIZED\_DEACT\_TYPE

## STOP\_DLC

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK secondary\_rc AP\_STOP\_DLC\_PENDING

If the verb does not execute because it has been canceled, the Program returns the following parameter:

primary\_rc AP\_CANCELLED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# STOP\_INTERNAL\_PU

The STOP\_INTERNAL\_PU verb requests the dependent LU requester (DLUR) initiate SSCP-PU session deactivation for a previously defined local PU that is served by DLUR.

# **VCB** Structure

```
typedef struct stop_internal_pu
{
    unsigned short opcode;    /* verb operation code */
    unsigned char reserv2;    /* reserved */
    unsigned char format;    /* format */
    unsigned short primary_rc;    /* primary return code */
    unsigned long secondary_rc;    /* secondary return code */
    unsigned char pu_name[8];    /* internal PU name */
    unsigned char stop_type;    /* type of stop requested */
} STOP_INTERNAL_PU;
```

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_STOP\_INTERNAL\_PU

```
format
```

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## pu\_name

Name of the internal PU for which the SSCP-PU session will be deactivated. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## stop\_type

Specifies stop type requested for the PU. An orderly stop will deactivate all underlying PLU-SLU and SSCP-LU sessions before deactivating the SSCP-PU session.

AP\_ORDERLY\_STOP AP\_IMMEDIATE\_STOP

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

```
primary_rc
```

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_STOP\_TYPE

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK

secondary\_rc

AP\_PU\_NOT\_DEFINED

AP\_PU\_ALREADY\_DEACTIVATING AP\_PU\_NOT\_ACTIVE

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# STOP\_LS

STOP\_LS requests the deactivation of a link station. It is returned specifying whether the link was stopped successfully. STOP\_LS can also be used to disable remote activation of a link station or to disable activation on demand of a link station. STOP\_LS is also used to instruct the Program to stop automatically retrying the activation of any link station.

# VCB Structure

```
typedef struct stop_ls
{
    unsigned short opcode; /* verb operation code */
    unsigned char reserv2; /* reserved */
    unsigned char format; /* format */
    unsigned short primary_rc; /* primary return code */
    unsigned long secondary_rc; /* secondary return code */
    unsigned char stop_type; /* stop type */
    unsigned char ls_name[8]; /* name of link station */
    unsigned char disable; /* whether the link is disabled */
    unsigned char reserved[3]; /* reserved */
} STOP_LS;
```

Supplied Parameters

The application supplies the following parameters:

opcode

AP\_STOP\_LS

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## stop\_type

Manner in which the link station should be stopped.

## AP\_ORDERLY\_STOP

Node should perform cleanup operations before stopping the link station.

## AP\_IMMEDIATE\_STOP

Node should stop the link station immediately.

## ls\_name

Name of link station to be stopped. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. The value of **ls\_name** must match that on the DEFINE\_LS verb.

## disable

This indicates whether remote activation or activation on demand of this link station should be disabled. If set to AP\_NO, then the link station is returned to the state given by the values of **auto\_act\_supp** and **disable\_remote\_act** from the DEFINE\_LS verb. Otherwise, the following values are possible (and can be ORed together).

## AP\_AUTO\_ACT

The link cannot be reactivated on demand by the local node.

## AP\_REMOTE\_ACT

The link cannot be activated by the remote node. For a link

configured with **disable\_remote\_act** set to AP\_YES, this bit is ignored (activation by a remote node is always disabled by STOP\_LS).

If the **disable** field is not set to AP\_NO, then STOP\_LS can be issued for a link that is not active or that is in the process of deactivating, for the purpose of setting the **disable** field.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_UNRECOGNIZED\_DEACT\_TYPE

## AP\_LINK\_NOT\_DEFD

If the verb does not execute because of a state error, the Program returns the following parameters:

## primary\_rc

AP\_STATE\_CHECK

```
secondary_rc
AP_LINK_DEACT_IN_PROGRESS
```

If the verb does not execute because it was canceled, the Program returns the following parameter:

## primary\_rc

AP\_CANCELLED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# STOP\_PORT

STOP\_PORT requests that a port be stopped. It is returned specifying whether the port was stopped successfully. STOP\_PORT is also used to instruct the Program to stop automatically retrying the activation of any link stations on the port.

# **VCB** Structure

typedef struct stop\_port

```
1
unsigned short opcode; /* verb operation code */
unsigned char reserv2; /* reserved */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
unsigned char stop_type; /* Stop Type */
unsigned char port_name[8]; /* name of port */
} STOP PORT;
```

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_STOP\_PORT

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## stop\_type

Manner in which the port should be stopped.

## AP\_ORDERLY\_STOP

Node should perform cleanup operations before stopping the port.

## AP\_IMMEDIATE\_STOP

Node should stop the port immediately.

## port\_name

Name of port to be stopped. This is an 8-byte string in a locally displayable character set, which must match that on the DEFINE\_PORT verb.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

```
primary_rc
```

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_PORT\_NAME

AP\_UNRECOGNIZED\_DEACT\_TYPE

## STOP\_PORT

If the verb does not execute because of a state error, the Program returns the following parameters:

primary\_rc AP\_STATE\_CHECK secondary\_rc AP\_STOP\_PORT\_PENDING

If the verb does not execute because it has been canceled, the Program returns the following parameter:

primary\_rc AP\_CANCELLED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# **ACTIVATE\_SESSION**

The ACTIVATE\_SESSION verb requests activation of a session between the local LU and a specified partner LU using the characteristic of a particular mode.

# VCB Structure

## Format 1

typedef struct activate\_session

unsigned	short	opcode;	/*	verb operation code	*/
unsigned	char	reserv2;	/*	reserved	*/

				/*	LU name	*/
	unsigned	char	polarity;	/*	requested session	*/
					polarity	*/
	unsigned	char	<pre>session_id[8];</pre>	/*	session identifier	*/
}	ACTIVATE_SESSIG	DN;				

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_ACTIVATE\_SESSION

#### format

Identifies the format of the VCB. Set this field to zero or one to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU requested to activate a session. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Alias of the local LU requested to activate a session. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_alias** and the **lu\_name** are set to all zeros then the verb is forwarded to the LU associated with the control point (the default LU).

## plu\_alias

Alias by which the partner LU is known to the local LU. This name must match the name of a partner LU established during configuration. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field is used to specify the required partner LU.

#### mode\_name

Name of a set of networking characteristics defined during configuration. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### fqplu\_name

Fully qualified LU name for the partner LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only significant if the **plu\_alias** field is set to all zeros.

#### polarity

The polarity requested for the session. Possible values are:

AP\_POL\_EITHER AP\_POL\_FIRST\_SPEAKER AP\_POL\_BIDDER

If AP\_POL\_EITHER is selected, ACTIVATE\_SESSION activates a first speaker session if available; otherwise, a bidder session is activated. For AP\_POL\_FIRST\_SPEAKER or AP\_POL\_BIDDER, ACTIVATE\_SESSION only succeeds if a session of the requested polarity is available.

#### cnos\_permitted

This field may be set to AP\_YES or AP\_NO. If the activation of a new session is not possible because the session limits for the specified mode are reset, and this field is set to AP\_YES, then the Program initiates implicit CNOS processing to initialize the session limits. Execution of this verb will be suspended while CNOS processing takes place.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

primary\_rc AP\_OK

secondary\_rc AP\_AS\_SPECIFIED

#### AP\_AS\_NEGOTIATED

session\_id

8-byte identifier of the activated session.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_EXCEEDS\_MAX\_ALLOWED

AP\_INVALID\_CNOS\_PERMITTED AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS AP\_INVALID\_MODE\_NAME AP\_INVALID\_PLU\_NAME

If the verb exceeds the session limit for the mode, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

Secondary\_rc AP\_EXCEEDS\_MAX\_ALLOWED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

If the verb does not execute because of other errors, the Program returns one of the following parameters:

## primary\_rc

AP\_ACTIVATION\_FAIL\_NO\_RETRY

AP\_ACTIVATION\_FAIL\_RETRY

# DEACTIVATE\_CONV\_GROUP

The DEACTIVATE\_CONV\_GROUP verb requests the deactivation of the session corresponding to the specified conversation group. Although this verb is part of the Node Operator Facility API, it is primarily intended for use by application programmers writing transaction programs that use the Personal Communications or Communications Server APPC API. The conversation group identifier is returned by the MC\_ALLOCATE, ALLOCATE, MC\_GET\_ATTRIBUTES, GET\_ATTRIBUTES and RECEIVE\_ALLOCATE verbs defined in *Client/Server Communications Programming*.

## VCB Structure

typedef struct deactivate\_conv\_group

1				
	unsigned short	opcode;	<pre>/* verb operation code</pre>	*/
	unsigned char	reserv2;	/* reserved	*/
	unsigned char	format;	/* format	*/
	unsigned short	primary_rc;	/* primary return code	*/
	unsigned long	<pre>secondary_rc;</pre>	/* secondary return code	*/
	unsigned char	lu_name[8];	/* local LU name	*/
	unsigned char	lu_alias[8];	/* local LU alias	*/
	unsigned long	conv_group_id;	/* conversation group identifier	*/
	unsigned char	type;	<pre>/* deactivation type</pre>	*/
	unsigned char	reserv3[3];	/* reserved	*/
	unsigned long	sense_data;	<pre>/* deactivation sense data</pre>	*/
}	DEACTIVATE_CONV_GROUP	);		

## **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_DEACTIVATE\_CONV\_GROUP

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU requested to deactivate the conversation group. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

## lu\_alias

Alias of the local LU requested to deactivate the conversation group. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and **lu\_alias** are set to all zeros, the verb is forwarded to the LU associated with the control point (the default LU).

## conv\_group\_id

Conversation group identifier for the session to be deactivated.

**type** Type of deactivation. This field is a bitmask consisting of a deactivation type ORed with a flag indicating whether the verb should complete asynchronously or synchronously.

Deactivation types:

## AP\_DEACT\_CLEANUP

The session is terminated immediately, without waiting for a response from the partner LU.

## AP\_DEACT\_NORMAL

The session terminates after all conversations using the session are ended.

Verb behavior:

## AP\_ASYNCHRONOUS\_DEACTIVATION

The verb returns immediately.

#### AP\_SYNCHRONOUS\_DEACTIVATION

The verb returns only after the session has been deactivated.

#### sense\_data

Specifies the sense data for use in the CLEANUP type of deactivation.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc AP\_INVALID\_CLEANUP\_TYPE

> AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

## DEACTIVATE\_SESSION

The DEACTIVATE\_SESSION verb requests the deactivation of a particular session, or all sessions on a particular mode.

# VCB Structure

typedef struct deactivate session

ι						
	unsigned	short	opcode;	/*	verb operation code	*/
	unsigned	char	reserv2;	/*	reserved	*/
	unsigned	char	format;	/*	format	*/
	unsigned	short	primary_rc;	/*	primary return code	*/
	unsigned	long	<pre>secondary_rc;</pre>	/*	secondary return code	*/
	unsigned	char	lu_name[8];	/*	local LU name	*/
	unsigned	char	lu_alias[8];	/*	local LU alias	*/
	unsigned	char	<pre>session_id[8];</pre>	/*	session identifier	*/
	unsigned	char	plu_alias[8];	/*	partner LU alias	*/
	unsigned	char	<pre>mode_name[8];</pre>	/*	mode name	*/
	unsigned	char	type;	/*	deactivation type	*/
	unsigned	char	reserv3[3];	/*	reserved	*/
	unsigned	long	sense_data;	/*	deactivation sense data	*/
	unsigned	char	<pre>fqplu_name[17];</pre>	/*	fully qualified partner	*/
				/*	LU name	*/
	unsigned	char	reserv4[20];	/*	reserved	*/
}	DEACTIVATE_SESS	SION;				

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEACTIVATE\_SESSION

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU requested to deactivate a session. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Alias of the local LU requested to deactivate a session. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** fields are set to all zeros then the verb is forwarded to the LU associated with the control point (the default LU).

## session\_id

8-byte identifier of the session to deactivate. If this field is set to all zeros, Personal Communications or Communications Server deactivates all sessions for the partner LU and mode.

#### plu\_alias

Alias by which the partner LU is known to the local LU. This name must match the name of a partner LU established during configuration. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field is used to specify the required partner LU.

#### mode\_name

Name of a set of networking characteristics defined during configuration. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

**type** Type of deactivation. This field is a bitmask consisting of a deactivation type ORed with a flag indicating whether the verb should complete asynchronously or synchronously.

#### Deactivation types:

## AP\_DEACT\_CLEANUP

The session is terminated immediately, without waiting for a response from the partner LU.

## AP\_DEACT\_NORMAL

The session terminates after all conversations using the session are ended.

Verb behavior:

#### AP\_ASYNCHRONOUS\_DEACTIVATION

The verb returns immediately.

## AP\_SYNCHRONOUS\_DEACTIVATION

The verb returns only after the session has been deactivated.

## sense\_data

Specifies the sense data to be used for the CLEANUP type of deactivation.

## fqplu\_name

Fully qualified LU name for the partner LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only significant if the **plu\_alias** field is set to all zeros.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

Note that if the **session\_id** cannot be matched with any existing sessions, it is assumed that this is because the session has already been deactivated. In this case the verb completes successfully.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_MODE\_NAME

AP\_INVALID\_PLU\_NAME AP\_INVALID\_CLEANUP\_TYPE AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS

## DEACTIVATE\_SESSION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

## PATH\_SWITCH

The PATH\_SWITCH verb requests Personal Communications or Communications Server to switch routes on a connection that supports high-performance routing (HPR). If a better path cannot be found, the connection is left unchanged.

# VCB Structure

typedef struct path\_switch

```
unsigned short opcode; /* verb operation code */
unsigned char reserv2; /* reserved */
unsigned char format; /* format */
unsigned short primary_rc; /* primary return code */
unsigned long secondary_rc; /* secondary return code */
unsigned char rtp_connection_name[8];
/* RTP connection name */
```

} PATH\_SWITCH;

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_PATH\_SWITCH

```
format
```

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## rtp\_connection\_name

Identifies the RTP connection to path-switch. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

# primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_RTP\_CONNECTION

If the verb does not execute because of a state error, the Program returns the following parameters:

```
primary_rc
AP_STATE_CHECK
```

secondary\_rc AP\_PATH\_SWITCH\_IN\_PROGRESS

If the verb does not execute because the path switch attempt fails, the Program returns the following parameter:

## primary\_rc

AP\_UNSUCCESSFUL

If the verb does not execute because the node is stopping, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# **Chapter 6. Query Verbs**

This chapter describes verbs used to query information about node configuration and status.

Only certain parameters are supported on SNA API clients.

## QUERY\_ADJACENT\_NN

This verb applies only to Communications Server.

QUERY\_ADJACENT\_NN is only used at a network node and returns information about adjacent network nodes (that is, those network nodes to which CP-CP sessions are active or have been active or have been active at some time).

The adjacent node information is returned as a formatted list. To obtain information about a specific network node or to obtain the list information in several chunks, the **adj\_nncp\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered on the **adj\_nncp\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected the list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

## **VCB** Structure

<pre>} QUERY_ADJACENT_NN;</pre>		-	
typedef struct adj_n	ncp_data		
unsigned sho unsigned cha unsigned cha unsigned lon unsigned lon unsigned lon unsigned cha } ADJ_NNCP_DATA;	<pre>r adj_nncp_name[17]; r cp_cp_sess_status; g out_of_seq_tdus; g last_frsn_sent; g last_frsn_rcvd;</pre>	<pre>/* size of this entry /* CP name of adj. network node /* CP-CP session status /* out of sequence TDUs /* last FRSN sent /* last FRSN received /* reserved</pre>	*/ */ */ */

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_ADJACENT\_NN

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information: The **adj\_nncp\_name** specified (see the following parameter, **adj\_nncp\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## adj\_nncp\_name

Fully-qualified, 17 byte, name of adjacent network node composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

The number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## adj\_nncp\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## adj\_nncp\_data.adj\_nncp\_name

17-byte fully-qualified CP name of adjacent network node which is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## adj\_nncp\_data.cp\_cp\_sess\_status

Status of the CP-CP session. This is set to one of the following:

AP-ACTIVE AP\_CONWINNER\_ACTIVE AP\_CONLOSER\_ACTIVE AP\_INACTIVE

## adj\_nncp\_data.out\_of\_seq\_tdus

Number of out of sequence TDUs received from this node.

## adj\_nncp\_data.last\_frsn\_sent

The last flow reduction sequence number sent to this node.

## adj\_nncp\_data.last\_frsn\_rcvd

The last flow reduction sequence number received from this node.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_ADJ\_NNCP\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# QUERY\_ADJACENT\_NODE

QUERY\_ADJACENT\_NODE returns information about adjacent nodes configured on DEFINE\_ADJACENT\_NODE.

Information is returned in an ordered list. Each entry in the list consists of an ADJACENT\_NODE\_DATA overlay containing information about the adjacent CP, followed by an ADJACENT\_NODE\_LU\_DATA overlay for each LU associated with the adjacent CP.

Entries are ordered by **cp\_name**, then by **fqlu\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If AP\_LIST\_FROM\_NEXT is selected, the list will start from the next entry according to the defined ordering (whether the specified entry exists or not).

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_ADJACENT\_NODE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information. The **cp\_name** specified (see the following parameter, **cp\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first adjacent node in the directory maintained by the Program.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## cp\_name

Fully qualified name of the adjacent node. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## adjacent\_node\_data.overlay\_size

The number of bytes in this entry, including any ADJACENT\_NODE\_LU\_DATA structures, and hence the offset to the next entry returned (if any).

## adjacent\_node\_data.sub\_overlay\_size

The number of bytes in the node part of the entry, not including any ADJACENT\_NODE\_LU\_DATA structures; this is the offset to the first ADJACENT\_NODE\_LU\_DATA field in the entry.

## adjacent\_node\_data.cp\_name

Fully qualified name of the adjacent node. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## adjacent\_node\_data.description

Resource description (as specified on DEFINE\_ADJACENT\_NODE). The length of this field should be a multiple of four bytes, and nonzero.

## adjacent\_node\_data.num\_of\_lus

The number of LUs defined for this adjacent node. An ADJACENT\_NODE\_LU\_DATA structure for each LU follows.

## adjacent\_node\_lu\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## adjacent\_node\_lu.wildcard\_lu

Indicates whether the LU name is defined as a wildcard.

## adjacent\_node\_lu.fqlu\_name

Fully qualified name of the adjacent node. The name is 17 bytes long and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_CP\_NAME

## AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

## QUERY\_CN

QUERY\_CN returns information about adjacent Connection Networks. This information is structured as determined data (data gathered dynamically during execution) and defined data (the data supplied by the application on DEFINE\_CN).

The information is returned as a formatted list. To obtain information about a specific CN, or to obtain the list information in several chunks, the **fqcn\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered on the **fqcn\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If AP\_LIST\_FROM\_NEXT is selected, the list will start from the next entry according to the defined ordering (whether the specified entry exists or not).

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_QUERY\_CN

## attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information: The **fqcn\_name** specified (see the following parameter, **fqcn\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## fqcn\_name

Fully qualified, 17-byte, connection network name. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## cn\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## cn\_data.fqcn\_name

Fully qualified, 17-byte, connection network name. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### cn\_data.det\_data.num\_act\_ports

Dynamic value giving number of active ports on the connection network.

## cn\_data.def\_data.description

Resource description (as specified on DEFINE\_CN). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### cn\_data.def\_data.num\_ports

Number of ports on the connection network.

## cn\_data.def\_data.tg\_chars.effect\_cap

Actual units of effective capacity. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemm. Each unit of effective capacity is equal to 300 bits per second.

## cn\_data.def\_data.tg\_chars.connect\_cost

Cost per connect time. Valid values are integer values in the range 0–255, where 0 is the lowest cost per connect time and 255 is the highest.

#### cn\_data.def\_data.tg\_chars.byte\_cost

Cost per byte. Valid values are integer values in the range 0–255, where 0 is the lowest cost per byte and 255 is the highest.

## cn\_data.def\_data.tg\_chars.security

Security values as described in the list below.

# AP\_SEC\_NONSECURE

No security exists.

# AP SEC PUBLIC SWITCHED NETWORK

Data transmitted over this connection network will flow over a public switched network.

### AP\_SEC\_UNDERGROUND\_CABLE

Data is transmitted over secure underground cable.

#### AP\_SEC\_SECURE\_CONDUIT

The line is a secure conduit that is not guarded.

## AP\_SEC\_GUARDED\_CONDUIT

Conduit is protected against physical tapping.

#### AP SEC ENCRYPTED

Encryption over the line.

# AP SEC GUARDED RADIATION

Line is protected against physical and radiation tapping.

### cn\_data.def\_data.tg\_chars.prop\_delay

Propagation delay representing the time it takes for a signal to travel the length of the link, in microseconds. The value is encoded as a 1-byte floating-point number, represented by the formula 0.1mmm \* 2 eeeee, where the bit representation of the byte is eeeeemmm. Default values are listed below.

### AP PROP DELAY MINIMUM

No propagation delay.

### AP\_PROP\_DELAY\_LAN Less than 480 microseconds delay.

AP\_PROP\_DELAY\_TELEPHONE

Between 480 and 49 512 microseconds delay.

# AP\_PROP\_DELAY\_PKT\_SWITCHED\_NET

Between 49 512 and 245 760 microseconds delay.

# AP\_PROP\_DELAY\_SATELLITE

Longer than 245 760 microseconds delay.

### AP\_PROP\_DELAY\_MAXIMUM Maximum propagation delay.

# cn\_data.def\_data.tg\_chars.modem\_class

Reserved. This field should always be set to zero.

# cn\_data.def\_data.tg\_chars.user\_def\_parm\_1

User defined parameter in the range 0–255.

## cn\_data.def\_data.tg\_chars.user\_def\_parm\_2 User defined parameter in the range 0–255.

cn data.def data.tg chars.user def parm 3 User defined parameter in the range 0–255.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc AP\_INVALID\_CN\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc

# QUERY\_CN\_PORT

QUERY\_CN\_PORT returns information about ports defined on adjacent connection networks. The information is returned as a formatted list. To obtain information about a specific port, or to obtain the list information in several chunks, the **port\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. Note that the **fqcn\_name** field must always be set to the name of a valid connection network.

See "Querying the Node" on page 10 for background on how the list formats are used.

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information: The combination of **fqcn\_name** and **port\_name** specified (see the following parameters, **fqcn\_name** and **port\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### fqcn\_name

Fully qualified, 17-byte, connection network name. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field must always be set.

#### port\_name

8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### cn\_port\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

### cn\_port\_data.fqcn\_name

Fully qualified, 17-byte, connection network name. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## cn\_port\_data.port\_name

Port name in an 8-byte, locally displayable character set. All 8 bytes are significant.

## cn\_port\_data.tg\_num

Transmission group number for specified port.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_CN\_NAME

AP\_INVALID\_PORT\_NAME AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# QUERY\_CONVERSATION

QUERY\_CONVERSATION returns list information about conversations running over the specified LU. To obtain information about a specific conversation or to obtain the list information in several chunks, the conv\_id field should be set. Otherwise (if the list\_options field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. Note that the lu\_alias field must always be set. The lu\_name, if nonzero, will be used in preference to the lu\_alias.

See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the conv\_id. If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the index (whether the specified entry exists or not).

# VCB Structure

# **Supplied Parameters**

The application supplies the following parameters:

# opcode

AP\_QUERY\_CONVERSATION

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

### list\_options

This indicates what should be returned in the list information. The **index** specified (see following) represents an index value that is used to specify the starting point of the actual information to be returned.

### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### lu\_name

Name of the local LU. This is an 8–byte alphanumeric type A EBCDIC string (not starting with a number), and is right-padded with EBCDIC spaces.

#### lu\_alias

Alias by which the local LU is known by the local TP. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

### conv\_id

Conversation ID.

#### session\_id

If this is all binary zeroes, this field is not used to filter the returned conversations. If it is not zeroes, only those conversations whose session IDs match the supplied value are returned.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

# num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

### conv\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### conv\_summary.conv\_id

Conversation ID.

The value of this parameter was returned by the ALLOCATE verb in the invoking transaction action or by RECEIVE\_ALLOCATE in the invoked transaction program.

## conv\_summary.local\_tp\_name

Name of the local transaction program.

### conv\_summary.partner\_tp\_name

Name of the partner transaction program. This is only valid for a locally-initiated conversation. For a remotely initiated conversation, it is blank.

#### conv\_summary.tp\_id

The transaction program identifier assigned to the transaction program. This identifier is either assigned by the API stub, or by the NOF transaction program manager.

#### conv\_summary.sess\_id

Identifier of the session allocated to this conversation.

#### conv\_summary.conv\_start\_time

The elapsed time in centiseconds from the time the node was started to the time the conversation was started.

#### conv\_summary.bytes\_sent

The number of bytes sent so far on this conversation.

#### conv\_summary.bytes\_received

The number of bytes received so far on this conversation.

#### conv\_summary\_conv\_state

Current state of the conversation that is identified by **conv\_id**. For half-duplex conversations, it is one of the following:

#### AP\_RESET\_STATE

AP\_SEND\_STATE AP\_RECEIVE\_STATE AP\_CONFIRM\_STATE AP\_CONFIRM\_SEND\_STATE AP\_CONFIRM\_DEALL\_STATE AP\_PEND\_POST\_STAT AP\_PEND\_DEALL\_STATE AP\_END\_CONV\_STATE AP\_SEND\_PENDING\_STATE AP\_POST\_ON\_RECEIPT\_STATE

For full-duplex conversations, it is one of the following:

AP\_RESET\_STATE AP\_SEND\_RECEIVE\_STATE AP\_SEND\_ONLY\_STATE AP\_RECEIVE\_ONLY\_STATE

# conv\_summary.duplex\_type

Specifies whether this conversation is half or full-duplex.

AP\_HALF\_DUPLEX AP\_FULL\_DUPLEX

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_BAD\_CONV\_ID

AP\_INVALID\_LU\_ALIAS AP\_INVALID\_LU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

# QUERY\_COS

QUERY\_COS returns route calculation information for a specific class of service. The information is returned as a formatted list. To obtain information about a specific COS, or to obtain the list information in several chunks, the **cos\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used. This list is ordered on the **cos\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

# VCB Structure

```

} COS DATA;

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_QUERY\_COS

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information: The **cos\_name** specified (see the following parameter, **cos\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### **AP\_LIST\_INCLUSIVE**

The returned list starts from the entry specified by the index value.

#### cos\_name

Class-of-service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## cos\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### cos\_data.cos\_name

Class-of-service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### cos\_data.description

Resource description (as specified on DEFINE\_COS). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### cos\_data.transmission\_priority

Transmission priority. This is set to one of the following values:

AP\_LOW AP\_MEDIUM AP\_HIGH AP\_NETWORK

#### cos\_data.num\_of\_node\_rows

Number of node rows for this COS.

## cos\_data.num\_of\_tg\_rows

Number of TG rows for this COS.

#### cos\_data.trees

Number of route tree caches built for this COS since the last initialization.

#### cos\_data.calcs

Number of session activation requests (and therefore route calculations) specifying this class of service.

#### cos\_data.rejs

Number of session activation requests that failed because there was no acceptable (using the specified class of service) route from this node to the named destination through the network. A route is only acceptable if it is made up entirely of active TGs and nodes that can provide the specified class of service.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_COS\_NAME

### AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

# QUERY\_DEFAULT\_PU

QUERY\_DEFAULT\_PU allows the user to query the default PU defined using a DEFINE\_DEFAULT\_PU verb.

# VCB Structure

typedef struct query\_default\_pu

unsigned sh	ort opcode;	<pre>/* verb operation code</pre>	*/
unsigned ch	ar reserv2;	/* reserved	*/
unsigned ch	ar format;	/* format	*/
unsigned sh	ort primary rc;	/* primary return code	*/
unsigned lo	ng secondary rc	; /* secondary return code	*/
unsigned ch	ar def_pu_name[	8]; /* default PU name	*/
unsigned ch	ar description[	RD_LEN];	
		/* resource description	*/
unsigned ch	ar def_pu_sess[	8]; /* PU name of active	*/
		/* default session	*/
unsigned ch	ar reserv3[16];	/* reserved	*/
<pre>} QUERY_DEFAULT_PU;</pre>			

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_QUERY\_DEFAULT\_PU

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## def\_pu\_name

Name of the PU specified on the most recent DEFINE\_DEFAULT\_PU verb. This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If no DEFINE\_DEFAULT\_PU verb has been issued then this field will be set to all zeros.

## description

Resource description (as specified on DEFINE\_DEFAULT\_PU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

### def\_pu\_sess

Name of the PU associated with the currently active default PU session. This will be different from the **def\_pu\_name** field if a default PU has been defined, but the session associated with it is not active. In this case, Personal Communications or Communications Server continues to use the session associated with the previous default PU until the session associated with the defined default PU becomes active. If there are no active PU sessions then this field will be set to all zeros.

# QUERY\_DEFAULT\_PU

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

# QUERY\_DEFAULTS

QUERY\_DEFAULTS allows the user to query the defaults defined using the DEFINE\_DEFAULTS verb.

# **VCB** Structure

typedef struct query_de {	faults		
unsigned short unsigned char	opcode; reserv2;	<pre>/* verb operation code /* reserved</pre>	*/ */
unsigned char		-	*/
unsigned short		/* primary return code	*/
unsigned long		/* secondary return code	
DEFAULT_CHARS		/* default information	*/
<pre>} QUERY_DEFAULTS;</pre>	_		
typedef struct default_	chars		
۱ unsigned char	description[RD_		
	. 5-7	/* resource description	*/
unsigned char		/* default mode name	*/
unsigned char	<pre>implicit_plu_fc</pre>		*/
		/* disallow implicit /* PLUs ?	*/
unsigned char	specific securi	,	~/
unorghea char	speerine_seeuri	/* generic security	*/
		/* sense codes	*/
unsigned char	limited_timeout	;/* timeout for limited	*/
		/* sessions	*/
unsigned char } DEFAULT_CHARS;	reserv[244];	/* reserved	*/

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_QUERY\_DEFAULTS

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

## default\_chars.description

Resource description (as specified on DEFINE\_DEFAULTS). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

### default\_chars.mode\_name

Name of the mode specified on the most recent DEFINE\_DEFAULTS verb. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If no DEFINE\_DEFAULTS verb has been issued then this field will be set to all zeros.

# default\_chars.implicit\_plu\_forbidden

Controls whether the Program will put implicit definitions in place for unknown Partner LUs (AP\_YES or AP\_NO).

# default\_chars.specific\_secuity\_codes

Controls whether the Program will use specific sense codes on a security authentication or authorization failure (AP\_YES or AP\_NO). Note that the specific sense codes will only be returned to those partner LUs which have reported support for them on the session.

# default\_chars.limited\_timeout

Specifies the timeout after which free limited-resource conwinnner sessions will be deactivated. Range 0 to 65535 seconds.

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

# QUERY\_DIRECTORY\_ENTRY

QUERY\_DIRECTORY\_ENTRY returns a list of LUs from the directory database. The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific LU, or to obtain the list information in several chunks, the **resource\_name** and **resource\_type** fields should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

When the local node is a network node, information is returned as follows:

1st Network Node 1st LU located at Network Node 2nd LU locate at Network Node ... nth LU located at Network Node

nth LU located at Network Node 1st End Node served by this Network Node 1st LU located at End Node(1) 2nd LU located at End Node(1) ... nth LU located at End Node(1) ... nth End Node served by this Network Node 1st LU located at End Node(n) 2nd LU located at End Node(n)

2nd Network Node ...etc..

When the Program is operating as an End Node the first entry returned in the first entry returned in the resource list is the EN CP. (No entry is returned for the End Node's Network Node server.)

This list of directory entries returned may be filtered by the parent name (and type). In this case, both the **parent\_name** and **parent\_type** fields should be set (otherwise these fields should be set to all zeros). Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

<pre>} QUERY DIRECTORY ENTRY</pre>	•		

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_QUERY\_DIRECTORY\_ENTRY

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above. In addition to affecting the format of the VCB, only format 1 returns resources of AP\_DLUR\_LU\_RESOURCE.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

### AP\_DETAIL

Returns detailed information.

The combination of the **resource\_name** and **resource\_type** specified (see the following parameters, **resource\_name** and **resource\_type**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### resource\_name

Network qualified resource name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### resource\_type

Resource type. See one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE AP\_DLUR\_LU\_RESOURCE

This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### parent\_name

Parent name filter. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If this field is set, then only directory entries belonging to the specified parent are returned (and in this case, the **parent\_name** field must also be set). This field is if it is set to all zeros.

#### parent\_type

The type of parent specified in the **parent\_name** field. The type must be specified if the **parent\_name** field is nonzero, otherwise this field should be set to zero. The can be set to one of the following:

AP\_ENCP\_RESOURCE AP\_NNCP\_RESOURCE

This field is ignored if list\_options is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

# num\_entries

Number of directory entries returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### directory\_entry\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### directory\_entry\_summary.resource\_name

Network qualified resource name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### directory\_entry\_summary.resource\_type

Resource type. This can be one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE AP\_DLUR\_LU\_RESOURCE

(Not returned if format is set to zero.)

## directory\_entry\_summary.description

Resource description as specified on:

DEFINE\_LOCAL\_LU DEFINE\_DIRECTORY\_ENTRY DEFINE\_ADJACENT\_LEN\_NODE or DEFINE\_ADJACENT\_NODE

## directory\_entry\_summary.real\_owning\_cp\_type

NN and BrNN only: Real owning CP type. This can be one of the following:

## AP\_NONE

The real owning CP is a parent resource.

# AP\_ENCP\_RESOURCE

The real owning CP is not the parent resource and is an EN.

Other node types: This field is set to AP\_NONE.

### directory\_entry\_summary.real\_owning\_cp\_name

NN and BrNN only: Fully qualified real owning CP name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If the real owning CP is the parent, this field is set to binary zeroes.

If the real owning CP is not the parent, then this field is set to the name of the real owning CP.

The real owning CP is not the parent in the directory of the NNS of a BrNN if the resource is owned by an EN in the domain of the BrNN. In this case, the real owning CP is the EN, but the parent is the BrNN.

Other node types: This field is set to binary zeroes.

### directory\_entry\_detail.overlay\_size

The number of bytes in this entry, and therefore the offset to the next entry returned (if any).

## directory\_entry\_detail.resource\_name

Network qualified resource name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# directory\_entry\_detail.resource\_type

Resource type. This can be one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE

#### directory\_entry\_detail.description

Resource description as specified on:

DEFINE\_LOCAL\_LU DEFINE\_DIRECTORY\_ENTRY DEFINE\_ADJACENT\_LEN\_NODE or DEFINE\_ADJACENT\_NODE

# directory\_entry\_detail.parent\_name

Fully qualified parent name of the node serving the LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## directory\_entry\_detail.parent\_type

Parent resource type. This can be one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE

### directory\_entry\_detail.entry\_type

Specifies the type of the directory entry. This can be one of the following values:

#### AP\_HOME

Local resource.

## AP\_CACHE

Cached entry.

### **AP\_REGISTER**

Registered resource (NN only).

### directory\_entry\_detail.location

Specifies the location of the resource, which can be one of the following values:

## AP\_LOCAL

The resource is at the local node.

#### AP\_DOMAIN

The resource belongs to an attached end node.

## AP\_CROSS\_DOMAIN

The resource is not within the domain of the local node.

### directory\_entry\_detail.real\_owning\_cp\_type

NN and BrNN only: Real owning CP type. This can be one of the following:

## AP\_NONE

The real owning CP is a parent resource.

# AP\_ENCP\_RESOURCE

The real owning CP is not the parent resource and is an EN.

Other node types: This field is set to AP\_NONE.

#### directory\_entry\_detail.real\_owning\_cp\_name

NN and BrNN only: Fully qualified real owning CP name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If the real owning CP is the parent, this field is set to binary zeroes.

If the real owning CP is not the parent, then this field is set to the name of the real owning CP.

The real owning CP is not the parent in the directory of the NNS of a BrNN if the resource is owned by an EN in the domain of the BrNN. In this case, the real owning CP is the EN, but the parent is the BrNN.

Other node types: This field is set to binary zeroes.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_RES\_NAME

AP\_INVALID\_RES\_TYPE AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

# QUERY\_DIRECTORY\_LU

QUERY\_DIRECTORY\_LU returns a list of LUs from the directory database. The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific LU, or to obtain the list information in several chunks, the **lu\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **lu\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

Note that DLUS-served LUs present in the directory are also returned by this query.

# VCB Structure

} DIRECTORY LU DETAIL;
```

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_QUERY\_DIRECTORY\_LU

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

### AP\_SUMMARY

Returns summary information only.

## AP\_DETAIL

Returns detailed information.

The **lu\_name** specified (see the following parameter, **lu\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## lu\_name

Network qualified LU name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

### buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of directory entries returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### directory\_lu\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

### directory\_lu\_summary.lu\_name

Network qualified LU name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### directory\_lu\_summary.description

Resource description (as specified on DEFINE\_LOCAL\_LU, or DEFINE\_ADJACENT\_NODE). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### directory\_lu\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## directory\_lu\_detail.lu\_name

Network qualified LU name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## directory\_lu\_detail.description

Resource description (as specified on DEFINE\_LOCAL\_LU, or DEFINE\_ADJACENT\_NODE). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### directory\_lu\_detail.server\_name

Network qualified name of the node serving the LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### directory\_lu\_detail.lu\_owner\_name

Network qualified name of the node owning the LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### directory\_lu\_detail.location

Specifies the location of the resource, which can be one of the following values:

### AP\_LOCAL

The resource is at the local node.

#### AP\_DOMAIN

The resource belongs to an attached end node.

### AP\_CROSS\_DOMAIN

The resource is not within the domain of the local node.

# directory\_lu\_detail.entry\_type

Specifies the type of the directory entry. This can be one of the following values:

## AP\_HOME

Local resource.

# AP\_CACHE

Cached entry.

## AP\_REGISTER

Registered resource (NN only).

### directory\_lu\_detail.wild\_card

Specifies the type of wildcard the LU will match.

## AP\_OTHER

Unknown type of LU entry.

#### AP EXPLICIT

The full **lu\_name** will be used for locating this LU.

### AP\_PARTIAL\_WILDCARD

Only the nonspace portions of **lu\_name** will be used for locating this LU.

#### AP\_FULL\_WILDCARD

All **lu\_names** will be directed to this LU.

## directory\_lu\_detail.apprent\_lu\_owner\_name

NN and BrNN only: Fully qualified apparent LU owner CP name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If the apparent LU owner is the real LU owner, this field is set to binary zeroes.

If the apparent LU owner is not the real owner, then this field is set to the name of the apparent LU owner.

The real LU owner is not the apparent LU owner in the directory of the NNS of a BrNN if the resource is owned by an EN in the domain of the BrNN. In this case, the real LU owner is the EN, but the apparent owner is the BrNN.

Other node types: This field is set to binary zeroes.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_LU\_NAME

## AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

# QUERY\_DIRECTORY\_STATS

This verb applies only to Communications Server.

QUERY\_DIRECTORY\_STATS returns directory database statistics. (The statistics that refer to cache information are reserved in the case of an end node). The verb can be used to gauge the level of network locate traffic. In the case of a network node this information can be used to tune the size of the directory cache, which is configurable at node-initialization time.

# **VCB** Structure

```
typedef struct query_directory_stats
```

}	QUERY_DIRECTOR	Y_STATS;				

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_QUERY\_DIRECTORY\_STATS

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc AP\_OK

max\_caches

Reserved.

# QUERY\_DIRECTORY\_STATS

cur\_caches Reserved.

cur\_home\_entries

Current number of home entries.

# cur\_reg\_entries

Current number of registered entries.

## cur\_directory\_entries

Total number of entries currently in the directory.

## cache\_hits

Reserved.

# cache\_misses

Reserved.

# in\_locates

Number of directed locates received.

# in\_bcast\_locates

Number of broadcast locates received.

### out\_locates

Number of directed locates sent.

## out\_bcast\_locates

Number of broadcast locates sent.

# not\_found\_locates

Number of directed locates returned with a "not found."

## not\_found\_bcast\_locates

Number of broadcast locates returned with a "not found."

# locates\_outstanding

Current number of outstanding locates, both directed and broadcast.

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

# QUERY\_DLC

QUERY\_DLC returns a list of information about the DLCs defined at the node. This information is structured as determined data (data gathered dynamically during execution) and defined data (the data supplied by the application on DEFINE\_DLC).

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific DLC, or to obtain the list information in several chunks, the **dlc\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **dlc\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If AP\_LIST\_FROM\_NEXT is selected the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

       unsigned char retry flags;
                                         /* conditions for automatic
                                                                        */
                                         /* retries
                                                                        */
       unsigned short max activaion attempts;
                                          /* how many automatic retries? */
       unsigned short activation delay timer;
                                         /* delay between automatic
                                                                        */
                                         /* retries
                                                                        */
       unsigned char reserv3[6];
                                         /* reserved
                                                                        */
       unsigned short dlc spec data len; /* Length of DLC specific data */
} DLC DEF DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_DLC

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

# AP\_DETAIL

Returns detailed information.

The **dlc\_name** specified (see the following parameter, **dlc\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

### dlc\_name

DLC name. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

### buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

### num\_entries

Number of entries actually returned.

### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## dlc\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

### dlc\_summary.dlc\_name

DLC name. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

# dlc\_summary.description

Resource description (as specified on DEFINE\_DLC). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

### dlc\_summary.state

State of the DLC. This field is set to one of the following values:

AP\_ACTIVE AP\_NOT\_ACTIVE AP\_PENDING\_INACTIVE

# dlc\_summary.dlc\_type

Type of DLC. The Program supports the following types:

AP\_ANYNET AP\_LLC2 AP\_OEM\_DLC AP\_SDLC AP\_TWINAX AP\_X25

## dlc\_detail.overlay\_size

The number of bytes in this entry (including dlc\_spec\_data), and hence the offset to the next entry returned (if any).

#### dlc\_detail.dlc\_name

DLC name. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

### dlc\_detail.det\_data.state

State of the DLC. This field is set to one of the following values:

AP\_ACTIVE AP\_NOT\_ACTIVE AP\_PENDING\_INACTIVE

### dlc\_detail.def\_data.description

Resource description (as specified on DEFINE\_DLC). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### dlc\_detail.def\_data.dlc\_type

Type of DLC. The Program supports the following types:

AP\_ANYNET AP\_LLC2 AP\_OEM\_DLC AP\_SDLC AP\_TWINAX AP\_X25

## dlc\_detail.def\_data.neg\_ls\_supp

Specifies whether the DLC supports negotiable link stations (AP\_YES or AP\_NO).

# dlc\_detail.def\_data.port\_types

Specifies the allowable port types for the supplied **dlc\_type**. The value corresponds to one or more of the following values ORed together:

AP\_PORT\_NONSWITCHED AP\_PORT\_SWITCHED AP\_PORT\_SATF

## dlc\_\_detail.def\_data.retry\_flags

This field specifies the conditions under which link stations, defined on this DLC, are subject to automatic retry if the flag AP\_INHERIT\_RETRY is set on both DEFINE\_LS and DEFINE\_PORT in **def\_data.retry\_flags**. It is a bit field, and may take any of the following values bitwise ORed together.

#### AP\_RETRY\_ON\_START

Link activation will be retried if no response is received from the remote node when activation is attempted. If the underlying port is inactive when activation is attempted, the Program will attempt to activate it.

#### AP\_RETRY\_ON\_FAILURE

Link activation will be retried if the link fails while active or pending active. If the underlying port has failed when activation is attempted, the Program attempts to activate it.

#### AP\_RETRY\_ON\_DISCONNECT

Link activation will be retried if the link is stopped normally by the remote node.

## AP\_DELAY\_APPLICATION\_RETRIES

Link activation retries, initiated by applications (using START\_LS or on-demand link activation) will be paced using the **activation\_delay\_timer**.

# AP\_INHERIT\_RETRY

This flag has no effect.

## dlc\_detail.def\_data.max\_activation\_attempts

This field has no effect unless at least one flag is set in DEFINE\_LS in **def\_data.retry\_flags**, **def\_data.max\_activation\_attempts** on DEFINE\_LS is set to AP\_USE\_DEFAULTS, and **def\_data.max\_activation\_attempts** on DEFINE\_PORT is set to AP\_USE\_DEFAULTS.

This field specifies the number of retry attempts the Program allows when the remote node is not responding, or the underlying port is inactive. This includes both automatic retries and application-driven activation attempts.

If this limit is ever reached, no further attempts are made to automatically retry. This condition is reset by STOP\_LS, STOP\_PORT, STOP\_DLC or a successful activation. START\_LS or OPEN\_LU\_SSCP\_SEC\_RQ results in a single activation attempt, with no retry if activation fails.

Zero means 'no limit'. The value AP\_USE\_DEFAULTS means 'no limit'.

#### dlc\_detail.def\_data.activation\_delay\_timer

This field has no effect unless at least one flag is set in DEFINE\_LS in **def\_data.retry\_flags**, **def\_data.max\_activation\_attempts** on DEFINE\_LS is set to AP\_USE\_DEFAULTS, and **def\_data.max\_activation\_attempts** on DEFINE\_PORT is set to AP\_USE\_DEFAULTS.

This field specifies the number of seconds that the Program waits between automatic retry attempts, and between application-driven activation attempts if the AP\_DELAY\_APPLICATION\_RETRIES bit is set in **def\_data.retry\_flags**.

The value of zero or AP\_USE\_DEFAULTS results in the use of default timer duration of thirty seconds.

### dlc\_detail.def\_data.dlc\_spec\_data\_len

Unpadded length, in bytes, of data specific to the type of DLC. The data will be concatenated to the DLC\_DETAIL structure. This data will be padded to end on a 4-byte boundary. This field should always be set to zero.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_DLC\_NAME

# AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc

## QUERY\_DLUR\_DEFAULTS

QUERY\_DLUR\_DEFAULTS allows the user to query the defaults defined using the DEFINE\_DLUR\_DEFAULTS verb.

## VCB Structure

typedef struct query\_dlur\_defaults

ι					
	unsigned short	opcode;	/*	verb operation code	*/
	unsigned char	reserv2;	/*	reserved	*/
	unsigned char	format;	/*	format	*/
	unsigned short	primary rc;	/*	primary return code	*/
	unsigned long	secondary rc;	/*	secondary return code	*/
	DESCRIPTION	description;		resource description	*/
	unsigned char	dlus name[17];	/*	DLUS name	*/
	unsigned char	bkup_dlus_name[1	7];/*	Backup DLUS name	*/
	unsigned char	reserv3;		reserved	*/
	unsigned short	dlus retry timed	out;/*	DLUS Retry Timeout	*/
	unsigned short	dlus retry limit	; /*	DLUS Retry Limit	*/
	unsigned char	reserv4[16];	/*	reserved	*/
}	QUERY_DLUR_LU;				

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_DLUR\_DEFAULTS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### description

Resource description. The length of this field should be a multiple of four bytes and nonzero.

#### dlus\_name

Name of the DLUS node that will serve as the default. This is set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### bkup\_dlus\_name

Name of the DLUS node that will serve as the backup default. This is set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### dlus\_retry\_timeout

Interval in seconds between the second and subsequent attempts to contact a DLUS. The interval between the initial attempt and the first retry is always one second.

#### dlus\_retry\_limit

Maximum number of retries after an initial failure to contact a DLUS. If X'FFFF' is specified, the Program retries indefinitely.

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameters:

#### primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the system has not been built with DLUR support, the Program returns the following parameter:

#### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because a STOP\_NODE verb has been issued, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## QUERY\_DLUR\_LU

QUERY\_DLUR\_LU returns a list of information about DLUR-supported LUs.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific LU, or to obtain the list information in several chunks, the **lu\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **lu\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

The list of LUs returned can be filtered by **pu\_name** or by whether the LU is local or downstream or by both. If filtering by PU is desired, the **pu\_name** field should be set (otherwise this field should be set to all zeros). If filtering by location is desired, the **filter** field should be set to AP\_INTERNAL or AP\_DOWNSTREAM (otherwise, if no filtering is required, this field should be set to AP\_NONE).

## VCB Structure

# Supplied Parameters

The application supplies the following parameters:

## opcode

AP\_QUERY\_DLUR\_LU

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf ptr** must be set to NULL.

## buf size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information:

## **AP\_SUMMARY**

Returns summary information only.

## AP DETAIL

Returns detailed information.

The lu\_name specified (see the following parameter, lu\_name) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP LIST FROM NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## lu name

Name of LU being queried. This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### pu\_name

PU name filter. This should be set to all zeros or an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this field is set then only LUs associated with the specified PU are returned. This field is ignored if it is set to all zeros.

**filter** Location filter. Specifies whether the returned LUs should be filtered by location (AP\_INTERNAL or AP\_DOWNSTREAM). If no filter is required, this field should be set to AP\_NONE.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

## num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## dlur\_lu\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## dlur\_lu\_summary.lu\_name

Name of LU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## dlur\_lu\_detail.overlay\_size

The number of bytes in this entry (including appended RSCV), and hence the offset to the next entry returned (if any).

## dlur\_lu\_detail.lu\_name

Name of LU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### dlur\_lu\_detail.pu\_name

Name of PU associated with the LU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## dlur\_lu\_detail.dlus\_name

Name of the DLUS node if the SSCP-LU session is active. This is a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the SSCP-LU session is not active, this field will be set to all zeros.

## dlur\_lu\_detail.lu\_location

Location of LU. The only value returned is:

## AP\_INTERNAL

AP\_DOWNSTREAM

## dlur\_lu\_detail.nau\_address

Network addressable unit address of the LU. This is in the range 1–255.

## dlur\_lu\_detail.plu\_name

Name of PLU if the LU has an active PLU-SLU session. This is a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the PLU-SLU session is not active, this field will be set to all zeros.

#### dlur\_lu\_detail.rscv\_len

This value will always be zero.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_LU\_NAME

AP\_INVALID\_FILTER\_OPTION AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## QUERY\_DLUR\_PU

QUERY\_DLUR\_PU returns a list of information about DLUR-supported PUs.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific PU, or to obtain the list information in several chunks, the **pu\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **pu\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

The list of PUs returned can be filtered either by **dlus\_name** or by whether the PU is local or downstream or by both. If filtering by DLUS is desired, the **dlus\_name** field should be set (otherwise this field should be set to all zeros). If filtering by PU location is desired, the **filter** field should be set to AP\_INTERNAL or AP\_DOWNSTREAM (otherwise, if no filtering is required, this field should be set to AP\_NONE).

                                                                                */
} FQPCID;
```

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_DLUR\_PU

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

## AP\_SUMMARY

Returns summary information only.

## AP\_DETAIL

Returns detailed information.

The **pu\_name** specified (see the following parameter, **pu\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### pu\_name

Name of PU being queried. This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### dlus\_name

DLUS filter. This should be set to all zeros or to a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. If this field is set then only PUs associated with an SSCP-PU session to the specified DLUS node are returned. This field is ignored if it is set to all zeros.

filter This field should be set to AP\_NONE.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

## num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## dlur\_pu\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## dlur\_pu\_summary.pu\_name

Name of PU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### dlur\_pu\_summary.description

Resource description (as specified on DEFINE\_INTERNAL\_PU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## dlur\_pu\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## dlur\_pu\_detail.pu\_name

Name of PU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### dlur\_pu\_detail.description

Resource description (as specified on DEFINE\_INTERNAL\_PU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## dlur\_pu\_detail.defined\_dlus\_name

Name of the DLUS node defined by either a DEFINE\_INTERNAL\_PU verb or DEFINE\_LS verb (with **dspu\_services** set to AP\_DLUR). This is a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## dlur\_pu\_detail.bkup\_dlus\_name

Name of backup DLUS node defined by either a DEFINE\_INTERNAL\_PU verb or DEFINE\_LS verb (with **dspu\_services** set to AP\_DLUR). This is a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### dlur\_pu\_detail.pu\_id

PU identifier defined in a DEFINE\_INTERNAL\_PU verb or obtained in an XID from a downstream PU. This a 4-byte hexadecimal string. Bits 0–11 are set to the Block number and bits 12–31 are set to the ID number that uniquely identifies the PU.

## dlur\_pu\_detail.pu\_location

Location of PU. The only value returned is:

AP\_INTERNAL AP\_DOWNSTREAM

## dlur\_pu\_detail.active\_dlus\_name

Name of the DLUS node that the PU is currently using. This is a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the SSCP-PU session is not active, this field will be set to all zeros.

#### dlur\_pu\_detail.ans\_support

Auto Network Shutdown support. This field is reserved if the SSCP-LU session is inactive. The support setting is sent to DLUR from the DLUS at SSCP-PU activation. It specifies whether link-level contact should be continued if the subarea node initiates an auto network shutdown procedure for the SSCP controlling the PU. This can be one of the following values:

AP\_CONT AP\_STOP

## dlur\_pu\_detail.pu\_status

Status of the PU (as seen by DLUR). This can be set to one of the following values:

## AP\_RESET

The PU is in reset state.

#### AP\_PEND\_ACTPU

The PU is waiting for an ACTPU from the host.

#### AP\_PEND\_ACTPU\_RSP

Having forwarded an ACTPU to the PU, DLUR is now waiting for the PU to respond to it.

## AP\_ACTIVE

The PU is active.

## AP\_PEND\_DACTPU\_RSP

Having forwarded a DACTPU to the PU, DLUR is waiting for the PU to respond to it.

## AP\_PEND\_INOP

DLUR is waiting for all necessary events to complete before it deactivates the PU.

## dlur\_pu\_detail.dlus\_session\_status

Status of the DLUS pipe currently being used by the PU. This can be one of the following values:

AP\_PENDING\_ACTIVE AP\_ACTIVE AP\_PENDING\_INACTIVE AP\_INACTIVE

## dlur\_pu\_detail.fqpcid.pcid

Procedure correlator ID used on the pipe. This is an 8-byte hexadecimal string. If the SSCP-PU session is not active this field will be set to zeros.

## dlur\_pu\_detail.fqpcid.fqcp\_name

Fully qualified Control Point name used on the pipe. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the SSCP-PU session is not active this field will be set to zeros.

## dlur\_pu\_detail.dlus\_retry\_timeout

Interval in seconds between second and subsequent attempts to contact the DLUS specified in the **dlus\_name** and **bkup\_dlus\_name** fields. The interval between the initial attempt and the first retry is always one second. If zero is specified, the default value configured through DEFINE\_DLUR\_DEFAULTS is used.

## def\_data.dlus\_retry\_limit

Maximum number of retries after an initial failure to contact the DLUS specified in the **dlus\_name** and **bkup\_dlus\_name** fields. If zero is specified, the default value configured through

DEFINE\_DLUR\_DEFAULTS is used. If X'FFFF' is specified, the Program retrys indefinitely.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_FILTER\_OPTION AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_DLUS

QUERY\_DLUS returns a list of information about DLUS nodes known by DLUR.

The information is returned as a list. To obtain information about a specific DLUS node, or to obtain the list information in several chunks, the **dlus\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **dlus\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

Note that this verb returns pipe statistics.

## **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_QUERY\_DLUS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

#### **AP\_DETAIL**

Returns detailed information.

The **dlus\_name** specified (see the following parameter, **dlus\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### dlus\_name

Name of the DLUS being queried. This should be set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC

spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

## num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## dlus\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## dlus\_data.dlus\_name

Name of the DLUS. This is a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## dlus\_data.is\_default

Specifies whether the DLUS node has been designated as the default by a DEFINE\_DLUR\_DEFAULTS verb (AP\_YES or AP\_NO).

## dlus\_data.is\_backup\_default

Specifies whether the DLUS node has been designated as the backup default by a DEFINE\_DLUR\_DEFAULTS verb (AP\_YES or AP\_NO).

## dlus\_data.pipe\_state

State of the pipe to the DLUS. It can have one of the following values:

## AP\_ACTIVE

AP\_PENDING\_ACTIVE AP\_INACTIVE AP\_PENDING\_INACTIVE

#### dlus\_data.num\_active\_pus

Number of PUs currently using the pipe to the DLUS.

## dlus\_data.pipe\_stats.reqactpu\_sent

Number of REQACTPUs sent to DLUS over the pipe.

## dlus\_data.pipe\_stats.reqactpu\_rsp\_received

Number of RSP(REQACTPU)s received from DLUS over the pipe.

## dlus\_data.pipe\_stats.actpu\_received

Number of ACTPUs received from DLUS over the pipe.

## QUERY\_DLUS

dlus\_data.pipe\_stats.actpu\_rsp\_sent Number of RSP(ACTPU)s sent to DLUS over the pipe.

- dlus\_data.pipe\_stats.reqdactpu\_sent Number of REQDACTPUs sent to DLUS over the pipe.
- dlus\_data.pipe\_stats.reqdactpu\_rsp\_received Number of RSP(REQDACTPU)s received from DLUS over the pipe.
- dlus\_data.pipe\_stats.dactpu\_received Number of DACTPUs received from DLUS over the pipe.

dlus\_data.pipe\_stats.dactpu\_rsp\_sent Number of RSP(DACTPU)s sent to DLUS over the pipe.

dlus\_data.pipe\_stats.actlu\_received Number of ACTLUs received from DLUS over the pipe.

dlus\_data.pipe\_stats.actlu\_rsp\_sent Number of RSP(ACTLU)s sent to DLUS over the pipe.

dlus\_data.pipe\_stats.dactlu\_received Number of DACTLUs received from DLUS over the pipe.

dlus\_data.pipe\_stats.dactlu\_rsp\_sent Number of RSP(DACTLU)s sent to DLUS over the pipe.

dlus\_data.pipe\_stats.sscp\_pu\_mus\_rcvd Number of SSCP-PU MUs received from DLUS over the pipe.

dlus\_data.pipe\_stats.sscp\_pu\_mus\_sent Number of SSCP-PU MUs sent to DLUS over the pipe.

dlus\_data.pipe\_stats.sscp\_lu\_mus\_rcvd Number of SSCP-LU MUs received from DLUS over the pipe.

dlus\_data.pipe\_stats.sscp\_lu\_mus\_sent Number of SSCP-LU MUs sent to DLUS over the pipe.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_DLUS\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_DOWNSTREAM\_LU

This verb applies only to Communications Server.

QUERY\_DOWNSTREAM\_LU returns information about downstream LUs served by DLUR or PU concentration or both. This information is structured as determined data (data gathered dynamically during execution) and defined data. (Defined data is supplied by the application on the DEFINE\_DOWNSTREAM\_LU verb. Note that for DLUR-supported LUs, implicitly defined data is put in place when the downstream LU is activated).

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific local LU or to obtain the list information in several chunks, the **dslu\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored.

The returned LUs may be filtered by the type of service the local node provides or the LU's associated downstream PU or both. If filtering by type of service is desired, the **dspu\_services** field should be set to AP\_PU\_CONCENTRATION or AP\_DLUR (otherwise, this field should be set to AP\_NONE). If filtering by PU is desired, the **dspu\_name** field should be set (otherwise, this field should be set to all zeros).

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_DOWNSTREAM\_LU

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information:

## AP\_SUMMARY

Returns summary information only.

## AP\_DETAIL

Returns detailed information.

The **dslu\_name** specified (see the following parameter, **dslu\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## dslu\_name

Name of the local LU that is being queried. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### dspu\_name

PU name filter. This should be set to all zeros or an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this field is set, then only LUs associated with the specified PU are returned. This field is ignored if it is set to all zeros.

#### dspu\_services

DSPU services filter. If set to AP\_PU\_CONCENTRATION, only

downstream LUs served by PU concentration are returned. If set to AP\_DLUR, only DLUR-supported LUs are returned. Otherwise, if set to AP\_NONE, information on all downstream LUs is returned.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

## num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## downstream\_lu\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## downstream\_lu\_summary.dslu\_name

Name of the local LU that is being queried. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## downstream\_lu\_summary.dspu\_name

Name of local PU that this LU is using. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## downstream\_lu\_summary.description

Resource description (as specified on DEFINE\_DOWNSTREAM\_LU or DEFINE\_DOWNSTREAM\_LU\_RANGE). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### downstream\_lu\_summary.dspu\_services

Specifies the services which the local node provides to the downstream LU across the link. This is set to one of the following:

## AP\_PU\_CONCENTRATION

Local node that provides PU concentration for the downstream LU.

#### AP\_DLUR

Local node that provides DLUR support for the downstream LU.

downstream\_lu\_summary.nau\_address

Network addressable unit address of the LU, which is in the range 1–255.

#### downstream\_lu\_summary.lu\_sscp\_sess\_active

Indicates whether the LU-SSCP session is active (AP\_YES or AP\_NO).

#### downstream\_lu\_summary.plu\_sess\_active

Indicates whether the PLU-SLU session is active (AP\_YES or AP\_NO).

### downstream\_lu\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## downstream\_lu\_detail.dslu\_name

Name of the local LU that is being queried. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## downstream\_lu\_detail.det\_data.lu\_sscp\_sess\_active

Indicates whether the LU-SSCP session to the downstream LU is active (AP\_YES or AP\_NO).

#### downstream\_lu\_detail.det\_data.plu\_sess\_active

Indicates whether the PLU-SLU session to the downstream LU is active (AP\_YES or AP\_NO).

## downstream\_lu\_detail.det\_data.dspu\_services

Specifies the services that the local node provides to the downstream LU across the link. This is set to one of the following values:

#### AP\_PU\_CONCENTRATION

Local node that provides PU concentration for the downstream LU.

#### AP\_DLUR

Local node that provides DLUR support for the downstream LU.

#### downstream\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_ru\_size

Maximum receive RU size. If

**downstream\_lu\_detail.det\_data.dspu\_services** is set to AP PU CONCENTRATION, then this field is reserved.

## downstream\_lu\_detail.det\_data.lu\_sscp\_stats.send\_ru\_size Maximum send RU size. If downstream\_lu\_detail.det\_data.dspu\_services is set to AP\_PU\_CONCENTRATION, then this field is reserved.

downstream\_lu\_detail.det\_data.lu\_sscp\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.max\_send\_pac\_win This field will always be set to zero.

downstream\_lu\_detail.det\_data.lu\_sscp\_stats.cur\_send\_pac\_win This field will always be set to zero.

- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.max\_rcv\_pac\_win This field will always be set to zero.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.cur\_rcv\_pac\_win This field will always be set to zero.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.

## QUERY\_DOWNSTREAM\_LU

- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.sidh Session ID high byte.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.sidl Session ID low byte.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.odai
   Origin Destination Address Indicator. When bringing up a session, the
   sender of the BIND sets this field to zero if the local node contains the
   primary link station, and sets it to one if the BIND sender is the node
   containing the secondary link station.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.ls\_name Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.
- downstream\_lu\_detail.det\_data.lu\_sscp\_stats.pacing\_type Receive pacing in use on the LU-SSCP session. This takes the value AP\_NONE.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.rcv\_ru\_size Maximum receive RU size.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.send\_ru\_size Maximum send RU size.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.max\_send\_pac\_win Maximum size of the send pacing window on this session.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.cur\_send\_pac\_win Current size of the send pacing window on this session.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.cur\_rcv\_pac\_win Current size of the receive pacing window on this session.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.send\_data\_frames Number of normal flow data frames sent.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.send\_data\_bytes Number of normal flow data bytes sent.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.rcv\_data\_frames Number of normal flow data frames received.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.

- downstream\_lu\_detail.det\_data.ds\_plu\_stats.rcv\_data\_bytes Number of normal flow data bytes received.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.sidh Session ID high byte.
- downstream\_lu\_detail.det\_data.ds\_plu\_stats.sidl Session ID low byte.

downstream\_lu\_detail.det\_data.ds\_plu\_stats.odai Origin Destination Address Indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node

## containing the secondary link station. downstream\_lu\_detail.det\_data.ds\_plu\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

downstream\_lu\_detail.det\_data.plu\_stats.pacing\_type Receive pacing type in use on the downstream PLU-SLU session. This can take the values AP\_NONE or AP\_PACING\_FIXED.

downstream\_lu\_detail.det\_data.us\_plu\_stats.rcv\_ru\_size Maximum receive RU size.

- downstream\_lu\_detail.det\_data.us\_plu\_stats.send\_ru\_size Maximum send RU size.
- downstream\_lu\_detail.det\_data.us\_plu\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

downstream\_lu\_detail.det\_data.us\_plu\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

- downstream\_lu\_detail.det\_data.us\_plu\_stats.max\_send\_pac\_win Maximum size of the send pacing window on this session.
- downstream\_lu\_detail.det\_data.us\_plu\_stats.cur\_send\_pac\_win Current size of the send pacing window on this session.
- downstream\_lu\_detail.det\_data.us\_plu\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session.

downstream\_lu\_detail.det\_data.us\_plu\_stats.cur\_rcv\_pac\_win Current size of the receive pacing window on this session.

downstream\_lu\_detail.det\_data.us\_plu\_stats.send\_data\_frames Number of normal flow data frames sent.

downstream\_lu\_detail.det\_data.us\_plu\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.

downstream\_lu\_detail.det\_data.us\_plu\_stats.send\_data\_bytes Number of normal flow data bytes sent.

downstream\_lu\_detail.det\_data.us\_plu\_stats.rcv\_data\_frames Number of normal flow data frames received.

- downstream\_lu\_detail.det\_data.us\_plu\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.
- downstream\_lu\_detail.det\_data.us\_plu\_stats.rcv\_data\_bytes Number of normal flow data bytes received.

#### downstream\_lu\_detail.det\_data.us\_plu\_stats.sidh

Session ID high byte. If **downstream\_lu\_detail.det\_data\_.dspu\_services** is set to AP\_PU\_CONCENTRATION, then this field is reserved.

#### downstream\_lu\_detail.det\_data.us\_plu\_stats.sidl

Session ID low byte. If **downstream\_lu\_detail.det\_data\_.dspu\_services** is set to AP\_PU\_CONCENTRATION, then this field is reserved.

## downstream\_lu\_detail.det\_data.us\_plu\_stats.odai

Origin Destination Address Indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node containing the secondary link station. If **downstream\_lu\_detail.det\_data\_.dspu\_services** is set to AP\_PU\_CONCENTRATION, then this field is reserved.

## downstream\_lu\_detail.det\_data.us\_plu\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. If **downstream\_lu\_detail.det\_data\_dspu\_services** is set to AP\_PU\_CONCENTRATION, then this field is reserved.

#### downstream\_lu\_detail.det\_data.us\_plu\_stats.pacing\_type

Receive pacing type in use on the upstream PLU-SLU session. This can take the values AP\_NONE or AP\_PACING\_FIXED.

#### downstream\_lu\_detail.det\_data.host\_lu\_name

Name of the host LU that the downstream LU is mapped to, or was mapped to when the PLU-SLU session was last active. This may differ from **def\_data.host\_lu\_name**, as that may be the name of the host LU pool.

#### downstream\_lu\_detail.det\_data.host\_pu\_name

Name of the host PU that the downstream PU is mapped to, or was mapped to when the PLU-SLU session was last active.

## downstream\_lu\_detail.def\_data.description

Resource description (as specified on DEFINE\_DOWNSTREAM\_LU or DEFINE\_DOWNSTREAM\_LU\_RANGE).

## downstream\_lu\_detail.def\_data.nau\_address

Network addressable unit address of the LU, which is in the range 1–255.

#### downstream\_lu\_detail.def\_data.dspu\_name

Name of PU associated with the LU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### downstream\_lu\_detail.def\_data.host\_lu\_name

Name of the host LU or host LU pool that the downstream LU is mapped to. In the case of an LU, this is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. In the case of an LU pool, the Program does not specify a character set for this field. This field is reserved for DLUR-served downstream LUs.

#### downstream\_lu\_detail.def\_data.allow\_timeout

Specifies whether the Program is allowed to time out host LUs used by this downstream LU if the session is left inactive for the **timeout** period specified on the host LU definition (AP\_YES or AP\_NO).

#### downstream\_lu\_detail.def\_data.delayed\_logon

Specifies whether the Program should delay connecting the downstream

## QUERY\_DOWNSTREAM\_LU

LU to the host LU until the first data is received from the downstream LU. Instead, a simulated logon screen will be sent to the downstream LU (AP\_YES or AP\_NO).

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_LU\_NAME

## AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_DOWNSTREAM\_PU

This verb applies only to Communications Server.

QUERY\_DOWNSTREAM\_PU returns information about downstream PUs (defined using a DEFINE\_LS verb).

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific local PU or to obtain the list information in several chunks, the **dspu\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field is ignored.

The list of PUs can be filtered by the type of service the local node provides for the downstream PU. To do this, the **dspu\_services** field should be set to AP\_PU\_CONCENTRATION or AP\_DLUR.

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

}

AP\_QUERY\_DOWNSTREAM\_PU

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

#### **AP\_DETAIL**

Returns detailed information.

The **dslu\_name** specified (see the following parameter, **dslu\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### dspu\_name

Name of the downstream PU that is being queried. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### dspu\_services

DSPU services filter. If set to AP\_PU\_CONCENTRATION, only downstream LUs served by PU concentration are returned. If set to AP\_DLUR, only DLUR-supported LUs are returned. Otherwise, if set to AP\_NONE, information on all downstream LUs is returned.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### downstream\_pu\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### downstream\_pu\_data.dspu\_name

Name of the downstream PU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## downstream\_pu\_data.description

Resource description (as specified on DEFINE\_LS).

#### downstream\_pu\_data.ls\_name

Name of link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## downstream\_pu\_data.pu\_sscp\_sess\_active

Indicates whether the PU\_SSCP session to the downstream PU is active. Set to either AP\_YES or AP\_NO.

#### downstream\_pu\_data.dspu\_services

Specifies the services that the local node provides to the downstream PU across the link. This is set to one of the following values:

#### AP\_PU\_CONCENTRATION

Local node that provides PU concentration for the downstream LU.

#### AP\_DLUR

Local node that provides DLUR support for the downstream LU.

- downstream\_pu\_data.pu\_sscp\_stats.rcv\_ru\_size Maximum receive RU size. If downstream\_lu\_detail.det\_data.dspu\_services is set to AP\_PU\_CONCENTRATION, then this field is reserved.
- downstream\_pu\_data.pu\_sscp\_stats.send\_ru\_size Maximum send RU size. If downstream\_lu\_detail.det\_data.dspu\_services is set to AP\_PU\_CONCENTRATION, then this field is reserved.
- downstream\_pu\_data.pu\_sscp\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.
- downstream\_pu\_data.pu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.
- downstream\_pu\_data.pu\_sscp\_stats.max\_send\_pac\_win This field will always be set to zero.

downstream\_pu\_data.pu\_sscp\_stats.cur\_send\_pac\_win This field will always be set to zero.

downstream\_pu\_data.pu\_sscp\_stats.max\_rcv\_pac\_win This field will always be set to zero.

downstream\_pu\_data.pu\_sscp\_stats.cur\_rcv\_pac\_win This field will always be set to zero.

downstream\_pu\_data.pu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.

downstream\_pu\_data.pu\_sscp\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.

downstream\_pu\_data.pu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.

downstream\_pu\_data.pu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.

- downstream\_pu\_data.pu\_sscp\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.
- downstream\_pu\_data.pu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.
- downstream\_pu\_data.pu\_sscp\_stats.sidh Session ID high byte.
- downstream\_pu\_data.pu\_sscp\_stats.sidl Session ID low byte.
- downstream\_pu\_data.pu\_sscp\_stats.odai

Origin Destination Address Indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node containing the secondary link station.

downstream\_pu\_data.pu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### downstream\_pu\_data.pu\_sscp\_stats.pacing\_type

Receive pacing type in use on the upstream PU-SSCP session. This will take the value AP\_NONE.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_PU\_TYPE AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_DSPU\_TEMPLATE

This verb applies only to Communications Server.

QUERY\_DSPU\_TEMPLATE returns information about defined downstream PU templates used for PU concentration over implicit links. This information is returned as a list. To obtain information about a specific downstream PU template or to obtain the list information in several chunks, the **template\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field is ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

## VCB Structure

typedef struct query\_dspu\_template

1					
	unsigned short	opcode;	/*	verb operation code	*/
	unsigned char	attributes;	/*	Verb attributes	*/
	unsigned char	reserv2;	/*	reserved	*/
	unsigned char	format;	/*	format	*/
	unsigned short	primary_rc;		primary return code	*/
	unsigned long	<pre>secondary_rc;</pre>		secondary return code	*/
	unsigned char			pointer to buffer	*/
	unsigned long	buf_size;		buffer size	*/
	unsigned long			total buffer size required	*/
	unsigned short	num_entries;			*/
	unsigned short			total number of entries	*/
	unsigned char	list_options;			*/
	unsigned char	reserv3;			*/
	unsigned char	<pre>template_name[8];</pre>	/*	name of DSPU template	*/
} QUERY_	DSPU_TEMPLATE;				
typedef	struct dspu tem	plate data			
{		-			
	unsigned short	overlay_size;	/*	size of this entry	*/
	unsigned char	<pre>template_name[8];</pre>	/*	name of DSPU template	*/
	unsigned char	description;	/*	resource description	*/
	unsigned char	reserv1[12];	/*	reserved	*/

	unsigned short			current active instances	*/
	unsigned short	num_of_dslu_templa	tes		
			/*	number of DSLU templates	*/
} DSPU_1	EMPLATE_DATA;				

Each **dspu\_template\_data** is followed by **num\_of\_dslu\_templates** downstream LU templates. Each downstream LU template has the following format.

typedef struct dslu_ten	typedef struct dslu_template_data			
<pre> {     unsigned short     unsigned char     DSLU_TEMPLATE } DSLU_TEMPLATE; </pre>	overlay_size; reserv1[2]; dslu_template;	/* size of this entry */ /* reserved */ /* downstream LU template */		
typedef struct dslu_tem {	nplate			
unsigned char unsigned char unsigned char unsigned char unsigned char unsigned char } DSLU_TEMPLATE;	<pre>min_nau; max_nau; allow_timeout; delayed_logon; reserv1[10]; host_lu[8];</pre>	<pre>/* min NAU address in range</pre>		

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_QUERY\_DSPU\_TEMPLATE

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information:

The **template\_name** specified (see the following parameter, **template\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### template\_name

Name of the DSPU template. This is an 8–byte string in a locally-displayable character set. This field is ignored if **list\_options** is set to AP FIRST IN LIST.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### dspu\_template\_data.overlay\_size

The number of bytes in this entry (including any downstream LU templates, and hence the offset to the next entry returned, if any).

#### dspu\_template\_data.template\_name

Name of the DSPU template. This is an 8–byte string in a locally-displayable character set.

## dspu\_template\_data.description

Resource description (as specified on QUERY\_DSPU\_TEMPLATE).

## dspu\_template\_data.max\_instance

This is the maximum number of instances of the template which can be active concurrently.

#### dspu\_template\_data.active\_instance

This is the number of instances of the template which are currently active.

#### dspu\_template\_data.num\_of\_dslu\_templates

Number of downstream LU templates for this downstream PU template. Following this field are **num\_of\_dslu\_templates\_application\_id** entries, one for each application registered for the focal point category.

#### dslu\_template\_data.overlay\_size

The number of bytes in this entry (and hence the offset to the next entry returned, if any).

#### dslu\_template\_data.dslu\_template.min\_nau

Minimum NAU address in the range.

## dslu\_template\_data.dslu\_template.max\_nau

Maximum NAU address in the range.

#### dslu\_template\_data.dslu\_template.allow\_timeout

Specifies whether the Program is allowed to time out host LUs used by this downstream LU if the session is left inactive for the **timeout** period specified on the host LU definition (AP\_YES or AP\_NO).

## dslu\_template\_data.dslu\_template.delayed\_logon

Specifies whether the Program should delay connecting the downstream LU to the host LU until the first data is received from the downstream LU. Instead, a simulated logon screen is sent to the downstream LU (AP\_YES or AP\_NO).

#### dslu\_template\_data.dslu\_template.host\_lu

Name of the host LU or host LU pool that all the downstream LUs within the range will be mapped onto. This is an 8-byte alphanumeric type A-EBCDIC string (starting with a letter), padded to the right with EBCDIC Spaces.

## QUERY\_DSPU\_TEMPLATE

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK secondary\_rc

AP\_INVALID\_TEMPLATE\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameter:

## primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameters:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## QUERY\_FOCAL\_POINT

QUERY\_FOCAL\_POINT returns information about focal points that Personal Communications or Communications Server knows about.

This information is returned as a list. To obtain information about a specific focal point category or to obtain the list information in several chunks, the **ms\_category** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

**Note:** If no focal point is found, then one FP\_DATA structure will be returned with **fp\_data.fp\_type** set to AP\_NO\_FP. See the following structure.

## VCB Structure

typedef struct query focal point /\* verb operation code unsigned short opcode; \*/ unsigned char reserv2; /\* reserved unsigned char format; /\* format unsigned short primary\_rc; /\* primary return code unsigned long secondary\_rc; /\* secondary return code unsigned char \*buf\_ptr; /\* pointer to buffer unsigned long buf\_size; /\* buffer size /\* reserved \*/ \*/ \*/ \*/ \*/ \*/ unsigned long total\_buf\_size; /\* total buffer size required unsigned short num\_entries; /\* number of entries \*/ \*/ unsigned short total num entries; /\* total number of entries \*/ unsigned char list\_options; /\* listing options \*/ /\* reserved /\* name of MS category unsigned char reserv3; \*/ unsigned char ms category[8]; \*/ } QUERY FOCAL POINT; typedef struct fp data unsigned short overlay size; /\* size of this entry \*/ unsigned char ms appl name[8]; /\* focal point application name \*/ unsigned char ms category[8]; /\* focal point category \*/ unsigned char description[RD LEN]; \*/ /\* resource description unsigned char fp\_fqcp\_name[17]; /\* focal pt fully qual CP name \*/ bkup appl name[8]; /\* backup focal pt appl name unsigned char \*/ unsigned char bkup fp fqcp name[17]; /\* backup FP fully qualified \*/ /\* CP name \*/ unsigned char implicit\_appl\_name[8]; /\* implicit FP appl name \*/ unsigned char implicit fp fqcp name[17]; /\* implicit FP fully \*/ /\* qualified CP name \*/ /\* focal point type unsigned char fp\_type; \*/ fp status; unsigned char /\* focal point status \*/ tp\_status; /\* focal point status
fp\_routing; /\* type of MDS routing to use
reserva[20]: /\* reserved unsigned char \*/ unsigned char /\* reserved reserva[20]; \*/ unsigned short number\_of\_appls; /\* number of applications \*/ } FP DATA;

Each **fp\_data** is followed by **number\_of\_appls** application names. Each application name has the following format:

typedef struct application\_id

unsigned char appl\_name[8]; /\* application name
} APPLICATION ID;

\*/

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_QUERY\_FOCAL\_POINT

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information: The **ms\_category** specified (see the following parameter, **ms\_category**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### ms\_category

Management services category. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services categories as described in SNA management services, or an 8-byte type 1134 EBCDIC installation defined name. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

# num\_entries

The number of entries actually returned.

# total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# fp\_data.overlay\_size

The number of bytes in this entry (including any application names, and hence the offset to the next entry returned (if any)).

#### fp\_data.ms\_appl\_name

Name of the currently active focal point application. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services applications as described in SNA management services, or an 8-byte type 1134 EBCDIC installation defined name.

#### fp\_data.ms\_category

Management services category. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services categories as described in SNA management services, or an 8-byte type 1134 EBCDIC installation defined name.

# fp\_data.description

Resource description (as specified on DEFINE\_FOCAL\_POINT). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# fp\_data.fp\_fqcp\_name

Currently active focal point's fully qualified control point name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# fp\_data.bkup\_appl\_name

Name of backup focal point application. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services applications as described in SNA management services, or an 8-byte type 1134 EBCDIC installation defined name.

# fp\_data.bkup\_fp\_fqcp\_name

Backup focal point's fully qualified control point name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# fp\_data.implicit\_appl\_name

Name of implicit focal point application (specified using the DEFINE\_FOCAL\_POINT verb). This can either be one of the four byte architecturally defined values (right-padded with EBCDIC spaces) for management services applications as described in SNA management services, or an 8-byte type 1134 EBCDIC installation defined name. This field will be the same as the **ms\_appl\_name** if the implicit focal point is the currently active focal point.

# fp\_data.implicit\_fp\_fqcp\_name

Implicit focal point's fully qualified control point name (as specified using the DEFINE\_FOCAL\_POINT verb). This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field will be the same as the **fp\_fqcp\_name** if the implicit focal point is the currently active focal point.

# fp\_data.fp\_type

Type of focal point. Refer to *SNA Management Services* for further detail. This will be one of the following values:

AP\_EXPLICIT\_PRIMARY\_FP AP\_BACKUP\_FP AP\_DEFAULT\_PRIMARY\_FP AP\_IMPLICIT\_PRIMARY\_FP AP\_DOMAIN\_FP AP\_HOST\_FP AP\_NO\_FP

# fp\_data.fp\_status

Status of the focal point. This can be one of the following values:

# AP\_NOT\_ACTIVE

The focal point is currently not active.

# AP\_ACTIVE

The focal point is currently active.

#### **AP\_PENDING**

The focal point is pending active. This occurs after an implicit request has been sent to the focal point and before the response has been received.

#### **AP\_NEVER\_ACTIVE**

No focal point information is available for the specified category although application registrations for the category have been accepted.

#### fp\_data.fp\_routing

Type of routing that applications should specify when using MDS transport to send data to the focal point.

# AP\_DEFAULT

Default routing is used to deliver the MDS\_MU to the focal point.

# AP\_DIRECT

The MDS\_MU will be routed on a session directly to the focal point.

#### fp\_data.number\_of\_appls

Number of applications registered for this focal point category. Following this field will be **number\_of\_appls application\_id entries**, one for each application registered for the focal point category.

#### application\_id.appl\_name

Name of application registered for focal point category. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services applications as described in SNA management services, or an 8-byte type 1134 EBCDIC installation defined name.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_MS\_CATEGORY

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_HPR\_STATS

This verb applies only to Communications Server.

QUERY\_HPR\_STATS returns statistics describing the HPR performance of the node. QUERY\_HPR\_STATS is only supported by nodes that support the RTP Tower.

# VCB Structure

typedef struct query\_hpr\_stats

	unsigned unsigned unsigned	char	opcode; reserv2; format:	/*	verb operation code reserved format	*/ */ */

```
} QUERY_HPR_STATS;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_HPR\_STATS

# format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

# num\_orig\_rs\_sent

The total number HPR Route Setup requests sent that originated in this node, since the node started.

# num\_orig\_rs\_rej

The total number of HPR Route Setup requests that originated in this node and have been rejected by other nodes since the node started.

# num\_inter\_rs\_rcvd

The total number of HPR Route Setup requests processed by this node acting as an intermediate node since the node started.

# num\_inter\_rs\_rej

The total number of HPR Route Setup requests processed by this node acting as an intermediate node, that have been rejected by the node since the node started.

# num\_dest\_rs\_rcvd

The total number of HPR Route Setup requests received by this node, that has this node as the destination, since the node started.

#### num\_dest\_rs\_rej

The total number of HPR Route Setup requests received by this node, that has this node as the destination and that have been rejected by the node since the node started.

#### active\_isr\_hpr\_sessions

The number of ISR sessions using HPR-APPN Boundary Function that are currently active in the node.

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node does not support the HPR RTP Tower function, the Program returns the following parameter:

# primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

# QUERY\_ISR\_SESSION

This verb applies only to Communications Server.

QUERY\_ISR\_SESSION is only used at a Network Node and returns list information about sessions for which the network node is providing intermediate session routing.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific session, or to obtain the list information in several chunks, the fields in the **fqpcid** structure should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), the fields in this structure is ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by **fqpcid.pcid** first and then by EBCDIC lexicographical ordering on **fqpcid.fqcp\_name**. The ordering by **fqpcid.pcid\_name** is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

The format of the **fqpcid** structure is an 8-byte Procedure Correlator Identifier (PCID) and the network qualified CP name of the session originator.

In addition to the detail information for each session, a route selection control vector (RSVC) is returned if this is specified on the START\_NODE parameters. This RSVC defines the route through the network that the session takes in a hop-by-hop form.

**Note:** The ISR session detail overlay may be followed by a Route Selection Control Vector (RSCV) as defined by *SNA formats*. This control vector defines the session route through the network and is carried on the BIND. The inclusion of this RSCV is decided when the node is started (as an option of the START\_NODE), and can be altered later using DEFINE\_ISR\_STATS. If these verbs have been used to specify that RSCVs should not be stored, then the **rscv\_len** is set to zero.

# **Supplied Parameters**

The application supplies the following parameters:

# opcode

AP\_QUERY\_ISR\_SESSION

# format

Identifies the format of the VCB and also the format of the returned overlays. Set this field to zero to specify the version of the VCB and overlays listed above.

# buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

# buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

# list\_options

This indicates what should be returned in the list information.

# AP\_SUMMARY

Returns summary information only.

#### AP\_DETAIL

Returns detailed information.

The **fqpcid** specified (see the following parameter, **fqpcid**) represent an index value that is used to specify the starting point of the actual information to be returned.

# AP\_FIRST\_IN\_LIST

The index value is ignored and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### session\_type

Does this verb query DLUR-maintained sessions, or regular ISR sessions?

AP_ISR_SESSION	ISR sessions
AP_DLUR_SESSIONS	DLUR sessions

#### fqpcid.pcid

Procedure Correlator ID. This is an 8-byte hexadecimal string. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# fqpcid.fqcp\_name

Fully qualified Control Point name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

# total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### isr\_session\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# isr\_session\_summary.fqpcid.pcid

Procedure Correlator ID.

# isr\_session\_summary.fqpcid.fqcp\_name

Fully qualified Control Point name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# isr\_session\_detail.overlay\_size

The number of bytes in this entry (including any appended RSCV), and hence the offset to the next entry returned (if any).

# isr\_session\_detail.sub\_overlay\_size

This field gives the size of this detail overlay. If an RSCV is appended, then this is the offset to the start of the RSCV. This field can be equal to or greater than the size of the format of one detail structure (allowing future expansion).

# isr\_session\_detail.fqpcid.pcid

Procedure Correlator ID.

# isr\_session\_detail.fqpcid.fqcp\_name

Fully qualified Control Point name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# session\_detail.trans\_pri

Transmission priority. This is set to one of the following values:

AP\_LOW AP\_MEDIUM AP\_HIGH AP\_NETWORK

# session\_detail.cos\_name

Class-of-service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

# session\_detail.ltd\_res

Specifies whether the session uses a limited resource link (AP\_YES or AP\_NO).

#### isr\_session\_detail.pri\_sess\_stats.rcv\_ru\_size Maximum receive RU size.

isr\_session\_detail.pri\_sess\_stats.send\_ru\_size Maximum send RU size.

isr\_session\_detail.pri\_sess\_stats.max\_send\_btu\_size
 Maximum BTU size that can be sent on primary session hop.

# isr\_session\_detail.pri\_sess\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received on the primary session hop.

isr\_session\_detail.pri\_sess\_stats.max\_send\_pac\_win
 Maximum size of the send pacing window on the primary session hop.

# 

# isr\_session\_detail.pri\_sess\_stats.max\_rcv\_pac\_win

Maximum size of the receive pacing window on the primary session hop.

#### isr\_session\_detail.pri\_sess\_stats.cur\_rcv\_pac\_win

Current size of the receive pacing window on the primary session hop.

#### isr\_session\_detail.pri\_sess\_stats.send\_data\_frames

Number of normal flow data frames sent on the primary session hop.

# isr\_session\_detail.pri\_sess\_stats.send\_data\_frames

Number of normal flow data frames sent on the primary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

#### isr\_session\_detail.pri\_sess\_stats.send\_fmd\_data\_frames

Number of normal flow FMD data frames sent on the primary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

#### isr\_session\_detail.pri\_sess\_stats.send\_data\_bytes

Number of normal flow data bytes sent on the primary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.pri\_sess\_stats.rcv\_data\_frames

Number of normal flow data frames received on the primary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.pri\_sess\_stats.rcv\_fmd\_data\_frames

Number of normal flow FMD data frames received on the primary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.pri\_sess\_stats.rcv\_data\_bytes

Number of normal flow data bytes received on the primary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.pri\_sess\_stats.sidh

Session ID high byte.

# isr\_session\_detail.pri\_sess\_stats.sidl

Session ID low byte.

# isr\_session\_detail.pri\_sess\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station. It sets it to one if the BIND sender is the node containing the secondary link station.

# isr\_session\_detail.pri\_sess\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate the session statistics with the link over which session data flows.

#### isr\_session\_detail.sec\_sess\_stats.rcv\_ru\_size Maximum receive RU size.

# isr\_session\_detail.pri\_sess\_stats.pacing\_type

Receive pacing type in use on primary session. This may take the values AP\_NONE, AP\_PACING\_FIXED or AP\_PACING\_ADAPTIVE.

# isr\_session\_detail.sec\_sess\_stats.send\_ru\_size Maximum send RU size.

# isr\_session\_detail.sec\_sess\_stats.max\_send\_btu\_size

Maximum BTU size that can be sent on secondary session hop.

# isr\_session\_detail.sec\_sess\_stats.max\_rcv\_btu\_size

Maximum BTU size that can be received on the secondary session hop.

# isr\_session\_detail.sec\_sess\_stats.max\_send\_pac\_win Maximum size of the send pacing window on the secondary session hop.

# isr\_session\_detail.sec\_sess\_stats.cur\_send\_pac\_win

Current size of the send pacing window on the secondary session hop.

# isr\_session\_detail.sec\_sess\_stats.max\_rcv\_pac\_win

Maximum size of the receive pacing window on the secondary session hop.

# isr\_session\_detail.sec\_sess\_stats.cur\_rcv\_pac\_win

Current size of the receive pacing window on the secondary session hop.

# isr\_session\_detail.sec\_sess\_stats.send\_data\_frames

Number of normal flow data frames sent on the secondary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.sec\_sess\_stats.send\_fmd\_data\_frames

Number of normal flow FMD data frames sent on the secondary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.sec\_sess\_stats.send\_data\_bytes

Number of normal flow data bytes sent on the secondary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# $isr\_session\_detail.sec\_sess\_stats.rcv\_data\_frames$

Number of normal flow data frames received on the secondary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.sec\_sess\_stats.rcv\_fmd\_data\_frames

Number of normal flow FMD data frames received on the secondary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.sec\_sess\_stats.rcv\_data\_bytes

Number of normal flow data bytes received on the secondary session hop. Zero will be returned in this field if collection of statistics has been disabled using DEFINE\_ISR\_STATS.

#### isr\_session\_detail.sec\_sess\_stats.sidh Session ID high byte.

isr\_session\_detail.sec\_sess\_stats.sidl Session ID low byte (from LFSID).

# isr\_session\_detail.sec\_sess\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station. It sets it to one if the BIND sender is the node containing the secondary link station.

# isr\_session\_detail.sec\_sess\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a

locally displayable character set. All 8 bytes are significant. This field can be used to correlate the intermediate session statistics with a particular link station.

#### isr\_session\_detail.sec\_sess\_stats.pacing\_type

Receive pacing type in use on primary session. This can take the values AP\_NONE, AP\_PACING\_FIXED, or AP\_PACING\_ADAPTIVE.

# isr\_session\_detail.sess\_lu\_type

The LU type of the session specified on the BIND. This field takes one of the following values:

AP\_LU\_TYPE\_0 AP\_LU\_TYPE\_1 AP\_LU\_TYPE\_2 AP\_LU\_TYPE\_3 AP\_LU\_TYPE\_4 AP\_LU\_TYPE\_6 AP\_LU\_TYPE\_7 AP\_LU\_TYPE\_7 AP\_LU\_TYPE\_UNKNOWN (LU type 5 is intentionally omitted.)

AP\_LU\_TYPE\_UNKNOWN will always be returned unless collection of names has been enabled using DEFINE\_ISR\_STATS.

#### isr\_session\_detail.sess\_lu\_level

The LU level of the session. This field takes one of the following values:

AP\_LU\_LEVEL\_0 AP\_LU\_LEVEL\_1 AP\_LU\_LEVEL\_2 AP\_LU\_LEVEL\_UNKNOWN

For LU types other than 6, this field is set to AP\_LU\_LEVEL\_0. AP\_LU\_LEVEL\_UNKNOWN will always be returned unless collection of names has been enabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.pri\_tg\_number

The TG number associated with the link traversed by the primary session hop. If the primary session stage traverses an RTP connection, zero is returned. Zero will always be returned unless collection of names has been enabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.sec\_tg\_number

The TG number associated with the link traversed by the primary session hop. If the primary session stage traverses an RTP connection, zero is returned. Zero will always be returned unless collection of names has been enabled using DEINE\_ISR\_STATS.

#### isr\_session\_detail.rtp\_tcid

The local TC ID for the RTP connection, returned in cases where this ISR session forms part of an ANR/ISR boundary. In other cases, this field is set to zero. Zero will always be returned unless collection of names has been enabled using DEINE\_ISR\_STATS.

#### isr\_session\_detail.time\_active

The elapsed time since the activation of the session, measured in hundredths of a second. Zero will always be returned unless collection of names has been enabled using DEINE\_ISR\_STATS.

# isr\_session\_detail.isr\_state

The current state of the session. This field is set to one of the following values:

AP\_ISR\_INACTIVE AP\_ISR\_PENDING\_ACTIVE AP\_ISR\_ACTIVE AP\_ISR\_PENDING\_INACTIVE

# isr\_session\_detail.mode\_name

The mode name for the session. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. All binary zeros will always be returned unless collection of names has been enabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.pri\_lu\_name

The primary LU name of the session. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. Each name can have a maximum of 8 bytes with no embedded spaces. If this name is not available, all binary zeros are returned in this field. All binary zeros will always be returned unless a collection of names has been enabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.sec\_lu\_name

The secondary LU name of the session. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. Each name can have a maximum of 8 bytes with no embedded spaces. If this name is not available, all binary zeros are returned in this field. All binary zeros will always be returned unless a collection of names has been enabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.pri\_adj\_cp\_name

The primary stage adjacent CP name of this session. If the primary session stage traverses an RTP connection, the CP name of the remote RTP endpoint is returned. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. Each name can have a maximum of 8 bytes with no embedded spaces. If this name is not available, all binary zeros are returned in this field. All binary zeros will always be returned unless a collection of names has been enabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.sec\_adj\_cp\_name

The secondary stage adjacent CP name of this session. If the secondary session stage traverses an RTP connection, the CP name of the remote RTP endpoint is returned. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. Each name can have a maximum of 8 bytes with no embedded spaces. If this name is not available, all binary zeros are returned in this field. All binary zeros will always be returned unless a collection of names has been enabled using DEFINE\_ISR\_STATS.

# isr\_session\_detail.rscv\_len

Length of the RSCV which is appended to the session\_detail structure. (If none is appended, then the length is zero.) The RSCV will be padded to end on a 4-byte boundary.

# QUERY\_ISR\_SESSION

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK secondary\_rc AP\_INVALID\_FQPCID

> AP\_INVALID\_LIST\_OPTION AP\_INVALID\_SESSION\_TYPE

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameter:

#### primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the node has not been built with network node support, the Program returns the following parameter:

# primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_LOCAL\_LU

QUERY\_LOCAL\_LU returns information about local LUs. QUERY\_LOCAL\_LU can be issued to retrieve information about the Personal Communications or Communications Server control point LU.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific local LU, or to obtain the list information in several chunks, the **lu\_name** or **lu\_alias** field should be set. If the **lu\_name** field is nonzero it will be used to determine the index. If the **lu\_name** field is set to all zeros, the **lu\_alias** will be used to determine the index. If both the **lu\_name** and the **lu\_alias** fields are set to all zeros then the LU associated with the control point (the default LU) will be used. If the **list\_options** field is set to AP\_FIRST\_IN\_LIST then both of these fields will be ignored. (In this case, the returned list will be ordered by LU alias if the AP\_LIST\_BY\_ALIAS **list\_options** is set, otherwise it will be ordered by LU name). See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered on either **lu\_alias** or **lu\_name** according to the options specified. The field is ordered by EBCDIC lexicographical ordering.

The list of local LUs returned can be filtered by the name of the PU that they are associated with. In this case, the **pu\_name** field should be set (otherwise this field should be set to all zeros).

} LOCAL\_LU\_DEF\_DATA;

# **Supplied Parameters**

The application supplies the following parameters:

# opcode

AP\_QUERY\_LOCAL\_LU

# format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

# buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

# list\_options

This indicates what should be returned in the list information:

# AP\_SUMMARY

Returns summary information only.

# AP\_DETAIL

Returns detailed information.

The **lu\_name** (or **lu\_alias** if the **lu\_name** is set to all zeros) specified represents an index value that is used to specify the starting point of the actual information to be returned.

# AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

# AP\_LIST\_BY\_ALIAS

The returned list is ordered by **lu\_alias**. This option is only valid when AP\_FIRST\_IN\_LIST is specified. If AP\_LIST\_FROM\_NEXT or AP\_LIST\_INCLUSIVE is specified, the list ordering will depend on whether an **lu\_name** or **lu\_alias** has been supplied as a starting point.

#### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the index. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** field are set to all zeros, the LU associated with the control point (the default LU) is used. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### pu\_name

PU name filter. This should be set to all zeros or an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this field is set then only Local LUs associated with this PU are returned. This field is ignored if it is set to all zeros.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# local\_lu\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### local\_lu\_summary.lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string.

#### local\_lu\_summary.lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

# local\_lu\_summary.description

Resource description (as specified on DEFINE\_LOCAL\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### local\_lu\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### local\_lu\_detail.lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string.

# local\_lu\_detail.def\_data.description

Resource description (as specified on DEFINE\_LOCAL\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# local\_lu\_detail.def\_data.lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

# local\_lu\_detail.def\_data.nau\_address

Network addressable unit address of the LU, which is in the range 0–255. A nonzero value implies the LU is a dependent LU. Zero implies the LU is an independent LU.

# local\_lu\_detail.def\_data.syncpt\_support

Reserved.

# local\_lu\_detail.def\_data.lu\_session\_limit

Maximum number of sessions for the local LU. A value of zero indicates that there is no limit.

# local\_lu\_detail.def\_data.default\_pool

AP\_YES if the LU is a member of the dependent LU 6.2 default pool. Always AP\_NO for independent LUs.

# local\_lu\_detail.def\_data.pu\_name

Name of the PU that this LU will use. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is only used by dependent LUs, and will be set to all binary zeros for independent LUs.

# local\_lu\_detail.def\_data.lu\_attributes

Configured LU attributes. This field either takes the value AP\_NONE, or the following option ORed together:

# AP\_DISABLE\_PWSUB

Password substitution support disabled for the local LU.

# local\_lu\_detail.def\_data.sscp\_id

This field specifies the ID of the SSCP permitted to activate this LU. It is a 6-byte binary field. This field is only used by dependent LUs, and should be set to all binary zeros for independent LUs or if the LU can be activated by any SSCP.

# local\_lu\_detail.def\_data.disable

This field indicates whether the LOCAL LU should be disabled or enabled. The LU can be dynamically enabled or disabled by re-issuing the DEFINE\_LOCAL\_LU with this parameter set as appropriate (AP\_YES or AP\_NO). When a disabled LU is enabled, the Program issues a NOTIFY (online). When an enabled LU is disabled, the Program issues a NOTIFY (off-line). If the LU is bound when it is disabled, then the Program issues an UNBIND followed by a NOTIFY (offline).

# local\_lu\_detail.def\_data.attach\_routing\_data

This field indicates data passed out unchanged on a DYNAMIC\_LOAD\_INDICATION resulting from attaches arriving for the transaction program at this local LU. For example, this field may be used to set a path to the transaction program's working directory.

# local\_lu\_detail.def\_data.lu\_model

Model type and number of the LU. This field is only used by dependent

LUs and should be set to AP\_UNKNOWN for independent LUs. For dependent LUs, this is set to one of the following values:

AP\_3270\_DISPLAY\_MODEL\_2 AP\_3270\_DISPLAY\_MODEL\_3 AP\_3270\_DISPLAY\_MODEL\_4 AP\_3270\_DISPLAY\_MODEL\_5 AP\_RJE\_WKSTN AP\_PRINTER AP\_SCS\_PRINTER AP\_UNKNOWN

For dependent LUs, if **model\_name** is not set to all binary zeros, then this field is ignored. If a value other than AP\_UNKNOWN is specified and the host system supports SDDLU (Self-Defining Dependent LU), the node will generate an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. The PSID subvector will contain the machine type and model number corresponding to the value of this field. This field may be changed dynamically by re-issuing the verb. Changes will not come into effect until after the LU is closed and deactivated.

#### local\_lu\_detail.def\_data.model\_name

Model name of the LU. This field is only used by dependent LUs and should be set to binary zeros for independent LUs.

If this field is not set to binary zeros and the host system supports SDDLU, the node generates an unsolicited PSID NMVT reply in order to dynamically define the local LU at the host. The PSID subvector contains the name supplied in this field. The field may be changed dynamically reissuing the verb. Changes do not come into effect until after the LU is closed and deactivated.

# local\_lu\_detail.det\_data.lu\_sscp\_session\_active

Specifies whether the LU-SSCP session is active (AP\_YES or AP\_NO). If the **def\_data.nau\_address** is zero, then this field is reserved.

# local\_lu\_detail.det\_data.appl\_conn\_active

Specifies whether an application is using the LU (AP\_YES or AP\_NO). If the **def\_data.nau\_address** is zero, then this field is reserved.

- local\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_ru\_size This field is always reserved.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.send\_ru\_size This field is always reserved.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.max\_send\_pac\_win This field will always be set to zero.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.cur\_send\_pac\_win This field will always be set to zero.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.max\_rcv\_pac\_win This field will always be set to zero.

- **local\_lu\_detail.det\_data.lu\_sscp\_stats.cur\_rcv\_pac\_win** This field will always be set to zero.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.
- **local\_lu\_detail.det\_data.lu\_sscp\_stats.rcv\_data\_bytes** Number of normal flow data bytes received.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.sidh Session ID high byte.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.sidl Session ID low byte.
- local\_lu\_detail.det\_data.lu\_sscp\_stats.odai

Origin Destination Address Indicator. When bringing up a session, the sender of the ACTLU sets this field to zero if the local node contains the primary link station, and sets it to one if the ACTLU sender is the node containing the secondary link station.

# local\_lu\_detail.det\_data.lu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate this session with the link over which the session flows.

**Note:** The LU-SSCP statistics (**local\_lu\_detail.det\_data.lu\_sscp\_stats**) are valid only when **nau\_address** is not zero. Otherwise the fields are reserved.

# local\_lu\_detail.det\_data.lu\_sscp\_stats.pacing\_type

Receive pacing type in use on the LU-SSCP session. This will be set to AP\_NONE.

# local\_lu\_detail.det\_data.sscp\_id

This is a 6–byte field containing the SSCP ID received in the ACTPU for the PU used by this LU.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

# secondary\_rc

AP\_INVALID\_LU\_ALIAS

AP\_INVALID\_LU\_NAME AP\_INVALID\_LIST\_OPTION

# QUERY\_LOCAL\_LU

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_LOCAL\_TOPOLOGY

All APPN nodes maintain a local topology database that holds information about the transmission groups (TGs) to all adjacent nodes.

QUERY\_LOCAL\_TOPOLOGY allows information about these TGs to be returned.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific local TG, or to obtain the list information in several chunks, the **dest**, **dest\_type**, and **tg\_num** fields should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), these fields will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used. This list is ordered on **dest** first, then on **dest\_type** and finally on **tg\_num**. The **dest** name is ordered by name length first, then by lexicographical ordering for names of the same length. The **dest\_type** field follows the order: AP\_LEN\_NODE, AP\_NETWORK\_NODE, AP\_END\_NODE, AP\_VRN. The **tg\_num** is ordered numerically.

If AP\_LIST\_INCLUSIVE is selected, the returned list starts from the first valid record of that name.

If AP\_LIST\_FROM\_NEXT is selected, the list will begin from the first valid record with a name following the one specified.

# **Supplied Parameters**

The application supplies the following parameters:

# opcode

AP\_QUERY\_LOCAL\_TOPOLOGY

# format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

# buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

# list\_options

This indicates what should be returned in the list information:

# AP\_SUMMARY

Returns summary information only.

# **AP\_DETAIL**

Returns detailed information.

The combination of the **dest**, **dest\_type** and **tg\_num** specified (see the following parameters, **dest**, **dest\_type**, and **tg\_num**) represents an index value that is used to specify the starting point of the actual information to be returned .

# AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

**dest** Fully qualified destination node name for the TG. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# dest\_type

Node type of the destination node for this TG. This can be one of the following values:

AP\_NETWORK\_NODE AP\_VRN AP\_END\_NODE AP\_LEARN\_NODE

If the **dest\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### tg\_num

Number associated with the TG. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

# total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### local\_topology\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### local\_topology\_summary.dest

Fully qualified destination node name for the TG. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# local\_topology\_summary.dest\_type

Type of the destination node for this TG. This is set to one of the following values:

AP\_NETWORK\_NODE AP\_VRN AP\_END\_NODE Note that if **dest\_type** is set to AP\_END\_NODE, this specifies that the TG destination is either to a LEN node or to an end node.

# local\_topology\_summary.tg\_num

Number associated with the TG.

#### local\_topology\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# local\_topology\_detail.dest

Fully qualified destination node name for the TG. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### local\_topology\_detail.dest\_type

Type of the destination node for this TG. This is set to one of the following values:

AP\_NETWORK\_NODE AP\_VRN AP\_END\_NODE

Note that if **dest\_type** is set to AP\_END\_NODE, this specifies that the TG destination is either to a LEN node or to an end node.

# local\_topology\_detail.tg\_num

Number associated with the TG.

#### local\_topology\_detail.dlc\_data.length

Length of DLC address of connection to a VRN (set to zero if **dest\_type** is not AP\_VRN).

#### local\_topology\_detail.dlc\_data.address

DLC address of connection to VRN.

#### local\_topology\_detail.rsn

Resource Sequence Number. This is assigned by the network node that owns this resource.

#### local\_topology\_detail.status

Specifies the status of the TG. This can be one or more of the following values ORed together:

AP\_TG\_OPERATIVE AP\_TG\_CP\_CP\_SESSIONS AP\_TG\_QUIESCING AP\_TG\_HPR AP\_TG\_RTP AP\_NONE

local\_topology\_detail.tg\_chars

TG characteristics (See "DEFINE\_CN" on page 31).

# local\_topology\_detail.cp\_cp\_session\_active

Specifies whether the local node's contention winner CP-CP session is active (AP\_NO or AP\_YES).

# local\_topology\_detail.branch\_link\_type

BrNN only. This branch link type of this TG. This is set to one of the following:

# **AP\_UPLINK**

This link is an uplink.

# AP\_DOWNLINK

The link is a downlink to an EN.

# AP\_DOWNLINK\_TO\_BRNN

The TG is a downlink to a BrNN that is showing its EN face.

# **AP\_OTHERLINK**

This link is an otherlink.

Other node types: This field is not meaningful and is always set to AP\_BRNN\_NOT\_SUPPORTED.

# local\_topology\_detail.branch\_tg

NN only. Specifies whether the TG is a branch TG.

#### AP\_NO

The TG is not a branch TG.

# AP\_YES

The TG is a branch TG.

Other node types: This field is not meaningful and is always set to AP\_NO.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

# secondary\_rc

AP\_INVALID\_TG

# AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_LS

QUERY\_LS returns a list of information about the link stations defined at the node. This information is structured as determined data (data gathered dynamically during execution) and defined data (the data supplied by the application on DEFINE\_LS).

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific LS, or to obtain the list information in several chunks, the **ls\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **ls\_name**. Ordering is according to name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

The list of link stations returned can be filtered by the name of the port that they belong to. In this case, the **port\_name** field should be set (otherwise this field should be set to all zeros).

} LS_DET_DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_QUERY\_LS

# attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

# format

Identifies the format of the VCB. Set this field to one to specify the format 1 version of the VCB listed above. If this is set to 0, the Program returns the format 0 LS\_DET\_DATA structure.

# buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

# buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

# list\_options

This indicates what should be returned in the list information:

# AP\_SUMMARY

Returns summary information only.

# AP\_DETAIL

Returns detailed information.

The **ls\_name** specified (see the following parameter, **ls\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

# AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### ls\_name

Link station name. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### port\_name

Port name filter. This should be set to all zeros or an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this field is set then only link stations belonging to this port are returned. This field is ignored if it is set to all zeros.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

# buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

# num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# ls\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### ls\_summary.ls\_name

Name of link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### ls\_summary.description

Resource description (as specified on DEFINE\_LS). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# ls\_summary.dlc\_type

Type of DLC. The Program supports the following types:

AP\_ANYNET AP\_LLC2 AP\_OEM\_DLC AP\_SDLC AP\_TWINAX AP\_X25

Additional DLC types can be defined by specifying the new type on the DEFINE\_DLC verb. See "DEFINE\_DLC" on page 46 for more information.

#### ls\_summary.state

State of this link station. This field is set to one of the following values:

AP\_NOT\_ACTIVE AP\_PENDING\_ACTIVE AP\_ACTIVE AP\_PENDING\_INACTIVE

#### ls\_summary.act\_sess\_count

The total number of active sessions (both endpoint and intermediate) using the link.

## ls\_summary.det\_adj\_cp\_name

Fully qualified, 17-byte, adjacent CP name determined during link activation. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This will be null if the LS is inactive.

If **ls\_summary.adj\_cp\_type** is not one of AP\_NETWORK\_NODE, AP\_END\_NODE, AP\_APPN\_NODE, or AP\_BACK\_LEVEL\_LEN\_NODE, then this field is reserved.

#### ls\_summary.det\_adj\_cp\_type

Type of the adjacent node determined during link activation. It is one of the following values:

AP\_END\_NODE AP\_NETWORK\_NODE AP\_LEARN\_NODE AP\_VRN

This will be AP\_LEARN\_NODE if the LS is inactive.

If **ls\_summary.adj\_cp\_type** is not one of AP\_NETWORK\_NODE, AP\_END\_NODE, AP\_APPN\_NODE, or AP\_BACK\_LEVEL\_LEN\_NODE, then this field is reserved.

# ls\_summary.port\_name

Name of port associated with this link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### ls\_summary.adj\_cp\_name

Fully qualified, 17-byte, adjacent control point name composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This will be null for an implicit link.

# ls\_summary.adj\_cp\_type

Type of the adjacent node. It is one of the following values:

AP\_END\_NODE AP\_NETWORK\_NODE AP\_APPN\_NODE AP\_BACK\_LEVEL\_LEN\_\_NODE AP\_HOST\_XID3 AP\_HOST\_XID0 AP\_DSPU\_XID AP\_DSPU\_NOXID

## ls\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## ls\_detail.ls\_name

Name of link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

### ls\_detail.det\_data.act\_sess\_count

Total number of active sessions (both endpoint and intermediate) using the link.

#### ls\_detail.det\_data.dlc\_type

Type of DLC. The Program supports the following types:

AP\_ANYNET AP\_LLC2 AP\_OEM\_DLC AP\_SDLC AP\_TWINAX AP\_X25

Additional DLC types can be defined by specifying the new type on the DEFINE\_DLC verb. See "DEFINE\_DLC" on page 46 for more information.

#### ls\_detail.det\_data.state

State of this link station. This field is set to one of the following values:

AP\_NOT\_ACTIVE AP\_PENDING\_ACTIVE AP\_ACTIVE AP\_PENDING\_INACTIVE

#### ls\_detail.det\_data.sub\_state

This field provides more detailed information about the state of this link station. This field is set to one of the following values:

AP\_SENT\_CONNECT\_OUT AP\_PENDING\_XID\_EXCHANGE AP\_SENT\_ACTIVATE\_AS AP\_SENT\_SET\_MODE AP\_ACTIVE AP\_SENT\_DEACTIVATE\_AS\_ORDERLY AP\_SENT\_DISCONNECT AP\_WAITING\_STATS AP\_RESET

#### ls\_detail.det\_data.det\_adj\_cp\_name

Fully qualified, 17-byte, adjacent control point name determined during link activation. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If **ls\_summary.adj\_cp\_type** is not one of AP\_NETWORK\_NODE, AP\_END\_NODE, AP\_APPN\_NODE, or AP\_BACK\_LEVEL\_LEN\_NODE, then this field is reserved.

#### ls\_detail.det\_data.det\_adj\_cp\_type

Type of the adjacent node determined during link activation. It is one of the following values:

AP\_END\_NODE AP\_NETWORK\_NODE AP\_LEARN\_NODE AP\_VRN

If **ls\_summary.adj\_cp\_type** is not one of AP\_NETWORK\_NODE, AP\_END\_NODE, AP\_APPN\_NODE, or AP\_BACK\_LEVEL\_LEN\_NODE, then this field is reserved.

#### ls\_detail.det\_data.dlc\_name

Name of the DLC. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### ls\_detail.det\_data.dynamic

Specifies whether the link was defined explicitly (by a DEFINE\_LS command), or implicitly or dynamically (either in response to a connection request from the adjacent node, or to connect dynamically to another node across a connection network). This can be AP\_YES or AP\_NO.

#### ls\_detail.det\_data.migration

Specifies whether the adjacent node is a migration level node (such as a low entry networking (LEN) node), or a full APPN network node or end node (AP\_YES, AP\_NO, or AP\_UNKNOWN).

#### ls\_detail.det\_data.tg\_num

Number associated with the TG.

#### ls\_detail.det\_data.ls\_stats.in\_xid\_bytes

Total number of XID (Exchange Identification) bytes received on this link station.

#### ls\_detail.det\_data.ls\_stats.in\_msg\_bytes

Total number of data bytes received on this link station.

#### ls\_detail.det\_data.ls\_stats.in\_xid\_frames

Total number of XID (Exchange Identification) frames received on this link station.

#### ls\_detail.det\_data.ls\_stats.in\_msg\_frames

Total number of data frames received on this link station.

#### ls\_detail.det\_data.ls\_stats.out\_xid\_bytes

Total number of XID (Exchange Identification) bytes sent on this link station.

#### ls\_detail.det\_data.ls\_stats.out\_msg\_bytes

Total number of data bytes sent on this link station.

## ls\_detail.det\_data.ls\_stats.out\_xid\_frames

Total number of XID (Exchange Identification) frames sent on this link station.

## ls\_detail.det\_data.ls\_stats.out\_msg\_frames

Total number of data frames sent on this link station.

#### ls\_detail.det\_data.ls\_stats.in\_invalid\_sna\_frames

Total number of SNA incorrect frames received on this link station.

## ls\_detail.det\_data.ls\_stats.in\_session\_control\_frames

Total number of session control frames received on this link station.

#### ls\_detail.det\_data.ls\_stats.out\_session\_control\_frames

Total number of session control frames sent on this link station.

#### ls\_detail.det\_data.ls\_stats.echo\_rsps

Number of echo responses received from the adjacent node. Echo requests are sent periodically to gauge the propagation delay to the adjacent node.

## ls\_detail.det\_data.ls\_stats.current\_delay

Time (in milliseconds) that it took for the last test signal to be sent and returned from this link station to the adjacent link station.

## ls\_detail.det\_data.ls\_stats.max\_delay

Longest time taken (in milliseconds) for a test signal to be sent and returned from this link station to the adjacent link station.

## ls\_detail.det\_data.ls\_stats.min\_delay

Shortest time taken (in milliseconds) for a test signal to be sent and returned from this link station to the adjacent link station.

#### ls\_detail.det\_data.ls\_stats.max\_delay\_time

Time since system startup (in hundredths of a second) when the longest delay occurred.

#### ls\_detail.det\_data.ls\_stats.good\_xids

Total number of successful XID exchanges that have occurred on this link station since it was started.

#### ls\_detail.det\_data.ls\_stats.bad\_xids

Total number of unsuccessful XID exchanges that have occurred on this link station since it was started.

## ls\_detail.det\_data.start\_time

Time since system startup (in hundredths of a second) when the link station was last activated (that is, the mode setting commands completed).

## ls\_detail.det\_data.stop\_time

Time since system startup (in hundredths of a second) when the link station was last deactivated.

#### ls\_detail.det\_data.up\_time

The total time (in hundredths of a second) that this link station has been active since system startup.

#### ls\_detail.det\_data.current\_state\_time

The total time (in hundredths of a second) that this link station has been in the current state.

#### ls\_detail.det\_data.deact\_cause

The cause of the last deactivation of the link station. The field is set to one of the following values:

#### AP\_NONE

The link station has never been deactivated.

## AP\_DEACT\_OPER\_ORDERLY

The link station was deactivated as a result of an orderly STOP command from an operator.

#### AP\_DEACT\_OPER\_IMMEDIATE

The link station was deactivated as a result of an immediate STOP command from an operator.

## AP\_DEACT\_AUTOMATIC

The link station was deactivated automatically, for example because there were no more sessions using the link station.

## **AP\_DEACT\_FAILURE**

The link station was deactivated because of a failure.

#### ls\_detail.det\_data.hpr\_support

The level of high-performance routing (HPR) supported on this TG (AP\_NONE, AP\_BASE or AP\_RTP), taking account of the capabilities of the local and adjacent nodes.

#### ls\_detail.det\_data.anr\_label

The HPR automatic network routing (ANR) label allocated to the local link.

#### ls\_detail.det\_data.hpr\_link\_lvl\_error

Specifies whether link-level error recovery is being used for HPR traffic on the link.

#### ls\_detail.def\_data.auto\_act

Specifies whether the link currently allows remote activation or activation on demand. The following values are returned (and may be ORed together:

#### AP\_AUTO\_ACT

The link can be activated on demand by the local node.

#### AP\_REMOTE\_ACT

The link can be activated by the remote node.

## ls\_detail.det\_data.ls\_role

The link station role for this link station. This is initially set to the link station role defined for the link station. If the defined role is negotiable, this value changes to the negotiated role (primary or secondary) during the XID exchange, and reverts back to negotiable when the link is deactivated.

#### AP\_LS\_NEG

The link station role is negotiable.

#### AP\_LS\_PRI

The link station role is primary.

## AP\_LS\_SEC

The link station role is secondary.

#### ls\_detail.det\_data.node\_id

Node ID received from adjacent node during XID exchange. This a 4-byte hexadecimal string.

## ls\_detail.det\_data.active\_isr\_count

Number of active intermediate sessions using the link.

#### ls\_detail.det\_data.active\_lu\_sess\_count

The count of active LU-LU sessions using the link.

#### ls\_detail.det\_data.active\_sscp\_sess\_count

The count of active LU-SSCP and PU-SSCP sessions using the link.

## ls\_detail.det\_data.reverse\_anr\_label.length

The length of the reverse Automatic Network Routing (ANR) label for the link station. If the link does not support HPR, or the label is not known, this field is zeroed.

#### ls\_detail.det\_data.reverse\_anr\_label.label

The reverse Automatic Network Routing (ANR) label for the link station. If the link does not support HPR, or the label is not known, this field is zeroed.

#### ls\_detail.det\_data.local\_address

The local address of this link station.

## ls\_detail.det\_data.max\_send\_btu\_size

The maximum BTU size that can be sent on this link, as determined by negotiation with the adjacent node. If link activation has not yet been attempted, zero is returned.

#### ls\_detail.det\_data.brnn\_link\_type

BrNN only. This branch link type. It is one of the following:

#### **AP\_UPLINK**

This link is an uplink.

## **AP\_DOWNLINK**

The link is a downlink.

#### AP\_OTHERLINK

This link is an otherlink.

## AP\_UNKNOWN\_LINK\_TYPE

This link is an otherlink.

## AP\_BRNN\_NOT\_SUPPORTED

This link supports PU 2.0 traffic only.

Other node types: This field is not meaningful and is always set to AP\_BRNN\_NOT\_SUPPORTED.

## ls\_detail.det\_data.adj\_cp\_is\_brnn

All node types: Specifies whether the adjacent node is a BrNN.

## AP\_UNKNOWN

It is not known whether the adjacent node is a BrNN.

#### AP\_NO

The adjacent node is not a BrNN.

## AP\_YES

The adjacent node is BrNN.

## ls\_detail.def\_data.description

Resource description (as specified on DEFINE\_LS). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### ls\_detail.def\_data.port\_name

Name of port associated with this link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. If the link is to a VRN, this field specifies the name of the actual port used to connect to the VRN (as specified in the DEFINE\_CN verb).

#### ls\_detail.def\_data.adj\_cp\_name

Fully qualified 17-byte adjacent control point name, which is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and

is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This is defined if **back\_lvl\_len\_end\_node** is not set to AP\_NO, or if the port associated with the link station is defined to be switched.

## ls\_detail.def\_data.adj\_cp\_type

Adjacent node type.

## AP\_NETWORK\_NODE

Specifies that the node is an APPN network node.

#### AP\_END\_NODE

Specifies that the node is an APPN end node or an up-level LEN node.

## AP\_APPN\_NODE

Specifies that the node is an APPN network node, an APPN end node, or an up-level LEN node. The node type will be learned during XID exchange.

#### AP\_BACK\_LEVEL\_LEN\_NODE

Specifies that the node is a back-level LEN node.

#### AP\_HOST\_XID3

Specifies that the node is a host and that the Node Operator Facility responds to a polling XID from the node with a format 3 XID.

## AP\_HOST\_XID0

Specifies that the node is a host and that the Node Operator Facility responds to a polling XID from the node with a format 0 XID.

#### AP\_DSPU\_XID

Specifies that the node is a downstream PU and that the Node Operator Facility includes XID exchange in link activation.

#### AP\_DSPU\_NOXID

Specifies that the node is a downstream PU and that the Node Operator Facility does not include XID exchange in link activation.

**Note:** A link station to a VRN is always dynamic and is therefore not defined.

#### ls\_detail.def\_data.dest\_address.length

Length of destination link station's address on adjacent node.

#### ls\_detail.def\_data.dest\_address.address

Link station's destination address on adjacent node.

#### ls\_detail.def\_data.auto\_act\_supp

Specifies whether the link will be activated automatically after it has been started by a START\_LS verb, and stopped by a STOP\_LS. (AP\_YES or AP\_NO).

## ls\_detail.def\_data.tg\_number

Preassigned TG number (in the range one to 20). This number is used to represent the link when the link is activated. Zero indicates that the TG number is not preassigned but is negotiated when the link is activated.

#### ls\_detail.def\_data.limited\_resource

Specifies whether this link station is to be deactivated when there are no sessions using the link. This is set to one of the following values:

#### AP\_NO

The link is not a limited resource and will not be deactivated automatically.

## AP\_YES or AP\_NO\_SESSIONS

The link is a limited resource and will be deactivated automatically when no active sessions are using it.

## AP\_INACTIVITY

The link is a limited resource and will be deactivated automatically when no active sessions are using it, or when no data has flowed on the link for the time period specified by the **link\_deact\_timer** field.

## ls\_detail.def\_data.solicit\_sscp\_sessions

AP\_YES requests the host to initiate sessions between the SSCP and the local control point and dependent LUs. AP\_NO requests no sessions with the SSCP on this link.

#### ls\_detail.def\_data.pu\_name

Name of the local PU that is going to use this link if **solicit\_sscp\_sessions** is set to AP\_YES. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If **solicit\_sscp\_sessions** is set to AP\_NO, this field is reserved.

## ls\_detail.def\_data.disable\_remote\_act

Specifies whether remote activation of this link is supported (AP\_YES or AP\_NO).

#### ls\_detail.def\_data.dspu\_services

Specifies the services that the local node provides to the downstream PU across this link if **solicit\_sscp\_sessions** is set to AP\_NO. This is set to one of the following:

## AP\_PU\_CONCENTRATION

Local node will provide PU concentration for the downstream PU.

#### AP\_DLUR

Local node will provide DLUR services for the downstream PU.

## AP\_NONE

Local node will provide no services for this downstream PU.

If **solicit\_sscp\_sessions** is set to AP\_YES, this field is reserved.

#### ls\_detail.def\_data.dspu\_name

Name of the downstream PU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This is only valid if **solicit\_sscp\_sessions** is set to AP\_NO.

#### ls\_detail.def\_data.dlus\_name

Name of DLUS node which DLUR solicits SSCP services from when the link to the downstream node is activated. This is either set to all zeros or a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the field is set to all zeros, then the global default DLUS (if defined by the DEFINE\_DLUR\_DEFAULTS verb) is solicited when the link is activated. If the **dlus\_name** is set to zeros and there is no global default DLUS, then DLUR will not initiate SSCP contact when the link is activated. This field is reserved if **dspu\_services** is not set to AP\_DLUR.

## ls\_detail.def\_data.bkup\_dlus\_name

Name of DLUS node which serves as the backup for the downstream PU. This is either set to all zeros or to a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the field is set to all zeros, then the global backup default DLUS (if defined by the DEFINE\_DLUR\_DEFAULTS verb) is used as the backup for this PU. This field is reserved if **dspu\_services** is not set to AP\_DLUR.

## ls\_detail.def\_data.hpr\_supported

Specifies whether HPR is supported on this link (AP\_YES or AP\_NO).

## ls\_detail.def\_data.hpr\_link\_lvl\_error

Specifies whether the HPR link-level error recovery tower is supported on this link (AP\_YES or AP\_NO). Note that the parameter is reserved if **hpr\_supported** is set to AP\_NO.

## ls\_detail.def\_data.link\_deact\_timer

Limited resource link deactivation timer (in seconds).

If **limited\_resource** is set to AP\_YES or AP\_NO\_SESSIONS, a link is automatically deactivated if no data traverses the link for the duration of this timer, and no sessions are using the link.

If **limited\_resource** is set to AP\_INACTIVITY then a link is automatically deactivated if no data traverses the link for the duration of this timer.

#### ls\_detail.def\_data.default\_nn\_server

Specifies whether a link can be automatically activated by an end node to support CP-CP sessions to a network node server. (AP\_YES or AP\_NO). The link must be defined to support CP-CP sessions for this field to take effect.

## ls\_detail.def\_data.ls\_attributes

Specifies further information about the adjacent node.

#### ls\_detail.def\_data.ls\_attributes[0]

Host type.

## AP\_SNA

Standard SNA host.

## AP FNA

FNA (VTAM-F) host.

#### AP\_HNA

HNA host.

## ls\_detail.def\_data.ls\_attributes[1]

This is a bit field. It may take the value AP\_NO, or any of the following values bitwise ORed together

## AP\_SUPPRESS\_CP\_NAME

Network Name CV suppression option for a link to a back-level LEN node. If this bit is set, no Network Name CV is included in XID exchanges with the adjacent node. (This bit is ignored unless **adj\_cp\_type** is set to AP\_BACK\_LEVEL\_LEN\_NODE or AP\_HOST\_XID3.)

#### AP\_REACTIVATE\_ON\_FAILURE

If the link is active and then fails, Personal Communications or

Communications Server will attempt to reactivate the link. If the reactivation attempt fails, the link will remain inactive.

## AP\_USE\_PU\_NAME\_IN\_XID\_CVS

If the adjacent node is defined to be a host or **solicit\_sscp\_sessions** is set to AP\_YES on a link to an APPN node, and the AP\_SUPPRESS\_CP\_NAME bit is not set, then the fully-qualified CP name in Network Name CVs sent on Format 3 XIDs is replaced by the name supplied in **def\_data.pu\_name**, fully-qualified with the network ID of the CP.

## ls\_detail.def\_data.adj\_node\_id

Defined node ID of adjacent node.

## ls\_detail.def\_data.local\_node\_id

Node ID sent in XIDs on this link station. This is a 4-byte hexadecimal string. If this field is set to zero, the **node\_id** is used in XID exchanges. If this field is nonzero, it replaces the value for XID exchanges on this LS.

#### ls\_detail.def\_data.cp\_cp\_sess\_support

Specifies whether CP-CP sessions are supported (AP\_YES or AP\_NO).

#### ls\_detail\_def\_data.use\_default\_tg\_chars

Specifies whether the TG characteristics supplied on the DEFINE\_LS were discarded in favor of the default characteristics supplied on the DEFINE\_PORT (AP\_YES or AP\_NO). This field does not apply to implicit links.

#### ls\_detail.def\_data.tg\_chars

TG characteristics (See "DEFINE\_CN" on page 31).

#### ls\_detail.def\_data.target\_pacing\_count

Numeric value between 1 and 32 767 inclusive indicating the desired pacing window size for BINDs on this TG. The number is only significant when fixed bind pacing is being performed. Note that Personal Communications or Communications Server does not currently use this value.

#### ls\_detail.def\_data.max\_send\_btu\_size

Maximum BTU size that can be sent.

#### ls\_detail.def\_data.ls\_role

The link station role that this link station should assume. This can be any one of AP\_LS\_NEG, AP\_LS\_PRI or AP\_LS\_SEC to select a role of negotiable, primary or secondary. The field can also be set to AP\_USE\_PORT\_DEFAULTS to select the value configured on the DEFINE\_PORT verb.

## ls\_detail.def\_data.max\_ifrm\_rcvd

The maximum number of I-Frames that can be received by the XID sender before acknowledgment. Set to zero if the default value from DEFINE PORT should be used.

#### ls\_detail.def\_data.dlus\_retry\_timeout

Interval in seconds between second and subsequent attempts to contact DLUS specified in the **Is\_detail.def\_data.dlus\_name** and **Is\_detail.def\_data.bkup\_dlus\_name** fields. The interval between the initial attempt and the first retry is always one second. If zero is specified, the default value configured through DEFINE\_DLUR\_DEFAULTS is used. This field is ignored if **def\_data.dspu\_services** is not set to AP\_DLUR.

## ls\_detail.def\_data.dlus\_retry\_limit

Maximum number of retries after an initial failure to contact a DLUS specified in the **Is\_detail.def\_data.dlus\_name** and **Is\_detail.def\_data.bkup\_dlus\_name** fields. If zero is specified, the default value configured through DEFINE\_DLUR\_DEFAULTS is used. If X'FFFF' is specified, the Program retries indefinitely. This field is ignored if **def\_data.dspu\_services** is not set to AP\_DLUR.

## ls\_detail.def\_data.link\_spec\_data\_len

Unpadded length, in bytes, of data passed unchanged to link station component during initialization. The data is concatenated to the LS\_DETAIL structure. This data will be padded to end on a 4-byte boundary.

## ls\_detail.def\_data.conventional\_lu\_compression

Specifies whether data compression is requested for sessions on this link. Note that this field is only valid for links carrying LU 0 to 3 traffic.

## AP\_NO

The local node should not compress or decompress conventional LU data flowing over this link.

## AP\_YES

Data compression should be enabled for conventional LU sessions on this link if the host requests compression.

## ls\_detail.def\_data.conventional\_lu\_cryptography

Specifies whether session level encryption is required for conventional LU sessions. This field only applies for links carrying conventional LU traffic.

## AP\_NONE

Session level encryption is not performed by the Program.

## **AP\_MANDATORY**

Mandatory session level encryption is performed by the Program if an import key is available to the LU. Otherwise, it must be performed by the application that uses the LU (if this is PU Concentration, it is performed by a downstream LU).

## **AP\_OPTIONAL**

This value allows the cryptography used to be driven by the host application on a per session basis. If the host request cryptography for a session dependent on this PU, then the behaviour of the Program is as for AP\_MANDATORY. If the host does not request cryptography, then the behaviour is the same as AP\_NONE.

## ls\_detail.def\_data.retry\_flags

This field specifies the conditions under which activation of this link station is subject to automatic retry. It is a bit field, and may take any of the following values bit-wise ORed together.

## AP\_RETRY\_ON\_START

Link activation will be retried if no response is received from the remote node when activation is attempted. If the underlying port is inactive when activation is attempted, the Program will attempt to activate it.

## AP\_RETRY\_ON\_FAILURE

Link activation will be retried if the link fails while active or pending active. If the underlying port has failed when activation is attempted, the Program attempts to activate it.

#### AP\_RETRY\_ON\_DISCONNECT

Link activation will be retried if the link is stopped normally by the remote node.

## AP\_DELAY\_APPLICATION\_RETRIES

Link activation retries, initiated by applications (using START\_LS or on-demand link activation) will be paced using the **activation\_delay\_timer**.

## AP\_DELAY\_INHERIT\_RETRY

In addition to the retry conditions specified by flags in this field, those specified in the **retry\_flags** field of the underlying port definition will also be used.

## ls\_detail.def\_data.max\_activation\_attempts

This field has no effect unless at least one flag is set in retry\_flags.

This field specifies the number of retry attempts the Program allows when the remote node is not responding, or the underlying port is inactive. This includes both automatic retries and application-driven activation attempts.

If this limit is ever reached, no further attempts are made to automatically retry. This condition is reset by STOP\_LS, STOP\_PORT, STOP\_DLC or a successful activation. START\_LS or OPEN\_LU\_SSCP\_SEC\_RQ results in a single activation attempt, with no retry if activation fails.

Zero means 'no limit'. The value AP\_USE\_DEFAULTS results in the use of **max\_activiation\_attempts** supplied on DEFINE\_PORT.

#### ls\_detail.def\_data.activation\_delay\_timer

This field has no effect unless at least one flag is set in retry\_flags.

This field specifies the number of seconds that the Program waits between automatic retry attempts, and between application-driven activation attempts if the AP\_DELAY\_APPLICATION\_RETRIES bit is set in **def\_data.retry\_flags**.

The value AP\_USE\_DEFAULTS results in the use of **activiation\_delay\_timer** supplied on DEFINE\_PORT.

If zero is specified, the Program uses a default timer duration of thirty seconds.

## ls\_detail.def\_data.branch\_link\_type

BrNN only. Specifies whether a link is an uplink or a downlink. This field only applies if the field **def\_data.adj\_cp\_type** is set to AP\_NETWORK, NODE, AP\_END\_NODE, AP\_APPN\_NODE, or AP\_BACK\_LEVEL\_LEN\_NODE.

#### **AP\_UPLINK**

This link is an uplink.

#### **AP\_DOWNLINK**

The link is a downlink.

If the field **adj\_cp\_type** is set to AP\_NETWORK\_NODE, then this field must be set to AP\_UPLINK.

Other node types: This field is ignored.

## ls\_detail.det\_data.adj\_brnn\_cp\_support

BrNN only. Specifies whether the adjacent CP is allowed to be, required to be, or prohibited from being an NN(BrNN), for example, a BrNN showing its NN face. This field only applies if the field **adj\_cp\_type** is set to

AP\_NETWORK\_ NODE or AP\_APPN\_NODE, (and the node type learned during XID exchange is network node).

## AP\_BRNN\_ALLOWED

The adjacent CP is allowed (but not required) to be an NN(BrNN).

# AP\_BRNN\_REQUIRED

The adjacent CP is not allowed to be an NN(BrNN).

## AP\_BRNN\_PROHIBITED

The adjacent CP is not allowed to be an NN(BrNN).

If the field **adj\_cp\_type** is set to AP\_NETWORK\_NODE and the field **auto\_act\_supp** is set to AP\_YES, then this field must be set to AP\_BRNN\_REQUIRED or AP\_BRNN\_PROHIBITED.

Other node types: This field is ignored.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_LINK\_NAME

## AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_LS\_EXCEPTION

QUERY\_LS\_EXCEPTION returns a list of information about the link stations defined at the node. This information is structured as determined data (data gathered dynamically during execution) and defined data (the data supplied by the application on DEFINE\_LS).

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific LS, or to obtain the list information in several chunks, the **ls\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **ls\_name**. Ordering is according to name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

The list of link stations returned can be filtered by the name of the port that they belong to. In this case, the **port\_name** field should be set (otherwise this field should be set to all zeros).

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_QUERY\_LS\_EXCEPTION

## format

Identifies the format of the VCB. Set this field to one to specify the format 1 version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information.

The **index** specified in the following parameter represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignore and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned lists starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### exception\_index

Index of the LS exception entry. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### ls\_name

Name of the link station that returned entries relate. This is an 8–byte string in a locally displayable character set. All 8 bytes are significant. If this field is set to null, then entries that relate to any or all links stations are returned.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

## num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## ls\_exception.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## ls\_exception.exception\_index

The index assigned for this LS exception entry. The value of the index begins at zero and increases incrementally up to a maximum value of  $2^{**}31-1$  (2,147,483,647) before wrapping.

## ls\_exception.time

Time and date that the LS exception entry was generated.

## ls\_exception.ls\_name

Name of link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## ls\_exception.adj\_cp\_name

Fully qualified, 17-byte, adjacent CP name. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) The value of this field is determined as follows:

If an adjacent CP name was received on XID, it is returned.

If an adjacent CP name was received on XID, but a locally-defined value is available, it is returned.

Otherwise, null is returned.

## ls\_exception.node\_id

Node ID received from adjacent node during XID exchange (or null if none is received). This is a 4–byte hexadecimal string.

## ls\_exception.tg\_number

Number associated with the TG to this link station. Range 0 through 256. A value of 256 indicates that the TG number was unknown at the time of the failure.

## ls\_exception.general\_sense

The error sense data associated with the start sequence of activation of a link up to the beginning of the XID sequence. This is generated by the node.

## ls\_exception.retry

Indicates whether the node will retry the start request to activate the link.

## AP\_NO

The node will not retry the start request.

#### AP\_YES

The node will retry the start request.

#### ls\_exception.end\_sense

Sense data associated with the termination of the activation attempt. This is generated by the DLC layer.

#### ls\_exception.xid\_local\_sense

Locally generated sense data sent in XID.

#### ls\_exception.xid.remote\_sense

Remotely generated sense data received in XID.

#### ls\_exception.xid\_error\_byte

Offset of error bit in error byte in XID (range 0 through 65535). The value 65535 indicates that this field has no meaning.

## ls\_exception.xid\_error\_bit

Offset of error bit in error byte in XID (range 0 through 7). The value 8 indicates that this field has no meaning.

## ls\_exception.dlc\_type

Type of DLC. The Program supports the following types:

AP\_SDLC AP\_X25 AP\_TR

Additional DLC types can be defined by specifying the new type on the DEFINE\_DLC verb. See "DEFINE\_DLC" on page 46 for more information.

#### ls\_exception.local\_addr.length

The length of local link station's address.

#### ls\_exception.local\_addr.address

The local link station's address.

#### ls\_exception.destination\_addr.length

The length of destination link station's address on adjacent node.

#### ls\_exception.destination\_addr.address

Destination link station's address on adjacent node.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_EXCEPTION\_INDEX

#### AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_LU\_0\_TO\_3

QUERY\_LU\_0\_TO\_3 returns information about local LUs of type 0, 1, 2, or 3. This information is structured as determined data (data gathered dynamically during execution) and defined data (the data supplied by the application on DEFINE\_LU\_0\_TO\_3).

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific local LU, or to obtain the list information in several chunks, the **lu\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored.

Only certain parameters are supported on SNA API clients. See the note pad icon throughout this chapter for specific details.

This icon represents important information that can affect the operation of Communications Server and Personal Communications.

} LU 0 TO 3 DEF DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_QUERY\_LU\_0\_TO\_3

## attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information.

#### **AP\_SUMMARY**

Returns summary information only.

AP\_SUMMARY value is also supported for SNA API clients.

## **AP\_DETAIL**

Returns detailed information.

The **lu\_name** specified (see the following parameter, **lu\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list

AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## lu\_name

Name of the local LU that is being queried. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

The list\_options value is ignored for SNA API clients.

## pu\_name

PU name. Only LUs that use this PU will be returned. If a list of all LUs is required then this field should be set to all binary zeros. The list\_options value is ignored for SNA API clients. The list\_options value is ignored for SNA API clients.

The pu\_name value is ignored for SNA API clients.

#### host\_attachment

Filter for host attachment.

## AP\_NONE

Return information about all LUs.

AP\_NONE is the only value supported for SNA API clients.

## AP\_DLUR\_ATTACHED

Return information about all LUs that are supported by DLUR.

## AP\_DIRECT\_ATTACHED

Return information about only those LUs that are directly attached to the host system.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## lu\_0\_to\_3\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### lu\_0\_to\_3\_summary.pu\_name

Name of local PU that this LU is using. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

The lu\_0\_to\_3\_summary.pu\_name value is not returned on SNA API clients.

#### lu\_0\_to\_3\_summary.lu\_name

Name of the local LU that is being queried. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## lu\_0\_to\_3\_summary.description

Resource description (as specified on DEFINE\_LU\_0\_TO\_3). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

The lu\_0\_to\_3\_summary.description value is not returned on SNA API clients.

#### lu\_0\_to\_3\_summary.nau\_address

Network addressable unit address of the LU, which is in the range 1–255.

The lu\_0\_to\_3\_summary.nau\_address value is not returned on SNA API clients.

#### lu\_0\_to\_3\_summary.lu\_sscp\_sess\_active

Specifies whether the LU-SSCP session is active (AP\_YES or AP\_NO).

The lu\_0\_to\_3\_summary.lu\_sscp\_sess\_active value is not returned on SNA API clients.

**lu\_0\_to\_3\_summary.appl\_conn\_active** Specifies whether an application is using the LU (AP\_YES or AP\_NO).

The lu\_0\_to\_3\_summary.aapl\_conn\_active value is not returned on SNA API clients.

#### lu\_0\_to\_3\_summary.plu\_sess\_active

Specifies whether the PLU-SLU session is active (AP\_YES or AP\_NO).

The lu\_0\_to\_3\_summary.plu\_sess\_active value is not returned on SNA API clients.

## lu\_0\_to\_3\_summary.host\_attachment

LU host attachment type:

## AP\_DLUR\_ATTACHED

LU is attached to host system using DLUR.

## AP\_DIRECT\_ATTACHED

LU is directly attached to host system.

## lu\_0\_to\_3\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## lu\_0\_to\_3\_detail.lu\_name

Name of the local LU that is being queried. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_sess\_active

Specifies whether the LU-SSCP session is active (AP\_YES or AP\_NO).

#### lu\_0\_to\_3\_detail.det\_data.appl\_conn\_active

Specifies whether this LU is currently being used by an application (AP\_YES or AP\_NO).

#### **lu\_0\_to\_3\_detail.det\_data.plu\_sess\_active** Specifies whether the PLU-SLU session is active (AP\_YES or AP\_NO).

## **lu\_0\_to\_3\_detail.det\_data.host\_attachment** LU host attachment type:

#### AP\_DLUR\_ATTACHED

LU is attached to host system using DLUR.

## AP\_DIRECT\_ATTACHED

LU is directly attached to host system.

## **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.rcv\_ru\_size** This field is always reserved.

- **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.send\_ru\_size** This field is always reserved.
- **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.max\_send\_btu\_size** Maximum BTU size that can be sent.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.max\_send\_pac\_win
  This field will always be set to zero.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.cur\_send\_pac\_win This field will always be set to zero.
- **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.max\_rcv\_pac\_win** This field will always be set to zero.
- **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.cur\_rcv\_pac\_win** This field will always be set to zero.

- **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.send\_data\_frames** Number of normal flow data frames sent.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.
- lu \_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.
- **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.rcv\_fmd\_data\_frames** Number of normal flow FMD data frames received.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.sidh Session ID high byte.
- **lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.sidl** Session ID low byte.
- lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.odai

Origin Destination Address Indicator. When bringing up a session, the sender of the ACTLU sets this field to zero if the local node contains the primary link station, and sets it to one if the ACTLU sender is the node containing the secondary link station.

#### lu\_0\_to\_3\_detail.det\_data.lu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate this session with the link over which the session flows.

- **lu\_0\_to\_3\_detail.det\_data.plu\_stats.rcv\_ru\_size** Maximum receive RU size.
- lu\_0\_to\_3\_detail.det\_data.plu\_stats.send\_ru\_size Maximum send RU size.
- lu\_0\_to\_3\_detail.det\_data.plu\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.
- **lu\_0\_to\_3\_detail.det\_data.plu\_stats.max\_rcv\_btu\_size** Maximum BTU size that can be received.
- lu\_0\_to\_3\_detail.det\_data.plu\_stats.max\_send\_pac\_win
   Maximum size of the send pacing window on this session.

- **lu\_0\_to\_3\_detail.det\_data.plu\_stats.send\_data\_frames** Number of normal flow data frames sent.

#### **lu\_0\_to\_3\_detail.det\_data.plu\_stats.send\_fmd\_data\_frames** Number of normal flow FMD data frames sent.

- **lu\_0\_to\_3\_detail.det\_data.plu\_stats.send\_data\_bytes** Number of normal flow data bytes sent.
- lu\_0\_to\_3\_detail.det\_data.plu\_stats.rcv\_data\_frames Number of normal flow data frames received.
- **lu\_0\_to\_3\_detail.det\_data.plu\_stats.rcv\_fmd\_data\_frames** Number of normal flow FMD data frames received.
- lu\_0\_to\_3\_detail.det\_data.plu\_stats.rcv\_data\_bytes Number of normal flow data bytes received.
- lu\_0\_to\_3\_detail.det\_data.plu\_stats.sidh Session ID high byte.
- lu\_0\_to\_3\_detail.det\_data.plu\_stats.sidl Session ID low byte.

## lu\_0\_to\_3\_detail.det\_data.plu\_stats.odai

Origin Destination Address Indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to one if the BIND sender is the node containing the secondary link station.

## lu\_0\_to\_3\_detail.det\_data.plu\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## lu\_0\_to\_3\_detail.det\_data.plu\_stats.pacing\_type

Receive pacing type in use on the PLU-SSCP session. This can take the values AP\_NONE or AP\_PACING\_FIXED.

## lu\_0\_to\_3\_detail.det\_data.plu\_name

Primary LU name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. (If the PLU-SLU session is inactive this field is reserved).

#### lu\_0\_to\_3\_detail.det\_data.session\_id

Eight byte internal identifier of the PLU-SLU session.

- lu\_0\_to\_3\_detail.det\_data.app\_spec\_det\_data Reserved.
- lu\_0\_to\_3\_detail.det\_data.app\_type Reserved.

## lu\_0\_to\_3\_detail.det\_data.sscp\_id

This is a 6–byte field containing the SSCP ID received in the ACTPU for the PU used by this LU.

If **lu\_sscp\_sess\_active** is not AP\_YES, then this field will be zeroed.

## lu\_0\_to\_3\_detail.det\_data.bind\_lu\_type

The LU type of the LU that issued the original BIND. If there is an active LU-LU session, then this can be one of the following:

AP\_LU\_TYPE\_0 AP\_LU\_TYPE\_1 AP\_LU\_TYPE\_2 AP\_LU\_TYPE\_3 AP\_LU\_TYPE\_6 (for downstream dependent LU 6.2) If there is no active LU—LU session, then this field takes the following value:

## AP\_LU\_TYPE\_UNKNOWN

## lu\_0\_to\_3\_detail.def\_data.description

Resource description (as specified on DEFINE\_LU\_0\_TO\_3). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## lu\_0\_to\_3\_detail.def\_data.nau\_address

Network addressable unit address of the LU, which is in the range 1–255.

## lu\_0\_to\_3\_detail.def\_data.pool\_name

Name of pool to which this LU belongs. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If the LU does not belong to a pool, this field is set to all binary zeros.

## lu\_0\_to\_3\_detail.def\_data.pu\_name

Name of the PU (as specified on the DEFINE\_LS verb) that this LU will use. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## lu\_0\_to\_3\_detail.def\_data.priority

LU priority when sending to the host. This is set to one of the following values:

AP\_NETWORK AP\_HIGH AP\_MEDIUM AP\_LOW

## lu\_0\_to\_3\_detail.def\_data.lu\_model

Model type and number of the LU. This is set to one of the following values:

AP\_3270\_DISPLAY\_MODEL\_2 AP\_3270\_DISPLAY\_MODEL\_3 AP\_3270\_DISPLAY\_MODEL\_4 AP\_3270\_DISPLAY\_MODEL\_5 AP\_RJE\_WKSTN AP\_PRINTER AP\_SCS\_PRINTER AP\_UNKNOWN

## lu\_0\_to\_3\_detail.def\_data.sscp\_id

This field specifies the ID of the SSCP permitted to activate this LU. It is a 6–byte binary field. If the field is set to binary zeros, then the LU may be activated by any SSCP.

## lu\_0\_to\_3\_detail.def\_data.timeout

Timeout for LU specified in seconds. If a timeout is supplied and the user of the LU specified **allow\_timeout** on the OPEN\_LU\_SSCP\_SEC\_RQ (or, in the case of PU concentration, on the Downstream LU definition), then the LU will be deactivated after the PLU-SLU session is left inactive for this period and one of the following conditions holds:

• The session passes over a limited resource link

- Another application wishes to use the LU before the session is used again
- If the timeout is set to zero, the LU will not be deactivated.

## lu\_0\_to\_3\_detail.def\_data.app\_spec\_def\_data

Application-specified data from DEFINE\_LU\_0\_TO\_3; the Program does not interpret this field, it is simply stored and returned on the QUERY\_LU\_0\_TO\_3 verb.

## lu\_0\_to\_3\_detail.def\_data.model\_name

The value returned is the value specified in the format 1 DEFINE\_LU\_0\_TO\_3 verb, or hex zeros if the DEFINE verb was format 0.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_LU\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_LU\_POOL

QUERY\_LU\_POOL returns a list of pools and the LUs that belong to them.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific LU pool or to obtain the list information in several chunks, the **pool\_name** and **lu\_name** fields should be set. If the **lu\_name** field is set to all zeros, then the information returned starts from the first LU in the specified pool. If the **list\_options** field is set to AP\_FIRST\_IN\_LIST, then both of these fields are ignored.

} LU_POC	DL_DETAIL;			

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_LU\_POOL

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

#### AP\_DETAIL

Returns detailed information.

The combination of the **pool\_name** and **lu\_name** specified (see the following parameters, **pool\_name** and **lu\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### pool\_name

Name of LU pool. This name is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### lu\_name

LU name. This name is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this is set to all binary zeros, the LUs belonging to the specified pool are listed from the beginning of the pool. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of directory entries returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

### lu\_pool\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### lu\_pool\_summary.pool\_name

Name of LU pool to which the specified LU belongs. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. (Note that if this field is specified on the request and the **lu\_name** field is set to all binary zeros, then only LUs in the pool are returned.)

## lu\_pool\_summary.description

LU pool description (as specified on DEFINE\_LU\_POOL).

#### lu\_pool\_summary.num\_active\_lus

The number of LUs in the specified pool that have active LU-SSCP sessions.

#### lu\_pool\_summary.num\_avail\_lus

The number of LUs in the specified pool available to satisfy an OPEN\_LU\_SSCP\_SEC\_REQ with **open\_force** set to AP\_YES. It includes all LUs whose PU is active or whose host link is automatically activated, and whose connection is free. This count is regardless of the LU **model\_type**, **model\_name**, and the DDDLU support of the PU. There might be less LUs available to satisfy an OPEN\_LU\_SSCP\_SEC\_REQ that specifies a particular value for **model\_type**.

#### lu\_pool\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### lu\_pool\_detail.pool\_name

Name of LU pool to which the specified LU belongs. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. (Note that if this field is specified on the request and the **lu\_name** field is set to all binary zeros, then only LUs in the pool are returned.)

#### lu\_pool\_detail.description

LU description (as specified on DEFINE\_LU\_0\_TO\_3).

#### lu\_pool\_detail.lu\_name

LU name of LU belonging to the pool. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this name is set to all zeros then, this indicates that the specified pool is empty.

#### lu\_pool\_detail.lu\_sscp\_sess\_active

Specifies whether the LU-SSCP session is active (AP\_YES or AP\_NO).

lu\_pool\_detail.appl\_conn\_active

Specifies whether the LU session is currently being used by an application (AP\_YES or AP\_NO).

lu\_pool\_detail.plu\_sess\_active

Specifies whether the PLU-SLU session is active (AP\_YES or AP\_NO).

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_LIST\_OPTION

AP\_INVALID\_POOL\_NAME AP\_INVALID\_LU\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_MDS\_APPLICATION

QUERY\_MDS\_APPLICATION returns a list of applications that have registered for MDS level messages.

Applications register by issuing the REGISTER\_MS\_APPLICATION verb described in Chapter 15, "Management Services Verbs," on page 615.

To obtain information about a specific application, or to obtain the list information in several chunks, the **application** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

## **VCB** Structure

# **Supplied Parameters**

The application supplies the following parameters:

## opcode

AP\_QUERY\_MDS\_APPLICATION

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information: The **application** specified (see the following parameter, **application**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### application

Application name. The name is an 8-byte alphanumeric type-A EBCDIC character string. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

The number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### mds\_application\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### mds\_application\_data.application

Name of registered application. The name is an 8-byte alphanumeric type-A EBCDIC character string.

#### mds\_application\_data.max\_rcv\_size

The maximum number of bytes that the application can receive in one chunk (this is specified when an application registers with MDS). For more information about MDS-level application registration refer to Chapter 15, "Management Services Verbs," on page 615.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_APPLICATION\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_MDS\_STATISTICS

QUERY\_MDS\_STATISTICS returns management services statistics. This verb can be used to gauge the level of MDS routing traffic.

## VCB Structure t

typedef {	struct query_md	s_statistics

} QUERY_	<pre>MDS_STATISTICS;</pre>				

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_MDS\_STATISTICS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc AP\_OK

alerts sent

Number of locally originated alerts sent using the MDS transport system.

## alert\_errors\_rcvd

Number of error messages received by MDS indicating a delivery failure for a message containing an alert.

#### uncorrelated\_errors\_rcvd

Number of error messages received by MDS indicating a delivery failure for a message containing an alert. Delivery failure occurs when the error message could not be correlated to an alert on the MDS send alert queue. MDS maintains a fixed-size queue where it caches alerts sent to the problem determination focal point. Once the queue reaches maximum size, the oldest alert will be discarded and replaced by the new alert. If a delivery error message is received, MDS attempts to correlate the error message to a cached alert so that the alert can be held until the problem determination focal point is restored.

**Note:** The two counts, **alert\_errors\_rcvd** and **uncorrelated\_errors\_rcvd** are maintained such that the size of the send alert queue can be tuned. An increasing **uncorrelated\_errors\_rcvd** over time indicates that the send alert queue size is too small.

#### mds\_mus\_rcvd\_local

Number of MDS\_MUs received from local applications.

#### mds\_mus\_rcvd\_remote

Number of MDS\_MUs received from remote nodes using the MDS\_RECEIVE and MSU\_HANDLER transaction programs.

#### mds\_mus\_delivered\_local

Number of MDS\_MUs successfully delivered to local applications.

#### mds\_mus\_delivered\_remote

Number of MDS\_MUs successfully delivered to a remote node using the MDS\_SEND transaction program.

#### parse\_errors

Number of MDS\_MUs received that contained header format errors.

## failed\_deliveries

Number of MDS\_MUs this node failed to deliver.

#### ds\_searches\_performed

Reserved.

#### unverified errors

Reserved.

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_MODE

QUERY\_MODE returns information about modes that have been used by a local LU with a particular partner LU. The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific mode, or to obtain the list information in several chunks, the **mode\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. Note that the **lu\_name** (or **lu\_alias**) and **plu\_alias** (or **fqplu\_name**) fields must always be set. The **lu\_name**, if nonzero, will be used in preference to the **lu\_alias**. See "Querying the Node" on page 10 for background on how the list formats are used.

The list only includes information for the local LU specified by the **lu\_name** (or **lu\_alias**). This list is ordered by the **fqplu\_name** followed by the **mode\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If **plu\_alias** is set to all zeros, the **fqplu\_name** value will be used, otherwise the **plu\_alias** is always used and the **fqplu\_name** is ignored.

The list of modes returned can be filtered according to whether they currently have any active sessions. If filtering is desired, the **active\_sessions** field should be set to AP\_YES (otherwise this field should be set to AP\_NO). This verb returns information that is determined once the mode begins to be used by a local LU with a partner LU. The QUERY\_MODE\_DEFINITION verb returns definition information only.

# VCB Structure

                                                                           */
       unsigned short
                       max neg sess limit; /* max negotiated session limit */
                                           /* max receive RU size
       unsigned short max_rcv_ru_size;
                                                                           */
       unsigned short pending_session_count;
                                           /* pending sess count for mode
                                                                           */
       unsigned short termination count; /* termination count for mode
                                                                           */
       unsigned char
                       implicit;
                                         /* implicit or explicit entry
                                                                           */
       unsigned char reserva[15];
                                           /* reserved
                                                                           */
```

} MODE\_DETAIL;

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_MODE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

### **AP\_SUMMARY**

Returns summary information only.

## AP\_DETAIL

Returns detailed information.

The combination of **lu\_name** (or **lu\_alias** if the **lu\_name** is set to all zeros), **plu\_alias** (or **fqplu\_name** if the **plu\_alias** is set to all zeros) and **mode\_name** specified (see the following parameters, **lu\_name**, **plu\_alias**, and **mode\_name**) represents an index value that is used to specify the starting point of the actual information to be returned . When a partner LU index is specified, information about other partner LUs is included in the list, if possible.

# AP\_FIRST\_IN\_LIST

If **plu\_alias** and **fqplu\_name** are set to all zeros, the returned list starts from the first partner LU in the list, and the **mode\_name** index is ignored. If either **plu\_alias** or **fqplu\_name** is specified, the list starts at this index, but the **mode\_name** index value is ignored, and the returned list starts from the first mode entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the index.

#### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** are set to all zeros then the LU associated with the control point (the default LU) is used.

#### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field will be used for determining the index.

## fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# active\_sessions

Active session filter. Specifies whether the returned modes should be filtered according to whether they currently have any active sessions (AP\_YES or AP\_NO).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

# num\_entries

Number of entries actually returned.

### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# mode\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# mode\_summary.mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## mode\_summary.description

Resource description (as specified on DEFINE\_MODE). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# mode\_summary.sess\_limit

Current session limit.

### mode\_summary.act\_sess\_count

Total number of active sessions using the mode. If the **active\_sessions** filter has been set to AP\_YES, then this field will always be greater than zero.

### mode\_summary.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## mode\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### mode\_detail.mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### mode\_detail.description

Resource description (as specified on DEFINE\_MODE).

# mode\_detail.sess\_limit

Current session limit.

# mode\_detail.act\_sess\_count

Total number of active sessions using the mode. If the **active\_sessions** filter has been set to AP\_YES, then this field will always be greater than zero.

# mode\_detail.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# mode\_detail.min\_conwinners\_source

Specifies the minimum number of sessions on which the local LU is the contention winner (or first speaker).

# mode\_detail.min\_conwinners\_target

Specifies the minimum number of sessions on which the local LU is the contention loser (or bidder).

# mode\_detail.drain\_source

Specifies whether the local LU satisfies waiting session requests before deactivating a session when session limits are changed or reset (AP\_NO or AP\_YES).

# mode\_detail.drain\_partner

Specifies whether the partner LU satisfies waiting session requests before deactivating a session when session limits are changed or reset (AP\_NO or AP\_YES).

### mode\_detail.auto\_act

Number of contention winner sessions that are automatically activated following the Change Number of Sessions exchange with the partner LU.

# mode\_detail.act\_cw\_count

Number of active, contention winner (or first speaker) sessions using this mode. (The local LU does not need to bid before using one of these sessions.)

### mode\_detail.act\_cl\_count

Number of active, contention loser (or bidder) sessions using this mode. (The local LU must bid before using one of these sessions.)

#### mode\_detail.sync\_level

Specifies the synchronization levels supported by the mode (AP\_NONE, AP\_CONFIRM, or AP\_SYNCPT).

#### mode\_detail.default\_ru\_size

Specifies whether a default upper bound for the maximum RU size will be used. If this parameter has a value of AP\_YES, the

**mode\_chars.max\_ru\_size\_upp** field specified on **define\_mode** is ignored, and the upper bound for the maximum RU size is set to the link BTU size minus the size of the TH and the RH.

AP\_YES AP NO

### mode\_detail.max\_neg\_sess\_limit

Maximum negotiable session limit. Specifies the maximum session limit for the mode name that a local LU can use during its CNOS processing as the target LU.

mode\_detail.max\_rcv\_ru\_size

Maximum received RU size.

# mode\_detail.pending\_session\_count

Specifies the number of sessions pending (waiting for session activation to complete).

## mode\_detail.termination\_count

If a previous CNOS verb has caused the mode session limit to be reset to zero, there might have been conversations using, or waiting to use these sessions. This field is a count of how many of these sessions have not yet been deactivated.

### mode\_detail.implicit

Specifies whether the entry was put in place because of an implicit (AP\_YES) or explicit (AP\_NO) definition.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

# secondary\_rc

AP\_INVALID\_MODE\_NAME

AP\_INVALID\_PLU\_NAME AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_MODE\_DEFINITION

QUERY\_MODE\_DEFINITION returns both information previously passed in on a DEFINE\_MODE verb and information about SNA-defined default modes.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific mode, or to obtain the list information in several chunks, the **mode\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **mode\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering).

If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

This verb returns definition information only. The QUERY\_MODE verb returns information that is determined once the mode starts to be used by a local LU with a partner LU.

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

### AP\_QUERY\_MODE\_DEFINITION

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

#### AP\_DETAIL

Returns detailed information.

The **mode\_name** specified (see the following parameter, **mode\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### **AP\_LIST\_INCLUSIVE**

The returned list starts from the entry specified by the index value.

# mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting

with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

# buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

# num\_entries

Number of entries actually returned.

# total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# mode\_def\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# mode\_def\_summary.mode\_name

8-byte mode name, which designates the network properties for a group of sessions.

# mode\_def\_summary.description

Resource description (as specified on DEFINE\_MODE). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# mode\_def\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# mode\_def\_detail.mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

# mode\_def\_detail.mode\_chars.description

Resource description (as specified on DEFINE\_MODE). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## mode\_def\_detail.mode\_chars.max\_ru\_size\_upp

Upper boundary for the maximum RU size to be used on sessions with this mode name.

# mode\_def\_detail.mode\_chars.receive\_pacing\_win

Specifies the session pacing window for the sessions when fixed pacing is used. Specifies the preferred minimum window size when adaptive pacing is used.

# mode\_def\_detail.mode\_chars.default\_ru\_size

Specifies whether a default upper bound for the maximum RU size will be used. If this parameter specifies AP\_YES, **max\_ru\_size\_upp** is ignored.

AP\_YES AP NO

## mode\_def\_detail.mode\_chars.max\_neg\_sess\_lim

Maximum negotiable session limit. Value used to negotiate the maximum number of sessions permissible between the local LU and the partner LU for the designated mode name.

# mode\_def\_detail.mode\_chars.plu\_mode\_session\_limit

Session limit to negotiate initially on this mode. This value indicates a preferred session limit and is used for implicit CNOS.

### Range: 0-32767

# mode\_def\_detail.mode\_chars.min\_conwin\_src

Minimum number of contention winner sessions that can be activated by local LU using this mode.

#### Range: 0-32767

# mode\_def\_detail.mode\_chars.cos\_name

Class-of-service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### mode\_def\_detail.mode\_chars.cryptography

Specifies whether cryptography is used on sessions using this mode (AP\_NONE or AP\_MANDATORY).

### mode\_def\_detail.mode\_chars.compression

Specifies the use of compression for sessions activated using this mode.

# AP\_COMP\_PROHIBITED

RLE compression is not supported on sessions for this mode.

## AP\_COMP\_REQUESTED

RLE compression is supported and requested (but not mandated) on sessions for this mode.

### mode\_def\_detail.mode\_chars.auto\_act

Specifies the number of session to be auto-activated for this mode. The value is used for implicit CNOS.

Range: 0-32767

#### mode\_def\_detail.mode\_chars.min\_consloser\_src

Specifies the minimum number of contention loser sessions to be activated by any one local LU for this mode. This value is used when CNOS (change number of sessions) exchange is initiated implicitly.

Range: 0-32767

#### mode\_def\_detail.mode\_chars.max\_ru\_size\_low

Specifies the lower bound for the maximum size of RUs sent and received on sessions in this mode. This value is used when the maximum RU size is negotiated during session activation.

Range: 0-61140

The field is ignored if **default\_ru\_size** is set to AP\_YES.

### mode\_def\_detail.mode\_chars.max\_receive\_pacing\_win

Specifies the maximum pacing window for sessions in this mode. For

adaptive pacing, this value is used to limit the receive pacing window it grants. For fixed pacing, this field is not used.

**Note:** The Program always uses adaptive pacing unless the adjacent node specifies that it does not support it.

Range: 0-32767

The value of zero means that there is no upper bound.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

# secondary\_rc

AP\_INVALID\_MODE\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_MODE\_TO\_COS\_MAPPING

QUERY\_MODE\_TO\_COS\_MAPPING returns information about the mode to COS mapping.

The information is returned as a formatted list. To obtain information about a specific mode, or to obtain the list information in several chunks, the **mode\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **mode\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

If the default COS (which unknown modes are mapped to) has been overridden using DEFINE\_MODE, QUERY\_MODE\_TO\_COS\_MAPPING also returns an entry with null **mode\_name** (all zeros) and the default COS. This entry is first in the ordering.

# VCB Structure

typedef struct query\_mode\_to\_cos\_mapping

1

	unsigned char		/*	COS name	*/
	unsigned char		/*	reserved	*/
} MODE_1	TO_COS_MAPPING_DA				

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

```
AP_QUERY_MODE_TO_COS_MAPPING
```

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

### list\_options

This indicates what should be returned in the list information: The **mode\_name** specified (see the following parameter, **mode\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### **AP\_LIST\_INCLUSIVE**

The returned list starts from the entry specified by the index value.

## mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST. This can be set to all zeros to indicate the entry for the default COS.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

### num\_entries

Number of entries actually returned.

# total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# mode\_to\_cos\_mapping\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## mode\_to\_cos\_mapping\_data.mode\_name

8-byte mode name, which designates the network properties for a group of sessions. If this is set to all zeros, it indicates the entry for the default COS.

### mode\_to\_cos\_mapping\_data.cos\_name

Class-of-service name associated with the mode name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_MODE\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_NMVT\_APPLICATION

QUERY\_NMVT\_APPLICATION returns a list of applications that have registered for network management vector transport (NMVT) level messages by previously issuing the REGISTER\_NMVT\_APPLICATION verb (see Chapter 15, "Management Services Verbs," on page 615 for more details).

The information is returned as a list. To obtain information about a specific application, or to obtain the list information in several chunks, the **application** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

# VCB Structure

```
typedef struct query nmvt application
         unsigned short opcode;
                                                    /* verb operation code
                                                                                              */
         unsigned char reserv2;
unsigned char format;
                                                    /* reserved
                                                                                              */
                                                    /* format
                                                                                              */

                                                                                              */
} NMVT_APPLICATION_DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_QUERY\_NMVT\_APPLICATION

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

# QUERY\_NMVT\_APPLICATION

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

## list\_options

This indicates what should be returned in the list information: The **application** specified (see the following parameter, **application**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

### application

Application name. The name is an 8-byte alphanumeric type-A EBCDIC character string or all EBCDIC zeros. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

### buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

The number of entries actually returned.

# total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# nmvt\_application\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

### nmvt\_application\_data.application

Name of registered application. The name is an 8-byte alphanumeric type-A EBCDIC character string.

# nmvt\_application\_data.ms\_vector\_key\_type

Management services vector key accepted by the application. When the application registers for NMVT messages, it specifies which management

services vector keys it will accept. For more information on NMVT application registration see Chapter 15, "Management Services Verbs," on page 615.

# nmvt\_application\_data.conversion\_required

Specifies whether the registered application requires messages to be converted from NMVT to MDS\_MU format (AP\_YES or AP\_NO). When the application registers for NMVT messages, it will specify whether this conversion is required. For more information on NMVT application registration, see Chapter 15, "Management Services Verbs," on page 615.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_APPLICATION\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_NN\_TOPOLOGY\_NODE

This verb applies only to Communications Server.

Each network node maintains a network topology database that holds information about the network nodes, VRNs and network-node-to-network-node TGs in the network.

QUERY\_NN\_TOPOLOGY\_NODE returns information about the network node and VRN entries in this database.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific node or to obtain the list information in several chunks, the **node\_name**, **node\_type** and **frsn** fields should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), these fields are ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is by **node\_name**, **node\_type**, and **frsn**. The **node\_name** is ordered by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). The **node\_type** field follows the order: AP\_NETWORK\_NODE, AP\_VRN. The **frsn** is ordered numerically.

If AP\_LIST\_INCLUSIVE is selected, the returned list starts from the first valid record of that name.

If AP\_LIST\_FROM\_NEXT is selected, the list will begin from the first valid record with a name following the one specified.

If the **frsn** field (flow reduction sequence number) is set to a nonzero value, then only database entries with FRSNs higher than this are returned. This allows a consistent topology database to be returned in a number of chunks by first getting the node's current FRSN. This would work as follows:

- 1. Issue QUERY\_NODE, which returns node's current FRSN.
- 2. Issue as many QUERY\_NN\_TOPOLOGY\_NODE (with FRSN set to zero) as necessary to get all the database entries in chunks.
- **3**. Issue QUERY\_NODE again and compare the new FRSN with the one returned in step 1.
- 4. If the two FRSNs are different, then the database has changed, so issue a QUERY\_NN\_TOPOLOGY\_NODE with the FRSN set to 1 greater than the FRSN supplied in step 1.

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_NN\_TOPOLOGY\_NODE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

## AP\_SUMMARY

Returns summary information only.

## AP\_DETAIL

Returns detailed information.

The combination of the **node\_name**, **node\_type**, and **frsn** specified (see the following parameters, **node\_name**, **node\_type**, and **frsn**) represents an index value that is used to specify the starting point of the actual information to be returned.

# AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### node\_name

Network qualified node name from network topology database. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# node\_type

Type of the node. This can be one of the following values:

AP\_NETWORK\_NODE AP\_VRN

If the **node\_type** is unknown, AP\_LEARN\_NODE must be specified.

**frsn** Flow Reduction Sequence Number. If this is nonzero, then only nodes with a FRSN greater than or equal to this value are returned.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

### num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# nn\_topology\_node\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# nn\_topology\_node\_summary.node\_name

Network qualified node name from network topology database. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# nn\_topology\_node\_summary.node\_type

Type of the node. This is set to one of the following values:

AP\_NETWORK\_NODE AP\_VRN

## nn\_topology\_node\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## nn\_topology\_node\_detail.node\_name

Network qualified node name from network topology database. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# nn\_topology\_node\_detail.node\_type

Type of the node. This is set to one of the following values:

AP\_NETWORK\_NODE AP\_VRN

# nn\_topology\_node\_detail.days\_left

Number of days before deletion of this node entry from the topology database. This will be set to zero for the local node entry (this entry is never deleted).

# nn\_topology\_node\_detail.frsn

Flow Reduction Sequence Number. It indicates the last time that this resource was updated at the local node.

# nn\_topology\_node\_detail.rsn

Resource Sequence Number. This is assigned by the network node that owns this resource.

## nn\_topology\_node\_detail.rar

The node's route additional resistance.

## nn\_topology\_node\_detail.status

Specifies the status of the node. This can be AP\_UNCONGESTED or one or more of the following values ORed together:

## AP\_CONGESTED

The number of ISR sessions is greater than the **isr\_sessions\_upper\_threshold**.

## AP\_ERR\_DEPLETED

The number of endpoint sessions has reached the maximum specified.

# AP\_IRR\_DEPLETED

The number of ISR sessions has reached the maximum.

# AP\_QUIESCING

A STOP\_NODE or type AP\_QUIESCE or AP\_QUIESCE\_ISR has been issued

# nn\_topology\_node\_detail.function\_support

Specifies which functions are supported. This can be one or more of the following values:

## AP\_PERIPHERAL BORDER\_NODE

Peripheral Border Node function is supported.

## AP\_EXTENDED BORDER\_NODE

Extended Border Node function is supported.

### AP\_CDS

Node supports central directory server function.

### **AP\_GATEWAY**

Node is a gateway Node. (This function is not yet architecturally defined.)

## AP\_INTERCHANGE\_NODE

This node is a Gateway Node. (This function is not yet architecturally defined.)

## AP\_ISR

Node supports intermediate session routing.

# AP\_HPR

Node supports the base functions of High-Performance Routing.

## AP\_RTP\_TOWER

Node supports the RTP tower of HPR.

### AP\_CONTROL\_OVER\_RTP\_TOWER

Node supports the control flows over the RTP tower.

**Note:** The AP\_CONTROL\_OVER\_RTP\_TOWER corresponds to the setting of both AP\_HPR and AP\_RTP\_TOWER.

#### nn\_topology\_node\_detail.branch\_aware

Specifies whether the node is branch aware.

# AP\_NO

The node is not branch aware.

# AP\_YES

The node is branch aware.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_NODE

# AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_NN\_TOPOLOGY\_STATS

This verb applies only to Communications Server.

QUERY\_NN\_TOPOLOGY\_STATS returns statistical information about the topology database and is only issued at a network node.

# **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_QUERY\_NN\_TOPOLOGY\_STATS

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

#### max\_nodes

Maximum number of node records in the topology database (zero means unlimited).

# cur\_num\_nodes

Current number of nodes in this node's topology database. If this value exceeds the maximum number of nodes allowed, an Alert is issued.

#### node\_in\_tdus

Total number of topology database updates (TDUs) received by this node.

# node\_out\_tdus

Total number of topology database updates (TDUs) built by this node to be sent to all adjacent network nodes since the last initialization.

## node\_low\_rsns

Total number of topology node updates received by this node with an RSN less than the current RSN. Both even and odd RSNs are included in this count. (These TDUs are not errors, but result when TDUs are broadcast to all adjacent network nodes. No update to this node's topology database occurs, but this node sends a TDU with its higher RSN to the adjacent node that sent this low RSN.)

# node\_equal\_rsns

Total number of topology node updates received by this node with an RSN equal to the current RSN. Both even and odd RSNS are included in this count. (These TDUs are not errors, but result when TDUs are broadcast to all adjacent network nodes. No update to this node's topology database occurs.)

# node\_good\_high\_rsns

Total number of topology node updates received by this node with an RSN greater than the current RSN. The node updates its topology and broadcasts a TDU to all adjacent network nodes. It is not required to send a TDU to the sender of this update, because that node already has the update.

## node\_bad\_high\_rsns

Total number of topology node updates received by this node with an odd RSN greater than the current RSN. These updates represent a topology inconsistency detected by one of the APPN network nodes. The node updates its topology and broadcasts a TDU to all adjacent network nodes.

## node\_state\_updates

Total number of topology node updates built as a result of internally

detected node state changes that affect APPN topology and routing. Updates are sent by TDUs to all adjacent network nodes.

### node\_errors

Total number of topology node update inconsistencies detected by this node. This occurs when this node attempts to update its topology database and detects a data inconsistency. This node creates a TDU with the current RSN incremented to the next odd number and broadcasts it to all adjacent network nodes.

# node\_timer\_updates

Total number of topology node updates built for this node's resource due to timer updates. Updates are sent by TDUs to all adjacent network nodes. These updates ensure that other network nodes do not delete this node's resource from their topology database.

# node\_purges

Total number of topology node records purged from this node's topology database. This occurs when a node record has not been updated in a specified amount of time. The owning node is responsible for broadcasting updates for its resource that it wants kept in the network topology.

### tg\_low\_rsns

Total number of topology TG updates received by this node with an RSN less than the current RSN. Both even and odd RSNs are included in this count. (These TDUs are not errors, but result when TDUs are broadcast to all adjacent network nodes. No update to this node's topology database occurs, but this node sends a TDU with its higher RSN to the adjacent node that sent this low RSN.)

# tg\_equal\_rsns

Total number of topology TG updates received by this node with an RSN equal to the current RSN. Both even and odd RSNs are included in this count. (These TDUs are not errors, but result when TDUs are broadcast to all adjacent network nodes. No update to this node's topology database occurs.)

## tg\_good\_high\_rsns

Total number of topology TG updates received by this node with an RSN greater than the current RSN. The node updates its topology and broadcasts a TDU to all adjacent network nodes.

### tg\_bad\_high\_rsns

Total number of topology TG updates received by this node with an odd RSN greater than the current RSN. These updates represent a topology inconsistency detected by one of the APPN Network Nodes. The node updates its topology and broadcasts a TDU to all adjacent network nodes.

### tg\_state\_updates

Total number of topology TG updates built as a result of internally detected node state changes that affect APPN topology and routing. Updates are sent by TDUs to all adjacent network nodes.

### tg\_errors

Total number of topology TG update inconsistencies detected by this node. This occurs when this node attempts to update its topology database and detects a data inconsistency. This node creates a TDU with the current RSN incremented to the next odd number and broadcasts it to all adjacent network nodes.

# tg\_timer\_updates

Total number of topology TG updates built for this node's resource due to timer updates. Updates are sent by TDUs to all adjacent network nodes. These updates ensure that other network nodes do not delete this node's resource from their topology database.

# tg\_purges

Total number of topology TG records purged from this node's topology database. This occurs when a node record has not been updated in a specified amount of time. The owning node is responsible for broadcasting updates for its resource that it wants kept in the network topology.

## total\_route\_calcs

Number of routes calculated for all classes of service since the last.

## total\_route\_rejs

Number of route requests for all classes of service that could not be calculated since the last initialization.

## total\_tree\_cache\_hits

Number of route computations that were satisfied by a cached routing tree. Note that this number may be greater than the total number of computed routes, because each route may require inspection of several trees.

# total\_tree\_cache\_misses

Number of route computations that were not satisfied by a cached routing tree, so that a new routing tree had to be built.

# total\_tdu\_wars

Number of TDU wars the local node has detected and prevented.

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_NN\_TOPOLOGY\_TG

This verb applies only to Communications Server.

Each network node maintains a network topology database which holds information about the network nodes, VRNs and network-node-to-network-node TGs in the network. QUERY\_NN\_TOPOLOGY\_TG returns information about the TG entries in this database.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific node or to obtain the list information in several chunks, the **owner**, **owner\_type**, **dest**, **dest\_type**, **tg\_num**, and **frsn** fields should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), these fields are ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is by **owner**, **owner\_type**, **dest**, **dest\_type**, **tg\_num**, and **frsn**. The **owner** name and **dest** name are ordered by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). The **owner\_type** and **dest\_type** follow the order: AP\_NETWORK\_NODE, AP\_VRN. The **tg\_num** and **frsn** are ordered numerically.

If AP\_LIST\_INCLUSIVE is selected, the returned list starts from the first valid record of that name.

If AP\_LIST\_FROM\_NEXT is selected, the list will begin from the first valid record with a name following the one specified.

If the **frsn** field (flow reduction sequence number) is set to a nonzero value, then only database entries with FRSNs higher than this are returned. This allows a consistent topology database to be returned in a number of chunks by first getting the node's current FRSN. This works as follows:

- 1. Issue QUERY\_NODE, which returns the node's current FRSN.
- 2. Issue as many QUERY\_NN\_TOPOLOGY\_TG (with FRSN set to zero) as necessary to get all the database entries in chunks.
- **3.** Issue QUERY\_NODE again and compare the new FRSN with the one returned in step 1.
- 4. If the two FRSNs are different, then the database has changed, so issue a QUERY\_NN\_TOPOLOGY\_TG with the FRSN set to 1 greater than the FRSN supplied in step 1.

} LINK ADDRESS;
```

**Note:** If the **frsn** field is set to a nonzero value, then only node entries with that FRSN are returned. If it is set to zero, then all node entries are returned.

# **Supplied Parameters**

The application supplies the following parameters:

opcode

```
AP_QUERY_NN_TOPOLOGY_TG
```

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# QUERY\_NN\_TOPOLOGY\_TG

### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

### AP\_SUMMARY

Returns summary information only.

#### **AP\_DETAIL**

Returns detailed information.

The combination of the **owner**, **owner\_type**, **dest**, **dest\_type**, **tg\_num**, and **frsn** specified (see the following parameters, **owner**, **owner\_type**, **dest**, **dest\_type**, **tg\_num**, and **frsn**) represents an index value that is used to specify the starting point of the actual information to be returned .

# AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

**owner** Name of the TG's originating node. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### owner\_type

Type of the node that owns the TG. This can be one of the following values:

AP\_NETWORK\_NODE AP\_VRN

If the **owner\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

**dest** Fully qualified destination node name for the TG. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

### dest\_type

Type of the destination node for this TG. This can be one of the following values:

AP\_NETWORK\_NODE AP\_VRN

If the **dest\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### tg\_num

Number associated with the TG. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

**frsn** Flow Reduction Sequence Number. If this is nonzero, then only nodes with a FRSN greater than or equal to this value are returned.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

# buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

# num\_entries

Number of entries actually returned.

### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# topology\_tg\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## topology\_tg\_summary.owner

Name of the TG's originating node. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### topology\_tg\_summary.owner\_type

Type of the node that owns the TG. This is set to one of the following values:

### AP\_NETWORK\_NODE AP VRN

#### topology\_tg\_summary.dest

Fully qualified destination node name for the TG. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## topology\_tg\_summary.dest\_type

Type of the destination node for this TG. This is set to one of the following values:

AP\_NETWORK\_NODE AP\_VRN

# topology\_tg\_summary.tg\_num

Number associated with the TG.

#### topology\_tg\_summary.frsn

Flow Reduction Sequence Number. It indicates the last time that this resource was updated at the local node.

### topology\_tg\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

### topology\_tg\_detail.owner

Name of the TG's originating node. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### topology\_tg\_detail.owner\_type

Type of the node that owns the TG. This is set to one of the following values:

AP\_NETWORK\_NODE AP\_VRN

#### topology\_tg\_detail.dest

Fully qualified destination node name for the TG. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### topology\_tg\_detail.dest\_type

Type of the destination node for this TG. This is set to one of the following values:

AP\_NETWORK\_NODE AP\_VRN

# topology\_tg\_detail.tg\_num

Number associated with the TG.

#### topology\_tg\_detail.frsn

Flow Reduction Sequence Number. It indicates the last time that this resource was updated at the local node.

#### topology\_node\_detail.days\_left

Number of days before deletion of this node entry from the topology database.

#### topology\_tg\_detail.dlc\_data.length

Length of DLC address of connection to a VRN (set to zero if **dest\_type** is not AP\_VRN).

# topology\_tg\_detail.dlc\_data.address

DLC address of connection to VRN. This is set to zero if **dest\_type** is not AP\_VRN.

# topology\_tg\_detail.rsn

Resource Sequence Number. This is assigned by the network node that owns this resource.

# topology\_tg\_detail.status

Specifies the status of the TG. This can be one or more of the following values ORed together:

AP\_TG\_OPERATIVE AP\_TG\_QUIESCING AP\_TG\_GARBAGE\_COLLECT AP\_TG\_CP\_CP\_SESSIONS AP\_TG\_HPR AP\_TG\_RTP AP\_TG\_NONE

### topology\_tg\_detail.tg\_chars

TG characteristics (See "DEFINE\_COS" on page 35).

## topology\_tg\_detail.subarea\_number

If the owner or destination node of the TG is subarea-capable, this field contains the subarea number of the type 4 or type 5 node that owns the link station associated with this TG on the subarea-capable node. Otherwise, this field is set to all binary zeros.

# topology\_tg\_detail.tg\_type

TG type. This field takes one of the following values:

AP\_APPN\_OR\_BOUNDARY\_TG APPN TG or boundary-function-based TG

AP\_INTERCHANGE\_TG Interchange TG

# AP\_VIRTUAL\_ROUTE\_BASED\_TG Virtual-route-based TG

#### AP\_UNKNOWN

The TG type of this TG reported in the topology is unknown.

# topology\_tg\_detail.intersubnet.tg

This TG is an intersubnetwork TG. This field takes the following values:

AP\_YES AP\_NO

## topology\_tg\_detail.cp\_cp\_session\_active

Specifies whether the owning node's contention winner CP-CP session is active (AP\_UNKNOWN, AP\_NO or AP\_YES).

# topology\_tg\_detail.branch\_tg

Specifies whether the TG is a branch TG.

### AP\_NO

The TG is not a branch TG.

AP\_YES

The TG is a branch TG.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_TG

AP\_INVALID\_ORIGIN\_NODE AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_NODE

QUERY\_NODE returns node specific information and statistics. In addition to returning information determined dynamically during execution, QUERY\_NODE also returns parameters which are set during node initialization.

# **VCB Structure**

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_NODE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

When this field is set to zero, the following four fields are Unsigned short rather than Unsigned\_COUNTER:def\_Is\_good\_xids,

def\_Is\_bad\_xids,dyn\_Is\_good\_xids, dyn\_Is\_bad\_xids.

When this field is set to two, the following fields are used as described: **fq\_nn\_server\_name** and **current\_isr\_sessions**.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

### cp\_create\_parms.crt\_parms\_len

Length of create parameters structure.

## cp\_create\_parms.description

Resource description. This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# cp\_create\_parms.node\_type

This is always:

AP\_END\_NODE AP\_NETWORK\_NODE AP\_LEN\_NODE AP\_BRANCH\_NETWORK\_NODE

## cp\_create\_parms.fqcp\_name

Node's 17-byte fully qualified control point name. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name has a maximum length of 8 bytes with no embedded spaces.)

## cp\_create\_parms.cp\_alias

Locally used control point alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## cp\_create\_parms.mode\_to\_cos\_map\_supp

Specifies whether mode to COS mapping is supported by the node (AP\_YES or AP\_NO). If this is set to AP\_YES then the COS specified on a DEFINE\_MODE verb must either be an SNA defined COS or have been defined by issuing a DEFINE\_COS verb.

## cp\_create\_parms.mds\_supported

Specifies whether management services supports Multiple Domain Support and Management Services Capabilities (AP\_YES or AP\_NO).

#### cp\_create\_parms.node\_id

Node identifier used in XID exchange. This a 4-byte hexadecimal string.

## cp\_create\_parms.max\_locates

Maximum number of locates that the node can process.

# cp\_create\_parms.dir\_cache\_size

Network node only: Size of the directory cache.

#### cp\_create\_parms.max\_dir\_entries

Maximum number of directory entries. This is unlimited if this field is set to zero.

## cp\_create\_parms.locate\_timeout

Specifies the time in seconds before a network search will time out. A value of zero indicates that the search has no timeout.

### cp\_create\_parms.reg\_with\_nn

Specifies whether resources will be registered with the network node server. Registration failure does not affect successful completion of node initialization. See "REGISTRATION\_FAILURE" on page 551 for details. This field is interpreted differently by an EN and a BrNN.

End Node:

## AP\_NO

The node does not register any LUs with its NN server. The NNS forwards all broadcast searches to the end node.

## AP\_YES

The node registers all local dependent (if the NNS supports option set 1116) and all local independent LUs with its NNS. The NNS only forwards directed locates to it (unless it owns dependent LUs that could not be registered).

Branch Network Node:

#### **AP\_REGISTER\_NONE**

The node does not register any LUs with its NN server.

#### AP\_REGISTER\_ALL

The node registers all local dependent (if it supports DLUR full multi-subnet and the NNS supports option set 1116) and all domain independent LUs with its NNS.

#### AP\_REGISTER\_LOCAL\_ONLY

The node registers all local dependent (if it supports DLUR full multi-subnet and the NNS supports option set 1116) and all local independent LUs with its NNS.

#### cp\_create\_parms.reg\_with\_cds

Specifies whether resources are allowed to be registered with a central directory server (CDS). This field is interpreted differently by an EN, NN, or BrNN.

End Node: Specifies whether the NNS is allowed to register with CDS end node resources. This field is ignored if **reg\_with\_nn** is set to AP\_NONE.

#### AP\_NO

EN resources cannot be registered with a CDS.

## AP\_YES

EN resources can be registered with a CDS.

Network Node: Specifies whether local resources and domain resources (that the owning EN allows to be registered with a CDS) can be registered with a CDS.

## AP\_NO

Local or domain resources cannot be registered with a CDS.

#### AP\_YES

Local or domain resources can be registered with a CDS. Registration failure does not affect successful completion of the START\_NODE verb.

Branch Network Node: Specifies whether the NNS is allowed to register with a CDS BrNN resources (local to the BrNN or from the BrNN's domain). This field is ignored if **reg\_with\_nn** is set to AP\_NO.

#### **AP\_REGISTER\_NONE**

The node does not register any LUs with its NN server.

## AP\_REGISTER\_ALL

The node registers all local dependent (if it supports DLUR full multi-subnet and the NNS supports option set 1116) and all domain independent LUs with its NNS.

#### AP\_REGISTER\_LOCAL\_ONLY

The node registers all local dependent (if it supports DLUR full multi-subnet and the NNS supports option set 1116) and all local independent LUs with its NNS.

## cp\_create\_parms.mds\_send\_alert\_q\_size

Size of the MDS send alert queue. When this limit is reached, the MDS component deletes the oldest entry on the queue.

## cp\_create\_parms.cos\_cache\_size

Size of the COS Database weights cache.

## cp\_create\_parms.tree\_cache\_size

Size of the topology database routing tree cache size.

## cp\_create\_parms.tree\_cache\_use\_limit

Maximum number of uses of a cached tree. Once this number is exceeded, the tree is discarded and recomputed. This allows the node to balance sessions among equal weight routes. A low value provides better load balancing at the expense of increased activation latency.

## cp\_create\_parms.max\_tdm\_nodes

Maximum number of nodes that can be stored in topology database (zero means unlimited).

## cp\_create\_parms.max\_tdm\_tgs

Maximum number of TGs that can be stored in topology database (zero means unlimited).

# cp\_create\_parms.max\_isr\_sessions

Maximum number of ISR sessions the node can participate in at once.

## cp\_create\_parms.isr\_sessions\_upper\_threshold See cp\_create\_parms.isr\_sessions\_lower\_threshold

## cp\_create\_parms.isr\_sessions\_lower\_threshold

The upper and lower thresholds control the node's congestion status. The node state changes from not congested to congested if the number of ISR

sessions exceeds the upper threshold. The node state changes back to not congested once the number of ISR sessions dips below the lower threshold.

## cp\_create\_parms.isr\_max\_ru\_size

Maximum RU size supported for intermediate sessions.

#### cp\_create\_parms.isr\_rcv\_pac\_window

Suggested receive pacing window size for intermediate sessions. This value is only used on the secondary hop of intermediate sessions if the adjacent node does not support adaptive pacing.

## cp\_create\_parms.store\_endpt\_rscvs

Specifies whether RSCVs are stored for diagnostic purposes (AP\_YES or AP\_NO).

#### cp\_create\_parms.store\_isr\_rscvs

Specifies whether RSCVs are stored for diagnostic purposes (AP\_YES or AP\_NO).

#### cp\_create\_parms.store\_dlur\_rscvs

Specifies whether the node stores RSCVs for diagnostic purposes (AP\_YES or AP\_NO). If this field is set to AP\_YES, then an RSCV is returned on the QUERY\_DLUR\_LU verb.

## cp\_create\_parms.dlur\_support

Specifies the level of support for DLUR provided by the node. This is a bit field and may take the following values:

## AP\_NO

DLUR is not supported.

#### AP\_YES

DLUR full multi-subnet is supported.

## (AP\_YES | AP\_LIMITED\_DLUR\_MULTI\_SUBNET)

DLUR limited, DLUR multi-subnet is supported. This is only valid if the node is an end node.

#### cp\_create\_parms.pu\_conc\_support

Specifies whether PU concentration is supported (always AP\_NO).

# cp\_create\_parms.nn\_rar

The network node's route additional resistance.

#### cp\_create\_parms.hpr\_support

Specifies the level of support for HPR that is provided by the node (AP\_NONE, AP\_BASE, or AP\_RTP).

#### cp\_create\_parms.mobile

Specifies whether the node is an HPR path-switch controller (AP\_YES or AP\_NO). If the **cp\_create\_parms.hpr\_support** field is not set to AP\_RTP this field is reserved.

## cp\_create\_parms.discovery\_support

Specifies whether Discovery functions are utilized by this node.

## AP\_DISCOVERY\_CLIENT

Discovery client functions are used by this node

#### AP\_DISCOVERY\_SERVER

Discovery server functions are used by this node.

#### cp\_create\_parms.discovery\_group\_name

Specifies the group name used on Discovery functions utilized by the node. If this field is set to all zeros, the default group name is used.

## cp\_create\_parms.implicit\_lu\_0\_to\_3

Specifies whether the node supports implicit definition of LUs of type 0 to 3 by ACTLU (AP\_YES or AP\_NO).

## cp\_create\_parms.default\_preference

Specifies the preferred method of routing when initiating sessions from this node.

**Note:** This can be overridden on a per LU basis using the DEFINE\_PARTNER\_LU verb.

This field can take the following values:

#### **AP\_NATIVE**

Use native (APPN) routing protocols only.

#### **AP\_NONNATIVE**

Use nonnative (AnyNet) routing protocols only.

#### AP\_NATIVE\_THEN\_NONNATIVE

Try native (APPN) protocols, and if the partner LU cannot be located, then retry session activation using nonnative (AnyNet) protocols.

## AP\_NONNATIVE\_THEN\_NATIVE

Try nonnative (AnyNet) protocols, and if the partner LU cannot be located, then retry session activation using native (APPN) protocols.

**Note:** The latter three values are only meaningful when an AnyNet DLC is available to the Node Operator Facility, and there is an AnyNet Link Station defined.

#### cp\_create\_parms.anynet\_supported

Specifies support for the AnyNet DLC. This field can be one of the following

#### **AP\_NONE**

No ANYNET function will be supported. The field **default\_preference** must take the value AP\_NATIVE.

#### AP\_ACCESS\_NODE

Use nonnative (AnyNet) routing protocols only.

### AP\_NATIVE\_THEN\_NONNATIVE

This node will support ANYNET access node functions.

#### **AP\_GATEWAY**

This node will start ANYNET gateway functions. This value is only valid if **node\_type** AP\_NETWORK\_NODE.

#### cp\_create\_parms.comp\_in\_series

Specifies whether the use of LZ compression preceded by RLE compression is allowed:

## AP\_YES

AP\_NO

## cp\_create\_parms.max\_ls\_exception\_events

Specifies the maximum number of LS\_EXCEPTION entries recorded by the node. Range 0 through 200.

#### cp\_create\_parms.max\_compress\_lvl

The maximum compression level supported by the node.

#### AP\_NONE

The node does not support compression.

## AP\_RLE\_COMPRESSION

The node can support RLE compression and decompression on LU 6.2 sessions, and RLE compression and LZ9 decompression on conventional LU sessions.

## AP\_LZ9\_COMPRESSION

The node can support LZ9 and RLE compression and decompression.

#### AP\_LZ10\_COMPRESSION

The node can support LZ10, LZ9, and RLE compression and decompression.

#### AP\_LZ12\_COMPRESSION

The node can support LZ12, LZ10, LZ9, and RLE compression and decompression.

## cp\_create\_parms.node\_spec\_data\_len

This field should always be set to zero.

#### cp\_create\_parms.ptf

Array for configuring and controlling future program temporary fix (PTF) operation.

# cp\_create\_parms.ptf[0]

REQDISCONT support. Personal Communications or Communications Server normally uses REQDISCONT to deactivate limited resource host links that are no longer required by session traffic. This byte can be used to suppress Personal Communications or Communications Server's use of REQDISCONT, or to modify the settings used on REQDISCONT requests sent by Personal Communications or Communications Server.

## AP\_SUPPRESS\_REQDISCONT

If this bit is set, Personal Communications or Communications Server does not use REQDISCONT (all other bits in this byte are ignored).

## AP\_OVERRIDE\_REQDISCONT

If this bit is set, Personal Communications or Communications Server overrides the normal settings on REQDISCONT, based on the following two bits:

#### AP\_REQDISCONT\_TYPE

If this bit is set, Personal Communications or Communications Server specifies a type of "immediate" on REQDISCONT. Otherwise, Personal Communications or Communications Server specifies a type of "normal". (This bit is ignored if AP\_OVERRIDE\_REQDISCONT is not set.)

# AP\_REQDISCONT\_RECONTACT

If this bit is set, Personal Communications or Communications Server specifies "immediate recontact" in REQDISCONT. Otherwise, Personal Communications or Communications Server specifies "no immediate recontact". (This bit is ignored if AP\_OVERRIDE\_REQDISCONT is not set.)

#### cp\_create\_parms.ptf[1]

ERP support.

Personal Communications or Communications Server normally processes an ACTPU(ERP) as an ERP (ACTPU(ERP) requests the PU-SSCP session be reset, but, unlike ACTPU(cold), does not request implicit deactivation of the subservient LU-SSCP and PLU-SLU sessions). SNA implementations can legally process ACTPU(ERP) as if it were ACTPU(cold).

#### AP\_OVERRIDE\_ERP

If this bit is set, Personal Communications or Communications Server processes all ACTPU requests as ACTPU(cold).

## cp\_create\_parms.ptf[2]

BIS support.

Personal Communications or Communications Server normally uses the BIS protocol prior to deactivating a limited resource LU 6.2 session. This byte allows the use of BIS to be overridden.

#### **AP\_SUPPRESS\_BIS**

If this bit is set, Personal Communications or Communications Server does not use the BIS protocol. Limited resource LU 6.2 session are deactivated immediately using UNBIND(cleanup).

#### up\_time

Time (in hundredths of a second) since the node was started (or restarted).

#### mem\_size

Size of the available storage, as obtained by storage management from the underlying operating system.

#### mem\_used

Number of bytes of storage that are currently allocated to a process.

#### mem\_warning\_threshold

Allocation threshold beyond which storage management considers the storage resources to be constrained.

#### mem\_critical\_threshold

Allocation threshold beyond which storage management considers the storage resources to be critically constrained.

## nn\_functions\_supported

Reserved.

#### functions\_supported

Specifies which functions are supported. This can be one or more of the following values:

AP\_NEGOTIABLE\_LS AP\_SEGMENT\_REASSEMBLY AP\_BIND\_REASSEMBLY AP\_PARALLEL\_TGS AP\_CALL\_IN AP\_ADAPTIVE\_PACING AP\_TOPOLOGY\_AWARENESS

#### en\_functions\_supported

Specifies the end-node functions supported.

# AP\_SEGMENT\_GENERATION

Node supports segment generation.

# AP\_MODE\_TO\_COS\_MAP

Node supports mode name to COS name mapping.

## AP\_LOCATE\_CDINIT

Node supports generation of locates and cross-domain initiate GDS variables for locating remote LUs.

#### AP\_REG\_WITH\_NN

Node will register its LUs with the adjacent serving network node.

# AP\_REG\_CHARS\_WITH\_NN

Node supports send register characteristics (can only be supported when send registered names is also supported).

#### nn\_status

Reserved.

#### nn\_frsn

Reserved.

#### nn\_rsn

Reserved.

# def\_ls\_good\_xids

Total number of successful XID exchanges that have occurred on all defined link stations since the node was last started.

## def\_ls\_bad\_xids

Total number of unsuccessful XID exchanges that have occurred on all defined link stations since the node was last started.

#### dyn\_ls\_good\_xids

Total number of successful XID exchanges that have occurred on all dynamic link stations since the node was last started.

#### dyn\_ls\_bad\_xids

Total number of unsuccessful XID exchanges that have occurred on all dynamic link stations since the node was last started.

#### dlur\_release\_level

Specifies the current DLUR release level.

## nns\_dlus\_served\_lu\_reg\_supp

End node only. Specifies whether the end node's network node server supports DLUS-served LU registration.

#### AP\_NO

Registration of DLUS-served LU registration is not supported by the network node server.

## AP\_YES

Registration of DLUS-served LUs is supported by the network node server.

## AP\_UNKNOWN

The end node does not have a network node server.

NN only: This field is set to AP\_NO.

## fq\_nn\_server\_name

Fully qualified, 17 byte long, name of the current network node server. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If this node is not an end node or does not have an active network node server, this field is set to null.

## current\_isr\_sessions

The number of active ISR sessions that are currently routed through this node. If this node is not a network node, this field is set to zero.

#### nn\_functions2

Specifies the network node functions supported.

### **AP\_BRANCH\_AWARENESS**

The node is branch aware.

#### branch\_ntwk\_arch\_version

Specifies the version of the branch network architecture supported or zero if the node does not support the branch network architecture.

## **AP\_BRANCH\_AWARENESS**

The node is branch aware.

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_PARTNER\_LU

QUERY\_PARTNER\_LU returns information about partner LUs that have been used by a local LU.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific partner LU, or to obtain the list information in several chunks, the **plu\_alias** field should be set (or the **fqplu\_name** if the **plu\_alias** is set to all zeros). If the **list\_options** field is set to AP\_FIRST\_IN\_LIST, both of these fields will be ignored. The **lu\_name** or **lu\_alias** field must always be set. The **lu\_name**, if nonzero, will be used in preference to the **lu\_alias**. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **fqplu\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

If **plu\_alias** is set to all zeros, the **fqplu\_name** value will be used; otherwise, the **plu\_alias** is always used and the **fqplu\_name** is ignored.

The list of partner LUs returned can be filtered according to whether they currently have any active sessions. If filtering is desired, the **active\_sessions** field should be set to AP\_YES (otherwise this field should be set to AP\_NO).

This verb returns information that is determined when at least one session is established with the partner LU.

The QUERY\_PARTNER\_LU\_DEFINITION verb returns definition information only.

} PLU DETAIL;
```

The application supplies the following parameters:

# **Supplied Parameters**

## opcode

AP\_QUERY\_PARTNER\_LU

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

## **AP\_DETAIL**

Returns detailed information.

The combination of the **lu\_name** (or **lu\_alias** if the **lu\_name** is set to all zeros) and **plu\_alias** (or **fqplu\_name** if the **plu\_alias** is set to all zeros) specified (see the following parameter, **lu\_name** and **plu\_alias**) represents an index value that is used to specify the starting point of the actual information to be returned:

# AP\_FIRST\_IN\_LIST

The **plu\_alias** and **fqplu\_name** fields are ignored and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the index.

## lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** are set to all zeros then the LU associated with the control point (the default LU) is used.

## plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field will be used as the index value.

# fqplu\_name

17-byte fully qualified network name for the partner LU. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# active\_sessions

Active session filter. Specifies whether the returned partner LUs should be filtered according to whether they currently have any active sessions (AP\_YES or AP\_NO).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

# buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

### num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### plu\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### plu\_summary.plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### plu\_summary.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is 17 bytes long and is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## plu\_summary.description

Resource description (as specified on DEFINE\_PARTNER\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## plu\_summary.act\_sess\_count

Total number of active sessions between the local LU and the partner LU. If the **active\_sessions** filter has been set to AP\_YES, then this field will always be greater than zero.

# plu\_summary.partner\_cp\_name

17-byte fully qualified network name for the control point of the partner LU. This name is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### plu\_summary.partner\_lu\_located

Specifies whether the control point name for the partner LU has been resolved (AP\_YES or AP\_NO).

## plu\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## plu\_detail.plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## plu\_detail.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## plu\_detail.description

Resource description (as specified on DEFINE\_PARTNER\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## plu\_detail.act\_sess\_count

Total number of active sessions between the local LU and the partner LU. If the **active\_sessions** filter has been set to AP\_YES, then this field will always be greater than zero.

## plu\_detail.partner\_cp\_name

17-byte fully qualified network name for the control point of the partner LU. This name is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# plu\_detail.partner\_lu\_located

Specifies whether the control point name for the partner LU has been resolved (AP\_YES or AP\_NO).

# plu\_detail.plu\_un\_name

Uninterpreted name of the partner LU. This is an 8-byte type-A EBCDIC character string.

# plu\_detail.parallel\_sess\_supp

Specifies whether parallel sessions are supported (AP\_YES or AP\_NO).

## plu\_detail.conv\_security

Specifies whether conversation security information can be sent to this partner LU (AP\_YES or AP\_NO). If it is set to AP\_NO, then any security information supplied by a transaction program is not sent to the partner LU. If there are currently no active sessions to this partner LU, this is set to AP\_UNKNOWN.

## plu\_detail.max\_mc\_ll\_send\_size

Maximum size of logical length (LL) record that can be sent to the partner LU. Data records that are larger than this are broken down into several LL records before being sent to the partner LU. The maximum value **max\_mc\_ll\_send\_size** can take is 32 767.

## plu\_detail.implict

Specifies whether the entry is the result of an implicit (AP\_YES) or explicit (AP\_NO) definition.

## plu\_detail.security\_details

Returns the conversation security support as negotiated on the BIND. This can be one or more of the following values:

## AP\_CONVERSATION\_LEVEL\_SECURITY

Conversation security information will be accepted on requests to or from the partner LU to allocate a conversation. The specific types of conversation security support are described by the following values.

## AP\_ALREADY\_VERIFIED

Both local and partner LU agree to accept already verified requests to allocate a conversation. An already verified request need carry only a user ID, and not a password.

## AP\_PERSISTENT\_VERIFICATION

Persistent verification is supported on the session between the local and partner LUs. This means that, once the initial request (carrying a user ID and, typically, a password) for a conversation has been verified, subsequent requests for a conversation need only carry the user ID.

## AP\_PASSWORD\_SUBSTITUTION

The local and partner LU support password substitution conversation security. When a request to allocate a conversation is issued, the request carries an encrypted form of the password. If password substitution is not supported, the password is carried in clear text (nonencrypted) format.

**Note:** If the session does not support password substitution, then an ALLOCATE or SEND\_CONVERSATION with security type of AP\_PGM\_STRONG will fail.

#### **AP\_UNKNOWN**

There are currently no active sessions to this partner LU.

#### plu\_detail.duplex\_support

Returns the conversation duplex support as negotiated on the BIND. This is one of the following values:

## AP\_HALF\_DUPLEX

Only half-duplex conversations are supported.

#### AP\_FULL\_DUPLEX

Full-duplex as well as half-duplex conversations are supported.

#### AP\_UNKNOWN

The conversation duplex support is not known because there are no active sessions to the partner LU.

## plu\_detail.preference

Returns the routing protocols preference as specified in the DEFINE\_PARTNER\_LU verb.

#### **AP\_NATIVE**

Use native (APPN) routing protocols only.

#### **AP\_NONNATIVE**

Use nonnative (AnyNet) protocols, and if the partner LU cannot be located, then retry session activation using nonnative (AnyNet) protocols.

## AP\_NATIVE\_THEN\_NONNATIVE

Try native (APPN) protocols, and if the partner LU cannot be located then retry session activation using native (APPN) protocols.

## AP\_USE\_DEFAULT\_PREFERENCE

Use the default preference defined when the node was started. (This is set on START\_NODE and can be recalled by QUERY\_NODE.)

Note that nonnative routing is only meaningful when an AnyNet DLC is available to the Program, and there is an AnyNet Link Station defined. See "DEFINE\_LS" on page 74 for more information.

If the field **anynet\_supported** supplied on START\_NODE was set to AP\_NO this field must take the value AP\_NATIVE or AP\_USE\_DEFAULT\_PREFERENCE.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc AP\_INVALID\_PLU\_NAME

> AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_PARTNER\_LU\_DEFINITION

QUERY\_PARTNER\_LU\_DEFINITION returns information that had previously been passed in on a DEFINE\_PARTNER\_LU verb.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific partner LU, or to obtain the list information in several chunks, the **plu\_alias** field (or the **fqplu\_name** if the **plu\_alias** is set to all zeros) should be set. If the **plu\_alias** field is nonzero it will be used to determine the index and the **fqplu\_name** is ignored. If the **plu\_alias** field is set to all zeros, the **fqplu\_name** will be used to determine the index. If the **list\_options** field is set to AP\_FIRST\_IN\_LIST then both of these fields will be ignored. (In this case the returned list will be ordered by **plu\_alias** if the AP\_LIST\_BY\_ALIAS **list\_options** is set, otherwise it will be ordered by **fqplu\_name**). See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered on either **plu\_alias** or **fqplu\_name** according to the options specified. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering). If AP\_LIST\_FROM\_NEXT is selected the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

Note this verb returns definition information only. The QUERY\_PARTNER\_LU verb returns information that is determined when at least one session is established with the partner LU.

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_QUERY\_PARTNER\_LU\_DEFINITION

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information:

#### AP\_SUMMARY

Returns summary information only.

## AP\_DETAIL

Returns detailed information.

The **plu\_alias** (or the **fqplu\_name** if the **plu\_alias** is set to all zeros) specified (see the following parameter, **plu\_alias**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

## AP\_LIST\_BY\_ALIAS

The returned list is ordered by **plu\_alias**. This option is only valid when AP\_FIRST\_IN\_LIST is specified. If AP\_LIST\_FROM\_NEXT or AP\_LIST\_INCLUSIVE is specified, the list ordering will depend on whether the **plu\_alias** or **fqplu\_name** has been supplied as a starting point.

## plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field is used to specify the required partner LU. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

## fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only significant if the **plu\_alias** field is set to all zeros. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries** 

# partner\_lu\_def\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### partner\_lu\_def\_summary.plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## partner\_lu\_def\_summary.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## partner\_lu\_def\_summary.description

Resource description (as specified on DEFINE\_PARTNER\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## partner\_lu\_def\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## partner\_lu\_def\_detail.plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

# partner\_lu\_def\_detail.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## partner\_lu\_def\_detail.plu\_chars.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## partner\_lu\_def\_detail.plu\_chars.plu\_alias

Partner LU alias.

## partner\_lu\_def\_detail.plu\_chars.description

Resource description (as specified on DEFINE\_PARTNER\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

# partner\_lu\_def\_detail.plu\_chars.plu\_un\_name

Uninterpreted name of the partner LU. This is an 8-byte type-A EBCDIC character string.

## partner\_lu\_def\_detail.plu\_chars.preference

The set of routing protocols to be preferred for session activation to this partner LU. This field can take the following values:

## **AP\_NATIVE**

Use native (APPN) routing protocols only.

## **AP\_NONNATIVE**

Use nonnative (AnyNet) routing protocols only.

## AP\_NATIVE\_THEN\_NONNATIVE

Try native (APPN) protocols, and if the partner LU cannot be located then retry session activation using nonnative (AnyNet) protocols.

## AP\_NONNATIVE\_THEN\_NATIVE

Try nonnative (AnyNet) protocols, and if the partner LU cannot be located then retry session activation using native (APPN) protocols.

## AP\_USE\_DEFAULT\_PREFERENCE

Use the default preference defined when the node was started.

**Note:** Nonnative routing is only meaningful when an AnyNet DLC is available to the Node Operator Facility, and there is an AnyNet link station defined.

# QUERY\_PARTNER\_LU\_DEFINITION

### partner\_lu\_def\_detail.plu\_chars.max\_mc\_ll\_send\_size

Maximum size of logical length (LL) record that can be sent to the partner LU. Data records that are larger than this are broken down into several LL records before being sent to the partner LU. The maximum value **max\_mc\_ll\_send\_size** can take is 32 767.

## partner\_lu\_def\_detail.plu\_chars.conv\_security\_ver

Specifies whether the partner LU is authorized to validate **user\_ids** on behalf of local LUs, that is whether the partner LU can set the already verified indicator in an Attach request.

AP\_YES AP\_NO

#### partner\_lu\_def\_detail.plu\_chars.parallel\_sess\_supp

Specifies whether parallel sessions are supported (AP\_YES or AP\_NO).

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_PLU\_NAME

## AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_PORT

QUERY\_PORT returns a list of information about a node's ports. This information is structured as determined data (data gathered dynamically during execution) and defined data (the data supplied by the application on DEFINE\_PORT).

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific port, or to obtain the list information in several chunks, the **port\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **port\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

The list of ports returned can be filtered by the name of the DLC that they belong to. In this case the **dlc\_name** field should be set (otherwise this field should be set to all zeros).

```

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_QUERY\_PORT

# attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information.

#### AP\_SUMMARY

Returns summary information only.

# AP\_DETAIL

Returns detailed information.

The **port\_name** specified (see the following parameter, **port\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### port\_name

Name of port being queried. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### dlc\_name

DLC name filter. This should be set to all zeros or an 8-byte string in a locally displayable character set. If this field is set then only ports belonging to this DLC are returned. This field is ignored if it is set to all zeros.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# port\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### port\_summary.port\_name

Name of port associated with this link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## port\_summary.description

Resource description (as specified on DEFINE\_PORT). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### port\_summary.port\_state

Specifies the current state of the port.

AP\_NOT\_ACTIVE AP\_PENDING\_ACTIVE AP\_ACTIVE AP\_PENDING\_INACTIVE

# port\_summary.dlc\_name

Name of the DLC. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### port\_detail.overlay\_size

The number of bytes in this entry (including any **link\_spec\_data**), and hence the offset to the next entry returned (if any).

## port\_detail.port\_name

Name of port associated with this link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### port\_detail.det\_data.port\_state

Specifies the current state of the port.

AP\_NOT\_ACTIVE

AP\_PENDING\_ACTIVE AP\_ACTIVE AP\_PENDING\_INACTIVE

## port\_detail.det\_data.dlc\_type

Type of DLC. The Program supports the following types:

AP\_ANYNET AP\_LLC2 AP\_OEM\_DLC AP\_SDLC AP\_TWINAX AP\_X25

#### port\_detail.det\_data.port\_sim\_rim

Specifies whether Set Initialization Mode (SIM) and Receive Initialization Mode (RIM) are supported (AP\_YES or AP\_NO).

#### port\_detail.det\_data.def\_ls\_good\_xids

Total number of successful XID exchanges that have occurred on all defined link stations on this port since the last time this port was started.

## port\_detail.det\_data.def\_ls\_bad\_xids

Total number of unsuccessful XID exchanges that have occurred on all defined link stations on this port since the last time this port was started.

## port\_detail.det\_data.dyn\_ls\_good\_xids

Total number of successful XID exchanges that have occurred on all dynamic link stations on this port since the last time this port was started.

#### port\_detail.det\_data.dyn\_ls\_bad\_xids

Total number of unsuccessful XID exchanges that have occurred on all dynamic link stations on this port since the last time this port was started.

#### port\_detail.det\_data.num\_implicit\_links

Total number of implicit links currently active on this port. This includes dynamic links, and implicit links created following use of Discovery. The number of such links allowed on this port is limited by the **implicit\_ls\_limit** field of PORT\_DEF\_DATA.

# port\_detail.det\_data.neg\_ls\_supp

Support for negotiable link stations, AP\_YES or AP\_NO.

#### port\_detail.det\_data.abm\_ls\_supp

Support for ABM link stations. This is not known until the DLC is started

AP\_NO AP\_YES AP\_UNKNOWN

## port\_detail.det\_data.start\_time

Time elapsed between the time the node was started and the last time this port was started, measured in hundredths of a second. If this port was started, zero is returned in this field.

#### port\_detail.def\_data.description

Resource description (as specified on DEFINE\_PORT). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### port\_detail.def\_data.dlc\_name

Name of associated DLC. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## port\_detail.def\_data.port\_type

Specifies the type of line used by the port. The value corresponds to one of the following values:

AP\_PORT\_NONSWITCHED AP\_PORT\_SWITCHED AP\_PORT\_SATF

## port\_detail.def\_data.port\_attributes[0]

This is the bit field. It may take the value AP\_NO, or the following:

# AP\_RESOLVE\_BY\_LINK\_ADDRESS

This specifies that an attempt is made to resolve incoming calls by

using the link address on CONNECT\_IN before using the CP name (or node ID) carried on the received XID3 to resolve them. This bit is ignored unless the field **port\_type** is set to AP\_PORT\_SWITCHED.

## port\_detail.def\_data.implicit\_uplink\_to\_en

BrNN only: Specifies whether implicit link stations off this port are uplink or downlink if the adjacent node is an end node. The value of this field will only be considered if there are no existing links to the same partner, as such links are used first to determine the link type.

## AP\_NO

Implicit links are downlink.

## AP\_YES

Implicit links are uplink.

Other node types: This is set to AP\_NO.

# port\_detail.def\_data.port\_number

Port number.

# port\_detail.def\_data.max\_rcv\_btu\_size Maximum BTU size that can be received.

port\_detail.def\_data.tot\_link\_act\_lim Total link activation limit.

## port\_detail.def\_data.inb\_link\_act\_lim Inbound link activation limit.

#### port\_detail.def\_data.out\_link\_act\_lim Outbound link activation limit.

## port\_detail.def\_data.ls\_role

Link station role. This can be negotiable (AP\_LS\_NEG), primary (AP\_LS\_PRI), or secondary (AP\_LS\_SEC). Reserved if **implicit\_hpr\_support** is set to AP\_NO.

# port\_detail.def\_data.implicit\_dspu\_template

Specifies the DSPU template, defined with the DEFINE\_DSPU\_TEMPLATE verb, that is used for definitions if the local node is to provide PU Concentration for an implicit link activated on this port. If the template specified does not exist (or is already at its instance limit) when the link is activated, activation fails. This is an 8-byte string in a locally-displayable character set. All 8 bytes are significant and must be set.

If the **def\_data.implicit\_dspu\_services** field is not set to AP\_PU\_CONCENTRATION, then this field is reserved.

## port\_detail.def\_data.implicit\_ls\_limit

Specifies the maximum number of implicit link stations that can be active on this port simultaneously, including dynamic links and links activated for Discovery. A value of 0 means that there is no limit, a value of AP\_NO\_IMPLICIT\_LINKS means that no implicit links are allowed.

#### port\_detail.def\_data.retry\_flags

This field specifies the conditions under which activation of this port are subject to automatic retry if the flag AP\_INHERIT\_RETRY is set on DEFINE\_LS in **def\_data.retry\_flags**. It is a bit field, and may take any of the following values bit-wise ORed together.

# AP\_RETRY\_ON\_START

Link activation will be retried if no response is received from the remote node when activation is attempted. If the underlying port is inactive when activation is attempted, the Program will attempt to activate it.

## AP\_RETRY\_ON\_FAILURE

Link activation will be retried if the link fails while active or pending active. If the underlying port has failed when activation is attempted, the Program attempts to activate it.

## AP\_RETRY\_ON\_DISCONNECT

Link activation will be retried if the link is stopped normally by the remote node.

# AP\_DELAY\_APPLICATION\_RETRIES

Link activation retries, initiated by applications (using START\_LS or on-demand link activation) will be paced using the **activation\_delay\_timer**.

## AP\_DELAY\_INHERIT\_RETRY

In addition to the retry conditions specified by flags in this field, those specified in the **retry\_flags** field of the underlying port definition will also be used.

## port\_detail.def\_data.max\_activation\_attempts

This field has no effect unless at least one flag is set in DEFINE\_LS in **def\_data.retry\_flags** and **def\_data.max\_activation\_attempts** on DEFINE\_LS is set to AP\_USE\_DEFAULTS.

This field specifies the number of retry attempts the Program allows when the remote node is not responding, or the underlying port is inactive. This includes both automatic retries and application-driven activation attempts.

If this limit is ever reached, no further attempts are made to automatically retry. This condition is reset by STOP\_LS, STOP\_PORT, STOP\_DLC or a successful activation. START\_LS or OPEN\_LU\_SSCP\_SEC\_RQ results in a single activation attempt, with no retry if activation fails.

Zero means 'no limit'. The value AP\_USE\_DEFAULTS results in the use of **max\_activiation\_attempts** supplied on DEFINE\_PORT.

# ls\_detail.def\_data.activation\_delay\_timer

This field has no effect unless at least one flag is set in DEFINE\_LS in **def\_data.retry\_flags** and **def\_data.max\_activation\_attempts** on DEFINE\_LS is set to AP\_USE\_DEFAULTS.

This field specifies the number of seconds that the Program waits between automatic retry attempts, and between application-driven activation attempts if the AP\_DELAY\_APPLICATION\_RETRIES bit is set in **def\_data.retry\_flags**.

The value AP\_USE\_DEFAULTS results in the use of **activiation\_delay\_timer** supplied on DEFINE\_PORT.

If zero is specified, the Program uses a default timer duration of thirty seconds.

# ls\_detail.def\_data.implicit\_dspu\_template

Specifies the DSPU template, defined with the DEFINE\_DSPU\_TEMPLATE verb, that is used for definitions if the local node is to provide PU Concentration for an implicit link activated on this port. If the template

specified does not exist (or is already at its instance limit) when the link is activated, activation fails. This is an 8-byte string in a locally-displayable character set. All 8 bytes are significant and must be set.

If the **def\_data.implicit\_dspu\_services** field is not set to AP\_PU\_CONCENTRATION, then this field is reserved.

## ls\_detail.def\_data.implicit\_dspu\_services

Specifies the services that the local node will provide to the downstream PU across implicit links activated on this port. This is set to one of the following values:

## AP\_DLUR

Local node will provide DLUR services for the downstream PU (using the default DLUS configured through the DEFINE\_DLUR\_DEFAULTS verb).

#### AP\_PU\_CONCENTRATION

Local node will provide PU Concentration for the downstream PU (and will put in place definitions as specified by the DSPU template specified in the field **def\_data.implicit\_dspu\_template**).

#### AP\_NONE

Local node will provide no services for this downstream PU.

#### ls\_detail.def\_data.implicit\_deact\_timer

Limited resource link deactivation timer (in seconds). If **implicit\_limited\_resource** is set to AP\_YES or AP\_NO\_SESSIONS, then an HPR-capable implicit link is automatically deactivated if no data traverses the link for the duration of this timer, and no sessions are using the link.

If **implicit\_limited\_resource** is set to AP\_INACTIVITY then an implicit link is automatically deactivated if no data traverses the link for the duration of this timer.

If zero is specified the default value of 30 is used. Otherwise the minimum value is 5. (If it is set any lower, the specified value will be ignored and 5 will be used.) Note that this parameter is reserved unless **implicit\_limited\_resource** is set to AP\_NO.

## port\_detail.def\_data.act\_xid\_exchange\_limit Activation XID exchange limit.

port\_detail.def\_data.nonact\_xid\_exchange\_limit

Nonactivation XID exchange limit.

# port\_detail.def\_data.ls\_xmit\_rcv\_cap

Specifies the link station transmit/receive capability. This is either two-way simultaneous (AP\_LS\_TWS) or two way alternating (AP\_LS\_TWA).

# port\_detail.def\_data.max\_ifrm\_rcvd

Maximum number of I-frames that can be received by local link stations before an acknowledgment is sent. Range: 1–127

#### port\_detail.def\_data.target\_pacing\_count

Numeric value between 1 and 32 767 inclusive indicating the desired pacing window size for BINDs on this TG. The number is only significant when fixed bind pacing is being performed. Personal Communications or Communications Server does not currently use this value.

## port\_detail.def\_data.max\_send\_btu\_size

Maximum BTU size that can be sent.

# port\_detail.def\_data.dlc\_data.length Port address length.

#### port\_detail.def\_data.dlc\_data.address Port address.

port\_detail.def\_data.hpr\_dlc\_data.length HPR Port address length.

# port\_detail.def\_data.hpr\_dlc\_data.address

HPR Port address. This is currently used when supporting HPR links. The field specifies the information sent by Personal Communications or Communications Server in the X'80' subfield of the X'61' control vector on XID3 exchanged on link stations using this port.

## port\_detail.def\_data.implicit\_cp\_cp\_sess\_support

Specifies whether CP-CP sessions are permitted for implicit link stations off this port (AP\_YES or AP\_NO).

## port\_detail.def\_data.implicit\_limited\_resource

Specifies whether implicit link stations off this port should be deactivated when there are no sessions using the link. This is set to one of the following values:

## AP\_NO

Implicit links are not limited resources and will not be deactivated automatically.

## AP\_YES or AP\_NO\_SESSIONS

Implicit links are a limited resource and will be deactivated automatically when no active sessions are using them.

## AP\_INACTIVITY

Implicit links are a limited resource and will be deactivated automatically when no active sessions are using them, or when no data has followed on the link for the time period specified by the **implicit\_deact\_timer** field.

## port\_detail.def\_data.implicit\_hpr\_support

Specifies whether HPR is supported on implicit links (AP\_YES or AP\_NO).

## port\_detail.def\_data.implicit\_link\_lvl\_error

Specifies whether HPR traffic is sent on implicit links using link-level error recovery (AP\_YES or AP\_NO).

## port\_detail.def\_data.default\_tg\_chars

TG characteristics (See "DEFINE\_COS" on page 35). These are used for implicit link stations off this port and also for defined link stations which specify **use\_default\_tg\_chars**.

## port\_detail.def\_data.discovery\_supported

Specifies whether Discovery search functions are performed on this port (AP\_YES or AP\_NO).

## port\_detail.def\_data.port\_spec\_data\_len

Unpadded length, in bytes, of data passed unchanged to the port on the ACTIVATE\_PORT signal. The data is concatenated to the PORT\_DETAIL structure.

## port\_detail.def\_data.link\_spec\_data\_len

Data passed unchanged to the link station component during initialization. The data is concatenated to the PORT\_DETAIL structure immediately following the port-specific data. The port-specific data and the link-specific data together will be padded to end on a 4-byte boundary. There will be no explicit padding between the port-specific data and the link-specific data.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_PORT\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_PU

QUERY\_PU returns a list of local PUs and the links associated with them.

The information is returned as a list. To obtain information about a specific PU, or to obtain the list information in several chunks, the **pu\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

The verb specifies whether local PUs are attached directly to the host system or attached via DLUR. The **host\_attachment** field can be used as a filter so that only information about the specified attachment type is returned.

# VCB Structure

                                                                   */
} SESSION STATS;
```

# Supplied Parameters

The application supplies the following parameters:

#### opcode

AP\_QUERY\_PU

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information.

The **pu\_name** specified (see the following parameter, **pu\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### pu\_name

Name of the first PU to be listed. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### host\_attachment

Filter for host attachment:

## AP\_NONE

Return information about all local PUs.

#### AP\_DLUR\_ATTACHED

Return information about all local PUs that are supported by DLUR.

## AP\_DIRECT\_ATTACHED

Return information about only those PUs that are directly attached to the host system.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# pu\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# pu\_data.pu\_name

PU name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## pu\_data.description

Resource description (as specified on DEFINE\_LS or DEFINE\_INTERNAL\_PU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### pu\_data.ls\_name

Name of the link station associated with this PU. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### pu\_data.pu\_sscp\_sess\_active

Specifies whether the PU-SSCP session is active (AP\_YES or AP\_NO).

#### pu\_data.host\_attachment

Local PU host attachment type:

AP\_DLUR\_ATTACHED PU is attached to host system using DLUR.

AP\_DIRECT\_ATTACHED PU is directly attached to host system.

pu\_data.pu\_sscp\_stats.rcv\_ru\_size This field is always reserved.

pu\_data.pu\_sscp\_stats.send\_ru\_size This field is always reserved.

pu\_data.pu\_sscp\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

pu\_data.pu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

pu\_data.pu\_sscp\_stats.max\_send\_pac\_win
 This field will always be set to zero.

pu\_data.pu\_sscp\_stats.cur\_send\_pac\_win
This field will always be set to zero.

pu\_data.pu\_sscp\_stats.max\_rcv\_pac\_win
This field will always be set to zero.

pu\_data.pu\_sscp\_stats.cur\_rcv\_pac\_win
This field will always be set to zero.

pu\_data.pu\_sscp\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.

pu\_data.pu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.

pu\_data.pu\_sscp\_stats.rcv\_data\_frames
 Number of normal flow data frames received.

pu\_data.pu\_sscp\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.

pu\_data.pu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.

pu\_data.pu\_sscp\_stats.sidh Session ID high byte.

pu\_data.pu\_sscp\_stats.sidl Session ID low byte.

#### pu\_data.pu\_sscp\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the ACTPU sets this field to zero if the local node contains the primary link station, and sets it to one if the ACTPU sender is the node containing the secondary link station.

pu\_data.pu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

### pu\_data.pu\_sscp\_stats.pacing\_type

Receiving pacing type in use on the PU-SSCP session. This will take the value AP\_NONE.

#### pu\_data.sscp\_id

This is a 6–byte field containing the SSCP ID received in the ACTPU for the PU.

If **pu\_sscp\_sess\_active** is not AP\_YES, then this field will be zeroed.

#### pu\_data.conventional\_lu\_compression

Specifies whether data compression is requested for sessions using this PU.

#### AP\_NO

The local node should not be compressing or decompressing data flowing on sessions using this PU.

#### AP\_YES

Data compression should be enabled for sessions dependent on this PU if the host requests compression.

### pu\_data.conventional\_lu\_cryptography

Specifies whether session level encryption is required for conventional LU sessions dependent on this PU.

#### AP\_NONE

Session level encryption is not performed by the Program.

#### **AP\_MANDATORY**

Mandatory session level encryption is performed by the Program if an import key is available to the LU. Otherwise, it must be performed by the application that uses the LU (if this is PU Concentration, then it is performed by a downstream LU).

### **AP\_OPTIONAL**

This value allows the cryptography used to be driven by the host application on a per session basis. If the host requests cryptography for a session dependent on this PU, then the behaviour of the Program is as for AP\_MANDATORY. If the host does not request cryptography, then the behaviour is the same as AP\_NONE.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_PU\_TYPE AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_RTP\_CONNECTION

QUERY\_RTP\_CONNECTION is used at a network node or an end node and returns list information about Rapid Transport Protocol (RTP) connections for which the node is an endpoint.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific RTP connection, or to obtain the list information in several chunks, the **rtp\_name** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **rtp\_name**. Ordering is according to name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with normal MIB ordering). If AP\_LIST\_FROM\_NEXT is selected the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

                                                                                   */
} RTP STATISTICS;
```

- **Note:** The **rtp\_connection\_detail** overlay will be followed by a Route Selection Control Vector (RSCV) as defined by SNA. After RTP connection setup and before any path switch, the RSCV for an RTP connection will be stored and displayed at each node as follows:
  - The RSCV will contain all the hops from the local node to the partner RTP node.
  - If the partner RTP node is not an endpoint of the session causing the RTP connection to be activated, the RSCV will also store one "boundary function hop" leading away from the partner RTP node.
  - The RSCV will never contain a boundary function hop leading into the local node, even if the local node does not contain a session endpoint.

After path switch has occurred, the RSCVs stored and displayed will only include the hops from the local node to the partner RTP node. (Never a boundary function hop.)

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_QUERY\_RTP\_CONNECTION

# QUERY\_RTP\_CONNECTION

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information.

#### AP\_SUMMARY

Returns summary information only.

# **AP\_DETAIL**

Returns detailed information.

The **rtp\_name** represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The **rtp\_name** is ignored and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### rtp\_name

RTP connection name. This name is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# rtp\_connection\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### rtp\_connection\_summary.rtp\_name

RTP connection name. This name is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

# rtp\_connection\_summary.first\_hop\_ls\_name

Link station name of the first hop of the RTP connection. This name is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### rtp\_connection\_summary.dest\_node\_name

Fully qualified, 17-byte name of the destination node of the RTP connection composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

# rtp\_connection\_summary.cos\_name

Class-of-service name for the RTP connection. This is an 8-byte alphanumeric type-A EBCDIC character string, padded to the right with EBCDIC spaces.

#### rtp\_connection\_summary.num\_sess\_active

Number of sessions currently active on the RTP connection.

# rtp\_connection\_detail.overlay\_size

The number of bytes in this entry (including any appended RSCV), and hence the offset to the next entry returned (if any).

# rtp\_connection\_detail.rtp\_name

RTP connection name. This name is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### rtp\_connection\_detail.first\_hop\_ls\_name

Link station name of the first hop of the RTP connection. This name is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### rtp\_connection\_detail.dest\_node\_name

Fully qualified, 17-byte name of the destination node of the RTP connection composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded-with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### rtp\_connection\_detail.isr\_boundary\_fn

AP\_YES if the RTP Connection is being used for any ISR session for which the local node is providing HPT-APPN Boundary Function, AP\_NO otherwise.

#### rtp\_connection\_detail.cos\_name

Class-of-service name for the RTP connection. This is an 8-byte alphanumeric type-A EBCDIC character string, padded to the right with EBCDIC spaces.

#### rtp\_connection\_detail.max\_btu\_size

Maximum BTU size for the RTP connection measured in bytes.

# QUERY\_RTP\_CONNECTION

### rtp\_connection\_detail.liveness\_timer

Liveness timer for the RTP connection, measured in seconds.

# rtp\_connection\_detail.local\_tcid

Local TCID for the RTP connection.

# rtp\_connection\_detail.remote\_tcid

Remote TCID for the RTP connection.

# rtp\_connection\_detail.rtp\_stats.bytes\_sent

Total number of bytes that the local node has sent on this RTP connection.

#### rtp\_connection\_detail.rtp\_stats.bytes\_received

Total number of bytes that the local node has received on this RTP connection.

#### rtp\_connection\_detail.rtp\_stats.bytes\_resent

Total number of bytes resent by the local node owing to loss in transit.

#### rtp\_connection\_detail.rtp\_stats.bytes\_discarded

Total number of bytes sent by the other end of the RTP connection and were discarded as duplicates of data already received.

#### rtp\_connection\_detail.rtp\_stats.packets\_sent

Total number of packets that the local node has sent on this RTP connection.

#### rtp\_connection\_detail.rtp\_stats.packets\_received

Total number of packets that the local node has received on this RTP connection.

#### rtp\_connection\_detail.rtp\_stats.packets\_resent

Total number of packets resent by the local node owing to loss in transit.

### rtp\_connection\_detail.rtp\_stats.packets\_discarded

Total number of packets sent by the other end of the RTP connection that were discarded as duplicates of data already received.

#### rtp\_connection\_detail.rtp\_stats.gaps\_detected

Total number of gaps detected by the local node. Each gap corresponds to one or more lost frames.

#### rtp\_connection\_detail.rtp\_stats.send\_rate

Current send rate on this RTP connection (measured in kilobits per second). This is the maximum allowed send rate as calculated by the ARB algorithm.

# rtp\_connection\_detail.rtp\_stats.max\_send\_rate

Maximum send rate on this RTP connection (measured in kilobits per second).

# rtp\_connection\_detail.rtp\_stats.min\_send\_rate

Minimum send rate on this RTP connection (measured in kilobits per second).

### rtp\_connection\_detail.rtp\_stats.receive\_rate

Current receive rate on this RTP connection (measured in kilobits per second). This is the actual receive rate calculated over the last measurement interval.

#### rtp\_connection\_detail.rtp\_stats.max\_receive\_rate

Maximum receive rate on this RTP connection (measured in kilobits per second).

# rtp\_connection\_detail.rtp\_stats.min\_receive\_rate

Minimum receive rate on this RTP connection (measured in kilobits per second).

# rtp\_connection\_detail.rtp\_stats.burst\_size

Current burst size on the RTP Connection measured in bytes.

### rtp\_connection\_detail.rtp\_stats.up\_time

Total number of seconds the RTP connection has been active.

#### rtp\_connection\_detail.rtp\_stats.smooth\_rtt

Smoothed measure of round-trip time between the local node and the partner RTP node (measured in milliseconds).

# rtp\_connection\_detail.rtp\_stats.last\_rtt

The last measured round-trip time between the local node and the partner RTP node (measured in milliseconds).

### rtp\_connection\_detail.rtp\_stats.short\_req\_timer

The current duration used for the SHORT\_REQ timer (measured in milliseconds).

#### rtp\_connection\_detail.rtp\_stats.short\_req\_timeouts

Total number of times the SHORT\_REQ timer has expired for this RTP connection.

#### rtp\_connection\_detail.rtp\_stats.liveness\_timeouts

Total number of times the liveness timer has expired for this RTP connection. The liveness timer expires when the connection has been idle for the period specified in **rtp\_connection\_detail.liveness\_timer**.

#### rtp\_connection\_detail.rtp\_stats.in\_invalid\_sna\_frames

Total number of SNA frames received and discarded as not valid on this RTP connection.

# rtp\_connection\_detail.rtp\_stats.in\_sc\_frames

Total number of session control frames received on this RTP connection.

#### rtp\_connection\_detail.rtp\_stats.out\_sc\_frames

Total number of session control frames sent on this RTP connection.

# rtp\_connection\_detail.num\_sess\_active

Number of sessions currently active on the RTP connection.

#### rtp\_connection\_detail.rscv\_len

Length of the appended Route Selection Control Vector for the RTP connection. (If none is appended, then the length is zero.) The RSCV will be padded to end on a 4-byte boundary to ensure correct alignment of the next detail entry, but the **rscv\_len** does not include this padding.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_RTP\_CONNECTION

# AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

# primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_SESSION

QUERY\_SESSION returns list information about sessions for which the node is an endpoint.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific session, or to obtain the list information in several chunks, the **session\_id** field should be set. Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. Note that the **lu\_name** (or **lu\_alias**) and **plu\_alias** (or **fqplu\_name**) fields must always be set. The **lu\_name**, if nonzero, will be used in preference to the **lu\_alias**. See "Querying the Node" on page 10 for background on how the list formats are used.

The list of sessions returned may be filtered by the name of the partner LU. To do this, the **fqplu\_name** or **plu\_alias** fields should be set. If **plu\_alias** is set to all zeros, the **fqplu\_name** value will be used, otherwise the **plu\_alias** is always used and the **fqplu\_name** is ignored.

The list of sessions returned can be filtered by the name of the mode that they are associated with. In this case the **mode\_name** field should be set (otherwise this field should be set to all zeros).

In addition to the detail information for each session, a route selection control vector (RSCV) will be returned (in key-length format) if this is specified on the START NODE parameters. This RSCV (specified in *SNA Formats*) defines the route through the network that the session takes in hop-by-hop form.

                   send data bytes;
                                      /* Number of data bytes sent
                                                                       */
                                      /* Num data frames received
  unsigned long
                   rcv data frames;
                                                                       */
  unsigned long
                   rcv fmd data frames;
                                      /* num of FMD data frames recvd */
                                      /* Num data bytes received
  unsigned long
                   rcv data bytes;
                                                                       */
  unsigned char
                   sidh;
                                      /* Session ID high byte
                                                                       */
   unsigned char
                   sidl;
                                      /* Session ID low byte
                                                                       */
                                      /* ODAI bit set
  unsigned char
                   odai;
                                                                       */
                   ls name[8];
                                      /* Link station name
  unsigned char
                                                                       */
                                      /* type of pacing in use
                                                                       */
  unsigned char
                   pacing_type;
} SESSION STATS;
```

**Note:** The session detail overlay may be followed by a route selection control vector (RSCV) as defined by *SNA Formats*. This control vector defines the session route through the network and is carried on the BIND. The RSCV is included (in key-length format) if the field on the START\_NODE verb is set to AP\_YES. If the START\_NODE **rscv\_len** is set to zero.

# **Supplied Parameters**

The application supplies the following parameters:

# opcode

AP\_QUERY\_SESSION

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

# buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

# buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

# list\_options

This indicates what should be returned in the list information.

# AP\_SUMMARY

Returns summary information only.

# AP\_DETAIL

Returns detailed information.

The combination of **lu\_name** (or **lu\_alias** if the **lu\_name** is set to all zeros), **pu\_alias** (or **fqplu\_name** if the **plu\_alias** is set to all zeros), **mode\_name** and **session\_id** specified (see the following parameters, **lu\_name**, **pu\_alias**, **mode\_name**, and **session\_id**) represent an index value that is used to specify the starting point of the actual information to be returned .

# AP\_FIRST\_IN\_LIST

The **session\_id** is ignored and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the index.

### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable

character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** fields are set to all zeros, the LU associated with the control point (the default LU) is used.

#### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field will be used for determining the index.

#### fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### mode\_name

Mode name filter. This should be set to all zeros or an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this field is set then only sessions associated with this mode are returned. This field is ignored if it is set to all zeros.

#### session\_id

8-byte identifier of the session. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### session\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### session\_summary.plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### session\_summary.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces.

#### session\_summary.mode\_name

Mode name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### session\_summary.session\_id

8-byte identifier of the session.

#### session\_summary.fqpcid.pcid

Procedure correlator ID. This is an 8-byte hexadecimal string.

#### session\_summary.fqpcid.fqcp\_name

Fully qualified control point name. This 17-byte name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### session\_detail.overlay\_size

The number of bytes in this entry (including any appended RSCV), and hence the offset to the next entry returned (if any).

### session\_detail.plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### session\_detail.fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces.

# session\_detail.mode\_name

Mode name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### session\_detail.session\_id

8-byte identifier of the session.

#### session\_detail.fqpcid.pcid

Procedure correlator ID. This is an 8-byte hexadecimal string.

# session\_detail.fqpcid.fqcp\_name

Fully qualified control point name. This 17-byte name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### session\_detail.cos\_name

Class-of-service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### session\_detail.trans\_pri

Transmission priority. This is set to one of the following values:

AP\_LOW AP\_MEDIUM AP\_HIGH AP\_NETWORK

#### session\_detail.ltd\_res

Specifies whether the session uses a limited resource link (AP\_YES or AP\_NO).

#### session\_detail.polarity

Specifies the polarity of the session (AP\_PRIMARY or AP\_SECONDARY).

# QUERY\_SESSION

session\_detail.contention

Specifies the session contention polarity. This indicates whether the local LU has 'first refusal' for the use of this session (AP\_CONWINNER) or whether it must bid before using the session (AP\_CONLOSER).

session\_detail.sess\_stats.rcv\_ru\_size Maximum receive RU size.

session\_detail.sess\_stats.send\_ru\_size Maximum send RU size.

session\_detail.sess\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

session\_detail.sess\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

session\_detail.sess\_stats.max\_send\_pac\_win Maximum size of the send pacing window on this session.

session\_detail.sess\_stats.cur\_send\_pac\_win Current size of the send pacing window on this session.

session\_detail.sess\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session.

session\_detail.sess\_stats.cur\_rcv\_pac\_win
Current size of the receive pacing window on this session.

session\_detail.sess\_stats.send\_data\_frames Number of normal flow data frames sent.

session\_detail.sess\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.

session\_detail.sess\_stats.send\_data\_bytes Number of normal flow data bytes sent.

session\_detail.sess\_stats.rcv\_data\_frames Number of normal flow data frames received.

session\_detail.sess\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.

session\_detail.sess\_stats.rcv\_data\_bytes Number of normal flow data bytes received.

session\_detail.sess\_stats.sidh Session ID high byte.

session\_detail.sess\_stats.sidl Session ID low byte.

session\_detail.sess\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station. It sets it to one if the BIND sender is the node containing the secondary link station.

session\_detail.sess\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate the session statistics with the link over which session data flows.

# session\_detail.sess\_stats.pacing\_type

Type of receive pacing in use on this session. This may take the values AP\_NONE, AP\_PACING\_FIXED, or AP\_PACING\_ADAPTIVE.

# session\_detail.duplex\_support

Returns the conversation duplex support as negotiated on the BIND. This is one of the following values:

### AP\_HALF\_DUPLEX

Only half-duplex conversations are supported.

#### AP\_FULL\_DUPLEX

Full-duplex as well as half-duplex conversations are supported. Expedited data is also supported.

#### session\_detail.sscp\_id

For dependent LU sessions, this field contains the SSCP ID received in the ACTPU from the host for the PU that the local LU is mapped to. For independent LU sessions, this field will be set to all binary zeros.

# session\_detail.session\_start\_time

The time that elapsed between the CP starting and this session becoming active, measured in one-hundredths of a second. If the session is not fully-active when the query is processed, zero is returned in this field.

#### session\_detail.session\_timeout

Specifies the timeout associated with the session. This is derived from the following values:

- LU6.2 timeout associated with the local LU
- LU6.2 timeout associated with the remote LU
- mode timeout
- global timeout
- limited resource timeout if this session is running over a limited resource link

# session\_detail.plu\_slu\_comp\_lvl

Specifies the compression level for data sent from the PLU to the SLU.

#### AP\_NONE

Compression is not used.

#### AP\_RLE\_COMPRESSION

RLE compression is used.

#### AP\_LZ9\_COMPRESSION

This node can supports LZ9 compression.

# AP\_LZ10\_COMPRESSION

The node can supports LZ10 compression.

# AP\_LZ12\_COMPRESSION

The node can supports LZ12 compression.

# session\_detail.slu\_plu\_comp\_lvl

Specifies the compression level for data sent from the SLU to the PLU.

#### AP\_NONE

Compression is not used.

#### AP\_RLE\_COMPRESSION

RLE compression is used.

# AP\_LZ9\_COMPRESSION

This node can supports LZ9 compression.

# AP\_LZ10\_COMPRESSION

The node can supports LZ10 compression.

# AP\_LZ12\_COMPRESSION

The node can supports LZ12compression.

### session\_detail.rscv\_len

Length of the RSCV that is appended to the **session\_detail** structure. (If none is appended, then the length is zero.) The RSCV will be padded to end on a 4-byte boundary.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_SESSION\_ID

AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_SIGNED\_ON\_LIST

QUERY\_SIGNED\_ON\_LIST retrieves information about users signed on to a particular LU.

The local LU is specified by **lu\_name** or **lu\_alias**. **Buf\_ptr**, **buf\_size**, **total\_buf\_size**, **num\_entries**, **total\_num\_entries** and **overlay\_size** have the usual meanings for a QUERY verb.

Entries are returned as a list of SIGNED\_ON\_LIST\_ENTRY structures, pointed to by **buf\_ptr**, or appended to the QUERY\_SIGNED\_ON\_LIST VCB if **buf\_ptr** is NULL. The list is ordered by **plu\_alias/fqplu\_name**, then by **user\_id** and then by **profile**. If **plu\_alias** is specified, **fqplu\_name** is ignored.

The **list\_options** can take the values AP\_FIRST\_IN\_LIST, AP\_LIST\_FROM\_NEXT, AP\_LIST\_INCLUSIVE. If **list\_options** is AP\_FIRST\_IN\_LIST, **plu\_alias**, **fqplu\_name**, **user\_id**, and **profile** are ignored. The **list** specifies which list to return entries from, which must be AP\_SIGNED\_ON\_TO\_LIST.

# VCB Structure

typedef struct query\_signed\_on\_list

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

```
AP_QUERY_SIGNED_ON_LIST
```

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

# num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information.

The combination of **lu\_name** (or **lu\_alias** if the **lu\_name** is set to all zeros), **pu\_alias** (or **fqplu\_name** if the **plu\_alias** is set to all zeros), **user\_id** and **profile** specified (see the following parameters, **lu\_name**, **pu\_alias**, **user\_id**, and **profile**) represent an index value that is used to specify the starting point of the actual information to be returned .

### AP\_FIRST\_IN\_LIST

The **pu\_alias**, **fqplu\_name**, **user\_id**, and **profile** are ignored and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the index.

#### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** fields are set to all zeros, the LU associated with the control point (the default LU) is used.

#### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field will be used for determining the index.

#### fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### user\_id

User ID. This should be set to a 10–byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. If this field is set then only sessions associated with this mode are returned. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### profile

This is a 10-byte alphanumeric EBCDIC string. Note, the Program currently supports only the blank profile (10 eBCDIC spaces). This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

**list** Signed-on list type. This must be set to AP\_SIGNED\_ON\_TO\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

# total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### signed\_on\_list\_entry.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### signed\_on\_list\_entry.plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### signed\_on\_list\_entry.user\_id

User ID. This is a 10-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

# signed\_on\_list\_entry.profile

10-byte alphanumeric EBCDIC string.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

# secondary\_rc

AP\_INVALID\_LU\_ALIAS

AP\_INVALID\_LU\_NAME AP\_INVALID\_PLU\_NAME AP\_INVALID\_USERID AP\_INVALID\_PROFILE AP\_INVALID\_LIST AP\_INVALID\_LIST\_OPTION

**Note:** The Program currently supports only the blank profile (10 EBCDIC spaces).

# QUERY\_SIGNED\_ON\_LIST

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node stopped, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

# **QUERY\_STATISTICS**

QUERY\_STATISTICS queries link station and port statistics. Personal Communications or Communications Server passes this query directly to the DLC. The format of the statistics depends on the DLC implementation.

# VCB Structure

```
typedef struct query_statistics
```

ι						
	unsigned	short	opcode;	/*	verb operation code	*/
	unsigned	char	reserv2;	/*	reserved	*/
	unsigned	char	format;	/*	format	*/
	unsigned	short	primary_rc;	/*	primary return code	*/
	unsigned	long	secondary_rc;	/*	secondary return code	*/
	unsigned	char	name[8];		LS or port name	*/
	unsigned	char	<pre>stats_type;</pre>	/*	LS or port statistics?	*/
	unsigned	char	<pre>table_type;</pre>	/*	statistics table requested	*/
	unsigned	char	reset_stats;	/*	reset the statistics?	*/
	unsigned	char	dlc_type;	/*	type of DLC	*/
	unsigned	char	<pre>statistics[256];</pre>	/*	current statistics	*/
	unsigned	char	reserva[20];	/*	reserved	*/
}	QUERY_STAT	TISTICS				

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_QUERY\_STATISTICS

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

name Name defined for the link station or port (depending on setting of stats\_type parameter). This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. Personal Communications or Communications Server uses this to correlate the response to the correct link station or port.

### stats\_type

The type of resource for which statistics are requested. This must be set to one of the following values:

```
AP_LS
AP_PORT
```

### table\_type

The type of statistics table requested. This must be set to one of the following categories of information:

### AP\_STATS\_TBL

Specifies that statistical information will be returned.

### AP\_ADMIN\_TBL

Specifies that administrative information will be returned.

# AP\_OPER\_TBL

Specifies that operational information will be returned. The format of the information returned for each category is DLC implementation specific.

#### reset\_stats

Specifies whether the statistics should be reset (AP\_YES or AP\_NO).

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### dlc\_type

Type of the DLC. The value of this field is DLC implementation specific. The values are as follows:

AP\_ANYNET AP\_LLC2 AP\_OEM\_DLC AP\_SDLC AP\_TWINAX AP\_X25

# statistics

Current statistics of link station or port.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

# primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_LINK\_NAME

AP\_INVALID\_PORT\_NAME AP\_INVALID\_STATS\_TYPE AP\_INVALID\_TABLE\_TYPE

If the verb does not execute because of a state error, the Program returns the following parameters:

### primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_LINK\_DEACTIVATED

#### AP\_PORT\_DEACTIVATED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_TP

QUERY\_TP returns information about transaction programs currently being used by a local LU.

The information is returned as a list. To obtain information about a specific transaction program, or to obtain the list information in several chunks, the **tp\_name** field should be set. If the **list\_options** field is set to AP\_FIRST\_IN\_LIST then this field will be ignored. Note that the **lu\_name** or **lu\_alias** field must always be set. The **lu\_name** field, if nonzero, will be used in preference to the **lu\_alias** field. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **tp\_name** using EBCDIC lexicographical ordering for names of the same length. This verb returns information that is determined once the TP starts to be used by a local LU. The QUERY\_TP\_DEFINITION verb returns definition information only.

# VCB Structure

# **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_QUERY\_TP

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP INTERNALLY VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

### list\_options

This indicates what should be returned in the list information: The combination of **lu\_name** (or **lu\_alias** if the **lu\_name** is set to all zeros) and **tp\_name** specified (see the following parameters, **lu\_name** and **tp\_name**) represents an index value that is used to specify the starting point of the actual information to be returned .

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the index.

#### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the

**lu\_name** and the **lu\_alias** are set to all zeros, the LU that is associated with the control point (the default LU) is used.

#### tp\_name

Transaction program name. This is a 64-byte string, padded to the right with spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

# primary\_rc

AP\_OK

# buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

# tp\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### tp\_data.tp\_name

Transaction program name. This is a 64-byte string, padded to the right with spaces.

#### tp\_data.description

Resource description (as specified on DEFINE\_TP). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### tp\_data.instance\_limit

Maximum number of concurrently active instances of the specified transaction program.

#### tp\_data.instance\_count

Number of instances of the specified transaction program that are currently active.

#### tp\_data.locally\_started\_count

Number of instances of the specified transaction program which have been started locally (by the transaction program issuing a TP\_STARTED verb).

#### tp\_data.remotely\_started\_count

Number of instances of the specified transaction program that have been started remotely (by a received Attach request).

#### tp\_spec\_data.pathname

Specifies the path and transaction program name.

### tp\_spec\_data.parameters

Specifies the parameters for the transaction program.

tp\_spec\_data.queued

Specifies whether the transaction program will be queued.

# tp\_spec\_data.load\_type

Specifies how the transaction program will be loaded.

#### tp\_spec\_data.dynamic\_load

Specifies whether the TP can be dynamically loaded (AP\_YES or AP\_NO).

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_TP\_NAME

AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_TP\_DEFINITION

QUERY\_TP\_DEFINITION returns both information previously passed in on a DEFINE\_TP verb and information about Personal Communications or Communications Server defined transaction programs.

The information is returned as a list in one of two formats, either summary or detailed information. To obtain information about a specific transaction program, or to obtain the list information in several chunks, the **tp\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered by the **tp\_name**, using EBCDIC lexicographical ordering. If AP\_LIST\_FROM\_NEXT is selected the returned list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

This verb returns definition information only. The QUERY\_TP verb returns information that is determined once the transaction program starts to be used by a local LU.

# VCB Structure

```
typedef struct query tp definition
                                     /* Verb operation code
  unsigned short opcode;
                                                                      */
  unsigned char attributes;
                                     /* verb attributes
                                                                      */

} TP SPEC DATA;
```

# **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_QUERY\_TP\_DEFINITION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### buf\_ptr

Pointer to a buffer into which list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

# list\_options

This indicates what should be returned in the list information:

#### **AP\_SUMMARY**

Returns summary information only.

#### **AP\_DETAIL**

Returns detailed information.

The **tp\_name** specified (see the following parameter, **tp\_name**) represents an index value that is used to specify the starting point of the actual information to be returned:

### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

# AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

# AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### tp\_name

Name of the defined transaction program. This is a 64-byte string, padded to the right with spaces. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

# **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf size**.

#### num\_entries

Number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### tp\_def\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# tp\_def\_summary.tp\_name

Defined transaction program name. This is a 64-byte string, padded to the right with spaces.

### tp\_def\_summary.description

Resource description (as specified on DEFINE\_TP). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### tp\_def\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

# tp\_def\_detail.tp\_name

Defined transaction program name. This is a 64-byte string, padded to the right with spaces.

#### tp\_def\_detail.tp\_chars.description

Resource description (as specified on DEFINE\_TP). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

### tp\_def\_detail.tp\_chars.conv\_type

Specifies the types of conversation supported by the transaction program:

AP\_BASIC AP\_MAPPED AP\_EITHER

#### tp\_def\_detail.tp\_chars.security\_rqd

Specifies whether conversation security information is required to start the transaction program (AP\_NO or AP\_YES).

#### tp\_def\_detail.tp\_chars.sync\_level

Specifies the synchronization levels supported by the transaction program:

#### AP\_NONE

The transaction program supports a synchronization level of None.

# AP\_CONFIRM\_SYNC\_LEVEL

The transaction program supports a synchronization level of Confirm.

#### **AP\_EITHER**

The transaction program supports a synchronization level of None or Confirm.

# AP\_SYNCPT\_REQUIRED

The transaction program supports a synchronization level of Sync-point.

### AP\_SYNCPT\_NEGOTIABLE

The transaction program supports a synchronization level of None, Confirm, or Sync-point.

#### tp\_def\_detail.tp\_chars.dynamic\_load

Specifies whether the transaction program can be dynamically loaded (AP\_YES or AP\_NO).

#### tp\_def\_detail.tp\_chars.enabled

Specifies whether the transaction program can be attached successfully (AP\_YES or AP\_NO). The default is AP\_NO.

#### tp\_def\_detail.tp\_chars.pip\_allowed

Specifies whether the transaction program can receive program initialization (PIP) parameters (AP\_YES or AP\_NO).

#### tp\_def\_detail.tp\_chars.duplex\_support

Indicates whether the transaction program is full or half duplex.

#### AP\_FULL\_DUPLEX

Specifies the transaction program is full duplex.

# AP\_HALF\_DUPLEX

Specifies the transaction program is half duplex.

# AP\_EITHER\_DUPLEX

Specifies the transaction program can be either half or full duplex

### tp\_def\_detail.tp\_chars.tp\_instance\_limit

Limit on the number of concurrently active transaction program instances.

# tp\_def\_detail.tp\_chars.incoming\_alloc\_timeout

Specifies the number of seconds that an incoming Attach will be queued waiting for a RECEIVE\_ALLOCATE. Zero implies no timeout, and so it will be held indefinitely.

### tp\_def\_detail.tp\_chars.rcv\_alloc\_timeout

Specifies the number of seconds that a RECEIVE\_ALLOCATE verb will be queued while waiting for an Attach. Zero implies no timeout, and so it will be held indefinitely.

#### tp\_def\_detail.tp\_chars.tp\_data\_len

Length of the implementation-dependent transaction program data.

#### tp\_def\_detail.tp\_chars.tp\_data

Implementation-dependent transaction program data that is passed unchanged on the DYNAMIC\_LOAD\_INDICATION.

#### tp\_spec\_data.pathname

Specifies the path and transaction program name.

# tp\_spec\_data.parameters

Specifies the parameters for the transaction program.

#### tp\_spec\_data.queued

Specifies whether the transaction program will be queued.

#### tp\_spec\_data.load\_type

Specifies how the transaction program will be loaded.

#### tp\_spec\_data.dynamic\_load

Specifies whether the TP can be dynamically loaded (AP\_YES or AP\_NO).

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_TP\_NAME

### AP\_INVALID\_LIST\_OPTION

If the verb does not execute because the node has not yet been started, the Program returns the following parameters:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

# QUERY\_TP\_DEFINITION

# Chapter 7. Safe-Store Verbs

This chapter describes verbs that are issued at network nodes.

# SAFE\_STORE\_TOPOLOGY

SAFE\_STORE\_TOPOLOGY is only used at a network node and safely stores topology information that can be later accessed if the node is restarted. The **restore** flag is used to indicate whether information is being stored (AP\_NO) or accessed (AP\_YES).

The store node information is returned as a formatted list. To obtain information about a specific network node or to obtain the list information in several chunks, the **index** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered on the **index\_node\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). Next, the list is ordered on **index\_node\_type** by numeric value. If TGs are being stored or restored, ordering is on **index.tg\_dest\_node\_name** (MIB ordering), then **index.tg\_dest\_node\_type** (by numeric value), and thirdly on **index.tg\_number** (by numeric value).

SAFE\_STORE\_TOPOLOGY verb supercedes the SFS\_ADJACENT\_NN, SFS\_NN\_TOPOLOGY\_NODE and SFS\_NN\_TOPOLOGY\_TG verbs. It stores topology information using control vectors as they appear in the topology, instead of translating to and from query overlays. Unknown control vectors are stored and restored, and a checksum is provided to prevent corrupt data from being introduced into the topology.

# VCB Structure

```
typedef struct safe store topology
                                                  /* verb operation code
         unsigned short opcode;
                                                                                            */

} SAFE_STORE_TG_DATA;
```

## **Supplied Parameters**

Supplied Parameters when restore = AP\_NO

The application supplies the following parameters:

#### opcode

AP\_SAFE\_STORE\_TOPOLOGY

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information. The **resource\_types** and **index** specified (see the following parameters, **resource\_types** and **index**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

### resource\_types

This bit field controls the topology data to be stored. Any combination of the following values may be bit-wise ORed together in this field:

## AP\_SFS\_NODES

Store topology nodes

AP\_SFS\_ADJ\_NODES

Store adjacent nodes

## AP\_SFS\_TGS

Store TGs

**Note:** At least one of these three flags must be set. Adjacent nodes and topology nodes are separate entities within APPN, so the first two flags can be set in any combination.

#### index.node\_name

Network qualified node name from the Network Topology Database. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST. This field is also ignored if neither AP\_SFS\_NODES nor AP\_SFS\_ADJ\_NODES is set in **resource\_types**.

## index.node\_type

Type of the node. This node is set to one of the following:

AP\_NETWORK\_NODE AP\_VRN AP\_LEARN\_NODE

If the **node\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST. This field is also ignored if neither AP\_SFS\_NODES nor AP\_SFS\_ADJ is set in **resource\_types**.

## index.tg\_dest\_node\_name

Fully qualified destination node name for the TG. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST. This field is also ignored if neither AP\_SFS\_NODES nor AP\_SFS\_ADJ\_NODES is set in **resource\_types**.

### index.tg\_dest\_node\_type

Type of the destiation node for this TG. This node is set to one of the following:

AP\_NETWORK\_NODE AP\_VRN

If the **tg\_dest\_node\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST. This field is also ignored if neither AP\_SFS\_TGS is not set in **resource\_types**.

#### index.tg\_number

The number associated with the TG. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST. This field is also ignored if neither AP\_SFS\_TGS is not set in **resource\_types**.

**frsn** Flow Reduction Sequence Number (FRSN). If this is nonzero, then only topology resources with a FRSN greater than or equal to this value is returned.

### safe\_store\_data.overlay\_size

The length of this entry, including any padding. This is the offset to the next SAFE\_STORE\_DATA overlay, if any.

#### safe\_store\_data.sub\_overlay\_size

The length of this entry, including any padding. This is the offset to the appended SAFE\_STORE\_DATA or SAFE\_STORE\_TG\_DATA. This field should always be used when accessing the appended data.

## safe\_store\_data.index

The index for this entry. This structure can be supplied on subsequent SAFE\_STORE\_TOPOLOGY verbs to list subsequent entries. If **dest\_tg\_name** is set to all binary zeros, a SAFE\_STORE\_NODE\_DATA overlay follows. Otherwise, a SAFE\_STORE\_TG\_DATA overlay follows.

## safe\_store\_data.checksum

The 128–bit checksum for the appended overlay and vectors. If this checksum and the following data becomes corrupted, it is highly probable that the corruption is detected and the verb is rejected.

#### safe\_store\_node\_data.overlay\_size

The length of this entry, including any padding. This is the offset to the appended SAFE\_STORE\_DATA or SAFE\_STORE\_TG\_DATA.

### safe\_store\_node\_data.sub\_overlay\_size

The length of this entry, including any padding. This is the offset to the appended SAFE\_STORE\_DATA or SAFE\_STORE\_TG\_DATA. This field should always be used to access the appended vectors.

### safe\_store\_node\_data.adjacent

AP\_YES or AP\_NO. If AP\_YES, this entry corresponds to an adjacent Network Node.

#### safe\_store\_node\_data.last\_frsn\_sent

If **adjacent** is set to AP\_YES, this field holds the last FRSN sent to the adjacent Network Node. Otherwise, this field is set to zero.

## safe\_store\_node\_data.last\_frsn\_rcvd

If **adjacent** is set to AP\_YES, this field holds the last FRSN sent to the adjacent Network Node. Otherwise, this field is set to zero.

### safe\_store\_node\_data.frsn

The Flow Reduction Sequence Number for this topology resource, if this node appears in the topology. Otherwise, this field is set to zero.

#### safe\_store\_node\_data.days\_left

The number of days this node remains in the topology database before being removed, unless its existence is can be confirmed. Zero signifies no limit.

#### safe\_store\_node\_data.vector\_len

The length of appended vectors. Zero signifies no vectors are appended.

#### safe\_store\_tg\_data.overlay\_size

The length of this entry, including any padding. This is the offset to the appended SAFE\_STORE\_DATA or SAFE\_STORE\_TG\_DATA.

## safe\_store\_tg\_data.sub\_overlay\_size

The length of this entry, including any padding. This is the offset to the appended vectors, if there are any. This field should always be used to accessed appended vectors.

## safe\_store\_tg\_data.frsn

The Flow Reduction Sequence Number for this TG.

#### safe\_store\_tg\_data.days\_left

The number of days this TG remains in the topology database before being removed, unless its existence is can be confirmed. Zero signifies no limit.

#### safe\_store\_tg\_data.vector\_len

The length of appended vectors. Zero signifies no vectors are appended.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### num\_entries

The number of entries actually returned.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_LIST\_OPTION

AP\_INVALID\_NODE AP\_INVALID\_RESOURCE\_TYPES AP\_INVALID\_TG

## **Supplied Parameters**

Supplied Parameters when restore = AP\_YES

The application supplies the following parameters:

opcode

AP\_SAFE\_STORE\_TOPOLOGY

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

## resource\_types

This bit field controls the topology data to be stored. Any combination of the following values may be bit-wise ORed together in this field:

## AP\_SFS\_NODES

Restore topology nodes

## AP\_SFS\_ADJ\_NODES

Restore adjacent nodes

## AP\_SFS\_TGS

Restore TGs

**Note:** At least one of these three flags must be set. Adjacent nodes and topology nodes are separate entities within APPN, so the first two flags can be set in any combination.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

primary\_rc AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameter:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_CHECKSUM\_FAILED

AP\_DATA\_CORRUPT AP\_INVALID\_RESOURCE\_TYPES

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameter:

#### primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the system has not been built with Network Node support, the Program returns the following parameter:

## primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the Node has not yet been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## SFS\_ADJACENT\_NN

**Note:** This verb has been superceded by SAFE\_STORE\_TOPOLOGY and is only retained for compatibility with previous versions of the Program.

SFS\_ADJACENT\_NN is used to safely store topology information that can be later accessed if the node is restarted. The **restore** flag is used to indicate whether information is being stored (AP\_NO) or accessed (AP\_YES).

When the **restore** flag is set to AP\_NO, SFS\_ADJACENT\_NN returns information about adjacent network nodes (that is, those network nodes which CP-CP sessions are active, have been active, or have been active at some time).

The SFS information is returned as a formatted list. To obtain information about a specific network node or to obtain the list information in several chunks, the **adj\_nncp\_name** field should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is ordered on the **adj\_nncp\_name**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). If AP\_LIST\_FROM\_NEXT is selected, the list starts from the next entry according to the defined ordering (whether the specified entry exists or not).

## VCB Structure

typedef struct sfs adjacent nn /\* verb operation code unsigned short opcode; \*/ unsigned char reserv2; /\* reserved \*/ unsigned char format; /\* format \*/ /\* primary return code unsigned short primary rc; \*/ /\* secondary return code unsigned long secondary\_rc; \*/ unsigned char \*buf ptr; /\* pointer to buffer \*/ /\* buffer size unsigned long buf size; \*/ unsigned long total buf size; /\* total buffer size required \*/ /\* to hold all information \*/ /\* number of entries \*/ unsigned short num entries; unsigned short total num entries; /\* total number of entries \*/ list\_options; unsigned char /\* listing options \*/ unsigned char restore; /\* store or restore; \*/ unsigned char adj nncp name[17]; /\* CP name of adj Network Node \*/ } SFS ADJACENT NN; typedef struct adj nncp data /\* size of this entry unsigned short overlay size; \*/ unsigned char adj nncp name[17]; /\* CP name of adj Network Node \*/ unsigned char cp\_cp\_sess\_status; /\* CP-CP session status \*/ unsigned COUNTER out of seq tdus; /\* out of sequence TDUs \*/ last frsn sent; unsigned long /\* last FSRN sent \*/ unsigned long last frsn rcvd; /\* last FRSN received \*/ unsigned char reserva[20]; /\* reserved } ADJ\_NNCP\_DATA;

## **Supplied Parameters**

### Supplied Parameters when restore = AP\_NO

The application supplies the following parameters:

## opcode

AP\_SFS\_ADJACENT\_NN

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information. The **adj\_nncp\_name** specified (see the following parameter, **adj\_nncp\_name**) represents an index value that is used to specify the starting point of the actual information to be returned.

### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

## AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

#### adj\_nncp\_name

Fully-qualified, 17 byte, CP name of the adjacent network node composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### num\_entries

The number of entries actually returned.

### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## adj\_nncp\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

## adj\_nncp\_data.adj\_nncp\_name

This is a 17-byte fully-qualified CP name of adjacent network node which is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### adj\_nncp\_data.cp\_cp\_sess\_status

Status of the CP-CP session (AP\_ACTIVE or AP\_INACTIVE).

#### adj\_nncp\_data.out\_of\_seq\_tdus

Number of out of sequence TDUs received from this node.

## adj\_nncp\_data.last\_frsn\_sent

The last flow reduction sequence number sent to this node.

#### adj\_nncp\_data.last\_frsn\_rcvd

The last flow reduction sequence number received from this node.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_OK

## secondary\_rc

AP\_INVALID\_ADJ\_NNCP\_NAME

AP\_INVALID\_LIST\_OPTION

## Supplied Parameters

## Supplied Parameters when restore = AP\_YES

The application supplies the following parameters:

### opcode

AP\_SFS\_ADJACENT\_NN

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### num\_entries

The number of entries actually returned.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

#### adj\_nncp\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### adj\_nncp\_data.adj\_nncp\_name

This is a 17-byte fully-qualified CP name of adjacent network node which is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### adj\_nncp\_data.cp\_cp\_sess\_status

This field is ignored when **restore** is set to AP\_YES.

## adj\_nncp\_data.out\_of\_seq\_tdus

This field is ignored when **restore** is set to AP\_YES.

#### adj\_nncp\_data.last\_frsn\_sent

The last flow reduction sequence number sent to this node.

#### adj\_nncp\_data.last\_frsn\_rcvd

The last flow reduction sequence number received from this node.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

primary\_rc AP\_OK

If the verb does not execute because the node has not been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because one or more of the relevant START\_NODE parameters were not sent, the Program returns the following parameter:

#### primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the system is not built with network node support, the Program returns the following parameter:

#### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## SFS\_DIRECTORY

In addition to the QUERY\_DIRECTORY\_ENTRY verb, there is the SFS\_DIRECTORY verb that allows the local directory cache on a network node to be safely stored and can be later accessed if the node is restarted. The **restore** flag is used to indicate whether information is being stored (AP\_NO) or accessed (AP\_YES).

When the **restore** flag is set to AP\_YES, SFS\_DIRECTORY allows the directory database to be rebuilt using **directory\_entry\_summary** overlays. To obtain information about a specific network node or to obtain the list information in several chunks, the **resource\_name** and **resource\_type** fields should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

Resource information on the cached entries and their parents is returned in the following order:

1st Network Node

1st LU located at Network Node 2nd LU locate at Network Node

nth LU located at Network Node 1st End Node served by this Network Node 1st LU located at End Node(1) 2nd LU located at End Node(1) ...

nth LU located at End Node(1)

nth End Node served by this Network Node 1st LU located at End Node(n) 2nd LU located at End Node(n)

...

2nd Network Node ...etc..

## VCB Structure

## **Supplied Parameters**

#### Supplied Parameters when restore = AP\_NO

The application supplies the following parameters:

#### opcode

AP\_SFS\_DIRECTORY

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information. The **resource\_name** and **resource\_type** specified (see the following parameters, **resource\_name** and **resource\_type**) represents an index value that is used to specify the starting point of the actual information to be returned.

#### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

#### resource\_name

Network qualified resource name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composes of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### resource\_type

Resource type. See one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE

This field is ignored if list\_options is set to AP\_FIRST\_IN\_LIST.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## buf\_size

Length of the information returned in the buffer.

## total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

## total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

## num\_entries

The number of entries actually returned.

## directory\_entry\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

### directory\_entry\_summary.resource\_name

Network qualified resource name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composes of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

## directory\_entry\_summary.resource\_type

Resource type. See one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_RES\_NAME

AP\_INVALID\_LIST\_OPTION AP\_INVALID\_RES\_TYPE

## directory\_entry\_summary.real\_owning\_cp\_type

NN and BrNN only: Real owning CP type. This can be one of the following:

AP\_NONE

The real owning CP is a parent resource.

## AP\_ENCP\_RESOURCE

The real owning CP is not the parent resource and is an EN.

Other node types: This field is set to AP\_NONE.

### directory\_entry\_summary.real\_owning\_cp\_name

NN and BrNN only: Fully qualified real owning CP name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If the real owning CP is the parent, this field is set to binary zeroes.

If the real owning CP is not the parent, then this field is set to the name of the real owning CP.

The real owning CP is not the parent in the directory of the NNS of a BrNN if the resource is owned by an EN in the domain of the BrNN. In this case, the real owning CP is the EN, but the parent is the BrNN.

Other node types: This field is set to binary zeroes.

## Supplied Parameters

#### Supplied Parameters when restore = AP\_YES

The application supplies the following parameters:

#### opcode

AP\_SFS\_DIRECTORY

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

## buf\_size

Size of the buffer supplied.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

#### resource\_name

Network qualified resource name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composes of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the application is restoring the first "chunk" of the directory, then this should be set to all zeros. Otherwise, the application should set this to the resource name of the last item in the previous "chunk".

#### resource\_type

Resource type. See one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE

This field should be set to zero if the application is restoring the first "chunk" of the directory.

## directory\_entry\_summary.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any). This must be the same as the **overlay\_size** value returned when **restore** is set to AP\_NO.

## directory\_entry\_summary.resource\_name

Network qualified resource name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composes of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## directory\_entry\_summary.resource\_type

Resource type. See one of the following:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE

## directory\_entry\_summary.real\_owning\_cp\_type

NN and BrNN only: Real owning CP type. This can be one of the following:

## AP\_NONE

The real owning CP is a parent resource.

## AP\_ENCP\_RESOURCE

The real owning CP is not the parent resource and is an EN.

Other node types: This field is set to AP\_NONE.

## directory\_entry\_summary.real\_owning\_cp\_name

NN and BrNN only: Fully qualified real owning CP name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

If the real owning CP is the parent, this field is set to binary zeroes.

If the real owning CP is not the parent, then this field is set to the name of the real owning CP.

The real owning CP is not the parent in the directory of the NNS of a BrNN if the resource is owned by an EN in the domain of the BrNN. In this case, the real owning CP is the EN, but the parent is the BrNN.

Other node types: This field is set to binary zeroes.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_RES\_NAME

AP\_INVALID\_LIST\_OPTION

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameter:

## primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the system is not built with network node support, the Program returns the following parameter:

### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the Node has not been started, the Program returns the following parameter:

## primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## SFS\_NN\_TOPOLOGY\_NODE

**Note:** This verb has been superceded by SAFE\_STORE\_TOPOLOGY and is only retained for compatibility with previous versions of the Program.

Each network node maintains a network topology database that holds information about all network nodes, VRNs, and network node to network node TGs in the network. The SFS\_NN\_TOPOLOGY\_NODE verb is used to safely store the topology database node entries that can be later accessed if the node is restarted. The **restore** flag is used to indicate whether information is being stored (AP\_NO) or accessed (AP\_YES).

To obtain information about a specific network node or to obtain the list information in several chunks, the **node\_name** and **node\_type** fields should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is by **node\_name**, and **node\_name\_type**, and **frsn**. Ordering is by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). Ordering for the **node\_type** is AP\_NETWORK\_NODE, then AP\_VRN. The **frsn** is ordered numerically.

- If AP\_LIST\_INCLUSIVE is selected, the returned list starts from the first valid record of that name.
- If AP\_LIST\_FROM\_NEXT is selected, the list will begin from the first valid record with a name following the one specified.

Note that if the **frsn** field is set to a nonzero value, only database entries with Flow Reduction Sequence Number (FRSNs) higher than this are returned. This allows a consistent topology database to be returned in a number of chunks by first getting the node's current FRSN. This works as follows:

- 1. Issue QUERY\_NODE that returns the node's current FRSN.
- 2. Issue as many SFS\_NN\_TOPOLOGY\_NODE (with FRSN set to zero) as necessary to get all the database entries in chunks.
- **3**. Issue QUERY\_NODE again and compare the new FRSN with the one returned in stage one.
- 4. If the two FRSNs are different then what has changed in the database, issue a SFS\_NN\_TOPOLOGY\_NODE with the FRSN set to one greater than the FRSN supplied in stage one.

## VCB Structure

typedef struct sfs\_nn\_topology\_node

```
/* verb operation code
/* reserved
unsigned short opcode;
                                                                */
unsigned char reserv2;
                                                                */
                                /* format
unsigned char format;

## **Supplied Parameters**

Supplied Parameters when restore = AP\_NO

The application supplies the following parameters:

#### opcode

AP\_SFS\_NN\_TOPOLOGY\_NODE

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information. The **node\_name**, **node\_types** and **frsn** specified (see the following parameters, **node\_name**, **node\_types** and **frsn**) represents an index value that is used to specify the starting point of the actual information to be returned.

### AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

## AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

#### node\_name

Network qualified node name from the Network Topology Database. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### node\_type

Type of the node. This node is set to one of the following:

AP\_NETWORK\_NODE AP\_VRN

If the **node\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

**frsn** Flow Reduction Sequence Number. If this is nonzero, then only topology resources with a FRSN greater than or equal to this value is returned.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### num\_entries

The number of entries actually returned.

#### nn\_topology\_node\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### nn\_topology\_node\_detail.node\_name

Network qualified node name from the Network Topology Database. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### nn\_topology\_node\_detail.node\_type

Type of the node. It is one of the following:

## AP\_NETWORK\_NODE

AP\_VRN

## nn\_topology\_node\_detail.days\_left

Number of days before deletion of this node entry from the topology database. This will be set to zero for the local node entry (this entry is never deleted). This must be set to zero when the record is restored (for example, **restore** is set to AP\_YES).

## nn\_topology\_node\_detail.frsn

The Flow Reduction Sequence Number. This indicates the last time that the resource was updated at the local node.

#### nn\_topology\_node\_detail.rsn

The Resource Sequence Number. This is assigned by the network node that owns this resource.

### nn\_topology\_node\_detail.rar

The network node's route additional resistance.

## nn\_topology\_node\_detail.status

This field specifies the status of the node and can be AP\_UNCONGESTED or one or more of the following ORed together:

## **AP\_CONGESTED**

The number of ISR sessions is greater than the **isr\_sessions\_upper\_threshold** specified on the START\_NODE verb.

## AP\_IRR\_DEPLETED

The number of ISR sessions has reached the maximum specified on the **max\_isr\_sessions** parameter of the START\_NODE verb.

#### AP\_ERR\_DEPLETED

The number of endpoint sessions has reached the maximum specified.

## **AP\_QUIESCING**

A STOP\_NODE of type AP\_QUIENCE or AP\_QUIENCE\_ISR was issued.

## nn\_topology\_node\_detail.function\_support

This field specifies which functions are supported. This can be one or more of the following:

## AP\_BORDER\_NODE

Border Node Function is supported.

## AP\_CDS

The Central Directory Server is supported.

## **AP\_GATEWAY**

The node is a Gateway Node (the function is not yet architecturally defined).

## AP\_ISR

This node supports the Intermediate Session Routing.

## AP\_HPR

This node supports the Intermediate Session Routing.

## AP\_RTP\_TOWER

This node supports the RTP Tower of HPR.

### AP\_CONTROL\_OVER\_RTP\_TOWER

This node supports the Control Flows Over the RTP Tower.

**Note:** The AP\_CONTROL\_OVER\_RTP\_TOWER node corresponds to the setting of both AP\_HPR and AP\_RTP\_TOWER.

If the verb does not execute successfully, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_LIST\_OPTION

AP\_INVALID\_NODE AP\_INVALID\_LIST\_OPTIONS

## Supplied Parameters

## Supplied Parameters when restore = AP\_YES

The application supplies the following parameters:

#### opcode

AP\_SFS\_NN\_TOPOLOGY\_NODE

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

#### nn\_topology\_node\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### nn\_topology\_node\_detail.node\_name

Network qualified node name from the Network Topology Database. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### nn\_topology\_node\_detail.node\_type

Type of the node. It is one of the following:

## AP\_NETWORK\_NODE

AP\_VRN

## nn\_topology\_node\_detail.days\_left

Number of days before deletion of this node entry from the topology database. If the node is not the local node, this field must be set to a value greater than zero.

## nn\_topology\_node\_detail.frsn

The Flow Reduction Sequence Number. This indicates the last time that the resource was updated at the local node.

## nn\_topology\_node\_detail.rsn

The Resource Sequence Number. This is assigned by the network node that owns this resource.

## nn\_topology\_node\_detail.rar

The network node's route additional resistance.

#### nn\_topology\_node\_detail.status

This field specifies the status of the node and can be AP\_UNCONGESTED or one or more of the following ORed together:

## AP\_CONGESTED

The number of ISR sessions is greater than the **isr\_sessions\_upper\_threshold** specified on the START\_NODE verb.

## AP\_IRR\_DEPLETED

The number of ISR sessions has reached the maximum specified on the **max\_isr\_sessions** parameter of the START\_NODE verb.

## AP\_ERR\_DEPLETED

The number of endpoint sessions has reached the maximum specified.

## AP\_QUIESCING

A STOP\_NODE of type AP\_QUIENCE or AP\_QUIENCE\_ISR was issued.

### nn\_topology\_node\_detail.function\_support

This field specifies which functions are supported. This can be one or more of the following:

#### AP\_BORDER\_NODE

Border Node Function is supported.

#### AP\_CDS

The Central Directory Server is supported.

### **AP\_GATEWAY**

The node is a Gateway Node (the function is not yet architecturally defined).

#### AP\_ISR

This node supports the Intermediate Session Routing.

## AP\_HPR

This node supports the Intermediate Session Routing.

## AP\_RTP\_TOWER

This node supports the RTP Tower of HPR.

## AP\_CONTROL\_OVER\_RTP\_TOWER

This node supports the Control Flows Over the RTP Tower.

**Note:** The AP\_CONTROL\_OVER\_RTP\_TOWER node corresponds to the setting of both AP\_HPR and AP\_RTP\_TOWER.

#### node\_type

Type of the node. This node is set to one of the following:

AP\_NETWORK\_NODE AP\_VRN

If the **node\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

**frsn** Flow Reduction Sequence Number. If this is nonzero, then only topology resources with a FRSN greater than or equal to this value is returned.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

primary\_rc AP\_OK

```
secondary_rc
AP_INVALID_DAYS_LEFT
```

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_INVALID\_DAYS\_LEFT

If the verb does not execute because of a parameter error, the Program returns the following parameters:

```
primary_rc
```

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_DAYS\_LEFT

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameters:

## primary\_rc

```
AP_FUNCTION_NOT_SUPPORTED
```

secondary\_rc

AP\_INVALID\_DAYS\_LEFT

If the verb does not execute because the system was not build with network node support, the Program returns the following parameters:

### primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because of a system error, the Program returns the following parameters:

primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

## SFS\_NN\_TOPOLOGY\_TG

**Note:** This verb has been superceded by SAFE\_STORE\_TOPOLOGY and is only retained for compatibility with previous versions of the Program.

Each network node maintains a network topology database that holds information about all network nodes, VRNs, and network node to network node TGs in the network. The SFS\_NN\_TOPOLOGY\_TG verb is used to safely store the topology database node entries that can be later accessed if the node is restarted. The **restore** flag is used to indicate whether information is being stored (AP\_NO) or accessed (AP\_YES). The verb uses **topology\_tg\_detail** overlay.

To obtain information about a specific network node or to obtain the list information in several chunks, the **owner**, **owner\_type**, **dest**, **dest\_type**, and **tg\_num** fields should be set.

Otherwise (if the **list\_options** field is set to AP\_FIRST\_IN\_LIST), this field will be ignored. See "Querying the Node" on page 10 for background on how the list formats are used.

This list is by **owner, owner\_type, dest, dest\_type, tg\_num**, and **frsn**. The **owner\_type** and **dest** name are ordered by name length first, and then by ASCII lexicographical ordering for names of the same length (in accordance with IBM's 6611 APPN MIB ordering). The ordering for **owner\_type** and **dest** are: AP\_NETWORK\_NODE, then AP\_VRN. The **tg\_num** and **frsn** is ordered numerically.

- If AP\_LIST\_INCLUSIVE is selected, the returned list starts from the first valid record of that name.
- If AP\_LIST\_FROM\_NEXT is selected, the list will begin from the first valid record with a name following the one specified.

Note that if the **frsn** field is set to a nonzero value, only database entries with Flow Reduction Sequence Number (FRSNs) higher than this are returned. This allows a consistent topology database to be returned in a number of chunks by first getting the node's current FRSN. This works as follows:

- 1. Issue QUERY\_NODE that returns the node's current FRSN.
- 2. Issue as many SFS\_NN\_TOPOLOGY\_NODE (with FRSN set to zero) as necessary to get all the database entries in chunks.
- **3**. Issue QUERY\_NODE again and compare the new FRSN with the one returned in stage one.
- 4. If the two FRSNs are different then what has changed in the database, issue a SFS\_NN\_TOPOLOGY\_NODE with the FRSN set to one greater than the FRSN supplied in stage one.

## Supplied Parameters

## Supplied Parameters when restore = AP\_NO

The application supplies the following parameters:

### opcode

AP\_SFS\_NN\_TOPOLOGY\_TG

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

## num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### list\_options

This indicates what should be returned in the list information. The **owner**,

**owner\_type**, **dest**, **dest\_type**, **tg\_num**, and **frsn** specified (see the following parameters, **owner**, **owner\_type**, **dest**, **dest\_type**, **tg\_num**, and **frsn**) represents an index value that is used to specify the starting point of the actual information to be returned.

## AP\_FIRST\_IN\_LIST

The index value is ignored, and the returned list starts from the first entry in the list.

### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

**owner** Name of the TG's originating node (always set to the local node name). This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### owner\_type

Type of the node. This node is set to one of the following:

AP\_NETWORK\_NODE AP\_VRN

If the **owner\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

**dest** Fully qualified destination node name for the TG. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

## dest\_type

Type of the node. This node is set to one of the following:

AP\_NETWORK\_NODE AP\_VRN

If the **dest\_type** is unknown, AP\_LEARN\_NODE must be specified. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

#### tg\_num

Number associated with the TG. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

**frsn** Flow Reduction Sequence Number. If this is nonzero, then only topology resources with a FRSN greater than or equal to this value is returned.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

#### buf\_size

Length of the information returned in the buffer.

#### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This can be higher than **buf\_size**.

## num\_entries

The number of entries actually returned.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

#### nn\_topology\_tg\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### nn\_topology\_detail.owner

Name of the TG's originating node. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## nn\_topology\_tg\_detail.owner\_type

Type of the node. It is one of the following:

AP\_NETWORK\_NODE AP\_VRN

#### nn\_topology\_tg\_detail.dest

Fully qualified destination node name for the TG. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

### nn\_topology\_tg\_detail.dest\_type

Type of the node. It is one of the following:

AP\_NETWORK\_NODE AP\_VRN

## nn\_topology\_tg\_detail.tg\_num

The number associated with the TG.

#### nn\_topology\_tg\_detail.frsn

The Flow Reduction Sequence Number. This indicates the last time that the resource was updated at the local node.

### nn\_topology\_tg\_detail.days\_left

The number of days this node remains in the topology database before

being removed, unless its existence is can be confirmed. If the node specified by the **owner** field is not the local node, this field must be set to a value greater than zero.

nn\_topology\_tg\_detail.dlc\_data.length The address length.

nn\_topology\_tg\_detail.dlc\_data.address The address.

## nn\_topology\_tg\_detail.rsn

The Resource Sequence Number. This is assigned by the network node that owns this resource.

## nn\_topology\_tg\_detail.status

This field specifies the status of the TG. This can be one or more of the following ORed together:

## AP\_TG\_OPERATIVE

AP\_TG\_CP\_CP\_SESSIONS AP\_TG\_QUIESCING AP\_TG\_HPR AP\_TG\_RTP AP\_NONE

## nn\_topology\_tg\_detail.tg\_chars

The TG characteristics. See "DEFINE\_CN" on page 31 for additional information.

## **Returned Parameters**

If the verb does not execute successfully because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_TG

AP\_INVALID\_ORIGIN\_NODE AP\_INVALID\_LIST\_OPTION

If the verb does not execute successfully, the Program returns the following parameters:

primary\_rc AP\_OK

## **Supplied Parameters**

Supplied Parameters when restore = AP\_YES

This application supplies the following parameters:

## opcode

AP\_SFS\_NN\_TOPOLOGY\_TG

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer where list information can be written. The application can append data to the end of the VCB, in which case **buf\_ptr** must be set to NULL.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

#### buf\_size

Length of the information returned in the buffer.

#### restore

Flag indicating whether the information should be restored (AP\_YES) or stored (AP\_NO). In this case, it is set to AP\_NO.

#### total\_num\_entries

Total number of entries that could have been returned. This can be higher than **num\_entries**.

### nn\_topology\_tg\_detail.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any). This must be the same as the **overlay\_size** value returned when **restore** = AP\_NO.

#### nn\_topology\_detail.owner

Name of the TG's originating node. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## nn\_topology\_tg\_detail.owner\_type

Type of the node that owns the TG. It is one of the following:

AP\_NETWORK\_NODE AP\_VRN

#### nn\_topology\_tg\_detail.dest

Fully qualified destination node name for the TG. This name is a 17-byte adjacent control point name, which is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only relevant for links to APPN nodes and is otherwise ignored. This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

### nn\_topology\_tg\_detail.dest\_type

Type of the node. It is one of the following:

AP\_NETWORK\_NODE AP\_VRN

## nn\_topology\_tg\_detail.tg\_num

The number associated with the TG.

#### nn\_topology\_tg\_detail.frsn

The Flow Reduction Sequence Number. This indicates the last time that the resource was updated at the local node.

#### nn\_topology\_tg\_detail.days\_left

The number of days this node remains in the topology database before

being removed, unless its existence is can be confirmed. If the node specified by the **owner** field is not the local node, this field must be set to a value greater than zero.

nn\_topology\_tg\_detail.dlc\_data.length The address length.

nn\_topology\_tg\_detail.dlc\_data.address The address.

## nn\_topology\_tg\_detail.rsn

The Resource Sequence Number. This is assigned by the network node that owns this resource.

## nn\_topology\_tg\_detail.status

This field specifies the status of the TG. This can be one or more of the following ORed together:

## AP\_TG\_OPERATIVE

AP\_TG\_CP\_CP\_SESSIONS AP\_TG\_QUIESCING AP\_TG\_HPR AP\_TG\_RTP AP\_NONE

## nn\_topology\_tg\_detail.tg\_chars

The TG characteristics. See "DEFINE\_CN" on page 31 for additional information.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

## secondary\_rc

AP\_INVALID\_DAYS\_LEFT

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameter:

## primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the system was not built with the network node support, the Program returns the following parameter:

## primary\_rc

AP\_INVALID\_VERB

If the verb does not execute because the node has not been started, the Program returns the following parameter:

primary\_rc AP\_NODE\_NOT\_STARTED

## SFS\_NN\_TOPOLOGY\_TG

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc

AP\_UNEXPECTED\_SYSYEM\_ERROR

# Chapter 8. Session Limit Verbs

This chapter describes verbs used to initialize, change, or reset session limits.

## CHANGE\_SESSION\_LIMIT

The CHANGE\_SESSION\_LIMIT verb requests that the session limits of a particular mode (or session group) be changed. Sessions can be activated or deactivated as a result of processing this verb.

## VCB Structure

```
typedef struct change session limit

                           sense data;
                                                        /* sense data
                                                                                                   */
} CHANGE SESSION LIMIT;
```

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_CHANGE\_SESSION\_LIMIT

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU requested to change session limits. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Alias of the local LU requested to change session limits. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** fields are set to all zeros then the verb is forwarded to the LU associated with the control point (the default LU).

### plu\_alias

Alias by which the partner LU is known to the local LU. This name must match the name of a partner LU established during configuration. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field is used to specify the required partner LU.

#### fqplu\_name

Fully qualified LU name for the partner LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only significant if the **plu\_alias** field is set to all zeros.

#### mode\_name

Name of a set of networking characteristics defined during configuration. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

SNASVCMG and CPSVCMG mode limits cannot be changed. **Set\_negotiable** specifies whether the maximum negotiable session limit for this mode should be modified to become the **plu\_mode\_session\_limit**.

## set\_negotiable

Specifies whether the maximum negotiable session limit for this mode should be modified to become the **plu\_mode\_session\_limit**.

AP\_YES AP\_NO

## plu\_mode\_session\_limit

Requested total session limit for this mode. The actual session limit (which can be negotiated with the partner LU), is the agreed maximum number of sessions supported between the local LU and the partner LU on this mode.

### min\_conwinners\_source

Minimum number of sessions in this mode for which the local LU is the contention winner.

## min\_conwinners\_target

Minimum number of sessions in this mode for which the partner LU is the contention winner.

#### auto\_act

Number of sessions to automatically activate after the session limit is changed. The actual number of automatically activated sessions is the minimum of this value and the negotiated minimum number of contention winner sessions for the local LU. When sessions are deactivated normally (specifying AP\_DEACT\_NORMAL) below this limit, new sessions are activated up to this limit.

## responsible

Indicates whether the source (local) or target (partner) LU is responsible for deactivating sessions after the session limit is changed (AP\_SOURCE or AP\_TARGET).

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

primary\_rc AP\_OK

secondary\_rc AP\_AS\_SPECIFIED

AP\_AS\_NEGOTIATED

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_LU\_MODE\_SESSION\_LIMIT\_ZERO

AP\_EXCEEDS\_MAX\_ALLOWED AP\_INVALID\_MODE\_NAME AP\_INVALID\_PLU\_NAME AP\_INVALID\_RESPONSIBLE AP\_INVALID\_SET\_NEGOTIABLE AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS

If the verb does not execute because of a state error, the Program returns the following parameters:

## primary\_rc

AP\_STATE\_CHECK

secondary\_rc AP\_MODE\_RESET

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of an allocation error, the Program returns the following parameters:

#### primary\_rc

AP\_ALLOCATION\_ERROR

#### secondary\_rc

AP\_ALLOCATION\_FAILURE\_NO\_RETRY

#### sense\_data

Sense data associated with allocation error.

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

If the verb does not execute because of an error, the Program returns the following parameters:

primary\_rc

AP\_CONV\_FAILURE\_NO\_RETRY AP\_CNOS\_PARTNER\_LU\_REJECT

secondary\_rc

AP\_CNOS\_COMMAND\_RACE\_REJECT

AP\_CNOS\_MODE\_NAME\_REJECT

## INITIALIZE\_SESSION\_LIMIT

The INITIALIZE\_SESSION\_LIMIT verb initializes the mode session limits.

## VCB Structure

```
typedef struct initialize_session_limit
   unsigned short opcode;
                                        /* verb operation code
                                                                     */
  unsigned char
                  reserv2;
                                        /* reserved
                                       /* format
  unsigned char
                  format;

                                                                     */
} INITIALIZE SESSION LIMIT;
```

## Supplied Parameters

The application supplies the following parameters:

#### opcode

AP\_INITIALIZE\_SESSION\_LIMIT

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### lu\_name

LU name of the local LU requested to initialize session limits. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Alias of the local LU requested to initialize session limits. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and **lu\_alias** are set to all zeros, the verb is forwarded to the LU associated with the control point (the default LU).

#### plu\_alias

Alias by which the partner LU is known to the local LU. This name must match the name of a partner LU established during configuration. This is an 8-byte string in a locally displayable character set. All 8 bytes are

significant and must be set. If this field is set to all zeros, the **fqplu\_name** field is used to specify the required partner LU.

#### fqplu\_name

Fully qualified LU name for the partner LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only significant if the **plu\_alias** field is set to all zeros.

#### mode\_name

Name of a set of networking characteristics defined during configuration. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

This verb is rejected if one of the mode names SNASVCMG or CPSVCMG is supplied in this field and limits take values other than plu\_mode\_session\_limit 2, min\_conwinners\_source 1, and min\_conwinners target 1.

## set\_negotiable

Specifies whether the maximum negotiable session limit for this mode should be modified to become the **plu\_mode\_session\_limit**.

AP\_YES AP\_NO

#### plu\_mode\_session\_limit

Requested total session limit for this mode. The actual session limit (which can be negotiated with the partner LU), is the agreed maximum number of sessions supported between the local LU and the partner LU on this mode. This must be set to a value in the range one to 32 767.

## min\_conwinners\_source

Minimum number of sessions in this mode for which the local LU is the contention winner. This must be set to a value in the range zero to 32 767.

### min\_conwinners\_target

Minimum number of sessions in this mode for which the partner LU is the contention winner. This must be set to a value in the range zero to 32 767.

### auto\_act

Number of sessions to automatically activate after the session limit is changed. The actual number of automatically activated sessions is the minimum of this value and the negotiated minimum number of contention winner sessions for the local LU. When sessions are deactivated normally (specifying AP\_DEACT\_NORMAL) below this limit, new sessions are activated up to this limit. This must be set to a value in the range zero to 32 767.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

## secondary\_rc AP\_AS\_SPECIFIED

AP\_AS\_NEGOTIATED

## INITIALIZE\_SESSION\_LIMIT

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK secondary\_rc

AP\_CANT\_CHANGE\_TO\_ZERO

AP\_EXCEEDS\_MAX\_ALLOWED AP\_INVALID\_SET\_NEGOTIABLE AP\_INVALID\_PLU\_NAME AP\_INVALID\_MODE\_NAME AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS AP\_INVALID\_SCVMG\_LIMITS

If the verb does not execute because of a state error, the Program returns the following parameters:

### primary\_rc

AP\_STATE\_CHECK

#### secondary\_rc

AP\_MODE\_NOT\_RESET

If the verb does not execute because the node has not yet been started, the Program returns the following parameters:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of an allocation error, the Program returns the following parameters:

### primary\_rc

AP\_ALLOCATION\_ERROR

### secondary\_rc

AP\_ALLOCATION\_FAILURE\_NO\_RETRY

#### sense\_data

Sense data associated with allocation error.

If the verb does not execute because of a system error, the Program returns the following parameter:

## primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

If the verb does not execute because of an error, the Program returns the following parameters:

primary\_rc

AP\_CONV\_FAILURE\_NO\_RETRY AP\_CNOS\_PARTNER\_LU\_REJECT

secondary\_rc

AP\_CNOS\_COMMAND\_RACE\_REJECT

AP\_CNOS\_MODE\_NAME\_REJECT

## **RESET\_SESSION\_LIMIT**

The RESET\_SESSION\_LIMIT verb requests that the mode session limits be reset.

## VCB Structure

```
typedef struct reset_session_limit
```

1						
	unsigned	short	opcode;	/*	verb operation code	*/
	unsigned	char	reserv2;	/*	reserved	*/
	unsigned	char	format;	/*	format	*/
	unsigned	short	primary_rc;	/*	primary return code	*/
	unsigned	long	<pre>secondary_rc;</pre>	/*	secondary return code	*/
	unsigned	char	lu_name[8];	/*	local LU name	*/
	unsigned	char	lu_alias[8];	/*	local LU alias	*/
	unsigned	char	plu_alias[8];		partner LU alias	*/
	unsigned	char	fqplu_name[17];	/*	fully qual partner LU name	*/
	unsigned	char	reserv3;	/*	reserved	*/
	unsigned	char	<pre>mode_name[8];</pre>	/*	mode name	*/
	unsigned	char	<pre>mode_name_select;</pre>	/*	select mode name	*/
	unsigned	char	<pre>set_negotiable;</pre>	/*	set max negotiable limit?	*/
	unsigned	char	reserv4[8];	/*	reserved	*/
	unsigned	char	responsible;	/*	responsible	*/
	unsigned	char	drain_source;	/*	drain source	*/
	unsigned	char	drain_target;	/*	drain target	*/
	unsigned	char	force;	/*	force	*/
	unsigned	0	sense_data;	/*	sense data	*/
}	RESET_SESS	SION_LIM	4IT;			

## Supplied Parameters

The application supplies the following parameters:

#### opcode

AP\_RESET\_SESSION\_LIMIT

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU requested to reset session limits. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Alias of the local LU requested to reset session limits. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If this is set to all zeros, the verb is forwarded to the LU associated with the control point (the default LU).

## plu\_alias

Alias by which the partner LU is known to the local LU. This name must match the name of a partner LU established during configuration. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field is used to specify the required partner LU.

### fqplu\_name

Fully qualified LU name for the partner LU. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This field is only significant if the **plu\_alias** field is set to all zeros.

#### mode\_name

Name of a set of networking characteristics defined during configuration. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### mode\_name\_select

Selects whether session limits should be reset on a single specified mode, or on all modes between the local and partner LUs.

AP\_ONE AP\_ALL

## set\_negotiable

Specifies whether the maximum negotiable session limit for this mode should be modified.

AP\_YES AP\_NO

## responsible

Indicates whether the source (local) or target (partner) LU is responsible for deactivating sessions after the session limit is reset (AP\_SOURCE or AP\_TARGET).

## drain\_source

Specifies whether the source LU satisfies waiting session requests before deactivating a session when session limits are changed or reset (AP\_NO or AP\_YES).

#### drain\_target

Specifies whether the target LU satisfies waiting session requests before deactivating a session when session limits are changed or reset (AP\_NO or AP\_YES).

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

## primary\_rc

AP\_OK

secondary\_rc AP\_FORCED

> AP\_AS\_SPECIFIED AP\_AS\_NEGOTIATED

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

```
secondary_rc
```

AP\_EXCEEDS\_MAX\_ALLOWED

**force** Specifies whether session limits will be set to zero even if CNOS negotiation fails (AP\_YES or AP\_NO).

AP\_INVALID\_PLU\_NAME AP\_INVALID\_MODE\_NAME AP\_INVALID\_MODE\_NAME\_SELECT AP\_INVALID\_RESPONSIBLE AP\_INVALID\_DRAIN\_SOURCE AP\_INVALID\_DRAIN\_TARGET AP\_INVALID\_FORCE AP\_INVALID\_SET\_NEGOTIABLE AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS

If the verb does not execute because of a state error, the Program returns the following parameters:

```
primary_rc
AP_STATE_CHECK
secondary_rc
```

AP\_MODE\_RESET

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

#### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of an allocation error, the Program returns the following parameter:

## primary\_rc

AP\_ALLOCATION\_ERROR

### secondary\_rc

AP\_ALLOCATION\_FAILURE\_NO\_RETRY

### sense\_data

Sense data associated with allocation error.

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

If the verb does not execute because of an error, the Program returns the following parameters:

## primary\_rc

AP\_CONV\_FAILURE\_NO\_RETRY

### AP\_CNOS\_PARTNER\_LU\_REJECT

#### secondary\_rc

AP\_CNOS\_COMMAND\_RACE\_REJECT

## AP\_CNOS\_MODE\_NAME\_REJECT

## **RESET\_SESSION\_LIMIT**

# **Chapter 9. Node Operator Facility API Indications**

The Node Operator Facility API generates indication verbs to notify a node operator about changes in the node. Indication verbs use the following general structure:

<pre>typedef struct indication_hdr</pre>	
{	
unsigned short opcode;	<pre>/* verb operation code */</pre>
unsigned char reserv2;	/* reserved */
unsigned char format;	/* format */
unsigned short primary_rc;	<pre>/* primary return code */</pre>
unsigned long secondary rc;	/* secondary return code */
unsigned char data lost;	<pre>/* previous indication lost */</pre>
<pre>} INDICATION_HDR;</pre>	

## **DLC\_INDICATION**

This indication is generated when the DLC goes from active to inactive, or from inactive to active.

## VCB Structure

typedef struct dlc indication

```
{
    unsigned short opcode;    /* verb operation code    */
    unsigned char attributes;    /* verb attributes    */
    unsigned char format;    /* format    */
    unsigned short primary_rc;    /* primary return code    */
    unsigned long secondary_rc;    /* secondary return code    */
    unsigned char data_lost;    /* previous indication lost    */
    unsigned char deactivated;    /* has session been deactivated? */
    unsigned char dlc_name[8];    /* link station name    */
    unsigned char description[RD_LEN]; /* reserved    */
    unsigned char reserva[20];    /* reserved    */
} DLC INDICATION;
```

## **Parameters**

opcode

AP\_DLC\_INDICATION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### deactivated

Set to AP\_YES when the DLC becomes inactive. Set to AP\_NO when the DLC becomes active.

#### dlc\_name

Name of DLC. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### description

Resource description (as specified on DEFINE\_DLC). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## **DLUR\_LU\_INDICATION**

This indication is generated whenever a DLUR LU is activated or deactivated. This allows a registered application to maintain a list of currently active DLUR LUs.

## **VCB** Structure

```
typedef struct dlur lu indication
                                                /* verb operation code
/* reserved
   unsigned short opcode;
                                                                                                  */
   unsigned char tormat; /* format
unsigned short primary_rc; /* primary return code
unsigned long secondary_rc; /* secondary return code
unsigned char data_lost; /* previous indication long
   unsigned char reserv2;
                                                                                                  */
                                                                                                  */
                                                                                                  */
                                                                                                  */
*/
*/
*/
                                                  /* previous indication lost
   unsigned char reason;
                                                   /* reason for this indication
                                                   /* LU name
   unsigned char lu name[8];
                       _____ame[8];
nau_address;
reserv5[7]
                                                 /* PU name
   unsigned char pu name[8];
                                                 /* NAU address
                                                                                                  */
   unsigned char
                                                                                                  */
   unsigned char
                                                   /* reserved
} DLUR_LU_INDICATION;
```

## **Parameters**

```
opcode
```

AP\_DLUR\_LU\_INDICATION

format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

primary\_rc

AP\_OK

secondary\_rc Equals zero.

## data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

**reason** Set to AP\_ADDED if the DLUR LU has just been activated by the DLUS. Set to AP\_REMOVED if the DLUR LU has been deactivated, either explicitly by the DLUS or implicitly by a link failure or the deactivation of the PU.

## lu\_name

Name of the LU. This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### pu\_name

Name of the PU that this LU uses. This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### nau\_address

Network addressable unit address of the LU, which must be in the range 1–255.

## **DLUR\_PU\_INDICATION**

This indication is generated whenever a DLUR PU is activated or deactivated. This allows a registered application to maintain a list of currently active DLUR PUs.

## VCB Structure

typedef struct dlur\_pu\_indication

unsigned short	opcode;	/*	verb operation code	*/
unsigned char	reserv2;		reserved	*/
unsigned char	format;	/*	format	*/
unsigned short	primary_rc;	/*	primary return code	*/
unsigned long	secondary rc;		secondary return code	*/
unsigned char	data lost;	/*	previous indication lost	*/
unsigned char	reason;	/*	reason for this indication	*/
unsigned char	pu name[8];	/*	PU name	*/
unsigned char	pu id[4];	/*	PU identifier	*/
unsigned char	pu location;	/*	downstream or local PU	*/
unsigned char	pu status;	/*	status of the PU	*/
unsigned char	dlus name[17];	/*	current DLUS name	*/
unsigned char	dlus session status;	/*	status of the DLUS pipe	*/
unsigned char	reserv5[2];	/*	reserved	*/
DLUR_PU_INDICATI	ON;			

## **Parameters**

}

opcode

AP\_DLUR\_PU\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

## secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

reason The cause of the indication. It is one of the following:

## AP\_ACTIVATION\_STARTED

The PU is activating.

## AP\_ACTIVATING

The PU has become active.

## **AP\_DEACTIVATING**

The PU has become inactive.

#### **AP\_FAILED**

The PU has failed.

#### AP\_ACTIVATION\_FAILED

The PU has failed to activate.

#### pu\_name

Name of the PU. This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

pu\_id The PU identifier defined in a DEFINE\_INTERNAL\_PU verb or obtained in an XID from a downstream PU. This is a 4–byte hexadecimal string. Bits 0–11 are set to the block number and bits 12–31 are set to the ID number that uniquely identifies the PU.

#### pu\_location

The location of the PU. This can be one of the following:

### AP\_INTERNAL

AP\_DOWNSTREAM

#### pu\_status

The status of the PU (as seen by DLUR). This can be set to one of the following:

#### AP\_RESET\_NO\_RETRY

The PU is in reset state and will not be retried.

#### AP\_RESET\_RETRY

The PU is in reset state and be retried.

#### AP\_PEND\_ACTPU

The PU is waiting for an ACTPU from the host.

## AP\_PEND\_ACTPU\_RSP

After forwarding an ACTPU to the PU, DLUR is waiting for the PU to respond.

## AP\_ACTIVE

The PU is activate.

### AP\_PEND\_DACTPU\_RSP

After forwarding an DACTPU to the PU, DLUR is waiting for the PU to respond.

## AP\_PEND\_INOP

DLUR is waiting for all necessary events to complete before it deactivates the PU.

#### dlus\_name

The name of the DLUS node that the PU is currently using (or attempting to use). This is a 17–byte string composed of two type A EBCDIC character strings concatenated by an EBCDIC dot, that is right padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.) If the PU activation has failed, this field will be set to all zeros.

### dlus\_session\_status

The status of the DLUS pipe currently being used by the PU. This can be one of the following:

AP\_PENDING\_ACTIVE AP\_ACTIVE AP\_PENDING\_INACTIVE AP\_INACTIVE

## **DLUS\_INDICATION**

This indication is generated when a pipe to a DLUS node goes from inactive to active (or vice versa). Pipe statistics are supplied when the pipe becomes inactive.

## VCB Structure

typedef struct dlus indication unsigned short opcode; /\* verb operation code \*/ /\* reserved reserv2; unsigned char \*/ format; /\* format

## **Parameters**

#### opcode

AP\_DLUS\_INDICATION

## format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

### primary\_rc

AP\_OK

## secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication

to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

### deactivated

Set to AP\_YES when the pipe becomes inactive. Set to AP\_NO when the pipe becomes active.

#### dlus\_name

Name of the DLUS. This is a 17-byte string composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, which is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### pipe\_stats.reqactpu\_sent

Number of REQACTPUs sent to DLUS over the pipe.

#### pipe\_stats.reqactpu\_rsp\_received

Number of RSP(REQACTPU)s received from DLUS over the pipe.

#### pipe\_stats.actpu\_received

Number of ACTPUs received from DLUS over the pipe.

#### pipe\_stats.actpu\_rsp\_sent

Number of RSP(ACTPU)s sent to DLUS over the pipe.

#### pipe\_stats.reqdactpu\_sent

Number of REQDACTPUs sent to DLUS over the pipe.

#### pipe\_stats.reqdactpu\_rsp\_received

Number of RSP(REQDACTPU)s received from DLUS over the pipe.

### pipe\_stats.dactpu\_received

Number of DACTPUs received from DLUS over the pipe.

## pipe\_stats.dactpu\_rsp\_sent

Number of RSP(DACTPU)s sent to DLUS over the pipe.

#### pipe\_stats.actlu\_received

Number of ACTLUs received from DLUS over the pipe.

#### pipe\_stats.actlu\_rsp\_sent

Number of RSP(ACTLU)s sent to DLUS over the pipe.

#### pipe\_stats.dactlu\_received

Number of DACTLUs received from DLUS over the pipe.

#### pipe\_stats.dactlu\_rsp\_sent

Number of RSP(DACTLU)s sent to DLUS over the pipe.

## pipe\_stats.sscp\_pu\_mus\_rcvd

Number of SSCP-PU MUs received from DLUS over the pipe.

## pipe\_stats.sscp\_pu\_mus\_sent

Number of SSCP-PU MUs sent to DLUS over the pipe.

### pipe\_stats.sscp\_lu\_mus\_rcvd

Number of SSCP-LU MUs received from DLUS over the pipe.

## pipe\_stats.sscp\_lu\_mus\_sent

Number of SSCP-LU MUs sent to DLUS over the pipe.

## DOWNSTREAM\_LU\_INDICATION

This verb applies only to Communications Server.

This indication is generated when the LU-SSCP session between the downstream LU and the host goes from inactive to active (or vice-versa) or when the PLU-SLU session goes from inactive to active (or vice-versa). LU-SSCP statistics are supplied when the LU-SSCP session deactivates and PLU-SLU statistics are supplied when the PLU-SLU session deactivates.

### opcode

AP\_DOWNSTREAM\_LU\_INDICATION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

## primary\_rc

AP\_OK

### secondary\_rc

Equals zero.

## data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

## dspu\_name

Name of the downstream PU associated with the downstream LU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## ls\_name

Name of link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set.

#### dslu\_name

Name of the downstream LU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### description

Resource description (as specified on DEFINE\_DOWNSTREAM\_LU).

#### nau\_address

Network addressable unit address of the LU which must be in the range 1–255.

#### lu\_sscp\_sess\_active

Indicates whether the LU-SSCP session to the downstream LU is active. Set to either AP\_YES or AP\_NO.

#### plu\_sess\_active

Indicates whether the PLU-SLU session to the downstream LU is active. Set to either AP\_YES or AP\_NO.

#### dspu\_services

Specifies the services which the local node provides to the downstream LU across the link. This is set to one of the following.

## DOWNSTREAM\_LU\_INDICATION

AP\_PU\_CONCENTRATION Local node provides PU concentration for the downstream PU.

AP\_DLUR

Local node provides DLUR support for the downstream PU.

lu\_sscp\_stats.rcv\_ru\_size This field is always reserved.

lu\_sscp\_stats.send\_ru\_size This field is always reserved.

lu\_sscp\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

lu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

lu\_sscp\_stats.max\_send\_pac\_win This field will always be set to zero.

**lu\_sscp\_stats.cur\_send\_pac\_win** This field will always be set to zero.

lu\_sscp\_stats.max\_rcv\_pac\_win This field will always be set to zero.

**lu\_sscp\_stats.cur\_rcv\_pac\_win** This field will always be set to zero.

lu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.

lu\_sscp\_stats.send\_fmd\_data\_frames
 Number of normal flow FMD data frames sent.

lu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.

lu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.

lu\_sscp\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.

lu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.

lu\_sscp\_stats.sidh

Session ID high byte.

lu\_sscp\_stats.sidl

Session ID low byte.

#### lu\_sscp\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node containing the secondary link station.

lu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

**lu\_sscp\_stats.pacing\_type** Receive pacing type in use on the upstream LU-SSCP session. This will take the value AP\_NONE.

ds\_plu\_stats.rcv\_ru\_size Maximum receive RU size.

ds\_plu\_stats.send\_ru\_size Maximum send RU size.

ds\_plu\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

ds\_plu\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

- ds\_plu\_stats.max\_send\_pac\_win Maximum size of the send pacing window on this session.
- ds\_plu\_stats.cur\_send\_pac\_win Current size of the send pacing window on this session

ds\_plu\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session.

ds\_plu\_stats.cur\_rcv\_pac\_win Current size of the receive pacing window on this session.

ds\_plu\_stats.send\_data\_frames Number of normal flow data frames sent.

ds\_plu\_stats.send\_fmd\_data\_frames

Number of normal flow FMD data frames sent.

## ds\_plu\_stats.send\_data\_bytes

Number of normal flow data bytes sent.

- ds\_plu\_stats.rcv\_data\_frames Number of normal flow data frames received.
- ds\_plu\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.
- ds\_plu\_stats.rcv\_data\_bytes Number of normal flow data bytes received.
- ds\_plu\_stats.sidh

Session ID high byte.

ds\_plu\_stats.sidl

Session ID low byte.

## ds\_plu\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node containing the secondary link station.

## ds\_plu\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## ds\_plu\_sscp\_stats.pacing\_type

Receive pacing type in use on the downstream PLU-SLU session. This can be set to AP\_NONE or AP\_PACING\_FIXED.

## DOWNSTREAM\_LU\_INDICATION

- us\_plu\_stats.rcv\_ru\_size Maximum receive RU size.
- us\_plu\_stats.send\_ru\_size Maximum send RU size.
- us\_plu\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.
- us\_plu\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.
- us\_plu\_stats.max\_send\_pac\_win Maximum size of the send pacing window on this session.
- us\_plu\_stats.cur\_send\_pac\_win Current size of the send pacing window on this session
- us\_plu\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session.
- us\_plu\_stats.cur\_rcv\_pac\_win Current size of the receive pacing window on this session.
- us\_plu\_stats.send\_data\_frames Number of normal flow data frames sent.
- us\_plu\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.
- us\_plu\_stats.send\_data\_bytes Number of normal flow data bytes sent.
- us\_plu\_stats.rcv\_data\_frames Number of normal flow data frames received.
- us\_plu\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.
- us\_plu\_stats.rcv\_data\_bytes

Number of normal flow data bytes received.

us\_plu\_stats.sidh

Session ID high byte. This field is reserved if **dspu\_services** is set to AP\_PU\_CONCENTRATION.

us\_plu\_stats.sidl

Session ID low byte. This field is reserved if **dspu\_services** is set to AP\_PU\_CONCENTRATION.

us\_plu\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node containing the secondary link station. This field is reserved if **dspu\_services** is set to AP\_PU\_CONCENTRATION.

## us\_plu\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field is reserved if **dspu\_services** is set to AP\_PU\_CONCENTRATION.

us\_plu\_stats.pacing\_type

Receive pacing type in use on the upstream PLU-SLU session. This can take the values AP\_NONE or AP\_PACING\_FIXED.

## DOWNSTREAM\_PU\_INDICATION

This verb applies only to Communications Server.

This indication is generated when the PU-SSCP session between the downstream PU and the host goes from inactive to active (or vice-versa). PU-SSCP statistics are supplied when the PU-SSCP session deactivates.

## VCB Structure

typedef struct downstream\_pu\_indication

## **Parameters**

## opcode

## AP\_DOWNSTREAM\_PU\_INDICATION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

### primary\_rc

AP\_OK

## secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

### dspu\_name

Name of the downstream PU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### description

Resource description (as specified on DEFINE\_LS).

## ls\_name

Name of link station. This is a 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### pu\_sscp\_sess\_active

Indicates whether the PU-SSCP session to the downstream PU is active. Set to either AP\_YES or AP\_NO.

#### dspu\_services

Specifies the services which the local node provides to the downstream PU across the link. This is set to one of the following.

### AP\_PU\_CONCENTRATION

Local node provides PU concentration for the downstream PU.

## AP\_DLUR

Local node provides DLUR support for the downstream PU.

### pu\_sscp\_stats.rcv\_ru\_size

This field is always reserved.

## pu\_sscp\_stats.send\_ru\_size

This field is always reserved.

### pu\_sscp\_stats.max\_send\_btu\_size

Maximum BTU size that can be sent.

### pu\_sscp\_stats.max\_rcv\_btu\_size

Maximum BTU size that can be received.

## pu\_sscp\_stats.max\_send\_pac\_win

This field will always be set to zero.

## pu\_sscp\_stats.cur\_send\_pac\_win

This field will always be set to zero.

pu\_sscp\_stats.max\_rcv\_pac\_win
 This field will always be set to zero.

pu\_sscp\_stats.cur\_rcv\_pac\_win This field will always be set to zero.

pu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.

pu\_sscp\_stats.send\_fmd\_data\_frames
 Number of normal flow FMD data frames sent.

pu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.

pu\_sscp\_stats.rcv\_fmd\_data\_frames
 Number of normal flow FMD data frames received.

pu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.

pu\_sscp\_stats.sidh Session ID high byte.

pu\_sscp\_stats.sidl

Session ID low byte.

pu\_sscp\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node containing the secondary link station.

pu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### pu\_sscp\_stats.pacing\_type

Receive pacing type in use on the upstream PU-SSCP session. This will take the value AP\_NONE.

## FOCAL\_POINT\_INDICATION

This indication is generated whenever a focal point is acquired, changed or revoked.

## VCB Structure

typedef struct focal point indication

```
unsigned short opcode;
                                                           /* verb operation code
                                                                                                               */

    unsigned char
                            fp_type;
    unsigned char
                            fp_status;
                                                            /* status of focal point
                                                                                                               */
    unsigned char
                             fp routing;
                                                           /* type of MDS routing to
                                                                                                               */
                                                            /* reach FP
                                                                                                               */
                                                            /* reserved
                                                                                                               */
    unsigned char
                            reserva[20];
} FOCAL_POINT_INDICATION;
```

## Parameters

#### opcode

AP\_FOCAL\_POINT\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### ms\_category

Category of focal point where the focal point has been acquired, changed or revoked. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services categories as described in *SNA Management Services*, or an 8-byte type 1134 EBCDIC installation defined name.

### fp\_fqcp\_name

The fully qualified control point name of the current focal point. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This name will be all zeros if the focal point has been revoked and not replaced (so that there is no currently active focal point).

## ms\_appl\_name

Name of the current focal point application. This can either be one of the 4-byte architecturally defined values (right-padded with EBCDIC spaces) for management services applications as described in *SNA Management Services*, or an 8-byte type-1134 EBCDIC installation defined name. This will be all zeros if the focal point has been revoked and not replaced (so that there is no currently active focal point).

## fp\_type

Type of focal point. Refer to SNA Management Services for further details.

AP\_EXPLICIT\_PRIMARY\_FP AP\_BACKUP\_FP AP\_DEFAULT\_PRIMARY\_FP AP\_DOMAIN\_FP AP\_HOST\_FP AP\_NO\_FP

### fp\_status

Status of the focal point:

## AP\_NOT\_ACTIVE

The focal point has gone from active to inactive.

## AP\_ACTIVE

The focal point has gone from inactive or pending active to active.

## fp\_routing

Type of routing that applications should specify when using MDS transport to send data to the focal point (only significant if the focal point status is AP\_ACTIVE):

## AP\_DEFAULT

Default routing is used to deliver the MDS\_MU to the focal point.

#### AP\_DIRECT

The MDS\_MU will be routed on a session directly to the focal point.

## **ISR\_INDICATION**

This verb applies only to Communications Server.

This indication is generated when an ISR session is activated or deactivated. When the session is deactivated, final session statistics are returned. When the session is activated the **pri\_sess\_stats** and **sec\_sess\_stats** fields are reserved.

## **VCB Structure**

## **Parameters**

The application supplies the following parameters:

opcode

AP\_ISR\_INDICATION

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## primary\_rc

AP\_OK

## secondary rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure which has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields may be set to null. The application should issue a QUERY verb to update the information which has been lost.

### deactivated

Set to AP\_YES when the ISR session is deactivated. Set to AP\_NO when the session is activated.

### fqpcid.pcid

Procedure Correlator ID. This is an 8-byte hexadecimal string.

### fqpcid.fqcp\_name

Fully qualified Control Point name. This name is 17-bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### fqplu\_name

Fully qualified primary LU name (as specified on the BIND request). This name is 17-bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This name will be all zeros if **deactivated** is AP\_YES.

## fqslu\_name

Fully qualified secondary LU name (as specified on the BIND request). This name is 17-bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.) This name will be all zeros if **deactivated** is AP\_YES.

### mode\_name

Mode name which designates the network properties for a group of sessions (as specified on the BIND request). This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This name will be all zeros if deactivated is AP\_YES.

cos\_name

Class of Service name. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces. This name will be all zeros if **deactivated** is AP\_YES.

transmission\_priority

The transmission priority associated with the session. This field is reserved if **deactivated** is AP\_YES.

sense\_data

The sense data sent or received on the UNBIND request. This field is reserved if **deactivated** is AP\_YES.

- pri\_sess\_stats.rcv\_ru\_size Maximum receive RU size.
- pri\_sess\_stats.send\_ru\_size Maximum send RU size.

pri\_sess\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

pri\_sess\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

pri\_sess\_stats.max\_send\_pac\_win Maximum size of the send pacing window on this session.

pri\_sess\_stats.cur\_send\_pac\_win Current size of the send pacing window on this session.

- pri\_sess\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session.
- pri\_sess\_stats.cur\_rcv\_pac\_win Current size of the receive pacing window on this session.
- pri\_sess\_stats.send\_data\_frames Number of normal flow data frames sent.
- pri\_sess\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.
- pri\_sess\_stats.send\_data\_bytes Number of normal flow data bytes sent.
- pri\_sess\_stats.rcv\_data\_frames Number of normal flow data frames received.
- pri\_sess\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.
- pri\_sess\_stats.rcv\_data\_bytes Number of normal flow data bytes received.
- pri\_sess\_stats.sidh

Session ID high byte.

pri\_sess\_stats.sidl

Session ID low byte.

### pri\_sess\_stats.odai

Origin destination address indicator. When bringing up a session, the

sender of the BIND sets this field to zero if the local node contains the primary link station. It sets it to one if the BIND sender is the node containing the secondary link station.

## pri\_sess\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate the session statistics with the link over which session traffic flows.

## pri\_sess\_stats.pacing\_type

Receive pacing type in use on the primary session. This can take the values AP\_NONE, AP\_PACING\_FIXED, or AP\_PACING\_ADAPTIVE.

#### sec\_sess\_stats.rcv\_ru\_size

Maximum receive RU size.

## sec\_sess\_stats.send\_ru\_size

Maximum send RU size.

sec\_sess\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

### sec\_sess\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

sec\_sess\_stats.max\_send\_pac\_win
Maximum size of the send pacing window on this session.

sec\_sess\_stats.cur\_send\_pac\_win
Current size of the send pacing window on this session.

# sec\_sess\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session.

sec\_sess\_stats.cur\_rcv\_pac\_win
Current size of the receive pacing window on this session.

## sec\_sess\_stats.send\_data\_frames Number of normal flow data frames sent.

sec\_sess\_stats.send\_fmd\_data\_frames
 Number of normal flow FMD data frames sent.

## sec\_sess\_stats.send\_data\_bytes

Number of normal flow data bytes sent.

#### sec\_sess\_stats.rcv\_data\_frames Number of normal flow data frames received.

sec\_sess\_stats.rcv\_fmd\_data\_frames
 Number of normal flow FMD data frames received.

#### sec\_sess\_stats.rcv\_data\_bytes

Number of normal flow data bytes received.

### sec\_sess\_stats.sidh Session ID high byte.

sec\_sess\_stats.sidl

Session ID low byte.

## sec\_sess\_stats.odai

Origin destination address indicator. When bringing up a session, the

sender of the BIND sets this field to zero if the local node contains the primary link station. It sets it to one if the BIND sender is the node containing the secondary link station.

## sec\_sess\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate the session statistics with the link over which session traffic flows.

## sec\_sess\_stats.pacing\_type

Receive pacing type in use on the secondary session. This can take the values AP\_NONE, AP\_PACING\_FIXED, or AP\_PACING\_ADAPTIVE.

## LOCAL\_LU\_INDICATION

This indication is generated whenever a LOCAL LU is defined or deleted. This allows a registered application to maintain a list of all local LUs currently defined.

## **VCB** Structure

typedef struct loc {	al_lu_indication

unsigned char	pacing_type;	<pre>/* type of pacing in use</pre>	*/
<pre>} SESSION_STATS;</pre>			

**Note:** The LU-SSCP statistics are only valid when both **nau\_address** is nonzero and the LU-SSCP session goes from active to inactive. In all other cases the fields are reserved.

## **Parameters**

opcode

AP\_LOCAL\_LU\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

## primary\_rc

AP\_OK

### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES, then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

reason Reason for indication being issued:

#### AP\_ADDED

The LU has been defined.

## **AP\_REMOVED**

The LU has been deleted, either explicitly using DELETE\_LOCAL\_LU or implicitly using DELETE\_LS, DELETE\_PORT or DELETE\_DLC.

#### AP\_SSCP\_ACTIVE

The LU-SSCP session has become active after the node has successfully processed an ACTLU.

## AP\_SSCP\_INACTIVE

The LU-SSCP session has become inactive after a normal DACTLU or a link failure.

#### lu\_name

Name of the LU. Name of the local LU whose state has changed. This is an 8-byte alphanumeric type A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

### description

Resource description (as specified on DEFINE\_LOCAL\_LU).

### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## nau\_address

Network addressable unit address of the LU, which must be in the range 0–255. A nonzero value implies the LU is a dependent LU. Zero implies the LU is an independent LU.

#### pu\_name

Name of the PU that this LU uses. This is an 8-byte alphanumeric type A EBCDIC string. This field is only significant if the LU is a dependent LU (that is, **nau\_address** is nonzero), and will be set to all binary zeros for independent LUs.

#### lu\_sscp\_sess\_active

Specifies whether the LU-SSCP session is active (AP\_YES or AP\_NO). If **nau\_address** is zero then this field is reserved.

**lu\_sscp\_stats.rcv\_ru\_size** This field is always reserved.

lu\_sscp\_stats.send\_ru\_size This field is always reserved.

lu\_sscp\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

lu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

lu\_sscp\_stats.max\_send\_pac\_win
This field will always be set to zero.

lu\_sscp\_stats.cur\_send\_pac\_win
 This field will always be set to zero.

lu\_sscp\_stats.max\_rcv\_pac\_win
 This field will always be set to zero.

**lu\_sscp\_stats.cur\_rcv\_pac\_win** This field will always be set to zero.

lu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.

lu\_sscp\_stats.send\_fmd\_data\_frames
 Number of normal flow FMD data frames sent.

lu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.

lu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.

lu\_sscp\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.

lu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.

lu\_sscp\_stats.sidh Session ID high byte.

lu\_sscp\_stats.sidl

Session ID low byte.

lu\_sscp\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the ACTLU sets this field to zero if the local node contains the primary link station, and sets it to 1 if the ACTLU sender is the node containing the secondary link station.

lu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate this session with the link over which the session flows.

lu\_sscp\_stats.pacing\_type

Receiving pacing type in use on the LU-SSCP session. This will take the value AP\_NONE.

## sscp\_id

This is a 6–byte field containing the SSCP ID received in the ACTPU for the PU used by this LU.

This field is only used by dependent LUs, and will be set to all binary zeros for independent LUs or if **lu\_sscp\_sess\_active** is not set to AP\_YES.

## LOCAL\_TOPOLOGY\_INDICATION

This indication is generated when a TG entry in a node's local topology database changes from active to inactive, or from inactive to active.

## VCB Structure

typedef struct local\_topology\_indication

unsigned	short	opcode;	/*	verb operation code	*/

## **Parameters**

opcode

#### AP\_LOCAL\_TOPOLOGY\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

**status** Specifies the status of the TG. This can be one or more of the following values ORed together:

AP\_TG\_OPERATIVE AP\_TG\_CP\_CP\_SESSIONS AP\_TG\_QUIESCING AP\_NONE

**dest** Fully qualified destination node name for the TG. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### dest\_type

Type of the node. It is one of the following values:

AP\_END\_NODE AP\_NETWORK\_NODE AP\_VRN

#### tg\_num

Number associated with the TG.

#### cp\_cp\_session\_active

Specifies whether the local node's contention winner CP-CP session is active (AP\_NO or AP\_YES).

#### branch\_link\_type

BrNN only. This branch link type of this TG. This is set to one of the following:

#### **AP\_UPLINK**

This link is an uplink.

#### **AP\_DOWNLINK**

The link is a downlink to an EN.

#### AP\_DOWNLINK\_TO\_BRNN

The TG is a downlink to a BrNN that is showing its EN face.

#### **AP\_OTHERLINK**

This link is an otherlink.

Other node types: This field is not meaningful and is always set to AP\_BRNN\_NOT\_SUPPORTED.

#### branch\_tg

NN only. Sepcifies whether the TG is a branch TG.

#### AP\_NO

The TG is not a branch TG.

#### AP\_YES

The TG is a branch TG.

Other node types: This field is not meaningful and is always set to AP\_NO.

# LS\_INDICATION

This indication is generated when the number of active sessions using the link changes, or the external state of the link station changes. Link station statistics are supplied when the link station becomes inactive.

# **VCB** Structure

typedef struct ls\_indication

} LS STATS;
```

# **Parameters**

opcode

AP\_LS\_INDICATION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### deactivated

Set to AP\_YES when the LS becomes inactive. Set to AP\_NO when the LS becomes active.

#### ls\_name

Name of link station. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### description

Resource description (as specified on DEFINE\_LS). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### adj\_cp\_name

Fully-qualified, 17-byte long, adjacent control point name. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### adj\_node\_type

Type of the node. It is one of the following values:

AP\_END\_NODE AP\_NETWORK\_NODE AP\_LEN\_NODE AP\_VRN

#### act\_sess\_count

Total number of active sessions (both endpoint and intermediate) using the link.

#### indication\_cause

Cause of the indication. It is one of the following values:

## AP\_ACTIVATION\_STARTED

The link is activating.

#### AP\_ACTIVATING

The link has become active.

# AP\_DEACTIVATION\_STARTED

The link is being deactivated.

#### **AP\_DEACTIVATING**

The link has become inactive.

#### AP\_SESS\_COUNT\_CHANGING The number of active sessions using the link has changed.

#### AP\_CP\_NAME\_CHANGING

An adjacent node has changed its control point name.

#### **AP\_FAILED**

The link has failed.

#### AP\_ACTIVATION\_FAILED

The link failed to activate.

#### AP\_PENDING\_RETRY

A retry timer has been started. When the timer expires, activation of the link is automatically retried.

#### AP\_DATA\_LOST

A previous indication has been lost. Note that link station statistics are only supplied when the link station goes from active to inactive (that is, deactivating is set to AP\_YES and **indication\_cause** is set to AP\_DEACTIVATING). In all other cases the fields are reserved.

#### ls\_stats.in\_xid\_bytes

Total number of XID (Exchange Identification) bytes received on this link station.

## ls\_stats.in\_msg\_bytes

Total number of data bytes received on this link station.

#### ls\_stats.in\_xid\_frames

Total number of XID (Exchange Identification) frames received on this link station.

#### ls\_stats.in\_msg\_frames

Total number of data frames received on this link station.

#### ls\_stats.out\_xid\_bytes

Total number of XID (Exchange Identification) bytes sent on this link station.

#### ls\_stats.out\_msg\_bytes

Total number of data bytes sent on this link station.

#### ls\_stats.out\_xid\_frames

Total number of XID (Exchange Identification) frames sent on this link station.

#### ls\_stats.out\_msg\_frames

Total number of data frames sent on this link station.

#### ls\_stats.in\_invalid\_sna\_frames

Total number of SNA incorrect frames received on this link station.

#### ls\_stats.in\_session\_control\_frames

Total number of session control frames received on this link station.

#### ls\_stats.out\_session\_control\_frames

Total number of session control frames sent on this link station.

#### ls\_stats.echo\_rsps

Number of echo responses received from the adjacent node. Echo requests are sent periodically to gauge the propagation delay to the adjacent node.

#### ls\_stats.current\_delay

Time (in milliseconds) that it took for the last test signal to be sent and returned from this link station to the adjacent link station.

#### ls\_stats.max\_delay

Longest time taken (in milliseconds) for a test signal to be sent and returned from this link station to the adjacent link station.

#### ls\_stats.min\_delay

Shortest time taken (in milliseconds) for a test signal to be sent and returned from this link station to the adjacent link station.

#### ls\_stats.max\_delay\_time

Time since system startup (in hundredths of a second) when the longest delay occurred.

#### ls\_stats.good\_xids

Total number of successful XID exchanges that have occurred on this link station since it was started.

#### ls\_stats.bad\_xids

Total number of unsuccessful XID exchanges that have occurred on this link station since it was started.

#### tg\_num

Number associated with the TG.

#### sense\_data

This sense data is set if Personal Communications or Communications Server detects an XID protocol error. This field is reserved unless **indication\_cause** is AP\_FAILED.

#### brnn\_link\_type

BrNN only. This branch link type. It is one of the following:

#### **AP\_UPLINK**

This link is an uplink.

#### **AP\_DOWNLINK**

The link is a downlink.

#### AP\_OTHERLINK

This link is an otherlink.

#### AP\_UNKNOWN\_LINK\_TYPE

This link is an otherlink.

Other node types: This field is not meaningful and is always set to AP\_BRNN\_NOT\_SUPPORTED.

#### adj\_cp\_is\_brnn

All node types: Specifies whether the adjacent node is a BrNN.

#### **AP\_UNKNOWN**

It is not known whether the adjacent node is a BrNN.

#### AP\_NO

The adjacent node is not a BrNN.

# AP\_YES

The adjacent node is BrNN.

# LU\_0\_TO\_3\_INDICATION

This indication is generated when the state of a local LU (Type 0-3) changes.

## **Parameters**

## opcode

AP\_LU\_0\_TO\_3\_INDICATION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

#### AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

If data lost is set to AP\_YES, this is set to AP\_EXTERNALLY\_VISIBLE.

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

## primary\_rc

AP\_OK

# secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### pu\_name

Name of local PU. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### lu\_name

Name of the local LU whose state has changed. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### description

Resource description (as specified on DEFINE\_LU\_0\_TO\_3). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### nau\_address

Network addressable unit address of the LU (which will be in the range 10–2554).

#### lu\_sscp\_sess\_active

Specifies whether the ACTLU has been successfully processed (AP\_YES or AP\_NO).

#### appl\_conn\_active

Set if the application is using this LU (AP\_YES or AP\_NO).

#### plu\_sess\_active

Specifies whether the PLU-SLU session has been activated (AP\_YES or AP\_NO).

#### host\_attachment

Specifies the LU host attachment type:

#### AP\_DLUR\_ATTACHED

LU is attached to host system using DLUR.

#### AP\_DIRECT\_ATTACHED

LU is directly attached to host system. Note the LU-SSCP and PLU-SLU statistics are only valid when the sessions go from active to inactive. In all other cases the fields are reserved.

## LU\_0\_TO\_3\_INDICATION

lu\_sscp\_stats.rcv\_ru\_size This field is always reserved.

lu\_sscp\_stats.send\_ru\_size This field is always reserved.

lu\_sscp\_stats.max\_send\_btu\_size Maximum BTU size that can be sent.

lu\_sscp\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received.

lu\_sscp\_stats.max\_send\_pac\_win
This field will always be set to zero.

**lu\_sscp\_stats.cur\_send\_pac\_win** This field will always be set to zero.

lu\_sscp\_stats.max\_rcv\_pac\_win This field will always be set to zero.

**lu\_sscp\_stats.cur\_rcv\_pac\_win** This field will always be set to zero.

lu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.

lu\_sscp\_stats.send\_fmd\_data\_frames
 Number of normal flow FMD data frames sent.

lu\_sscp\_stats.send\_data\_bytes Number of normal flow data bytes sent.

lu\_sscp\_stats.rcv\_data\_frames Number of normal flow data frames received.

lu\_sscp\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received.

lu\_sscp\_stats.rcv\_data\_bytes Number of normal flow data bytes received.

lu\_sscp\_stats.sidh Session ID high byte.

lu\_sscp\_stats.sidl

Session ID low byte.

lu\_sscp\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the ACTLU sets this field to zero if the local node contains the primary link station, and sets it to 1 if the ACTLU sender is the node containing the secondary link station.

lu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate this session with the link over which the session flows.

lu\_sscp\_stats.pacing\_type

Receiving pacing type in use on the LU-SSCP session. This will take the value AP\_NONE.

plu\_stats.rcv\_ru\_size

Maximum receive RU size.

plu\_stats.send\_ru\_size Maximum send RU size. plu\_stats.max\_send\_btu\_size Maximum BTU size that can be sent. plu\_stats.max\_rcv\_btu\_size Maximum BTU size that can be received. plu\_stats.max\_send\_pac\_win Maximum size of the send pacing window on this session. plu\_stats.cur\_send\_pac\_win Current size of the send pacing window on this session. plu\_stats.max\_rcv\_pac\_win Maximum size of the receive pacing window on this session. plu\_stats.cur\_rcv\_pac\_win Current size of the receive pacing window on this session. plu\_stats.send\_data\_frames Number of normal flow data frames sent. plu\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent. plu\_stats.send\_data\_bytes Number of normal flow data bytes sent. plu\_stats.rcv\_data\_frames Number of normal flow data frames received. plu\_stats.rcv\_fmd\_data\_frames Number of normal flow FMD data frames received. plu\_stats.rcv\_data\_bytes Number of normal flow data bytes received. plu\_stats.sidh Session ID high byte. plu\_stats.sidl Session ID low byte. plu\_stats.odai Origin destination address indicator. When bringing up a session, the sender of the ACTLU sets this field to zero if the local node contains the primary link station, and sets it to 1 if the ACTLU sender is the node containing the secondary link station. plu\_stats.ls\_name Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate this session with the link over which the session flows. plu\_stats.pacing\_type Receiving pacing type in use on the PLU-SLU session. This will take the value AP NONE or AP PACING FIXED.

#### sscp\_id

This is a 6–byte field containing the SSCP ID received in the ACTPU for the PU used by this LU.

If **lu\_sscp\_sess\_active** is not AP\_YES, then this field will be zeroed.

## MODE INDICATION

This indication is sent when a local LU and partner LU combination start to use a particular mode, and when the current session count for the local LU, partner LU, and mode combination changes.

	unsigned char	plu alias[8];	/* partner LU alias	*/
	unsigned char	fqplu name[17];	<pre>/* fully qualified partner</pre>	*/
			/* LU name	*/
	unsigned char	mode name[8];	/* mode name	*/
	unsigned char	<pre>description[RD LEN];</pre>	<pre>/* resource description</pre>	*/
	unsigned short	curr sess count;	<pre>/* current session count</pre>	*/
	unsigned char	reserva[20];	/* reserved	*/
}	MODE_INDICATION;			

# **Parameters**

#### opcode

AP\_MODE\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the data\_lost flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### removed

Specifies whether an entry is being removed (AP\_YES or AP\_NO). It is set when entry is being removed rather than added.

#### lu alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### fqplu\_name

17-byte fully qualified network name for the partner LU. This name is

composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### description

Resource description (as specified on DEFINE\_MODE). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### curr\_sess\_count

Current count of sessions for this local LU, partner LU, and mode combination.

## NN\_TOPOLOGY\_NODE\_INDICATION

This verb applies only to Communications Server.

This indication is generated when a node entry in a network node's topology database changes from active to inactive, or from inactive to active.

## VCB Structure

## Parameters

#### opcode

AP\_NN\_TOPOLOGY\_NODE\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### deactivated

Set to AP\_YES when the node becomes inactive. Set to AP\_NO when the node becomes active.

## node\_name

Network qualified node name from network topology database. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### node\_type

Type of the node. It is one of the following.

# AP\_NETWORK\_NODE

AP\_VRN

## branch\_aware

Specifies whether the node is branch aware.

## AP\_NO

The node is not branch aware.

## AP\_YES

The node is branch aware.

## NN\_TOPOLOGY\_TG\_INDICATION

This verb applies only to Communications Server.

This indication is generated when a TG entry in a network node's topology database changes from active to inactive, or from inactive to active.

## VCB Structure

typedef struct nn\_topology\_tg\_indication

unatornal about	an a a da .	1.	voub enquetion code	. /
unsigned short	opcode;		verb operation code	*/
unsigned char	reserv2;	/*	reserved	*/

		/*	CP-CP session is active	*/
unsigned char	branch_tg;	/*	TG is a branch TG	*/
unsigned char	reserva[16];	/*	reserved	*/
NN_TOPOLOGY_TG_I	NDICATION;			

## **Parameters**

}

#### opcode

#### AP\_NN\_TOPOLOGY\_TG\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

## secondary rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

**status** Specifies the status of the TG. This can be one or more of the following values ORed together:

AP\_TG\_OPERATIVE AP\_TG\_QUIESCING AP\_TG\_CP\_CP\_SESSIONS AP\_NONE

**owner** Name of the TG's originating node (always set to the local node name). This name is 17 bytes long and is right-padded with EBCDIC spaces. It is

composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

**dest** Fully qualified destination node name for the TG. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### tg\_num

Number associated with the TG.

#### owner\_type

Type of the node that owns the TG.

AP\_NETWORK\_NODE AP\_VRN

#### dest\_type

Type of the node.

AP\_NETWORK\_NODE AP\_VRN

## cp\_cp\_session\_active

Specifies whether the owning node's contention winner CP-CP session is active (AP\_NO or AP\_YES).

#### branch\_tg

Sepcifies whether the TG is a branch TG.

#### AP\_NO

The TG is not a branch TG.

#### AP\_YES

The TG is a branch TG.

## **PLU\_INDICATION**

This indication is generated when a local LU first connects to a partner LU. This will happen when the first ALLOCATE to this PLU is processed or when the first BIND is received from this PLU. This indication is also generated if the partner control point name changes.

## VCB Structure

typedef struct plu\_indication

unsigned short	opcode;	<pre>/* verb operation code</pre>	*/
unsigned char	reserv2;	/* reserved	*/
unsigned char	format;	/* format	*/
unsigned short	primary_rc;	/* primary return code	*/

unsigned char	reserva[20];	/* reserved	*/
DILL INDICATION.			

```
} PLU_INDICATION;
```

## **Parameters**

#### opcode

AP\_PLU\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether one or more indications have been lost (AP\_YES or AP\_NO). It is set when an internal component was unable to send a previous indication. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### removed

Specifies whether an entry is being removed (AP\_YES or AP\_NO). It is set when entry is being removed rather than added.

#### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### description

Resource description (as specified on DEFINE\_PARTNER\_LU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### partner\_cp\_name

17-byte fully qualified network name for the control point of the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### partner\_lu\_located

Specifies whether the partner control point name has been resolved (AP\_YES or AP\_NO), and thus whether the **partner\_cp\_name** field contains the control point name.

## **PORT\_INDICATION**

This indication is generated when the port goes from active to inactive (or vice versa).

## VCB Structure

typedef struct port\_indication

	unsigned	short	opcode;	/*	verb operation code	*/	
	unsigned	char	reserv2;	/*	reserved	*/	
	unsigned	char	attributes;	/*	verb attributes	*/	
	unsigned	char	format;	/*	format	*/	
	unsigned	short	primary_rc;	/*	primary return code	*/	
	unsigned	long	secondary_rc;	/*	secondary return code	*/	
	unsigned	char	data_lost;	/*	previous indication lost	*/	
	unsigned	char	deactivated;	/*	has session been deactivated?	*/	
	unsigned	char	<pre>port_name[8];</pre>	/*	link station name	*/	
	unsigned	char	<pre>description[RD_LEN];</pre>	/*	resource description	*/	
	unsigned	char	reserva[20];	/*	reserved	*/	
ł	PORT_INDIC	CATION;					

## **Parameters**

}

opcode

AP\_PORT\_INDICATION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### deactivated

Set to AP\_YES when the port becomes inactive. Set to AP\_NO when the port becomes active.

#### port\_name

Name of port. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

## description

Resource description (as specified on DEFINE\_PORT). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

## **PU\_INDICATION**

This indication is generated when the state of a local PU changes.

## VCB Structure

typedef struct pu\_indication /\* verb operation code unsigned short opcode; \*/ /\* attributes /\* reserved unsigned char attributes; \*/ \*/ reserv2; unsigned char /\* format unsigned char format; \*/ unsigned short primary\_rc; /\* primary return code /\* secondary return code \*/ secondary\_rc; data\_lost; unsigned long \*/ /\* previous indication lost unsigned char \*/ /\* PU Name \*/ unsigned char pu name[8]; unsigned char description[RD LEN]; /\* resource description \*/ unsigned char pu sscp sess active; \*/ /\* Is SSCP session active? /\* Host attachment unsigned char host attachment; \*/ unsigned char /\* reserved reserv1[2]; \*/ /\* PU-SSCP session statistics SESSION STATS pu sscp stats; \*/ unsigned char sscp id[6]; /\* SSCP ID \*/ } PU\_INDICATION; typedef struct session stats unsigned short rcv ru size; /\* session receive RU size \*/ unsigned short send\_ru\_size; /\* session send RU size \*/ unsigned short max send btu size; /\* max send BTU size \*/ unsigned short max rcv btu size; /\* max rcv BTU size \*/ /\* max send pacing window size unsigned short max send pac win; \*/ unsigned short cur\_send\_pac\_win; /\* curr send pacing window size \*/ unsigned short max\_rcv\_pac\_win; /\* max rcv pacing window size \*/ unsigned short cur\_rcv\_pac\_win; /\* curr receive pacing win size \*/ unsigned long send data frames; /\* number of data frames sent \*/ send fmd data frames; unsigned long /\* num FMD data frames sent \*/ unsigned long send data bytes; /\* number of data bytes sent \*/ unsigned long rcv data frames; /\* num of data frames received \*/ unsigned long rcv fmd data frames; /\* num FMD data frames received \*/ unsigned long /\* num data bytes received rcv data bytes; \*/ /\* session ID high byte unsigned char sidh; \*/ unsigned char sidl; /\* session ID low byte \*/ /\* ODAI bit set unsigned char odai; \*/ ls\_name[8]; /\* Link station name unsigned char \*/ unsigned char pacing type; /\* type of pacing in use \*/ } SESSION STATS;

## **Parameters**

opcode

AP\_PU\_INDICATION

#### attributes

The attributes of the verb. This field is a bit field. The first bit contains the visibility of the resource to be defined and corresponds to one of the following:

AP\_EXTERNALLY\_VISIBLE AP\_INTERNALLY\_VISIBLE

If data lost is set to AP\_YES, this is set to AP\_EXTERNALLY\_VISIBLE.

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### pu\_name

Name of the PU (configured on the DEFINE\_LS verb). This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### description

Resource description (as specified on DEFINE\_LS or DEFINE\_INTERNAL\_PU). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### pu\_sscp\_sess\_active

Specifies whether the ACTPU has been successfully processed (AP\_YES or AP\_NO).

#### host\_attachment

PU host attachment type:

#### AP\_DLUR\_ATTACHED

PU is attached to host system using DLUR.

#### AP\_DIRECT\_ATTACHED

PU is directly attached to host system.

**Note:** PU-SSCP statistics are valid only when the session state has moved from active to inactive.

In all other cases the following fields are reserved:

#### pu\_sscp\_stats.rcv\_ru\_size

This field is always reserved.

#### pu\_sscp\_stats.send\_ru\_size

This field is always reserved.

#### pu\_sscp\_stats.max\_send\_btu\_size

Maximum BTU size that can be sent.

## pu\_sscp\_stats.max\_rcv\_btu\_size

Maximum BTU size that can be received.

# pu\_sscp\_stats.max\_send\_pac\_win This field will always be set to zero.

# pu\_sscp\_stats.cur\_send\_pac\_win This field will always be set to zero.

#### pu\_sscp\_stats.max\_rcv\_pac\_win

This field will always be set to zero.

pu\_sscp\_stats.cur\_rcv\_pac\_win
 This field will always be set to zero.

- pu\_sscp\_stats.send\_data\_frames Number of normal flow data frames sent.
- pu\_sscp\_stats.send\_fmd\_data\_frames
   Number of normal flow FMD data frames sent.
- pu\_sscp\_stats.send\_data\_bytes

Number of normal flow data bytes sent.

#### pu\_sscp\_stats.rcv\_data\_frames

Number of normal flow data frames received.

pu\_sscp\_stats.rcv\_fmd\_data\_frames
 Number of normal flow FMD data frames received.

## pu\_sscp\_stats.rcv\_data\_bytes

Number of normal flow data bytes received.

## pu\_sscp\_stats.sidh

Session ID high byte.

#### pu\_sscp\_stats.sidl

Session ID low byte.

#### pu\_sscp\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the ACTPU sets this field to zero if the local node contains the primary link station, and sets it to 1 if the ACTPU sender is the node containing the secondary link station.

#### pu\_sscp\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate this session with the link over which the session flows.

#### pu\_stats.pacing\_type

Receiving pacing type in use on the PU-SSCP session. This will take the value AP\_NONE.

#### sscp\_id

This is a 6-byte field containing the SSCP ID received in the ACTPU for this PU.

If plu\_sscp\_sess\_active is not AP\_YES, then this field will be zeroed.

## **REGISTRATION\_FAILURE**

REGISTRATION\_FAILURE indicates that an attempt to register resources with the network node server failed.

## VCB Structure

## **Parameters**

```
opcode
```

AP\_REGISTRATION\_FAILURE

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES, then subsequent data fields may be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### resource\_name

Name of resource that failed to register. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### resource\_type

Resource type. One of the following values:

AP\_NNCP\_RESOURCE AP\_ENCP\_RESOURCE AP\_LU\_RESOURCE

#### description

Resource description (as specified on DEFINE\_LOCAL\_LU, or DEFINE\_ADJACENT\_NODE).

## **REGISTRATION\_FAILURE**

sense\_data

Sense data (specified in SNA Formats).

# **RTP\_INDICATION**

This indication is generated when:

- An RTP connection is connected or disconnected
- The active session count changes
- The connection performs a path-switch

When the connection is disconnected, final RTP statistics will be returned. At other times the **rtp\_stats** field is reserved.

## VCB Structure

	<pre>} RTP_STATISTICS;</pre>				

## **Parameters**

#### opcode

AP\_RTP\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

## primary\_rc

AP\_OK

## secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then the data contained might have changed more than once since the previous indication received.

#### connection\_state

The current state of the RTP connection. It is one of the following values:

#### AP\_CONNECTING

Connection setup has started, but is not yet complete.

#### **AP\_CONNECTED**

The connection is fully active.

## AP\_DISCONNECTED

The connection is no longer active.

#### rtp\_name

RTP connection name. This name is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### num\_sess\_active

Number of sessions currently active on the connection.

#### indication\_cause

Cause of the indication. It is one of the following values:

## AP\_ACTIVATED

The connection has become active.

#### AP\_DEACTIVATED

The connection has become inactive.

#### AP\_PATH\_SWITCHED

The connection has successfully completed a path switch.

#### AP\_SESS\_COUNT\_CHANGING

The number of active sessions using the connection has changed.

#### AP\_SETUP\_FAILED

The connection has failed before becoming fully active. Note that RTP connection statistics are only supplied when the connection becomes inactive, that is when **indication\_cause** is

AP\_DEACTIVATED or AP\_SETUP\_FAILED. In all other cases the fields are reserved.

#### rtp\_stats.bytes\_sent

Total number of bytes that the local node has sent on this RTP connection.

#### rtp\_stats.bytes\_received

Total number of bytes that the local node has received on this RTP connection.

#### rtp\_stats.bytes\_resent

Total number of bytes resent by the local node owing to loss in transit.

#### rtp\_stats.bytes\_discarded

Total number of bytes sent by the other end of the RTP connection that were discarded as duplicates of data already received.

#### rtp\_stats.packets\_sent

Total number of packets that the local node has sent on this RTP connection.

#### rtp\_stats.packets\_received

Total number of packets that the local node has received on this RTP connection.

#### rtp\_stats.packets\_resent

Total number of packets resent by the local node owing to loss in transit.

#### rtp\_stats.packets\_discarded

Total number of packets sent by the other end of the RTP connection that were discarded as duplicates of data already received.

#### rtp\_stats.gaps\_detected

Total number of gaps detected by the local node. Each gap corresponds to one or more lost frames.

## rtp\_stats.send\_rate

Current send rate on this RTP connection (measured in kilobits per second). This is the maximum allowed send rate as calculated by the ARB algorithm.

#### rtp\_stats.max\_send\_rate

Maximum send rate on this RTP connection (measured in kilobits per second).

#### rtp\_stats.min\_send\_rate

Minimum send rate on this RTP connection (measured in kilobits per second).

#### rtp\_stats.receive\_rate

Current receive rate on this RTP connection (measured in kilobits per second). This is the actual receive rate calculated over the last measurement interval.

#### rtp\_stats.max\_receive\_rate

Maximum receive rate on this RTP connection (measured in kilobits per second).

#### rtp\_stats.min\_receive\_rate

Minimum receive rate on this RTP connection (measured in kilobits per second).

#### rtp\_stats.burst\_size

Current burst-size on the RTP Connection measured in bytes.

#### rtp\_stats.up\_time

Total number of seconds the RTP connection has been active.

#### rtp\_stats.smooth\_rtt

Smoothed measure of round-trip time between the local node and the partner RTP node (measured in milliseconds).

## rtp\_stats.last\_rtt

The last measured round-trip time between the local node and the partner RTP node (measured in milliseconds).

#### rtp\_stats.short\_req\_timer

The current duration used for the SHORT\_REQ timer (measured in milliseconds).

#### rtp\_stats.short\_req\_timeouts

Total number of times the SHORT\_REQ timer has expired for this RTP connection.

#### rtp\_stats.liveness\_timeouts

Total number of times the liveness timer has expired for this RTP connection. The liveness timer expires when the connection has been idle for the period specified in **rtp\_connection\_detail.liveness\_timer**.

#### rtp\_stats.in\_invalid\_sna\_frames

Total number of SNA frames received and discarded as not valid on this RTP connection.

#### rtp\_stats.in\_sc\_frames

Total number of session control frames received on this RTP connection.

#### rtp\_stats.out\_sc\_frames

Total number of session control frames sent on this RTP connection.

## SESSION\_FAILURE\_INDICATION

This indication is generated whenever a session is deactivated. This indication is guaranteed; that is, generated without fail.

## VCB Structure

```
typedef struct session_failure_indication
```

unsigned	short	opcode;	/*	verb operation code	*/
unsigned		reserv2;		reserved	*/

## **Parameters**

## opcode

AP\_SESSION\_FAILURE\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string.

#### lu alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set.

#### fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

## SESSION\_FAILURE\_INDICATION

#### session\_id

8-byte identifier of the session.

#### sense\_data

The sense data detailing the cause of the session deactivation.

# SESSION\_INDICATION

This indication is generated when a session is activated or deactivated. When a session is deactivated, final session statistics will be returned. When a session is activated, the **sess\_stats** field is reserved.

# **VCB** Structure

typedef struct session\_indication

## **Parameters**

#### opcode

AP\_SESSION\_INDICATION

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### primary\_rc

AP\_OK

#### secondary\_rc

Equals zero.

#### data\_lost

Specifies whether data has been lost (AP\_YES or AP\_NO). It is set when an internal component detects a failure that has caused a previous indication to be lost. If the **data\_lost** flag is set to AP\_YES then subsequent data fields can be set to null. The application should issue a QUERY verb to update the information that has been lost.

#### deactivated

Set to AP\_NO when a session is activated. Set to AP\_YES when a session is deactivated.

#### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string.

#### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant.

#### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set.

#### fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### mode\_name

Mode name, which designates the network properties for a group of sessions. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### session\_id

8-byte identifier of the session.

#### fqpcid.pcid

Procedure correlator ID. This is an 8-byte hexadecimal string.

#### fqpcid.fqcp\_name

Fully qualified control point name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC

character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

#### sense\_data

The sense data sent or received on the UNBIND request. This field is reserved if **deactivated** is AP\_NO.

#### duplex\_support

Returns the conversation duplex support as negotiated on the BIND. This is one of the following values:

#### AP\_HALF\_DUPLEX

Only half-duplex conversations are supported.

#### AP\_FULL\_DUPLEX

Full-duplex as well as half-duplex conversations are supported.

#### **AP\_UNKNOWN**

The conversation duplex support is not known because there are no active sessions to the partner LU.

#### sess\_stats.rcv\_ru\_size

Maximum receive RU size.

#### sess\_stats.send\_ru\_size

Maximum send RU size.

## sess\_stats.max\_send\_btu\_size

Maximum BTU size that can be sent.

#### sess\_stats.max\_rcv\_btu\_size

Maximum BTU size that can be received.

#### sess\_stats.max\_send\_pac\_win

Maximum size of the send pacing window on this session.

#### sess\_stats.cur\_send\_pac\_win

Current size of the send pacing window on this session.

#### sess\_stats.max\_rcv\_pac\_win

Maximum size of the receive pacing window on this session.

## sess\_stats.cur\_rcv\_pac\_win

Current size of the receive pacing window on this session.

#### sess\_stats.send\_data\_frames

Number of normal flow data frames sent.

#### sess\_stats.send\_fmd\_data\_frames Number of normal flow FMD data frames sent.

#### sess\_stats.send\_data\_bytes

Number of normal flow data bytes sent.

#### sess\_stats.rcv\_data\_frames

Number of normal flow data frames received.

#### sess\_stats.rcv\_fmd\_data\_frames

Number of normal flow FMD data frames received.

#### sess\_stats.rcv\_data\_bytes

Number of normal flow data bytes received.

#### sess\_stats.sidh

Session ID high byte.

#### sess\_stats.sidl

Session ID low byte.

#### sess\_stats.odai

Origin destination address indicator. When bringing up a session, the sender of the BIND sets this field to zero if the local node contains the primary link station, and sets it to 1 if the BIND sender is the node containing the secondary link station.

#### sess\_stats.ls\_name

Link station name associated with statistics. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant. This field can be used to correlate the session statistics with the link over which session traffic flows.

#### sess\_stats.pacing\_type

Receive pacing type in use on this session. This can take the values AP\_NONE, AP\_PACING\_ADAPTVE or AP\_PACING\_FIXED.

#### sscp\_id

For dependent LU sessions, this field contains the SSCP ID received in the ACTPU from the host for the PU that the local LU is mapped to. For independent LU sessions, this field will be set to all binary zeros.

#### plu\_slu\_comp\_lvl

Specifies the compression level for data sent from the PLU to the SLU.

#### **AP\_NONE**

Compression is not used.

#### AP\_RLE\_COMPRESSION

RLE compression is used.

#### AP\_LZ9\_COMPRESSION

This node can support LZ9 compression.

#### AP\_LZ10\_COMPRESSION

The node can support LZ10 compression.

#### AP\_LZ12\_COMPRESSION

The node can support LZ12 compression.

#### slu\_plu\_comp\_lvl

Specifies the compression level for data sent from the SLU to the PLU.

#### AP\_NONE

Compression is not used.

#### AP\_RLE\_COMPRESSION

RLE compression is used.

#### AP\_LZ9\_COMPRESSION

This node can support LZ9 compression.

#### AP\_LZ10\_COMPRESSION

The node can support LZ10 compression.

#### AP\_LZ12\_COMPRESSION

The node can support LZ12 compression.

## UNREGISTER\_INDICATION\_SINK

UNREGISTER\_INDICATION\_SINK removes the identifications of processes and queues that are receiving unsolicited indications.

If the specified combination of **proc\_id**, **queue\_id**, and **indication\_opcode** has only been registered once, the entry is removed. If the specified combination has been registered more than once, the entry that matches **orig\_verb\_data**in the verb\_signal header of UNREGISTER\_INDICATION\_SINK is removed.

## VCB Structure

```
typedef struct unregister indication sink
  unsigned short opcode;
unsigned char reserv2;
unsigned char format;
unsigned short primary_rc;
unsigned long secondary_rc;
   unsigned short opcode;
                                              /* verb operation code
                                                                                    */
                                             /* reserved
                                                                                    */
                                             /* format
                                                                                    */
                                             /* primary return code
                                                                                    */
                                              /* secondary return code
                                                                                    */
   unsigned PROC ID
                     proc id;
                                              /* process identifier of sink
                                                                                    */
   unsigned QUEUE ID
                     queue id;
                                              /* queue identifier where
                                                                                    */
                                              /* indications will be sent
                                                                                    */
   unsigned short indication opcode;
                                              /* opcode of indication to
                                                                                    */
                                               /* be sunk
} UNREGISTER INDICATION SINK;
```

## **Parameters**

#### opcode

```
AP_UNREGISTER_INDICATION_SINK
```

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

proc\_id

Process ID of process where indication are being sent.

### queue\_id

Queue ID of queue where indications are being sent.

#### indication\_opcode

Opcode of indications that are being returned.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc

AP\_PARAMETER\_CHECK

```
secondary_rc
AP_INVALID_OP_CODE
```

### AP\_DYNAMIC\_LOAD\_ALREADY\_REGD

If the verb does not execute because of a state error, the Program returns the following parameters:

```
primary_rc
```

AP\_STATE\_CHECK

secondary\_rc

ÂP\_INVALID\_LU\_NAME

If the verb does not execute because one or more of the relevant START\_NODE parameters were not set, the Program returns the following parameter:

### primary\_rc

AP\_FUNCTION\_NOT\_SUPPORTED

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because a STOP\_NODE verb has been issued, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

# Chapter 10. Security Verbs

This chapter describes verbs used to define and delete security passwords.

## CONV\_SECURITY\_BYPASS

CONV\_SECURITY\_BYPASS allows an application to control whether the Program will enforce conversation-level security for a local LU. Once security has been bypassed, the Program will not do any authentication or authorization for the conversations on the local LU.

## VCB Structure

typedef struct conv\_security\_bypass

unsigned	short	opcode;	/*	verb operation code	*/
unsigned		reserv2;		reserved	*/
unsigned		format;	/*	format	*/
unsigned	short	primary rc;	/*	primary return code	*/
unsigned	long	secondary rc;		secondary return code	*/
unsigned	char	lu name[8];	/*	local LU name	*/
unsigned	char	lu alias[8];	/*	local LU alias	*/
unsigned	char	bypass security;	/*	should security be	*/
		_	/*	bypassed?	*/
unsigned	char	reserv3[3];	/*	reserved	*/
CONV_SECUR	ITY_BY	PASS;			

## **Supplied Parameters**

The application supplies the following parameters:

opcode

}

AP\_CONV\_SECURITY\_BYPASS

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Local LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_alias** and the **lu\_name** are set to all zeros, the verb is forwarded to the LU associated with the control point (the default LU).

### bypass\_security

Specifies whether security should be bypassed (AP\_YES or AP\_NO).

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_LU\_NAME

### AP\_INVALID\_LU\_ALIAS AP\_INVALID\_BYPASS\_SECURITY

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## CREATE\_PASSWORD\_SUBSTITUTE

CREATE\_PASSWORD\_SUBSTITUTE returns the password substitute, password verifier, and the send sequence number used to generate the substitute and verifier for the specified session.

## VCB Structure

```
typedef struct create_password_substitute
```

	unsigned short	opcode;	<pre>/* verb operation code</pre>	*/
	unsigned char	reserv2;	/* reserved	*/
	unsigned char	format;	/* format	*/
	unsigned short	primary_rc;	/* primary return code	*/
	unsigned long	secondary rc;	/* secondary return code	*/
	unsigned char	lu_alias[8];	/* LU alias	*/
	unsigned char	<pre>conv_group_id[8];</pre>	/* partner LU alias	*/
	unsigned char	user_id[10];	/* user ID	*/
	unsigned char	pw[10];	/* clear text password	*/
	unsigned char	seq_no[8];	/* sequence number	*/
	unsigned char	pw_sub[10];	/* password substitute	*/
	unsigned char	<pre>pw_verifier[10];</pre>	/* password verifier	*/
}	CREATE_PASSWORD_	SUBSTITUTE;		

## **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

```
AP_CREATE_PASSWORD_SUBSTITUTE
```

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set.

### conv\_group\_id

Conversation group identifier for the session used by the LU.

### user\_id

The user ID.

**pw** Clear text password to be used in the encryption algorithm.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc

AP\_OK

#### seq\_no

Send sequence number used in the encryption algorithm. Note, if the verb is successful, the internal value of the send sequence number for this session is incremented. The value returned is the value after incrementing.

#### pw\_sub

Password substitute generated by the encryption algorithm.

#### pw\_verifier

Password verifier generated by the encryption algorithm.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK secondary\_rc AP\_BAD\_LU\_ALIAS AP\_DEACT\_CG\_INVALID\_CGID

If the verb does not execute because the session does not support password substitution, the Program returns the following parameters:

### primary\_rc

AP\_STATE\_CHECK

### secondary\_rc

AP\_PW\_SUB\_NOT\_SUPP\_ON\_SESS

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DEFINE\_LU\_LU\_PASSWORD

DEFINE\_LU\_LU\_PASSWORD provides a password that is used for session-level verification between a local LU and a partner LU.

## VCB Structure

typedef struct define\_lu\_lu\_password

ι						
	unsigned	short	opcode;	/*	verb operation code	*/
	unsigned	char	reserv2;	/*	reserved	*/
	unsigned	char	format;	/*	format	*/
	unsigned	short	primary_rc;	/*	primary return code	*/
	unsigned	long	<pre>secondary_rc;</pre>	/*	secondary return code	*/
	unsigned	char	lu_name[8];	/*	local LU name	*/
	unsigned	char	lu_alias[8];	/*	local LU alias	*/
	unsigned	char	fqplu_name[17];	/*	fully qualified partner	*/
				/*	LU name	*/
	unsigned	char	verification_prot	ocol		
				/*	LULU verification protocol	*/
	unsigned	char	description[RD_LE	N];		
				/*	resource description	*/
	unsigned		reserv3[8];	/*	reserved	*/
			password[8];	/*	password	*/
}	DEFINE_LU_	_LU_PASS	SWORD;			

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_LU\_LU\_PASSWORD

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

### lu\_alias

Local LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_alias** and the **lu\_name** are set to all zeros, the verb is forwarded to the LU associated with the control point (the default LU).

#### fqplu\_name

Fully qualified partner LU name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### verification\_protocol

LU-LU verification protocol for use with this partner LU:

### AP\_BASIC\_PROTOCOL

Only the basic protocol will be used with this partner LU.

#### AP\_ENHANCED\_PROTOCOL

Only the enhanced protocol will be used with this partner LU.

### AP\_EITHER\_PROTOCOL

Either the basic or the enhanced protocol can be used with this partner LU, subject to the following details:

- The default setting of this field is AP\_EITHER\_PROTOCOL.
- The value AP\_EITHER\_PROTOCOL is provided to ease migration to the use of the enhanced protocol. The local LU accepts the basic protocol until the partner LU once agrees to run the enhanced protocol. From then on, the basic protocol is not accepted unless a subsequent DEFINE\_LU\_LU\_PASSWORD is issued to allow it.

### description

Resource description.

### password

Password. This is an 8-byte hexadecimal string. Note that the least significant bit of each byte in the password is not used in session-level verification.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_PLU\_NAME

AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DEFINE\_USERID\_PASSWORD

DEFINE\_USERID\_PASSWORD defines a password associated with a user ID.

## **VCB** Structure

```
define_userid_password
    unsigned short opcode;  /* verb operation code
unsigned char reserv2;  /* reserved
unsigned char format;  /* format
unsigned short primary_rc;  /* primary return code
unsigned long secondary_rc;  /* secondary return code
unsigned short define_type;  /* what the define type is
unsigned char user_id[10];  /* user id
unsigned char reservs[8];  /* reserved
USEPID PASSWOPD CHAPS password chars;
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
     USERID_PASSWORD_CHARS password_chars;
                                                                                   /* password characteristics
                                                                                                                                                  */
} DEFINE USERID PASSWORD;
typedef struct userid password chars
     unsigned char description[RD_LEN];
                                                                                   /* resource description
                                                                                                                                                  */
     unsigned short profile_count; /* number of
unsigned short reserv1; /* reserved
unsigned char password[10]; /* password
unsigned char profiles[10][10]; /* profiles
                                                                                 /* number of profiles
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
                                                                                                                                                  */
} USERID_PASSWORD_CHARS;
```

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

AP\_DEFINE\_USERID\_PASSWORD

### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

### define\_type

Specifies the type of user password being defined:

### AP\_ADD\_USER

Specifies a new user, or change of password for an existing user.

#### **AP\_ADD\_PROFILES**

Specifies an addition to the profiles for an existing user.

### user\_id

User identifier. This is a 10-byte type-AE EBCDIC character string, padded to the right with EBCDIC spaces.

### password\_chars.description

Resource description. This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

#### password\_chars.profile\_count

Number of profiles.

#### password\_chars.password

User's password. This is a 10-byte type-AE EBCDIC character string, padded to the right with EBCDIC spaces.

#### password\_chars.profiles

Profiles associated with user. Each of these is a 10-byte type-AE EBCDIC character string, padded to the right with EBCDIC spaces.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_NO\_PROFILES

AP\_UNKNOWN\_USER AP\_INVALID\_UPDATE\_TYPE AP\_TOO\_MANY\_PROFILES AP\_INVALID\_USERID AP\_INVALID\_PROFILE AP\_INVALID\_PASSWORD

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

#### primary\_rc

## DELETE\_LU\_LU\_PASSWORD

DELETE\_LU\_LU\_PASSWORD deletes an LU-LU password.

## VCB Structure

typedef struct delete\_lu\_lu\_password

ι.						
	unsigned	short	opcode;	/*	verb operation code	*/
	unsigned	char	reserv2;	/*	reserved	*/
	unsigned	char	format;	/*	format	*/
	unsigned	short	primary rc;	/*	primary return code	*/
	unsigned	long	secondary rc;	/*	secondary return code	*/
	unsigned	char	lu_name[8];	/*	LU name	*/
	unsigned	char	lu alias[8];	/*	local LU alias	*/
	unsigned	char	fqplu name[17];	/*	fully qualified partner	*/
				/*	LU name	*/
	unsigned	char	reserv3;	/*	reserved	*/
ł	DELETE LU	LU PASS	SWORD;			

## **Supplied Parameters**

}

The application supplies the following parameters:

#### opcode

AP\_DELETE\_LU\_LU\_PASSWORD

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

### lu\_name

LU name of the local LU. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Local LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_alias** and the **lu\_name** are set to all zeros, the verb is forwarded to the LU associated with the control point (the default LU).

### fqplu\_name

Fully qualified partner LU name. This name is 17 bytes long and is right-padded with EBCDIC spaces. It is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

#### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_INVALID\_PLU\_NAME

### AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_ALIAS

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DELETE\_USERID\_PASSWORD

DELETE\_USERID\_PASSWORD deletes a password associated with a user ID.

### VCB Structure

```
} DELETE USERID PASSWORD;
```

```
typedef struct userid_password_chars
{
    unsigned char description[RD_LEN]; /* resource description */
    unsigned short profile_count; /* number of profiles */
    unsigned short reserv1; /* reserved */
    unsigned char password[10]; /* password */
    unsigned char profiles[10][10]; /* profiles */
} USERID PASSWORD CHARS;
```

## **Supplied Parameters**

The application supplies the following parameters:

#### opcode

```
AP_DELETE_USERID_PASSWORD
```

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

### delete\_type

Specifies the type of delete:

#### AP\_REMOVE\_USER

Deletes the user password, and all associated profiles.

#### **AP\_REMOVE\_PROFILES**

Deletes the specified profiles.

#### user\_id

User identifier. This is a 10-byte type-AE EBCDIC character string, padded to the right with EBCDIC spaces.

### password\_chars.description

This field is ignored when processing this verb.

#### password\_chars.profile\_count

Number of profiles.

#### password\_chars.password

This field is ignored when processing this verb.

#### password\_chars.profiles

Profiles associated with user. Each of these is a 10-byte type-AE EBCDIC character string, padded to the right with EBCDIC spaces.

## **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

## primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

### secondary\_rc

AP\_NO\_PROFILES

AP\_UNKNOWN\_USER AP\_INVALID\_UPDATE\_TYPE

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## SIGN\_OFF

SIGN\_OFF instructs an LU to remove entries from signed on lists. Currently, only entries from the signed-on list are removed. The verb can specify that all entries are removed, or that only those in the appended sign\_off\_data structures.

## VCB Structure

typedef struct query\_sign\_off

unsigned short		/* verb operation code	*/
unsigned char unsigned char	reserv2; format;	/* reserved /* format	*/ */
			*/
unsigned short		/* primary return code	
unsigned long	<pre>secondary_rc;</pre>	/* secondary return code	*/
unsigned char	lu_name[8];	/* LU name	*/
unsigned char	lu_alias[8];	/* LU alias	*/
unsigned char	plū alias[8];	/* partner LU alias	*/
unsigned char	fqplu name[17];	<pre>/* fully gualified partner</pre>	*/
-		/* LU name	*/
unsigned char	list;	/* signed on to/from list	*/
unsigned char		/* sign off all entries in list	t */
unsigned char		/* remove entries immediately	*/
unsigned char	,	/* number of entries	*/
} QUERY SIGN OFF;		7* Humber of encires	~/
J QUERT_SIGN_OFF;			
typedef struct si	gn_off_data		
{			
unsigned char	user id[10];	/* user ID	*/
unsigned char	all profiles;	<pre>/* all profiles for this user</pre>	*/
unsigned char	profile[10];	/* specific profile	*/
<pre>} SIGN OFF DATA;</pre>	p [10],	,	,
, JIUN_OIL_DAIA,			

## Supplied Parameters

The application supplies the following parameters:

#### opcode

AP\_SIGN\_OFF

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the index.

### lu\_alias

Locally defined LU alias. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant and must be set. If both the **lu\_name** and the **lu\_alias** fields are set to all zeros, the LU associated with the control point (the default LU) is used.

### plu\_alias

Partner LU alias. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. If this field is set to all zeros, the **fqplu\_name** field will be used for determining the index.

#### fqplu\_name

17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an

EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

list Signed-on list type. This must be set to AP\_SIGNED\_ON\_TO\_LIST.

### AP\_SIGNED\_ON\_TO\_LIST

The list of users who are signed on to the remote LU from the local LU. Note, the remote LU is not informed when entries are removed from this list. This is the only value currently supported.

#### all\_in\_list

If set to AP\_YES, all users in the list specified by **list** are signed off.

#### immediate

If set to AP\_YES, users are removed immediately. If set to AP\_NO, users are removed once the remote LU has confirmed that the sign-off completed successfully. This field is reserved if **list** is AP\_SIGNED\_ON\_TO\_LIST.

#### num\_entries

Number of entries actually returned.

If **all\_in\_list** is AP\_NO, a list of users must be appended to the SIGN\_OFF VCB, as a series of SIGN\_OFF\_DATA structures. The parameters in the SIGN\_OFF\_DATA structure are as follows:

### sign\_off\_data.user\_id

The user ID.

### sign\_off\_data.all\_profiles

Total number of entries that could have been returned. This can be higher than **num\_entries**.

### sign\_off\_data.profile

This is a 10-byte alphanumeric EBCDIC string. Note, the Program currently supports only the blank profile (10 eBCDIC spaces). This field is ignored if **list\_options** is set to AP\_FIRST\_IN\_LIST.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

### primary\_rc

AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

#### secondary\_rc

AP\_INVALID\_LU\_ALIAS

AP\_INVALID\_LU\_NAME AP\_INVALID\_PLU\_NAME AP\_INVALID\_USERID AP\_INVALID\_PROFILE AP\_INVALID\_LIST AP\_INVALID\_LIST\_OPTION

Any SIGN\_OFF\_DATA **user\_id/profile** combinations that are not successfully processed by the Program, are returned to the application appended to the VCB,

and the returned value of **num\_entries** is the number of SIGN\_OFF\_DATA entries (which could not be processed) returned by the Program.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_LU\_ALIAS

AP\_INVALID\_LU\_NAME AP\_INVALID\_LU\_NAME AP\_INVALID\_LIST

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node stopped, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

# Chapter 11. APING and CPI-C Verbs

This chapter describes verbs used to ping another node and verbs used to define, delete, and query CPI-C side information.

## APING

APING allows a management application to ping a remote LU in the network. A verification data string (of specified length) can be appended to the end of the VCB and returned when the **partner\_ver\_len** field is set to a value greater than zero.

Personal Communications or Communications Server APING is implemented as an internal service transaction program, which uses the Personal Communications or Communications Server APPC API (described in *Personal Communications Client/Server Communications Programming*).

## **VCB** Structure

typedef struct aping

{	peder struc	c apin	ig			
,	unsigned s	hort	opcode;	/*	verb operation code	*/
	unsigned c	har	reserv2;	/*	reserved	*/
	unsigned c	har	format;	/*	format	*/
	unsigned s	hort	primary_rc;	/*	primary return code	*/
	unsigned 1		secondary_rc;	/*	secondary return code	*/
	unsigned c	har	lu_name[8];	/*	local LU name	*/
	unsigned c	har	lu_alias[8];	/*	local LU alias	*/
	unsigned 1	ong	sense_data;	/*	sense data	*/
	unsigned c	har	plu_alias[8];	/*	partner LU alias	*/
	unsigned c	har	<pre>mode_name[8];</pre>	/*	mode name	*/
	unsigned c	har	<pre>tp_name[64];</pre>	/*	destination TP name	*/
	unsigned c		security;	/*	security level	*/
	unsigned c	har	reserv3a[3];	/*	reserved	*/
	unsigned c	har	pwd[10];	/*	password	*/
	unsigned c	har	user_id[10];	/*	user ID	*/
	unsigned s	hort	dlen;	/*	length of data to send	*/
	unsigned s	hort	consec;	/*	number of consecutive sends	*/
	unsigned c	har	fqplu_name[17];	/*	fully qualified partner	*/
				/*	LU name	*/
	unsigned c		echo;		data echo flag	*/
	unsigned s	hort	iterations;	/*	number of iterations	*/
	unsigned 1	•	alloc_time;	-	time taken for ALLOCATE	*/
	unsigned 1	ong	min_time;	/*	min send/receive time	*/
	unsigned l	•	avg_time;		average send/receive time	*/
	unsigned 1	•	_		max send/receive time	*/
	unsigned s	hort	partner_ver_len;	/*	size of string to receive	*/
}	APING;					

## **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_APING

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### lu\_name

LU name of the local LU from which the APING verb is sent. This name is an 8-byte type-A EBCDIC character string. If this field is set to all zeros, the **lu\_alias** field will be used for determining the local LU.

#### lu\_alias

Alias for the local LU from which the APING verb is sent. This is an 8-byte string in a locally displayable character set. This field is only significant if the **lu\_name** field is set to all zeros, in which case all 8 bytes are significant

and must be set. If both the **lu\_name** and the **lu\_alias** are set to binary zeros then the default (control point) LU is used.

### plu\_alias

Alias by which the partner LU is known to the local transaction program. This is an 8-byte string in a locally displayable character set. All 8 bytes are significant and must be set. This name must match the name of a partner LU established during configuration. If this parameter is set to binary zeros, the **fqplu\_name** parameter is used instead.

#### mode\_name

Name of the mode to be used. This is an 8-byte alphanumeric type-A EBCDIC string (starting with a letter), padded to the right with EBCDIC spaces.

#### tp\_name

Name of the invoked transaction program. This is a 64-byte string. The Node Operator Facility does not check the character set of this string. The value of **tp\_name** must match that configured on the remote LU. The string is usually set to APINGD in EBCDIC padded to the right with EBCDIC spaces.

### security

Specifies the information the partner LU requires in order to validate access to the invoked transaction program:

AP\_NONE AP\_PGM AP\_SAME AP\_PGM\_STRONG

pwd Password associated with user\_id. This is a 10-byte type-AE EBCDIC character string, padded to the right with EBCDIC spaces. Only needed if security is set to AP\_PGM or AP\_PGM\_STRONG.

### user\_id

User ID required to access the partner transaction program. This is a 10-byte type-AE EBCDIC character string, padded to the right with EBCDIC spaces. Needed if **security** is set to AP\_PGM, AP\_PGM\_STRONG or AP\_SAME.

- **dlen** Length of data to be sent by APING transaction program. APING sends a string of zeros, of length **dlen**.
- **consec** Number of consecutive sends performed during each iteration. APING issues this number of MC\_SEND\_DATA verbs, each consisting of **dlen** bytes of data. If the **echo** parameter is set to AP\_YES, APING marks the last MC\_SEND\_DATA as AP\_SEND\_DATA\_P\_TO\_R\_FLUSH (Prepare to Receive Flush) and awaits a response containing data from the partner APINGD transaction program (by issuing a MC\_RECEIVE\_AND\_WAIT). If the **echo** parameter is set to AP\_NO, APING flushes the data and awaits a confirm (by marking the last MC\_SEND\_DATA as AP\_SEND\_DATA\_CONFIRM). In either case, the sequence described here corresponds to an SNA chain.

#### fqplu\_name

This is a 17-byte fully qualified network name for the partner LU. This name is composed of two type-A EBCDIC character strings concatenated by an EBCDIC dot, and is right-padded with EBCDIC spaces. (Each name

can have a maximum length of 8 bytes with no embedded spaces.) This field is only significant if the **plu\_alias** field is set to all zeros.

**echo** Specifies whether the APING transaction program expects a response when it has completed sending the required amount of data:

AP\_YES AP\_NO

### iterations

Number of iterations of consecutive sequences (defined by the **consec** parameter) issued by APING. In SNA terms, this parameter defines the number of chains that will be sent.

#### partner\_ver\_len

Maximum length of the partner transaction program verification data string that can be received by the management application.

## **Returned Parameters**

If the verb executes successfully, APING returns the following parameters:

#### primary\_rc

AP\_OK

#### sense\_data

This will be zero if the verb has returned successfully.

### alloc\_time

Time required (in milliseconds) for the MC\_ALLOCATE to the remote transaction program to complete.

#### min\_time

Minimum time (in milliseconds) required for a data-sending iteration. This parameter includes the time required for the partner to respond (either by sending data or issuing a confirm, depending on the setting of the **echo** parameter).

#### avg\_time

Average time (in milliseconds) required for a data-sending iteration. This parameter includes the time required for the partner to respond (either by sending data or issuing a confirm, depending on the setting of the **echo** parameter).

#### max\_time

Maximum time (in milliseconds) required for a data-sending iteration. This parameter includes the time required for the partner to respond (either by sending data or issuing a confirm, depending on the setting of the **echo** parameter).

### partner\_ver\_len

Length of verification string returned by the partner transaction program. The string itself is appended to the end of the VCB.

If the verb does not execute because of a parameter error, the Program returns the following parameters:

### primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_LU\_NAME

### AP\_INVALID\_LU\_ALIAS

APING uses the MC\_ALLOCATE, MC\_SEND\_DATA, MC\_RECEIVE\_AND\_WAIT, MC\_CONFIRM, and MC\_DEALLOCATE verbs provided by the Personal Communications or Communications Server APPC API. The parameters returned by these verbs in the case of unsuccessful execution are documented in *Personal Communications Client/Server Communications Programming*.

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## **CPI-C Verbs**

This section describes the verbs used to define, delete, and query CPI-C side information.

## DEFINE\_CPIC\_SIDE\_INFO

This verb adds or replaces a side information entry in memory. A CPI-C side information entry associates a set of conversation characteristics with a symbolic destination name. If there is already a side information entry in memory with the same symbolic destination name as the one supplied with this verb, it is overwritten with the data supplied to this call. Refer to *CPI-C Reference* for more information about the CPI-C support provided by Personal Communications or Communications Server.

### VCB Structure

```
typedef struct define cpic side info
  unsigned short opcode;
                                       /* verb operation code
                                                                         */
                                       /* reserved
  unsigned char reserv2;
                                                                         */

} CPIC_SIDE_INFO;
```

### **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

AP\_DEFINE\_CPIC\_SIDE\_INFO

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### sym\_dest\_name

Symbolic destination name that identifies the side information entry. This is up to 8 bytes long, padded with spaces, in the locally displayable character set. The allowed characters are the uppercase letters (A to Z) and the digits 0–9.

### def\_data.description

Resource description (returned on QUERY\_CPIC\_SIDE\_INFO). This is a 16-byte string in a locally displayable character set. All 16 bytes are significant.

### def\_data.side\_info.partner\_lu\_name

Fully qualified name of the partner LU. This name is 17 bytes long and is right-padded with spaces, in the locally displayable character set. It is composed of two character strings concatenated by a dot. (Each name can have a maximum length of 8 bytes with no embedded spaces.)

### def\_data.side\_info.tp\_name\_type

Transaction program name type. This field is set to one of the following values:

### XC\_APPLICATION\_TP

Specifies that the transaction program name supplied is not a service transaction program. All characters specified in the transaction program name must be valid characters in the locally displayable character set.

### XC\_SNA\_SERVICE\_TP

Specifies that the transaction program name supplied is that of a service transaction program. All characters, except the first, specified in the transaction program must be valid characters in the locally displayable character set. The first character must be a hexadecimal digit in the range X'01' to X'3F', excluding X'0E' and X'0F'.

### def\_data.side\_info.tp\_name

Transaction program name, a 64-byte character string in the locally displayable character set, right-padded with spaces.

### def\_data.side\_info.mode\_name

Mode name, an 8-byte character string in the locally displayable character set, padded to the right with spaces.

### def\_data.side\_info.conversation\_security\_type

Conversation security type. This field is set to one of the following values:

### XC\_SECURITY\_NONE XC\_SECURITY\_SAME XC\_SECURITY\_PROGRAM XC\_SECURITY\_PROGRAM\_STRONG.

### def\_data.side\_info.security\_user\_id

User ID. Personal Communications or Communications Server will use this field for enforcing conversation-level security.

### def\_data.side\_info.security\_password

Password. Personal Communications or Communications Server will use this field for enforcing conversation-level security.

### def\_data.user\_data

User data. This data is returned on QUERY\_CPIC\_SIDE\_INFO but not used or interpreted by Communications Server. Personal Communications may use it to store the LOCAL\_LU\_ALIAS name specified in the **Define CPI-C Side Information** configuration definition.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

primary\_rc AP\_OK

If the verb does not execute because of a parameter error, the Program returns the following parameters:

primary\_rc AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_SYM\_DEST\_NAME

AP\_INVALID\_LENGTH

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

# primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

## DELETE\_CPIC\_SIDE\_INFO

This verb deletes a CPI-C side information entry. Refer to *CPI-C Reference* for more information about the CPI-C support provided by Personal Communications or Communications Server.

### **VCB Structure**

## **Supplied Parameters**

The application supplies the following parameters:

### opcode

AP\_DELETE\_CPIC\_SIDE\_INFO

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

sym\_dest\_name

Symbolic destination name that identifies the side information entry. This is up to 8 bytes long, padded with spaces, in the locally displayable character set. The allowed characters are the uppercase letters (A to Z) and the digits 0–9.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because of a state error, the Program returns the following parameters:

### primary\_rc

AP\_STATE\_CHECK

```
secondary_rc
```

```
AP_INVALID_SYM_DEST_NAME
```

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

primary\_rc AP\_UNEXPECTED\_SYSTEM\_ERROR

## QUERY\_CPIC\_SIDE\_INFO

This verb returns the side information entry for a given symbolic destination name. The information is returned as a list. To obtain a specific side information entry, or a specific chunk of entries, the **sym\_dest\_name** field should be set. Otherwise this field should be set to all zeros.

### VCB Structure

```

### **Supplied Parameters**

The application supplies the following parameters:

#### opcode

```
AP_QUERY_CPIC_SIDE_INFO
```

### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### buf\_ptr

Pointer to a buffer into which list information can be written.

#### buf\_size

Size of buffer supplied. The data returned will not exceed this size.

#### num\_entries

Maximum number of entries to return. The number of entries will not exceed this value. A value of zero means no limit.

### list\_options

This indicates what should be returned in the list information. The **sym\_dest\_name** specified (see below) represents an index value that is used to specify the starting point of the actual information to be returned:

#### AP\_FIRST\_IN\_LIST

The index value is ignored and the returned list starts from the first entry in the list.

#### AP\_LIST\_FROM\_NEXT

The returned list starts from the next entry in the list after the one specified by the supplied index value.

#### AP\_LIST\_INCLUSIVE

The returned list starts from the entry specified by the index value.

### sym\_dest\_name

Symbolic destination name that identifies the side information entry. This is up to 8 bytes long, padded with spaces, in the locally displayable character set. The allowed characters are the uppercase letters (A to Z) and the digits 0-9.

### **Returned Parameters**

If the verb executes successfully, the Program returns the following parameters:

#### primary\_rc

AP\_OK

### buf\_size

Length of the information returned in the buffer.

### total\_buf\_size

Returned value indicating the size of buffer that would have been required to return all the list information requested. This may be higher than **buf\_size**.

#### num\_entries

Number of entries actually returned.

### total\_num\_entries

Total number of entries that could have been returned. This may be higher than **num\_entries**.

#### cpic\_side\_info\_data.overlay\_size

The number of bytes in this entry, and hence the offset to the next entry returned (if any).

#### cpic\_side\_info\_data.sym\_dest\_name

Symbolic destination name for the returned side information entry.

cpic\_side\_info\_data.def\_data

Defined CPI-C side information as supplied on DEFINE\_CPIC\_SIDE\_INFO verb.

**Note:** CPIC calls may change the side information returned on this verb after the DEFINE\_CPIC\_SIDE\_INFO has been processed by Personal Communications or Communications Server.

If the verb does not execute because of a state error, the Program returns the following parameters:

### primary\_rc

AP\_STATE\_CHECK

### secondary\_rc

AP\_INVALID\_SYM\_DEST\_NAME

If the verb does not execute because the node has not yet been started, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_NOT\_STARTED

If the verb does not execute because the node is stopping, the Program returns the following parameter:

### primary\_rc

AP\_NODE\_STOPPING

If the verb does not execute because of a system error, the Program returns the following parameter:

### primary\_rc

# **Chapter 12. Attach Manager Verbs**

The Personal Communications or Communications Server Attach Manager is used to manage the launching of APPC or CPI-C programs. A description of the Attach Manager function is provided in *Personal Communications Client/Server Communications Programming*.

Personal Communications or Communications Server Node Operator Facility supports three verbs to control the Attach Manager. These verbs are available to any application program that uses Personal Communications or Communications Server Node Operator Facility.

## DISABLE\_ATTACH\_MANAGER

The Personal Communications or Communications Server Attach Manager is enabled by default when the node is started. The user can issue this verb to disable all dynamic loading, This verb resets a global flag that the Attach Manager checks before launching a transaction program.

## VCB Structure

}

typedef struct disable\_am

unsigned s	short	opcode;	/*	Verb operation code	*/
unsigned o	char	reserv2;	/*	reserved	*/
unsigned o	char	format;	/*	format	*/
unsigned s	short	primary_rc;	/*	Primary return code	*/
unsigned 1	long	secondary rc;	/*	Secondary return code	*/
DISABLE_AM;	;	-			

## **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_DISABLE\_ATTACH\_MGR

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## **Returned Parameters**

If the verb executes successfully, the Attach Manager returns the following parameter:

### primary\_rc

AP\_OK

If the verb does not execute because the node has not yet been started, the Attach Manager returns the following parameter:

### primary\_rc

AP\_NODE\_NOT STARTED

If the verb does not execute because of a system error, the Attach Manager returns the following parameter:

### primary\_rc

## ENABLE\_ATTACH\_MANAGER

If the Attach Manager has been disabled, it can be re-enabled by issuing the Personal Communications or Communications Server Node Operator Facility verb, ENABLE\_AM. This sets a global flag that the Attach Manager checks before launching a Transaction Program.

## VCB Structure

## **Supplied Parameters**

The application supplies the following parameters:

opcode

AP\_ENABLE\_ATTACH\_MGR

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## **Returned Parameters**

If the verb executes successfully, the Attach Manager returns the following parameter:

primary\_rc AP\_OK

If the verb does not execute because the node has not yet been started, the Attach Manager returns the following parameter:

### primary\_rc

AP\_NODE\_NOT STARTED

If the verb does not execute because of a system error, the Attach Manager returns the following parameter:

### primary\_rc

## QUERY\_ATTACH\_MANAGER

The QUERY\_ATTACH\_MANAGER verb can be used to discover the status of the Attach Manager component, which can be started and stopped using the ENABLE\_ATTACH\_MANAGER and DISABLE\_ATTACH\_MANAGER commands.

## VCB Structure

typedef struct query\_am

ι				
	unsigned short	opcode;	<pre>/* Verb operation code</pre>	*/
	unsigned char	reserv2;	/* reserved	*/
	unsigned char	format;	/* format	*/
	unsigned short	primary_rc;	/* primary return code	*/
	unsigned long	<pre>secondary_rc;</pre>	/* secondary return code	*/
	unsigned short	active;	<pre>/* status of the Attach Manager</pre>	*/
} QUER	Y_AM;			

## **Supplied Parameters**

opcode

AP\_QUERY\_ATTACH\_MGR

format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## **Returned Parameters**

If the verb executes successfully, the following parameters are returned:

### primary\_rc

AP\_OK

active This field reports the status of the Attach Manager component:

AP\_YES

The Attach Manager is active.

AP\_NO

The Attach Manager is not active.

If the verb does not execute because of a parameter error, the following parameter is returned:

### primary\_rc

AP\_PARAMETER\_CHECK

If the verb does not execute because the node has not yet been started, the Attach Manager returns the following parameter:

### primary\_rc

AP\_NODE\_NOT STARTED

If the verb does not execute because of a system error, the Attach Manager returns the following parameter:

### primary\_rc

Part 2. Personal Communications and Communications Server Management Services API

# **Chapter 13. Introduction to Management Services API**

This chapter describes the management services API provided by Personal Communications or Communications Server.

## Management Services Verbs

Personal Communications or Communications Server supports the following management services (MS) verbs, providing an application program with a method for reporting potential problems to management services focal points available in an SNA network.

- ALERT\_INDICATION
- FP\_INDICATION
- MDS\_MU\_RECEIVED
- NMVT\_RECEIVED
- SEND\_MDS\_MU
- TRANSFER\_MS\_DATA

# **Entry Points**

Personal Communications or Communications Server provides a library file that handles management services verbs.

Management services verbs have a straightforward language interface. Your program fills in fields in a block of memory called a *verb control block* Then your program calls the entry point and passes a pointer to the verb control block. When its operation is complete, management services (MS) API returns, having used and then modified the fields in the verb control block. Your program can then read the returned parameters from the verb control block. Following is a list of entry points for management services verbs:

- WinMS()
- WinMSCleanup()
- WinMSGetIndication()
- WinMSRegisterApplication()
- WinMSStartup()
- WinMSUnregisterApplication()

**WINMS** is the only API supported on the Windows 2000 client; see "WinMS()" on page 606 for more information.

See Chapter 14, "Management Services Entry Points," on page 605 for detailed descriptions of the entry points.

# Verb Control Blocks (VCB)

*Programming Note:* The base operating system optimizes performance by executing some subsystems in the calling application's address space. This means that incorrect use of local descriptor table (LDT) selectors by application programs that have not been fully or correctly debugged can cause improper operation, or

perhaps system failures. Accordingly, application programs should not perform pointer arithmetic operations that involve changing the LDT selector field of a pointer.

The segment used for the verb control block (VCB) must be a read/write data segment. Your program can either declare the VCB as a variable in your program, allocate it or suballocate it from a larger segment. It must be sufficiently large to contain all the fields for the verb your program is issuing.

An application program should not change any part of the verb control block after it has been issued until the verb completes. When management services finishes the execution of a verb, it copies a complete, modified VCB back onto the original block. Therefore, if your program declares a verb control block as a variable, consider declaring it in static storage rather than on the stack of an internal procedure.

Fill all reserved and unused fields in each VCB with zeros (X'00'). In fact, it might be more time-efficient to set the entire verb control block to zeros before your program assigns the values to the parameters. Setting reserved fields to zeros is particularly important.

**Note:** If the VCB is not read/write, or if it is not at least 10 bytes (that is, large enough to hold the management services primary and secondary return codes), management services cannot access it, and the base operating system abnormally ends the process. This termination is recognized as a *general protection fault*, processor exception trap D.

Management services returns the INVALID\_VERB\_SEGMENT primary return code when the VCB is too short or the incorrect type of segment is used.

## Writing Management Services (MS) Programs

Personal Communications or Communications Server provides a dynamic link library (DLL) file, that handles Management Services verbs.

The DLL is reentrant; multiple application processes and threads can call the DLL concurrently.

Management Services verbs have a straightforward language interface. Your program fills in fields in a block of memory called a *verb control block* (VCB). Then it calls the Management Services DLL and passes a pointer to the verb control block. When its operation is complete, Management Services returns, having used and then modified the fields in the VCB. Your program can then read the returned parameters from the verb control block.

Table 3 shows source module usage of supplied header files and libraries needed to compile and link Management Services programs. Some of the header files may include other required header files.

Operating System*	Header File	Library	DLL Name
WIN32	WINMS.H	WINMS32.LIB	WINMS32.DLL

Table 3. Header Files and Libraries for Management Services

\* WIN32 = Windows 2000, Windows Server 2003, and Windows XP

# **SNA API Client Support**

Included with Communications Server are a set of clients for the Windows 2000 and OS/2<sup>®</sup> operating systems. These clients are referred to as SNA API clients in this book and only support a subset of the full management services verbs. Specifically, **WINMS** is the only API supported on the Windows 2000 client; see "WinMS()" on page 606 for more information.

The following is a list of the management services verbs supported:

- TRANSFER\_MS\_DATA
- SEND\_MDS\_MU

# Chapter 14. Management Services Entry Points

This chapter describes the entry points for management services verbs.

# WinMS()

This is the only entry point supported for Windows 2000.

This provides a synchronous entry point for issuing the following management services API verbs:

- SEND\_MDS\_MU
- TRANSFER\_MS\_DATA

# **Syntax**

void WINAPI WinMS(long vcb, unsigned short vcb\_size);

## Parameters

vcb Pointer to verb control block

## vcb\_size

Number of bytes in the verb control block

# Returns

No return value. The **primary\_rc** and **secondary\_rc** fields in the verb control block indicate any error.

# Remarks

This is the main synchronous entry point for the management services API. This call blocks until the verb completes.

# WinMSCleanup()

This function terminates and unregisters an application from the management services API.

# **Syntax**

BOOL WINAPI WinMSCleanup(void);

# Returns

The return value specifies whether the unregistration was successful. If the value is not zero, the application was successfully unregistered. The application was not unregistered if a value of zero is returned.

# Remarks

Use **WinMSCleanup()** to indicate unregistration of a management services application from the management services API.

**WinMSCleanup** unblocks any thread waiting in **WinMSGetIndication**. These return with WMSNOTREG (the application is not registered to receive indication). **WinMSCleanup** unregisters the application for all indications. **WinMSCleanup** returns any outstanding verb (synchronous or asynchronous) with the error AP\_CANCELLED. However, the verb completes inside the node.

It is not a requirement to use **WinMSStartup** and **WinMSCleanup**. However, an application must be consistent in its use of these calls. You should use both of them or never use either of them.

Note: See also WinMSStartup().

## WinMSGetIndication()

This allows the application to receive unsolicited indications.

## Syntax

### Parameters

buffer Pointer to a buffer into which to receive the indication.

## buffer\_size

Size of buffer. Returned: the size of the indication.

#### timeout

Time to wait for indication in milliseconds.

# **Returns**

The function returns a value indicating whether an indication was received.

0 Indication returned.

#### WMSTIMEOUT

Timeout waiting for indication.

## WMSSYSNOTREADY

The underlying network subsystem is not ready for network communication.

## WMSNOTREG

The application is not registered to receive indications.

#### **WMSBADSIZE**

The buffer is too small to receive the indication. Reissue the **WinMSGetIndication** call with a large enough buffer. The size of the indication is returned in the **buffer\_size** parameter.

### WMSBADPOINTER

Either the buffer or **buffer\_size** parameter is not valid.

#### WMSSYSERROR

An unexpected system error has occurred.

## Remarks

This is a blocking call, it returns in one of the following circumstances:

- An indication is returned
- The timeout expires
- The application issues a WinMSCleanup call
- The product is stopped
- A system error occurs

Note: See also WinMSRegisterApplication and WinMSUnregisterApplication.

# WinMSRegisterApplication()

This function registers the application as an NMVT-level application, an MDS-level application, or an alert handler. Such registrations determine which unsolicited indications the application receives.

- An NMVT-level application receives NMVT\_RECEIVED indications.
- An MDS-level application receives MDS\_MU\_RECEIVED indications and also FP\_NOTIFICATION indications when focal-point status changes.
- An alert handler receives ALERT\_INDICATION indications.

**Note:** It is also possible to register to receive NMVTs with conversion to MDS MUs.

Applications that do not process these indications should not call **WinMSRegisterApplication**.

# **Syntax**

BOOL WINAPI WinMSRegisterApplication(unsigned short reg\_type, unsigned char \*ms\_appl\_name, unsigned short vector\_key, unsigned char mds\_conv\_reqd, unsigned char \*ms\_category, unsigned short max\_rcv\_size, unsigned char alert\_dest, unsigned short \*primary\_rc, unsigned long \*secondary\_rc);

### Parameters

#### reg\_type

Registration type

0 .	
WMSNMVTAPP	NMVT-level application
	(or MDS-level application
	registering to receive NMVTs)
WMSMDSAPP	MDS-level application
WMSALERTHANDLER	Alert handler
	registering to receive NMVTs) MDS-level application

### ms\_appl\_name

Management services application name. Valid names can be either an 8-byte alphanumeric type-1134 EBCDIC string, padded with trailing space (X'40') characters if necessary, or one of the management services discipline-specific application programs specified in *SNA Management Services Reference* padded with trailing space (X'40') characters.

This name is used when **reg\_type** is WMSNMVTAPP or WMSMDSAPP. The name is not applicable when **reg\_type** is WMSALERTHANDLER.

#### vector\_key

Management services major vector keys accepted by the application Permitted values are:

Χ'ΥΥΥΥ'	specific major vector key
AP_SPCF_KEYS	major vector keys X'8061'
	through X'8064'
AP_ALL_KEYS	all major vector keys

This key is used when **reg\_type** is WMSNMVTAPP. The key is not applicable when **reg\_type** is WMSMDSAPP or WMSALERTHANDLER.

#### mds\_conv\_reqd

Specifies whether the registering application is MDS-level and requires NMVTs sent to it to be converted to MDS MUs (AP YES or AP NO)

This parameter is used when **reg\_type** is WMSNMVTAPP. The parameter is not applicable when **reg\_type** is WMSMDSAPP or WMSALERTHANDLER.

#### ms\_category

Specifies a management services category when the application desires information pertaining to the focal point for that category. The management services category can be either one of the category codes specified in the management services discipline-specific application programs table provided in *SNA Management Services Reference* padded with trailing space (X'40') characters or a user-defined category. User-defined category names should be an 8-byte alphanumeric type-1134 EBCDIC string, padded with trailing space (X'40') characters if necessary.

This parameter is used when **reg\_type** is WMSMDSAPP. The parameter is not applicable when **reg\_type** is WMSNMVTAPP or WMSALERTHANDLER.

### max\_rcv\_size

Maximum number of bytes the application is capable of receiving in one chunk. MDS MUs bigger that this size will be segmented, and each segment delivered in a separate MDS\_MU\_RECEIVED indication.

This parameter is used when **reg\_type** is WMSMDSAPP. The parameter is not applicable when **reg\_type** is WMSNMVTAPP or WMSALERTHANDLER.

#### alert\_dest

Specifies whether the application wishes to be the only destination of all alerts. If this is set to AP\_YES then all alerts will be routed to the application, and will not be routed anywhere else. If set to AP\_NO, alerts will be routed to the application and over the SNA network in the usual way.

This parameter is used when **reg\_type** is WMSALERTHANDLER. The parameter is not applicable when **reg\_type** is WMSNMVTAPP or WMSMDSAPP.

## primary\_rc

Returned: primary return code

#### secondary\_rc

Returned: secondary return code

## Returns

The function returns a value indicating whether the registration was successful. If the value is not zero, the registration was successful. If the value is zero, the registration was not successful.

## Remarks

Applications can make multiple calls to register more than one class of indications.

Applications that call **WinMSRegisterApplication** must call **WinMSGetIndication** to receive indications that are queued for them.

Note: See also WinMSUnregisterApplication and WinMSGetIndication.

# WinMSStartup()

This function allows an application to specify the version of management services API required and to retrieve the version of the API supported by the product. This function can be called by an application before issuing any further management services API calls to register itself.

# Syntax

## Parameters

## wVersionRequired

Specifies the version of management services API support required. The high-order byte specifies the minor version (revision) number; the low-order byte specifies the major version number.

## msdata

Returns the version of management services API and a description of management services implementation.

# Returns

The return value specifies whether the application was registered successfully and whether the management services API implementation can support the specified version number. If the value is zero, it was registered successfully and the specified version can be supported. Otherwise, the return value is one of the following values:

## WMSSYSERROR

The underlying network subsystem is not ready for network communication.

## WMSVERNOTSUPPORTED

The version of management services API support requested is not provided by this particular management services API implementation.

## WMSBADPOINTER

Incorrect msdata parameter.

## Remarks

WinMSStartup is intended to help with compatibility with future versions of the API. The current version supported is 1.0.

It is not a requirement to use **WinMSStartup** and **WinMSCleanup**. However, an application must be consistent in its use of these calls. You should use both of them or never use either of them.

Note: See also WinMSCleanup().

## WinMSUnregisterApplication()

This function unregisters the application, reversing the effect of an earlier **WinMSRegisterApplication** call, and stopping further indications from being queued for the application.

## **Syntax**

BOOL WINAPI WinMSUnregisterApplication(unsigned short reg\_type, unsigned char \*ms\_appl\_name, unsigned short \*primary\_rc, unsigned long \*secondary rc);

## Parameters

## reg\_type

Registration type. It can have one of the following values:

## WMSNMVTAPP

NMVT-level application

## WMSMDSAPP

MDS-level application

## WMSALERTHANDLER

Alert handler

## ms\_appl\_name

MS application name. Valid names can be either an 8-byte alphanumeric type-1134 EBCDIC string, padded with trailing space (X'40') characters if necessary, or one of the management services discipline-specific application programs specified in *SNA Management Services Reference* padded with trailing space (X'40') characters.

This parameter is used when **reg\_type** is WMSNMVTAPP or WMSMDSAPP. The parameter is not applicable when **reg\_type** is WMSALERTHANDLER.

## primary\_rc

Returned: primary return code

#### secondary\_rc

Returned: secondary return code

## Returns

The function returns a value indicating whether the unregistration was successful. If the value is not zero, the unregistration was successful. If the value is zero, the unregistration was not successful.

## Remarks

Each call to **WinMSUnregisterApplication** terminates a registration made by an earlier call to **WinMSRegisterApplication**. An application that has made multiple calls to **WinMSRegisterApplication** needs to make multiple calls to **WinMSUnregisterApplication** in order to terminate all its registrations.

WinMSUnregisterApplication and WinMSCleanup differ as follows:

- WinMSUnregisterApplication terminates an earlier registration to receive indications, but does not prevent the application from making other management services API calls (for example, WinMS).
- WinMSCleanup terminates use of the management services API.

## WinMSUnregisterApplication()

Indications might already be queued for an application when the application calls **WinMSUnregisterApplication**. Any such indications remain queued, and the application should call **WinMSGetIndication** to receive and process them. Once they have been unregistered, no new indications will be queued for the application.

Note: See also WinMSRegisterApplication and WinMSGetIndication.

WinMSUnregisterApplication()

# Chapter 15. Management Services Verbs

The management services API verbs provided by Personal Communications or Communications Server enable an application to send alerts and MDS MU's, and to receive indications when the node receives MDS or NMVT data or issues an alert.

## ALERT\_INDICATION

This verb indication is used by management services to send alert major vectors to a registered alert handler or registered held alert handler that will process them.

## VCB Structure

typedef struct ms\_alert\_indication

```
unsigned short opcode; /* AP_AlERT_INDICATION */
unsigned char reserv2; /* reserved */
unsigned char format; /* format */
unsigned short primary_rc; /* Primary return code */
unsigned long secondary_rc; /* Secondary return code */
unsigned short alert_length; /* Length of alert */
unsigned char reserv3[6]; /* reserved */
unsigned char *alert; /* Alert data */
} MS_ALERT_INDICATION;
```

# **Supplied Parameters**

#### opcode

AP\_ALERT\_INDICATION

- format
- Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### alert\_length

Length of the alert data.

**alert** Pointer to the alert data. The data pointer is set to NULL, and the data is contiguous with (and begins immediately following) the VCB.

# **FP\_NOTIFICATION**

If an MDS-level application has been registered for a particular management services category and the status of a focal point for that category changes, then management services sends this verb signal to the application.

# **VCB** Structure

# **Supplied Parameters**

opcode

AP\_FP\_NOTIFICATION

## format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

## fp\_routing

Type of routing that should be specified on the SEND\_MDS\_MU when sending a message to the focal point (AP\_DEFAULT or AP\_DIRECT).

## fp\_data\_length

Length of focal point data.

#### fp\_data

Focal point data containing a Focal Point Notification (X'E1') subvector and a Focal Point Identification (X'21') subvector. This data pointer is set to NULL, and the data is contiguous with (and begins immediately following) the VCB.

## MDS\_MU\_RECEIVED

This verb indication is sent by management services to a registered MDS-level application when:

- An MDS\_MU has been received from a peer MDS-level application
- An NMVT has been received, and
  - an appropriate NMVT-level application has not registered
  - The MDS-level application registered with a name that corresponds to the name carried within the management services major vector key in the incoming NMVT (management services performs the conversion from NMVT to MDS\_MU).

## VCB Structure

typedef struct ms\_mds\_mu\_received

unsigned	short	opcode;	/*	Verb operation code	*/
unsigned	char	reserv2;	/*	reserved	*/
unsigned	char	format;	/*	format	*/
unsigned	short	primary_rc;	/*	Primary return code	*/
unsigned	long	secondary_rc;	/*	Secondary return code	*/
unsigned		first_message;	/*	First message for curr MDS_MU	*/
unsigned	char	last_message;	/*	Last message for curr MDS_MU	*/
unsigned	char	pu_name[8];	/*	Physical unit name	*/
unsigned	char	reserv3[8];	/*	reserved	*/
unsigned	short	<pre>mds_mu_length;</pre>	/*	Length of incoming MDS_MU	*/
unsigned	char	<pre>*mds_mu;</pre>	/*	MDS_MU data	*/
MS MDS MU	RECEIVED	);		_	

## Supplied Parameters

#### opcode

}

AP\_MDS\_MU\_RECEIVED

#### format

Identifies the format of the VCB. This field is set to zero to specify the version of the VCB listed above.

#### first\_message

Flag indicating whether this is the first message for the MDS\_MU (AP\_YES or AP\_NO). If the **max\_rcv\_size** specified in the

**WinMSRegisterApplication** call is smaller than the length of the MDS\_MU being delivered, the MDS\_MU will be sent to the application in chunks.

#### last\_message

Flag indicating whether this is the last message for the MDS\_MU (AP\_YES or AP\_NO).

#### pu\_name

Name of the physical unit from which the NMVT (which has been converted to an MDS\_MU) originated. It is the responsibility of the application to respond to the incoming NMVT. The application uses SEND\_MDS\_MU to send the response. When sending responses the application must set the **pu\_name** field of the SEND\_MDS\_MU to the **pu\_name** supplied in the MDS\_MU\_RECEIVED signal. If the MDS\_MU was received from the MDS level transport mechanism, the **pu\_name** will be set to all binary zeros.

#### mds\_mu\_length

Length of MDS\_MU portion included with the signal.

### mds\_mu

MDS\_MU data. The data pointer is set to NULL, and the data is contiguous with (and begins immediately following) the VCB.

## NMVT\_RECEIVED

This verb signal is sent by management services to a registered NMVT-level application when an NMVT is received from a remote node.

In routing incoming NMVTs, management services applies the following rules:

- 1. Try to route to an NMVT-level application registered with the major vector key carried on the incoming NMVT, else...
- 2. If the major vector key is one of X'8061' through X'8064', try to route to a registered NMVT-level AP\_SPCF\_KEYS application, else...
- 3. Try to route to an NMVT-level registered AP\_ALL\_KEYS application, else...
- 4. Try to route the NMVT (after conversion to an MDS\_MU) to an MDS-level application, registered with the major vector key carried on the incoming NMVT, else...
- 5. If the major vector key is one of X'8061' through X'8064', try to route the NMVT (after conversion to an MDS\_MU) to a registered MDS-level application, else...
- 6. Try to route (after conversion to an MDS\_MU) to a registered AP\_ALL\_KEYS MDS-level application, else...
- 7. Negatively respond to the NMVT.

## VCB Structure

typedef struct ms nmvt received

opcode;	<pre>/* Verb operation code</pre>	*/
reserv2;	/* reserved	*/
format;	/* format	*/
primary rc;	/* Primary return code	*/
secondary rc;	/* Secondary return code	*/
pu name[8];	/* Physical unit name	*/
reserv3[6];	/* reserved	*/
nmvt length;	<pre>/* Length of incoming NMVT</pre>	*/
*nmvt;	/* NMVT data	*/
D;		
	<pre>reserv2; format; primary_rc; secondary_rc; pu_name[8]; reserv3[6]; nmvt_length;</pre>	<pre>reserv2; /* reserved format; /* format primary_rc; /* Primary return code secondary_rc; /* Secondary return code pu_name[8]; /* Physical unit name reserv3[6]; /* reserved nmvt_length; /* Length of incoming NMVT *nmvt; /* NMVT data</pre>

# **Supplied Parameters**

#### opcode

}

AP\_NMVT\_RECEIVED

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### pu\_name

Name of the physical unit from which the NMVT originated. It is the responsibility of the application to respond to the incoming NMVT. The application uses TRANSFER\_MS\_DATA to send the response. When sending responses, the application must set the **pu\_name** field of the TRANSFER\_MS\_DATA to the **pu\_name** supplied in the NMVT\_RECEIVED signal.

#### nmvt\_length

Length of NMVT data.

nmvt Full NMVT, containing management services major vector of the types

## NMVT\_RECEIVED

specified on the REGISTER\_NMVT\_APPLICATION. This data pointer is set to NULL, and the data is contiguous with (and begins immediately following) the VCB.

## SEND\_MDS\_MU

This verb is used by a MDS-level application to send network management data other than alerts using the WinMS entry point. If an error occurs during the sending of the MDS\_MU to the destination application, the error is reported back to the origin application in one of two ways. If the error is detected at the local node, the application will be notified via the return codes of the SEND\_MDS\_MU response. If the error is detected at a remote node, the error is reported by means of an error MDS\_MU transported in an MDS\_MU\_RECEIVED VCB. Management services can convert the outgoing MDS\_MU to an NMVT if the destination node is to be reached via an SSCP-PU session. The application does not need to know the identity of its local node. If the application supplies 8 EBCDIC blanks in the netid or **nau** or both subfields of the origin location name subvector of the MDS Routing Information GDS variable, Personal Communications or Communications Server will supply the appropriate values. If an application does not fill in either the **netid** or nau but supplies fewer than 8 blanks, Personal Communications or Communications Server will return a secondary return code of AP\_INVALID\_MDS\_MU\_FORMAT.

## VCB Structure

typedef struct ms\_send\_mds\_mu

unsigned	short	opcode;	/*	Verb operation code	*/
unsigned	char	reserv2;	/*	reserved	*/
unsigned	char	format;	/*	format	*/
unsigned	short	primary_rc;	/*	Primary return code	*/
unsigned	long	secondary rc;	/*	Secondary return code	*/

# **Supplied Parameters**

#### opcode

AP\_SEND\_MDS\_MU

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### options

Specifies optional processing on the data supplied on this verb. This parameter is a one-byte value, with individual bit settings indicating the options selected. If all options are specified, set this byte to zero. Bit 0 is the most significant, and bit 7 is the least significant bit. Bit 0: Adds Date/Time (X'01') subvector to the data if set to zero. Bit 1: Adds Product Set ID (X'10') subvector to the data if set to zero. If the application supplies data that already contains a Product Set ID subvector, then management services adds Personal Communications or Communications Server's Product Set ID subvector immediately before the existing one. Bit 2: reserved. Bit 3: Logs the data via the Personal Communications or Communications Server problem determination facility if set to zero.

**Note:** The following constants are provided in the management services header file that refer to bits 0, 1, and 3 specified above.

- SV\_TIME\_STAMP\_SUBVECTOR
- SV\_PRODUCT\_SET\_ID\_SUBVECTOR
- SV\_LOCAL\_LOGGING

Bit 4: Specifies whether management services is to use default or direct routing to send the management services data to the destination application (AP\_DEFAULT or AP\_DIRECT).

**Note:** To set bit 4, use AP\_DEFAULT or AP\_DIRECT shifted appropriately (for example, AP\_DIRECT<<3). Bits 5–7: reserved.

### originator\_id

Name of component that issued the verb. This field is only used by management services when logging the SEND\_MDS\_MU.

#### pu\_name

Name of the physical unit to send the data to. This should be set to either an 8-byte alphanumeric type-A EBCDIC string, padded to the right with EBCDIC spaces, or set to all binary zeros if no **pu\_name** is specified. Applications using SEND\_MDS\_MU to respond to MDS\_MU\_RECEIVED indications that were converted from incoming NMVTs should specify the **pu\_name** received in the MDS\_MU\_RECEIVED signal. MDS\_MUs that are to be transported using the MDS transport facility should set the **pu\_name** to all binary zeros.

- dlen Length of data.
- **dptr** Pointer to data. If this is set to NULL, management services assumes that the data is contiguous with (and begins immediately following) the VCB.

## **Returned Parameters**

If the verb executes successfully, the Program management services returns the following parameter:

### primary\_rc

AP\_OK

If the verb fails to execute because of a parameter error, the Program management services returns the following parameters:

#### primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

AP\_INVALID\_PU\_NAME

AP\_INVALID\_MDS\_MU\_FORMAT SV\_INVALID\_DATA\_SIZE

If the verb fails to execute because of a state error, the Program management services returns the following parameters:

primary\_rc AP\_STATE\_CHECK

## $secondary\_rc$

AP\_SSCP\_PU\_SESSION\_NOT\_ACTIVE

If the verb does not execute because of a system error, the Program management services returns the following parameter:

### primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## TRANSFER\_MS\_DATA

This verb is used by NMVT-level applications to send unsolicited alerts and to respond to previously-received NMVT requests.

TRANSFER\_MS\_DATA is also used by MDS-level applications to send unsolicited alerts. This verb can be used by the application using the WinMS call.

## VCB Structure

typedef struct ms\_transfer\_ms\_data

í				
	unsigned short	opcode;	<pre>/* Verb operation code */</pre>	/
	unsigned char	data type;	<pre>/* Data type supplied by app */</pre>	/
	unsigned char	format;	/* format */	/
	unsigned short	primary rc;	/* Primary return code */	/
	unsigned long	secondary_rc;	/* Secondary return code */	/
	unsigned char	options;	/* Verb options */	/
	unsigned char	reserv3;	/* reserved */	/
	unsigned char	originator_id[8];	/* Originator ID */	/
	unsigned char	pu_name[8];	/* Physical unit name */	/
	unsigned char	reserv4[4];	/* reserved */	/
	unsigned short	dlen;	/* Length of data */	/
	unsigned char	*dptr;	/* Data */	/
}	MS_TRANSFER_MS_D	ATA;		

# **Supplied Parameters**

The application supplies the following parameters:

```
opcode
```

SV\_TRANSFER\_MS\_DATA

#### data\_type

Specifies the type of data enclosed. management services processes the data as described below. Allowed values:

### SV\_NMVT

The data contains a complete NMVT request unit. Management services converts the data to MDS\_MU or CP\_MSU format if the data contains an alert, and the alert is to be sent to an MDS-level or migration-level focal point. This is the type required when an application is responding to an NMVT\_RECEIVED signal.

## SV\_ALERT\_SUBVECTORS

The data contains management services subvectors in the SNA-defined format for an Alert major vector. Management services adds an NMVT header and an alert major vector header. Subsequently, management services converts the data to MDS\_MU or CP\_MSU format if the alert is to be sent to an MDS-level or migration-level focal point.

#### SV\_USER\_DEFINED

The data contains a complete NMVT request unit. Management services always logs the data, but does not send it.

#### SV\_PDSTATS\_SUBVECTORS

The data contains problem determination statistics. Management services always logs the data, and if an alert handler has been registered, then management services sends it the data within an ALERT\_INDICATION.

#### format

Identifies the format of the VCB. Set this field to zero to specify the version of the VCB listed above.

#### options

Specifies optional processing on the data supplied on this verb. Note that management services processes the data primarily according to the **type** specified if there is any conflict between the **data\_type** and the option specified. This parameter is a one-byte value, with individual bit settings indicating the options selected. If all options are specified, set this byte to zero.

Bit 0 is the most significant, and bit 7 is the least significant bit. (Bits 1–3 are ignored if **data\_type** is set to SV\_USER\_DEFINED.) Bit 0: Adds Date/Time (X'01') subvector to the data if set to zero. Bit 1: Adds Product Set ID (X'10') subvector to the data if set to zero. If the application supplies data that already contains a Product Set ID subvector, management services adds Personal Communications or Communications Server's Product Set ID subvector immediately before the existing one.

Bit 2: Sends the data on an SNA session if set to zero. Management services sends the data on the default SSCP-PU session if the data does not contain an alert. If the data contains an alert, management services sends the data on either an SSCP-PU session, a CP-CP session or an LU-LU session, depending on which type of session Personal Communications or Communications Server uses to transmit alerts to the alert focal point.

Bit 3: Logs the data via the Personal Communications or Communications Server problem determination facility if set to zero.

- **Note:** The following constants are provided in the management services header file and they refer to the individual bits specified above.
  - SV\_TIME\_STAMP\_SUBVECTOR
  - SV\_PRODUCT\_SET\_ID\_SUBVECTOR
  - SV\_SEND\_ON\_SESSION
  - SV\_LOCAL\_LOGGING
- Bits 4–7: reserved.

#### originator\_id

Name of the component that issued the verb. This is an 8-byte string in a locally displayable character set. This field is only used by management services when logging the TRANSFER\_MS\_DATA.

#### pu\_name

Name of the physical unit to send the data to. This should be set to either an 8-byte alphanumeric type-A EBCDIC string, padded to the right with EBCDIC spaces, or set to all binary zeros if no **pu\_name** is specified. Applications using TRANSFER\_MS\_DATA to respond to NMVT\_RECEIVED signals should specify the **pu\_name** received in the NMVT\_RECEIVED signal. The data contained in TRANSFER\_MS\_DATA signals of type SV\_NMVT that do not specify a **pu\_name** will be sent over the default PU session if available. TRANSFER\_MS\_DATA signals containing alerts should not specify a **pu\_name** unless the application expressly wishes the alert data to be sent to a specific PU. This will bypass the normal management services alert routing algorithm.

dlen Length of data.

**dptr** Pointer to data. If this is set to NULL, then management services assumes that the data is contiguous with (and begins immediately following) the VCB.

# **Returned Parameters**

If the verb executes successfully, management services returns the following parameter:

# primary\_rc

AP\_OK

If the verb fails to execute because of a parameter error, management services returns the following parameters:

## primary\_rc

AP\_PARAMETER\_CHECK

secondary\_rc

SV\_INVALID\_DATA\_TYPE

SV\_DATA\_EXCEEDS\_RU\_SIZE AP\_INVALID\_PU\_NAME

If the verb fails to execute because of a state error, management services returns the following parameters:

## primary\_rc

AP\_STATE\_CHECK

### secondary\_rc

SV\_SSCP\_PU\_SESSION\_NOT\_ACTIVE

If the verb does not execute because of a system error, the Program management services returns the following parameter:

primary\_rc

AP\_UNEXPECTED\_SYSTEM\_ERROR

## TRANSFER\_MS\_DATA

Part 3. Appendixes

# Appendix A. IBM APPN MIB Tables

Table 4 gives details on implementing the tables from the IBM APPN management information block (MIB), as defined by RFC1593. The table defines:

- Node Operator Facility QUERY verb used to implement each MIB table
- Input parameter settings
- Any filtering operations required

(The mapping between the returned parameters and the MIB tables variables can be derived from the definition of the Node Operator Facility QUERY verbs). Personal Communications or Communications Server does not currently support the ibmappnNodePortDlcTraceTable and the ibmappnLsStatusTable MIB tables.

 Table 4. Implementing Tables from IBM Management Information Block (MIB)

IBM MIB Table	Node Operator Facility Verb and MIB Table Variables	Input Parameter Settings	
ibmappnNodePortTable	QUERY_PORT	port_name ibmappnNodePortName	
ibmappnNodePortIpTable	(Note 1)		
ibmappnNodePortDlsTable	QUERY_PORT (select entries with <b>dlc_type</b> of AP_SDLC)	<b>port_name</b> ibmappnNodePortDlsName	
ibmappnNodePortTrTable	QUERY_PORT	<b>port_name</b> ibmappnNodePortTrName	
ibmappnNodeLsTable	QUERY_LS	ls_name ibmappnNodeLsName	
ibmappnNodeLsIpTable	(Note 1)		
ibmappnNodeLsDlsTable	QUERY_LS (select entries with <b>dlc_type</b> of AP_SDLC)	ls_name ibmappnNodeLsDlsName	
ibmappnNodeLsTrTable	QUERY_LS	ls_name ibmappnNodeLsTrName	
ibmappnNnTopoRouteTable	QUERY_COS	cos_name ibmappnNnTopoRouteCos	
ibmappnNnAdjNodeTable	QUERY_ADJACENT_NN	adj_nncp_name ibmappnNnAdjNodeAdjName	
ibmappnNnTopologyTable	QUERY_NN_TOPOLOGY_NODE	node_name ibmappnNnNodeName node_type AP_LEARN_NODE frsn 0	
ibmappnNnTgTopologyTable	QUERY_NN_TOPOLOGY_TG	owner ibmappnNnTgOwner owner_type AP_LEARN_NODE dest ibmappnNnTgDest dest_type AP_LEARN_NODE tg_num ibmappnNnTgNum frsn 0	

Table 4. Implementing	Tables from IB	M Management Inf	formation Block (MIB)	(continued)
-----------------------	----------------	------------------	-----------------------	-------------

BM MIB TableNode Operator Facility Verb and MIB Table Variables		Input Parameter Settings		
ibmappnNnTopologyFRTable	QUERY_NN_TOPOLOGY_NODE	node_name ibmappnNnFRNode node_type AP_LEARN_NODE frsn ibmappnNnFRFrsn		
ibmappnNnTgTopologyFRTable	QUERY_NN_TOPOLOGY_TG	owner ibmappnNnTgFROwner owner_type AP_LEARN_NODE dest ibmappnNnTgFRDest dest_type AP_LEARN_NODE tg_num ibmappnNnTgFRNum frsn ibmappnNnTgFRFrsn		
ibmappnLocalTgTable	QUERY_LOCAL_TOPOLOGY	dest ibmappnLocalTGDest dest_type AP_LEARN_NODE tg_num ibmappnLocalTgNum		
ibmappnLocalEnTable	QUERY_LOCAL_TOPOLOGY (select entries with unique <b>dest</b> ) (Note 2)	dest ibmappnLocalEnName dest_type AP_END_NODE dest_type AP_LEARN_NODE		
ibmappnLocalEnTgTable	QUERY_LOCAL_TOPOLOGY (Note 3)	dest ibmappnLocalEnTgOrigin dest_type AP_LEARN_NODE tg_num ibmappnLocalEnTgNum		
ibmappnDirTable	QUERY_DIRECTORY_LU	lu_name ibmappnDirLuName		
ibmappnCosModeTable	QUERY_MODE_TO_COS_MAPPING	<pre>mode_name ibmappnCosModeName</pre>		
ibmappnCosNameTable	QUERY_COS	cos_name ibmappnCosName		

## Notes:

- 1. Personal Communications or Communications Server does not support IP as a DLC type.
- 2. Entries with the same **dest** are ordered consecutively by QUERY\_LOCAL\_TOPOLOGY.
- **3**. The ibmappnLocalEnTgTable views TGs from the attached end node's perspective (that is, as a TG from the end node). However, a network node compliant with the current level of the APPN architecture only stores end node TG information for TGs between itself and directly attached end nodes. Therefore all the entries in this table have ibmappnLocalEnTgDest set to the name of the local node (ibmappnNodeCpName).
