

WebSphere MQ

Using Java

Note!

Before using this information and the product it supports, be sure to read the general information under Appendix J, "Notices" on page 447.

Second edition (October 2002)

This is the second edition of this book that applies to WebSphere MQ. It applies to IBM® WebSphere® MQ classes for Java™ Version 5.3 and WebSphere MQ classes for Java Message Service Version 5.3, and to any subsequent releases and modifications until otherwise indicated in new editions.

Figures	ix	Setting up JMS Postcard	19
Tables	xi	Starting	19
About this book	xiii	Sign-on	20
Who this book is for	xiii	Sending a postcard	20
What you need to know to understand this book	xiii	JMS Postcard configuration	22
How to use this book	xiii	How JMS Postcard works	22
Terms used in this book	xiv	Post installation setup	25
Summary of changes	xv	Additional setup for publish/subscribe mode	26
Changes for this edition (SC34-6066-01)	xv	Queues that require authorization for non-privileged users	29
Changes for the first edition (SC34-6066-00)	xv	Using the sample JMS applet to verify the TCP/IP client	29
Part 1. Guidance for users	1	Using the sample applet with OS/400	30
Chapter 1. Getting started	3	Running the sample applet	30
What are WebSphere MQ classes for Java?	3	Running the point-to-point IVT	31
What are WebSphere MQ classes for Java Message Service?	3	Point-to-point verification without JNDI	31
Who should use WebSphere MQ Java?.	3	Point-to-point verification with JNDI	32
Connection options	4	IVT error recovery	34
Client connection	5	The publish/subscribe installation verification test	35
Bindings connection	5	Publish/subscribe verification without JNDI	35
Prerequisites	6	Publish/subscribe verification with JNDI	36
Chapter 2. Installation	9	PSIVT error recovery	37
What is installed	9	Running your own WebSphere MQ JMS programs	38
Installation directories	10	Solving problems	38
Environment variables	10	Tracing programs	38
STEPLIB configuration on z/OS and OS/390	12	Logging	39
Web server configuration	12	Chapter 5. Using the WebSphere MQ JMS administration tool	41
Running WebSphere MQ Java applications under the Java 2 Security Manager	13	Invoking the administration tool	41
Chapter 3. Using WebSphere MQ classes for Java (WebSphere MQ base Java)	15	Configuration	42
Configuring your queue manager to accept client connections	15	Using an unlisted InitialContextFactory	43
TCP/IP client	15	Security	43
Verifying with the sample application	16	Configuring for WebSphere Application Server V3.5	44
Running your own WebSphere MQ base Java programs	17	Administration commands	44
Solving WebSphere MQ base Java problems	17	Manipulating subcontexts	45
Tracing the sample application	17	Administering JMS objects	45
Error messages	18	Object types	45
Chapter 4. Using WebSphere MQ classes for Java Message Service (WebSphere MQ JMS)	19	Verbs used with JMS objects	47
JMS Postcard	19	Creating objects	47
		Properties	48
		Property dependencies	53
		The ENCODING property	54
		SSL properties	55
		Sample error conditions	56
		Part 2. Programming with WebSphere MQ base Java	57
		Chapter 6. Introduction for programmers	59
		Why should I use the Java interface?	59
		The WebSphere MQ classes for Java interface	60

Java Development Kit	60
WebSphere MQ classes for Java class library	61

Chapter 7. Writing WebSphere MQ base

Java programs 63

Should I write applets or applications?	63
Connection differences.	63
Client connections	63
Bindings mode	64
Defining which connection to use	64
Example code fragments	64
Example applet code	64
Example application code	67
Operations on queue managers.	69
Setting up the WebSphere MQ environment	69
Connecting to a queue manager	70
Accessing queues and processes	70
Handling messages.	71
Handling errors	72
Getting and setting attribute values	73
Multithreaded programs	74
Writing user exits	74
Connection pooling.	75
Controlling the default connection pool	76
The default connection pool and multiple components	77
Supplying a different connection pool	78
Supplying your own ConnectionManager	80
JTA/JDBC coordination using WebSphere MQ base	
Java	81
Installation	81
Usage	82
Known problems and limitations	83
Secure Sockets Layer (SSL) support	84
Enabling SSL	84
Using the distinguished name of the queue manager	84
Using certificate revocation lists	85
Supplying a customized SSLSocketFactory	86
Error handling when using SSL.	87
Compiling and testing WebSphere MQ base Java programs	87
Running WebSphere MQ base Java applets	88
Running WebSphere MQ base Java applications	88
Tracing WebSphere MQ base Java programs	88

Chapter 8. Environment-dependent behavior 91

Core details	91
Restrictions and variations for core classes	92
MQGMO_* values	92
MQPMRF_* values	92
MQPMO_* values	92
MQCNO_FASTPATH_BINDING	92
MQRO_* values	93
Miscellaneous differences with z/OS and OS/390	93
Features outside the core	94
MQQueueManager constructor option	94
MQQueueManager.begin() method	94
MQGetMessageOptions fields	94

Distribution lists.	94
MQPutMessageOptions fields	94
MQMD fields.	95

Part 3. Programming with WebSphere MQ JMS 189

Chapter 10. Writing WebSphere MQ JMS programs 191

The JMS model	191
Building a connection	192
Retrieving the factory from JNDI	192
Using the factory to create a connection	193
Creating factories at runtime	193
Choosing client or bindings transport	194
Obtaining a session	195
Sending a message	195
Setting properties with the set method	197
Message types	197
Receiving a message	198
Message selectors	199
Asynchronous delivery	199
Closing down	200
Java Virtual Machine hangs at shutdown	200
Handling errors	200
Exception listener	200
User exits	200
Using Secure Sockets Layer (SSL)	201
SSL administrative properties	201

Chapter 11. Programming publish/subscribe applications 205

Introduction	205
Getting started with WebSphere MQ JMS and publish/subscribe	205
Choosing a broker	205
Setting up the broker to run the WebSphere MQ JMS	206
Writing a simple publish/subscribe application connecting through WebSphere MQ	207
Import required packages	209
Obtain or create JMS objects	209

Publish messages	211
Receive subscriptions	211
Close down unwanted resources	211
TopicConnectionFactory administered objects	212
Topic administered objects	212
Using topics	213
Topic names	213
Creating topics at runtime	214
Subscriber options	216
Creating non-durable subscribers	216
Creating durable subscribers	216
Using message selectors	216
Suppressing local publications	216
Combining the subscriber options	217
Configuring the base subscriber queue	217
Subscription stores	219
Solving publish/subscribe problems	221
Incomplete publish/subscribe close down	221
Subscriber cleanup utility	222
Manual cleanup	224
Cleanup from within a program	225
Handling broker reports	225

Chapter 12. JMS messages 227

Message selectors	227
Mapping JMS messages onto WebSphere MQ messages	231
The MQRFH2 header	232
JMS fields and properties with corresponding MQMD fields	235
Mapping JMS fields onto WebSphere MQ fields (outgoing messages)	236
Mapping WebSphere MQ fields onto JMS fields (incoming messages)	241
Mapping JMS to a native WebSphere MQ application	243
Message body	243

Chapter 13. WebSphere MQ JMS Application Server Facilities 247

ASF classes and functions	247
ConnectionConsumer	247
Planning an application	248
Error handling	252
Application server sample code	253
MyServerSession.java	255
MyServerSessionPool.java	255
MessageListenerFactory.java	256
Examples of ASF use	257
Load1.java	257
CountingMessageListenerFactory.java	258

About this book

This book describes:

- WebSphere MQ classes for Java, which can be used to access WebSphere MQ systems
- WebSphere MQ classes for Java Message Service, which can be used to access both Java Message Service (JMS) and WebSphere MQ applications

Note: Consult the README file for information that expands and corrects information in this book. The README file is installed with the WebSphere MQ Java code and can be found in the doc subdirectory.

Who this book is for

This information is written for programmers who are familiar with the procedural WebSphere MQ application programming interface as described in the *WebSphere MQ Application Programming Guide*. It shows how to transfer this knowledge to become productive with the WebSphere MQ Java programming interfaces.

What you need to know to understand this book

You need:

- Knowledge of the Java programming language
- Understanding of the purpose of the message queue interface (MQI) as described in the *WebSphere MQ Application Programming Guide* and the chapter about Call Descriptions in the *WebSphere MQ Application Programming Reference*
- Experience of WebSphere MQ programs in general, or familiarity with the content of the other WebSphere MQ publications

Users intending to use the WebSphere MQ base Java with CICS[®] Transaction Server for OS/390[®] also need to be familiar with:

- Customer Information Control System (CICS) concepts
- Using the CICS Java Application Programming Interface (API)
- Running Java programs from within CICS

Users intending to use VisualAge[®] for Java to develop OS/390 UNIX[®] System Services High Performance Java (HPJ) applications should be familiar with the Enterprise Toolkit for OS/390 (supplied with VisualAge for Java Enterprise Edition for OS/390, Version 2).

How to use this book

Part 1 of this book tells you how to use WebSphere MQ base Java and WebSphere MQ JMS; Part 2 helps programmers wanting to use WebSphere MQ base Java; Part 3 helps programmers wanting to use WebSphere MQ JMS.

First, read the chapters in Part 1 that introduce you to WebSphere MQ base Java and WebSphere MQ JMS. Then use the programming guidance in Part 2 or 3 to understand how to use the classes to send and receive WebSphere MQ messages in the environment you want to use.

How to use this book

Remember to check the README file installed with the WebSphere MQ Java code for later or more specific information for your environment.

Terms used in this book

In this book we use the following abbreviations:

WebSphere MQ Java

WebSphere MQ classes for Java and WebSphere MQ classes for Java Message Service combined

WebSphere MQ base Java

WebSphere MQ classes for Java

WebSphere MQ JMS

WebSphere MQ classes for Java Message Service

The term **Version 5.3 products** means:

WebSphere MQ for AIX®, V5.3

WebSphere MQ for HP-UX, V5.3

WebSphere MQ for Linux on Intel and Linux on zSeries™, V5.3

WebSphere MQ for Solaris, V5.3

WebSphere MQ for Windows, V5.3

WebSphere MQ for iSeries

WebSphere MQ for z/OS

The term **WebSphere MQ for UNIX systems** means:

WebSphere MQ for AIX, V5.3

WebSphere MQ for HP-UX, V5.3

WebSphere MQ for Linux for Intel and Linux for zSeries, V5.3

WebSphere MQ for Solaris, V5.3

We also use the term **UNIX systems** as a general terms for the UNIX platforms.

The term **WebSphere MQ for Windows systems** means WebSphere MQ running on the Windows platforms:

Windows NT

Windows 2000

Windows XP

We also use the term **Windows systems** or just **Windows** as general terms for these Windows platforms.

Summary of changes

This section describes changes in this edition of *WebSphere MQ Using Java*. Changes since the previous edition of the book are marked by vertical lines to the left of the changes.

Changes for this edition (SC34-6066-01)

This edition includes the following changes:

- A section listing JMS exception messages.
See Appendix I, “JMS exception messages” on page 431.
- Miscellaneous corrections and clarifications.

Changes for the first edition (SC34-6066-00)

This edition includes the following changes:

- Changes for
 - Integration with the WebSphere MQ product
 - JMS Postcard
 - Secure Sockets Layer (SSL) support
- Miscellaneous corrections and clarifications.

Tidying up undeliverable messages	24		
Exchanging messages between different WebSphere MQ Postcard applications	24		
Customizing JMS Postcard	24		
Post installation setup	25		

Chapter 1. Getting started

This chapter gives an overview of WebSphere MQ classes for Java and WebSphere MQ classes for Java Message Service and their uses.

What are WebSphere MQ classes for Java?

WebSphere MQ classes for Java (also referred to as WebSphere MQ base Java) allow a program written in the Java programming language to:

- Connect to WebSphere MQ as a WebSphere MQ client
- Connect directly to a WebSphere MQ server

WebSphere MQ base Java enables Java applets, applications, and servlets to issue calls and queries to WebSphere MQ. This gives access to mainframe and legacy applications, typically over the Internet, without necessarily having any other WebSphere MQ code on the client machine. With WebSphere MQ base Java, Internet users can become true participants in transactions, rather than just givers and receivers of information.

What are WebSphere MQ classes for Java Message Service?

WebSphere MQ classes for Java Message Service (also referred to as WebSphere MQ JMS) is a set of Java classes that implement Sun's Java Message Service (JMS) interfaces to enable JMS programs to access WebSphere MQ systems. Both the point-to-point and publish/subscribe models of JMS are supported.

Using WebSphere MQ JMS as the API to write WebSphere MQ applications has a number of benefits. Some advantages derive from JMS being an open standard with multiple implementations. Other advantages come from additional features that are present in WebSphere MQ JMS, but not in WebSphere MQ base Java.

Benefits arising from the use of an open standard include:

- The protection of investment, both in skills and application code
- The availability of people skilled in JMS application programming
- The ability to plug in different JMS implementations to fit different requirements

Sun's Web site at <http://java.sun.com> provides more information about the benefits of the JMS API.

The extra function provided over WebSphere MQ base Java includes:

- Asynchronous message delivery. Messages can be delivered to an application as they arrive, on a separate thread.
- Message selectors.
- Support for publish/subscribe messaging.
- Structured, more abstract, message classes. Implementation details are left to the JMS provider.

Who should use WebSphere MQ Java?

If your enterprise fits any of the following scenarios, you can gain significant advantage by using WebSphere MQ classes for Java and WebSphere MQ classes for Java Message Service:

Who should use WebSphere MQ Java

- A medium or large enterprise that is introducing intranet-based client/server solutions. Here, Internet technology provides low cost easy access to global communications; WebSphere MQ connectivity provides high integrity with assured delivery and time independence.
- A medium or large enterprise with a need for reliable business-to-business communications with partner enterprises. Here again, the Internet provides low-cost easy access to global communications; WebSphere MQ connectivity provides high integrity with assured delivery and time independence.
- A medium or large enterprise that wants to provide access from the public Internet to some of its enterprise applications. Here, the Internet provides global reach at a low cost; WebSphere MQ connectivity provides high integrity through the queuing paradigm. In addition to low cost, the business can achieve improved customer satisfaction through 24 hour a day availability, fast response, and improved accuracy.
- An Internet Service provider, or other Value Added Network provider. These companies can exploit the low cost and easy communications provided by the Internet. They can also add value with the high integrity provided by WebSphere MQ connectivity. An Internet Service provider that exploits WebSphere MQ can immediately acknowledge receipt of input data from a Web browser, guarantee delivery, and provide an easy way for the user of the Web browser to monitor the status of the message.

WebSphere MQ and WebSphere MQ classes for Java Message Service provide an excellent infrastructure to access enterprise applications and develop complex Web applications. A service request from a Web browser can be queued then processed when possible, allowing a timely response to be sent to the end user, regardless of system loading. By placing this queue *close* to the user in network terms, the load on the network does not impact the timeliness of the response. Also, the transactional nature of WebSphere MQ messaging means that a simple request from the browser can be expanded safely into a sequence of individual back end processes in a transactional manner.

WebSphere MQ classes for Java also enables application developers to exploit the power of the Java programming language to create applets and applications that can run on any platform that supports the Java runtime environment. These factors combine to reduce the development time for multi-platform WebSphere MQ applications significantly. Also, if there are enhancements to applets in the future, end users automatically pick these up as the applet code is downloaded.

Connection options

Programmable options allow WebSphere MQ Java to connect to WebSphere MQ in either of the following ways:

- As a WebSphere MQ client using Transmission Control Protocol/Internet Protocol (TCP/IP)
- In bindings mode, connecting directly to WebSphere MQ

Table 1 on page 5 shows which of these connection modes can be used for each platform.

In addition, WebSphere MQ JMS publish/subscribe applications can connect directly across TCP/IP to the IBM WebSphere MQ Event Broker program. For more information about this connection see Chapter 11, "Programming publish/subscribe applications" on page 205.

Table 1. Platforms and connection modes

Server platform	Client	Bindings
Windows NT [®]	yes	yes
Windows [®] 2000	yes	yes
Windows XP	yes	yes
AIX	yes	yes
Solaris (v2.6, v2.8, V7, or SunOS v5.6, v5.7)	yes	yes
OS/400 [®]	yes	yes
HP-UX	yes	yes
OS/390 and z/OS [™]	no	yes
Linux on Intel	yes	yes
Linux on zSeries	yes	no

Notes:

1. HP-UX Java bindings support is available only for HP-UXv11 systems running the POSIX draft 10 pthreaded version of WebSphere MQ.
2. On Linux on zSeries, only TCP/IP client connectivity is supported.

The following sections describe these options in more detail.

Client connection

To use WebSphere MQ Java as a WebSphere MQ client, you can install it either on the WebSphere MQ server machine, which may also contain a Web server, or on a separate machine. If you install WebSphere MQ Java on the same machine as a Web server, you can download and run WebSphere MQ client applications on machines that do not have WebSphere MQ Java installed locally.

Wherever you choose to install the client, you can run it in three different modes:

From within any Java-enabled Web browser

In this mode, the locations of the WebSphere MQ queue managers that can be accessed are constrained by the security restrictions of the browser that is used.

Using an appletviewer

To use this method, you must have the Java Development Kit (JDK[™]) or Java Runtime Environment (JRE) installed on the client machine.

As a standalone Java program or in a Web application server

To use this method, you must have the Java Development Kit (JDK) or Java Runtime Environment (JRE) installed on the client machine.

Bindings connection

When used in bindings mode, WebSphere MQ Java uses the Java Native Interface (JNI) to call directly into the existing queue manager API, rather than communicating through a network. This provides better performance for WebSphere MQ applications than using network connections. Unlike the client mode, applications that are written using the bindings mode cannot be downloaded as applets.

Connections

To use the bindings connection, you must install WebSphere MQ Java on the WebSphere MQ server.

Prerequisites

To run WebSphere MQ base Java, you need the following software:

- WebSphere MQ for the server platform you want to use.
- Java Development Kit (JDK) for the server platform.
- Java Development Kit, Java Runtime Environment (JRE), or Java-enabled Web browser for client platforms. (See “Client connection” on page 5.)
- For z/OS and OS/390, OS/390 Version 2 Release 9 or higher, or z/OS, with UNIX System Services (USS).
- For OS/400, the iSeries™ Developer Kit for Java, 5769-JV1, and the Qshell Interpreter, OS/400 (5769-SS1) Option 30.

The following list shows the supported Java 2 Software Development Kits and Java Runtime Environments:

- IBM Developer Kit for AIX, Java Technology Edition, Version 1.3.1
- IBM Developer Kit for Linux, Java Technology Edition, Version 1.3.1
- IBM Developer Kit for OS/390, Java Technology Edition, Version 1.3.1
- IBM Developer Kit for Windows, Java Technology Edition, Version 1.3.0
- IBM iSeries Developer Kit for Java, Version 1.3
- HP-UX SDK, for the Java platform, Version 1.3.1
- Java 2 Standard Edition, for the Solaris Operating Environment, SDK 1.3.1

To fully support Secure Socket Layer (SSL) authentication, you need a Java Runtime Environment at Version 1.4.0 for your platform. SSL support enables WebSphere MQ Java and Java Message Service (JMS) applications to benefit from secure connection to the queue manager, providing authentication, message integrity, and data encryption.

Check the README file for the latest information about operating system levels this product has been tested against.

To use the WebSphere MQ JMS administration tool (see Chapter 5, “Using the WebSphere MQ JMS administration tool” on page 41), you need one of the following service provider packages, supplied with WebSphere MQ:

- Lightweight Directory Access Protocol (LDAP) - ldap.jar, providerutil.jar.
- File system - fscontext.jar, providerutil.jar.

These packages provide the Java Naming and Directory Service (JNDI) service. This is the resource that stores physical representations of the administered objects. Users of WebSphere MQ JMS probably use an LDAP server for this purpose, but the tool also supports the use of the file system context service provider. If you use an LDAP server, configure it to store JMS objects. For information to assist with this configuration, refer to Appendix C, “LDAP schema definition for storing Java objects” on page 407.

To use publish/subscribe applications, you need one of the following:

- SupportPac™ MA0C: MQSeries® Publish/Subscribe. You can find this at:
www.ibm.com/software/ts/mqseries/txppacs/ma0c.html
- WebSphere MQ Integrator Version 2
- WebSphere MQ Event Broker

Prerequisites

To use the XOpen/XA facilities of WebSphere MQ JMS on OS/400 you need a specific PTF. Check the README file for further information.

Chapter 2. Installation

This chapter tells you how to install the WebSphere MQ classes for Java and WebSphere MQ classes for Java Message Service code.

What is installed

The latest versions of both WebSphere MQ base Java and WebSphere MQ JMS (together known as WebSphere MQ Java) are installed with WebSphere MQ. You might need to override default installation options to make sure this is done.

Refer to the following books for more information about installing WebSphere MQ:

WebSphere MQ for AIX, V5.3 Quick Beginnings

WebSphere MQ for HP-UX, V5.3 Quick Beginnings

WebSphere MQ for iSeries V5.3 Quick Beginnings

WebSphere MQ for Linux for Intel and Linux for zSeries, V5.3 Quick Beginnings

WebSphere MQ for Solaris, V5.3 Quick Beginnings

WebSphere MQ for Windows, V5.3 Quick Beginnings

WebSphere MQ for z/OS System Setup Guide

WebSphere MQ base Java is contained in the following Java .jar files:

com.ibm.mq.jar	This code includes support for all the connection options.
com.ibm.mqbind.jar	This code supports only the bindings connection and is not supplied or supported on all platforms. We recommend that you do not use it in any new applications.

WebSphere MQ JMS is contained in the following Java .jar file:

com.ibm.mqjms.jar

The following Java libraries from Sun Microsystems are distributed with the WebSphere MQ JMS product:

connector.jar	Version 1.0
fscontext.jar	Version 1.2 Beta 3
jms.jar	Version 1.0.2
jndi.jar	Version 1.2.1 (except for z/OS and OS/390)
ldap.jar	Version 1.2.2 (except for z/OS and OS/390)
providerutil.jar	Version 1.2
jta.jar	Version 1.0.1

When installation is complete, files and samples are installed in the locations shown in "Installation directories" on page 10.

We also supply **postcard.jar** for the Postcard application; see "JMS Postcard" on page 19.

What is installed

After installation, update your environment variables, as shown in “Environment variables”.

Note: Do not install the product, then subsequently install or reinstall a version of SupportPac MA88, or your WebSphere MQ Java support might revert to an earlier level.

Installation directories

The WebSphere MQ Java V5.3 files are installed in the directories shown in Table 2.

Table 2. Product installation directories

Platform	Directory
AIX	/usr/mqm/java/
z/OS and OS/390	<i>install_dir</i> /mqm/java/
iSeries and AS/400®	/QIBM/ProdData/mqm/java/
HP-UX and Solaris	/opt/mqm/java/
Linux	/opt/mqm/java/
Windows systems	\Program Files\IBM\WebSphere MQ\java

Note: On z/OS and OS/390, *install_dir* is the directory in which you installed the product; this is likely to be /usr/lpp.

Some sample programs, such as the Installation Verification Programs (IVP), are supplied. Table 3 lists the directory path to these on different platforms. WebSphere MQ base Java samples are within a subdirectory base and WebSphere MQ JMS samples are within a subdirectory jms.

Table 3. Samples directories

Platform	Directory
AIX	/usr/mqm/samp/java/
z/OS and OS/390	<i>install_dir</i> /mqm/java/samples/
iSeries and AS/400	/QIBM/ProdData/mqm/java/samples/
HP-UX and Solaris	/opt/mqm/samp/java/
Linux	/opt/mqm/samp/java/
Windows systems	\Program Files\IBM\WebSphere MQ\tools\Java\

Note: On z/OS and OS/390, *install_dir* is the directory in which you installed the product; this is likely to be /usr/lpp.

Environment variables

After installation, update your CLASSPATH environment variable to include the WebSphere MQ base Java code and samples directories. Table 4 on page 11 shows typical CLASSPATH settings for the various platforms.

WebSphere MQ Java uses other environment variables. Some are platform dependent and are listed in Table 5 on page 12. MQ_JAVA_INSTALL_PATH and MQ_JAVA_DATA_PATH are common across platforms. On Windows systems, these variables are automatically set by the installation program, but on other platforms you need to set them manually to complete installation.

MQ_JAVA_INSTALL_PATH points to the product installation directory, as shown in Table 2 on page 10. MQ_JAVA_DATA_PATH points to the root directory for logging and tracing, and is included so that you can use the same directory for WebSphere MQ Java and the base WebSphere MQ product.

Table 4. Sample CLASSPATH statements for the product

Platform	Sample CLASSPATH
AIX	CLASSPATH=/usr/mqm/java/lib/com.ibm.mq.jar: /usr/mqm/java/lib/connector.jar: /usr/mqm/samp/java/base:
HP-UX and Solaris	CLASSPATH=/opt/mqm/java/lib/com.ibm.mq.jar: /opt/mqm/java/lib/connector.jar: /opt/mqm/samp/java/base:
Windows systems	CLASSPATH= <i>mq_root_dir</i> ^1\java\lib\com.ibm.mq.jar; <i>mq_root_dir</i> ^1\java\lib\connector.jar; <i>mq_root_dir</i> ^1\tools\java\base\ <i>mq_root_dir</i> ^1\java\lib\jta.jar;
z/OS and OS/390	CLASSPATH= <i>install_dir</i> ² /mqm/java/lib/com.ibm.mq.jar: <i>install_dir</i> /mqm/java/lib/connector.jar: <i>install_dir</i> /mqm/java/samples/base:
iSeries and AS/400	CLASSPATH=/QIBM/ProdData/mqm/java/lib/com.ibm.mq.jar: /QIBM/ProdData/mqm/java/lib/connector.jar: /QIBM/ProdData/mqm/java/samples/base:
Linux	CLASSPATH=/opt/mqm/java/lib/com.ibm.mq.jar: /opt/mqm/java/lib/connector.jar: /opt/mqm/samp/java/base:
<p>Notes:</p> <ol style="list-style-type: none"> <i>mq_root_dir</i> stands here for the directory used to install WebSphere MQ on Windows systems. This is normally C:\Program Files\IBM\WebSphere MQ\. <i>install_dir</i> is the directory in which you installed the product 	

To use WebSphere MQ JMS, you must include additional jar files in the classpath. These are listed in “Post installation setup” on page 25.

If there are existing applications with a dependency on the deprecated bindings package com.ibm.mqbind, you must also add the file com.ibm.mqbind.jar to your classpath.

You must update additional environment variables on some platforms, as shown in Table 5 on page 12.

Installation directories

Table 5. Environment variables for the product

Platform	Environment variable
AIX	LD_LIBRARY_PATH=/usr/mqm/java/lib
HP-UX	SHLIB_PATH=/opt/mqm/java/lib
Solaris	LD_LIBRARY_PATH=/opt/mqm/java/lib
Windows systems	PATH= <i>install_dir</i> \lib
z/OS and OS/390	LIBPATH= <i>install_dir</i> /mqm/java/lib
Linux	LD_LIBRARY_PATH=/opt/mqm/java/lib
Note: <i>install_dir</i> is the installation directory for the product	

Notes:

1. To use WebSphere MQ Bindings for Java on OS/400, ensure that the library QMQMJAVA is in your library list.
2. Ensure that you append the WebSphere MQ variables and do not overwrite any of the existing system environment variables. If you overwrite existing system environment variables, the application might fail during compilation or at runtime.

STEPLIB configuration on z/OS and OS/390

On z/OS and OS/390, the STEPLIB used at runtime must contain the WebSphere MQ SCSQAUTH library. From UNIX System Services, you can add this using a line in your .profile as shown below, replacing thlqual with the high level data set qualifier that you chose when installing WebSphere MQ:

```
export STEPLIB=thlqual.SCSQAUTH:$STEPLIB
```

In other environments, you typically need to edit the startup JCL to include SCSQAUTH on the STEPLIB concatenation:

```
STEPLIB DD DSN=thlqual.SCSQAUTH,DISP=SHR
```

Web server configuration

If you install WebSphere MQ Java on a Web server, you can download and run WebSphere MQ Java applications on machines that do not have WebSphere MQ Java installed locally. To make the WebSphere MQ Java files accessible to your Web server, set up your Web server configuration to point to the directory where the client is installed. Consult your Web server documentation for details of how to configure this.

Note: On z/OS and OS/390, the installed classes do not support client connection and cannot be usefully downloaded to clients. However, jar files from another platform can be transferred to z/OS and OS/390 and served to clients.

Running WebSphere MQ Java applications under the Java 2 Security Manager

WebSphere MQ Java can run with the Java 2 Security Manager enabled. To successfully run applications with the Security Manager enabled, you must configure your JVM with a suitable policy definition file.

The simplest way to do this is to change the policy file supplied with the JRE. On most systems this file is stored in the path `lib/security/java.policy`, relative to your JRE directory. You can edit policy files using your preferred editor or the `policytool` program supplied with your JRE.

You need to give authority to the `com.ibm.mq.jar` and `com.ibm.mqjms.jar` files so that they can:

- Create sockets (in client mode)
- Load the native library (in bindings mode)
- Read various properties from the environment

Here is an example of a policy file entry that allows WebSphere MQ Java to run successfully under the default security manager. Replace the string `/opt/mqm` in this example with the location where WebSphere MQ Java is installed on your system.

```
grant codeBase "file:/opt/mqm/java/lib/com.ibm.mq.jar" {
    permission java.net.SocketPermission "*", "connect";
    permission java.lang.RuntimePermission "loadLibrary.*";
};

grant codeBase "file:/opt/mqm/java/lib/com.ibm.mqjms.jar" {
    permission java.util.PropertyPermission "MQJMS_LOG_DIR", "read";
    permission java.util.PropertyPermission "MQJMS_TRACE_LEVEL", "read";
    permission java.util.PropertyPermission "MQJMS_TRACE_DIR", "read";
    permission java.util.PropertyPermission "MQ_JAVA_INSTALL_PATH", "read";
    permission java.util.PropertyPermission "file.separator", "read";
    permission java.util.PropertyPermission "user.name", "read";
    permission java.util.PropertyPermission "com.ibm.mq.jms.cleanup", "read";
};
```

This example of a policy file enables the WebSphere MQ Java classes to work correctly under the security manager, but you might still need to enable your own code to run correctly before your applications will work.

The sample code shipped with WebSphere MQ Java has not been specifically enabled for use with the security manager; however the IVT tests run with the above policy file and the default security manager in place.

Chapter 3. Using WebSphere MQ classes for Java (WebSphere MQ base Java)

This chapter tells you how to:

- Configure your system to run the sample applet and application programs to verify your WebSphere MQ base Java installation.
- Modify the procedures to run your own programs.

Remember to check the README file installed with the WebSphere MQ Java code for later or more specific information for your environment.

The procedures depend on the connection option you want to use. Follow the instructions in the section that is appropriate for your requirements.

Configuring your queue manager to accept client connections

Use the following procedures to configure your queue manager to accept incoming connection requests from the clients.

TCP/IP client

1. Define a server connection channel using the following procedures:

For the OS/400 platform:

- a. Start your queue manager by using the STRMQM command.
- b. Define a sample channel called JAVA.CHANNEL by issuing the following command:

```
CRTMQMCHL CHLNAME(JAVA.CHANNEL) CHLTYPE(*SVRCN) MQMNAME(QMGRNAME)
          MCAUSERID(SOMEUSERID)
          TEXT('Sample channel for WebSphere MQ classes for Java')
```

where QMGRNAME is the name of your queue manager, and SOMEUSERID is an OS/400 user ID with appropriate authority to the WebSphere MQ resources.

For z/OS or OS/390 platforms:

Note: You must have the Client attachment feature installed on your target queue manager in order to connect using TCP/IP.

- a. Start your queue manager by using the START QMGR command.
- b. Define a sample channel called JAVA.CHANNEL by issuing the following command:

```
DEF CHL('JAVA.CHANNEL') CHLTYPE(SVRCONN) TRPTYPE(TCP)
DESCR('Sample channel for WebSphere MQ classes for Java')
```

For other platforms:

- a. Start your queue manager by using the strmqm command.
- b. Type the following command to start the runmqsc program:
runmqsc [QMNAME]
- c. Define a sample channel called JAVA.CHANNEL by issuing the following command:

Using WebSphere MQ base Java

```
DEF CHL('JAVA.CHANNEL') CHLTYPE(SVRCONN) TRPTYPE(TCP) MCAUSER(' ') +  
DESCR('Sample channel for WebSphere MQ classes for Java')
```

2. Start a listener program with the following commands:

For Windows operating systems:

Issue the command:

```
runmqtsr -t tcp [-m QMNAME] -p 1414
```

Note: If you use the default queue manager, you can omit the -m option.

For UNIX operating systems:

Configure the inetd daemon, so that the inetd starts the WebSphere MQ channels. See *WebSphere MQ Clients* for instructions on how to do this.

For the OS/400 operating system:

Issue the command:

```
STRMQLSR MQMNAME(QMGRNAME)
```

where QMGRNAME is the name of your queue manager.

For the z/OS or OS/390 operating system:

- a. Ensure your channel initiator is started. If not, start it by issuing the START CHINIT command.
- b. Start the listener by issuing the command START LISTENER TRPTYPE(TCP) PORT(1414)

Verifying with the sample application

An installation verification program, MQIVP, is supplied with WebSphere MQ base Java. You can use this application to test all the connection modes of WebSphere MQ base Java. The program prompts for a number of choices and other data to determine which connection mode you want to verify. Use the following procedure to verify your installation:

1. To test a client connection:
 - a. Configure your queue manager, as described in “Configuring your queue manager to accept client connections” on page 15.
 - b. Carry out the rest of this procedure on the client machine.

To test a bindings connection, carry out the rest of this procedure on the WebSphere MQ server machine.

2. Change to your samples directory.
See Table 3 on page 10 to find where this is.

3. Type:
java MQIVP

The program tries to:

- a. Connect to, and disconnect from, the named queue manager.
 - b. Open, put, get, and close the system default local queue.
 - c. Return a message if the operations are successful.
4. At the prompt ⁽¹⁾:
 - To use a TCP/IP connection, enter a WebSphere MQ server host name.
 - To use native connection (bindings mode), leave the field blank. (Do not enter a name.)

Installation verification program

Here is an example of the prompts and responses you might see. The actual prompts and your responses depend on your WebSphere MQ network.

```
| Please enter the IP address of the MQ server           : ipaddress(1)  
| Please enter the port to connect to                 : (1414)(2)  
| Please enter the server connection channel name     : channelname(2)  
| Please enter the queue manager name                 : qmname  
| Success: Connected to queue manager.  
| Success: Opened SYSTEM.DEFAULT.LOCAL.QUEUE  
| Success: Put a message to SYSTEM.DEFAULT.LOCAL.QUEUE  
| Success: Got a message from SYSTEM.DEFAULT.LOCAL.QUEUE  
| Success: Closed SYSTEM.DEFAULT.LOCAL.QUEUE  
| Success: Disconnected from queue manager
```

```
| Tests complete -  
| SUCCESS: This MQ Transport is functioning correctly.  
| Press Enter to continue ...
```

Notes:

1. If you choose server connection, you do not see the prompts marked ⁽²⁾.
2. On z/OS and OS/390, leave the field blank at prompt ⁽¹⁾.
3. On OS/400, you can run the command `java MQIVP` only from the Qshell interactive interface (the Qshell is option 30 of OS/400, 5769-SS1). Alternatively, you can run the application by using the CL command `RUNJAVA CLASS(MQIVP)`.
4. To use the WebSphere MQ bindings for Java on OS/400, you must ensure that the library `QMQMJAVA` is in your library list.

Running your own WebSphere MQ base Java programs

To run your own Java applets or applications, use the procedures described for the verification programs, substituting your application name in place of MQIVP.

For information on writing WebSphere MQ base Java applications and applets, see Part 2, “Programming with WebSphere MQ base Java” on page 57.

Solving WebSphere MQ base Java problems

If a program does not complete successfully, run the installation verification applet or installation verification program, and follow the advice given in the diagnostic messages. Both of these programs are described in Chapter 3, “Using WebSphere MQ classes for Java (WebSphere MQ base Java)” on page 15.

If the problems continue and you need to contact the IBM service team, you might be asked to turn on the trace facility. Refer to the following sections for the appropriate procedures for your system.

Tracing the sample application

To trace the MQIVP program, enter the following:

```
java MQIVP -trace n
```

where *n* is a number between 1 and 5, depending on the level of detail required. (The greater the number, the more information is gathered.)

For more information about how to use trace, see “Tracing WebSphere MQ base Java programs” on page 88.

Error messages

Error messages

Here are some of the more common error messages that you might see:

Unable to identify local host IP address

The server is not connected to the network.

Connect the server to the network and retry.

MQRC_ADAPTER_CONN_LOAD_ERROR

If you see this z/OS error , ensure that the WebSphere MQ SCSQANLE and SCSQAUTH datasets are in your STEPLIB statement.

Chapter 4. Using WebSphere MQ classes for Java Message Service (WebSphere MQ JMS)

This chapter tells you how to:

- Set up and use JMS Postcard
- Set up your system to use the test and sample programs
- Run the point-to-point Installation Verification Test (IVT) program to verify your WebSphere MQ classes for Java Message Service installation
- Run the sample publish/subscribe Installation Verification Test (PSIVT) program to verify your publish/subscribe installation
- Run your own programs

JMS Postcard

JMS Postcard is a simple way to do the following:

- Verify that you have successfully installed WebSphere MQ and WebSphere MQ JMS on one computer and, optionally, on others as well
- Introduce you to messaging

Note: JMS Postcard is *not* supported on WebSphere MQ for z/OS or WebSphere MQ for iSeries.

Setting up JMS Postcard

To use JMS Postcard, make sure that the Java Messaging feature of WebSphere MQ for Windows (WebSphere MQ JMS) is installed. You also need a working Java Runtime Environment (JRE) at Java 1.3 level.

Before you can successfully run the JMS Postcard application, define the environment variables CLASSPATH, LIBPATH, MQ_JAVA_INSTALL_PATH, and MQ_JAVA_DATA_PATH. On Windows systems these variables are set as part of the install process. On other platforms you must set them yourself. For more information about these variables, see “Environment variables” on page 10.

Many operations that the Postcard application carries out on your behalf require the user to be a member of the WebSphere MQ administrators group (mqm). If you are not a member of mqm, get a member of the mqm group to set up the *default configuration* on your behalf. See “JMS Postcard default configuration” on page 22.

Starting

To start the JMS Postcard application, run the postcard script. This is supplied in the java/bin directory of the WebSphere MQ installation.

The first time that you run JMS Postcard, it asks you to complete the default configuration, which sets up a suitable queue manager to act as mailbox. See “JMS Postcard default configuration” on page 22.

Whenever you start a Postcard application, you must sign on and enter a nickname. (There are advanced options available on the sign-on dialog, see “Sign-on advanced options” on page 20 for details).

Sign-on

The sign-on dialog has a check box labelled Advanced. Check this to see the extended dialog where you can choose which queue manager is used by the Postcard program.

Notes:

1. If you have no queue managers at all, or just the default configuration, the checkbox is disabled.
2. Depending on what queue managers and clusters you have, the checkbox and options are in one of various combinations of enabled, disabled, and preselected.

Sign-on advanced options

Use default configuration as mailbox

This is the easiest way to use JMS Postcard on one or several computers. Make sure that the default configuration is installed on all the computers, that one of them holds the repository, and that all the others use the first one as their repository; this puts them all in the same cluster.

Choose queue manager as mailbox

Use the drop-down list to choose any one of your local queue managers. If you want to send postcards between two queue managers (on one or more computers) this way, make sure that one of the following conditions is true:

- The queue managers are in the same cluster (for more information about clusters, see the *WebSphere MQ Queue Manager Clusters* book).
- There are explicit connections between the queue managers.

Sending a postcard

To send a postcard successfully, you need two instances of the Postcard application with different nicknames. For example, suppose you start the Postcard application and use the nickname Will, and then start it again using the nickname Tim. Will can send postcards to Tim and Tim can send postcards to Will.

If Will and Tim are connected to the same queue manager, see “Running JMS Postcard with one queue manager”.

If Tim is on a different queue manager (on the same or a different computer from Will), see “Running JMS Postcard with two queue managers” on page 21.

When the postcard arrives successfully, you know that your WebSphere MQ installation and WebSphere MQ JMS are working correctly.

For an alternative way of verifying the installation of WebSphere MQ JMS, run the IVTRun application from the command line. See “Running the point-to-point IVT” on page 31 for more information about this.

Running JMS Postcard with one queue manager

If you have already started the Postcard application with a nickname, for example, Will, and you want to send a postcard to a second nickname on this computer, follow these steps:

1. Move the first Postcard (Will) to one side of your screen, then start a second Postcard by running the postcard shell script again.

2. Enter your second nickname, for example Tim.
3. On Will's Postcard fill in the **To** field with your second nickname, Tim. (You can leave the **On** field empty and Postcard will fill it in for you, or you can type in the queue manager name that you see below the **Message** box after **On**).
4. Click in the **Message** box, type your message in, and click the **Send** button.
5. Look in Tim's Postcard to see the message arrive, and double-click on it to see the postcard itself.
6. Try using Tim to send a message back to Will. You can do this by selecting the message that arrived in Tim's list, and clicking the **Reply** button.

Note: See "JMS Postcard configuration" on page 22 for advice about configuration.

Running JMS Postcard with two queue managers

If you have already started JMS Postcard with a nickname, for example Will, and you want to send a postcard to a second nickname on a second queue manager on this, or another, computer, follow these steps:

1. Start the second Postcard, choosing one of the following:
 - JMS Postcard
 - On this computer, run the **postcard** shell script again, then in the sign-on dialog check **Advanced** and select the second queue manager you want to use.
 - On another computer, run the **postcard** shell script; or, on Windows systems, open WebSphere MQ First Steps and click on JMS Postcard.
 - MQI Postcard on Windows systems:
 - either start from WebSphere MQ First Steps (to use the default configuration), or open the WebSphere MQ Explorer, right-click on the queue manager you want to use and click **All Tasks->Start a Postcard...**
2. When the sign-on dialog appears, enter your second nickname (for example, Tim).
3. In the Postcard application on Will's computer, fill in the **To** field with your second nickname (Tim), and in the **On** field put the queue manager name of the second postcard where Tim is. If you don't know this name, on Tim's computer in the Postcard look below the Message box after **On:**; alternatively if both queue managers are in the default configuration cluster, you can just type in the short TCP/IP name of Tim's computer and Postcard builds that into the queue manager name in the same way that the task that creates the default configuration does.
4. Type your message, and click **Send**.
Look in Tim's Postcard to see the message arrive, and double-click on it to see the postcard itself.
5. Try sending a message from Tim's computer back to Will.
You can do this by selecting the message that arrived in Tim's list, and clicking **Reply**.

Note: See "JMS Postcard configuration" on page 22.

See also "How JMS Postcard works" on page 22.

JMS Postcard configuration

The Postcard application needs a suitable queue manager to act as mailbox. See “JMS Postcard default configuration” for the easiest way to get one. You will be prompted to install this default configuration the first time you start the Postcard application (see “Starting” on page 19).

Instead of using the default configuration, you can also start the Postcard application using any other local queue manager.

If you want to send postcards to another computer, or to other queue managers, the default configuration must include the option of being joined in the same cluster. The other queue managers must either be in the same cluster or you must create a connection explicitly between them.

See also “How JMS Postcard works”.

JMS Postcard default configuration

Installing the default configuration creates a special queue manager (with queues and channels), and optionally joins it to a cluster, to enable you to use the JMS Postcard application to verify your installation and see messaging working.

On WebSphere MQ for Windows, the Default Configuration Wizard automatically opens when JMS Postcard is started and the wizard has not already been run on this computer.

On platforms other than Windows systems, you can also run the `DefaultConfiguration` script, provided that there are no existing queue managers on this computer. On Windows systems, run Default Configuration from First Steps.

Note: You must be a member of the WebSphere MQ administrators group (mqm) to complete default configuration successfully. If you are not a member of mqm, get a member of the mqm group to set up the default configuration on your behalf.

How JMS Postcard works

This section tells you how the JMS Postcard works, including:

- “Starting up”
- “Receiving messages” on page 23
- “Sending messages” on page 23
- “How the postcards get there” on page 23
- “Tidying up undeliverable messages” on page 24
- “Exchanging messages between different WebSphere MQ Postcard applications” on page 24
- “Customizing JMS Postcard” on page 24

Starting up

When JMS Postcard starts, it checks to see what queue managers exist on this computer, and initializes the sign-on dialog accordingly. If there are no queue managers at all, it prompts you to install the default configuration.

JMS Postcard uses the Java Message Service method `queueConnectionFactory.createQueueConnection()` to connect to the default queue manager.

Receiving messages

All the time JMS Postcard is running, it polls a queue called postcard for incoming messages from other Postcard applications. If there is no queue called postcard, JMS Postcard creates one.

When JMS Postcard starts running, it creates a Java Message Service QueueReceiver object for the local postcard queue, providing as a parameter a selector string that filters the messages to be received from the queue by the Correlation Identifier (CorrelId field). The selector string defines that the postcard client should only receive messages where the CorrelId field matches the nickname of the user. The words from the message data are then presented in the JMS Postcard window.

Sending messages

If you did not enter a computer name in the **On:** field, JMS Postcard assumes that the recipient is on the same queue manager.

If you entered a name, JMS Postcard checks for the existence of a queue manager with this name, first using the exact name supplied, and then using a prefix in the same format as that created by the default configuration.

In both cases, it issues a `session.createQueue('postcard')`, and sets the base queue manager name to the string supplied.

Finally, it builds a JMS BytesMessage from your nickname and the words you typed in, and runs `queueSender.send(theMessage)` to put the message onto the queue.

How the postcards get there

When other instances of Postcard on this computer use the same queue manager and queue, the messages are being put and got from the one queue. This does, however, verify that the WebSphere MQ code installed on this computer is configured and working correctly.

JMS Postcard can only send to another queue manager if a connection to that queue manager exists. This connection exists because either both queue managers are members of the same cluster, or you have explicitly created a connection yourself. JMS Postcard can therefore assume that it can connect to the queue manager, and connects to it, opens the queue, and puts a message, as already described, leaving all the work of getting the message there to the WebSphere MQ cluster code. In other words, JMS Postcard uses only one piece of code for putting the message, and does not need to know whether the message is going to another computer.

In JMS Postcard, when `session.createSender('postcard')` is called, the cluster code checks the repository to find the other queue manager, and to check that the queue exists, and throws an exception if this was not possible for any reason.

When `queueSender.send(theMessage)` is called, the cluster code opens a channel to the other queue manager (creating it if necessary) and sends the message.

Discard the channel afterwards, if the cluster optimizing code does not need it. If the queue managers are on different computers, that is all handled by the cluster code.

JMS Postcard

Tidying up undeliverable messages

If you sent a postcard message to John, but never ran a Postcard application with the nickname John, the message would sit on the queue for ever. To prevent this, JMS Postcard sets the Message Lifetime (Expiry) field in the Message Descriptor (MQMD) to 48 hours. After that time, the message is discarded, wherever it may be (possibly even still in transmission).

Exchanging messages between different WebSphere MQ Postcard applications

You can exchange messages between all the different types of Postcard application as follows:

- **MQI Postcard** on WebSphere MQ for Windows.
- **JMS Postcard** on Windows systems and other operating systems such as UNIX.
- **MQSeries Postcard** on previous versions of MQSeries for Windows, with the exception that it cannot *receive* messages from JMS Postcard.
- **MQ Everyplace Postcard** on WebSphere MQ Everyplace on pervasive devices. For this, a connection must be explicitly set up between the queue managers. See the WebSphere MQ Everyplace product documentation for further information.

Customizing JMS Postcard

Normally JMS Postcard uses standard Java Swing settings for font size and background color. But if it detects a `postcard.ini` file on startup, JMS Postcard uses settings specified in this file instead. You can also change the trace setting.

Edit the sample file `postcard.ini` in the `bin` directory of the WebSphere MQ classes for Java installation and set your preferred settings for font size, and screen foreground and background colors.

Note: The precise use of upper and lower case letters in the keywords, as in the following examples, must be strictly observed when you set these properties.

Setting screen colors

By setting the Background and Foreground properties, you can change the background and foreground colors of controls used in the Postcard application.

```
Background=000000  
Foreground=FFFFFF
```

This example selects white text on a black background. The values represent intensity levels for red, green, and blue colors using a hexadecimal scale from 00 to FF. Other examples of colors are FF0000 (bright red), 00FF00 (bright green) and 0000FF (bright blue).

Setting font size

```
MinimumFont=20
```

This example selects a minimum font size of 20 points. Any value smaller than 13 is ignored.

Using an external browser for online help

```
WebBrowser=nautilus
```

This setting is only applicable on non-Windows systems. The internal browser used for displaying online help information cannot be customized. This setting allows you to identify an alternative browser.

Tracing the Postcard application

Trace=1

Set this to start trace output. Note that the trace output is sent to the trc subdirectory of the directory defined by the MQ_JAVA_DATA_PATH system environment variable. If the application cannot write to this directory, trace output is directed to the system console.

You can also use the MQJMS_TRACE_LEVEL parameter on the java command line to start tracing. See “Tracing programs” on page 38 for more about tracing applications.

Post installation setup

Note: Remember to check the README file installed with the WebSphere MQ Java programs for information that may supersede this book.

To make all the necessary resources available to WebSphere MQ JMS programs, you need to update the following system variables:

Classpath

Successful operation of JMS programs requires a number of Java packages to be available to the JVM. You must specify these on the classpath after you have obtained and installed the necessary packages.

Add the following .jar files to the classpath:

- com.ibm.mq.jar
- com.ibm.mqjms.jar
- connector.jar
- jms.jar
- jndi.jar
- jta.jar
- providerutil.jar
- fscontext.jar
- ldap.jar

Notes:

1. For z/OS and OS/390, use `ibmjndi.jar` and `jndi.jar` from `/usr/lpp/ldap/lib` instead of `jndi.jar` and `ldap.jar`. These files are supplied with the operating system.
2. Include the `java/lib` directory itself in the classpath to access the properties files used by the base Java API.
3. Include `providerutil.jar`, `jndi.jar`, and either `ldap.jar` or `fscontext.jar` if you need to access a JNDI namespace.
4. In certain environments, typically J2EE application servers, classes contained in these jars are provided by the environment. In these circumstances, use the classes provided by the environment instead of those provided with WebSphere MQ.

Environment variables

There are a number of scripts in the `bin` subdirectory of the WebSphere MQ JMS installation. These are for use as convenient shortcuts for a number of common actions. Many of these scripts assume that the environment variables `MQ_JAVA_INSTALL_PATH` and `MQ_JAVA_DATA_PATH` are

Setup

defined, pointing to the directory in which WebSphere MQ JMS is installed and a directory for log and trace output, respectively. If you do not set these variables, you must edit the scripts in the bin directory accordingly.

On Windows NT, you can set the classpath and other environment variables by using the **Environment** tab of System Properties. On Windows 2000 and Windows XP, Environment is a button on the **Advanced** tab of System Properties. On UNIX, these are normally set from each user's logon scripts. On any platform, you can use scripts to maintain different classpaths and other environment variables for different projects.

Note: If you are migrating from the SupportPac MA88, be aware that the connector.jar is now packaged in the java/lib directory with the other jar files, with the following consequences:

- You need an entry for connector.jar in the classpath, as explained above.
- If you have previously implemented your own ConnectionManagers, as described in "Supplying your own ConnectionManager" on page 80, you must replace references to com.ibm.mq.resource and com.ibm.mq.resource.spi with references to javax.resource and javax.resource.spi respectively.

Additional setup for publish/subscribe mode

Before you can use the WebSphere MQ JMS implementation of JMS publish/subscribe, some additional setup is required:

- Ensure that you have access to a publish/subscribe broker.
- Ensure that the broker is running.
- Create the WebSphere MQ JMS system queues.

This step is not required for direct connection across a TCP/IP socket to a WebSphere MQ Event Broker broker.

You also need to know publish/subscribe concepts as discussed in Chapter 11, "Programming publish/subscribe applications" on page 205.

Ensure that you have access to a publish/subscribe broker

With WebSphere MQ JMS you have the choice of three brokers:

- WebSphere MQ with SupportPac MA0C (also known as MQSeries Publish/Subscribe)
- WebSphere MQ Integrator V2
- WebSphere MQ Event Broker

Differences between these brokers are discussed in Chapter 11, "Programming publish/subscribe applications" on page 205. Read the documentation for each broker for installation and configuration instructions.

Note: To use broker-based subscription stores, you must use SupportPac MA0C or the WebSphere MQ Event Broker. No other combination of queue manager and broker supports this option. For more information on subscription stores, see "Subscription stores" on page 219.

Ensure that the broker is running

MQSeries Publish/Subscribe

To verify that the broker is installed and running, use the command:

```
dspmqrk -m MY.QUEUE.MANAGER
```

where MY.QUEUE.MANAGER is the name of the queue manager on which the broker is running. If the broker is running, a message similar to the following is displayed:

```
WebSphere MQ message broker for queue manager MY.QUEUE.MANAGER running.
```

If the operating system reports that it cannot run the dspmqrk command, ensure that the MQSeries Publish/Subscribe broker is installed properly.

If the operating system reports that the broker is not active, start it using the command:

```
strmqbrk -m MY.QUEUE.MANAGER
```

WebSphere MQ Integrator V2

To verify that the broker provided in WebSphere MQ Integrator V2 is installed and running, refer to the product documentation.

The command to start the broker in WebSphere MQ Integrator V2 is:

```
mqsistart MYBROKER
```

where MYBROKER is the name of the broker.

WebSphere MQ Event Broker

To verify that the broker provided in WebSphere MQ Event Broker is installed and running, refer to the product documentation.

The command to start the broker in WebSphere MQ Event Broker is:

```
wmqpsstart MYBROKER
```

where MYBROKER is the name of the broker.

Create the WebSphere MQ JMS system queues

This does not apply if you use a direct connection across TCP/IP to WebSphere MQ Event Broker.

For a publish/subscribe implementation to work correctly, you must create a number of system queues. A script is supplied, in the bin subdirectory of the WebSphere MQ JMS installation, to assist with this task. To use the script, enter the following commands:

Setup for publish/subscribe

For iSeries and AS/400:

1. Copy the script from the integrated file system to a native file system library using a command similar to:

```
CPYFRMSTMF FROMSTMF('/QIBM/ProdData/mqm/java/bin/MQJMS_PSQ.mqsc')  
            TOMBR('/QSYS.LIB/QGPL.LIB/QCLSRC.FILE/MQJMS_PSQ.MBR')
```
2. Call the script file using STRMQMMQSC:

```
STRMQMMQSC SRCMBR(MQJMS_PSQ) SRCFILE(QGPL/QCLSRC)
```

For z/OS and OS/390:

1. Copy the script from the HFS into a PDS using a TSO command similar to

```
OGET '/usr/lpp/mqm/java/bin/MQJMS_PSQ.mqsc' 'USERID.MQSC(MQJMSPSQ)'
```

The PDS should be of fixed-block format with a record length of 80.

2. Either use the CSQUTIL application to execute this command script, or add the script to the CSQINP2 DD concatenation in your queue manager's started task JCL. In either case, refer to the *WebSphere MQ for z/OS System Setup Guide* and the *WebSphere MQ for z/OS System Administration Guide* for further details.

For other platforms:

```
runmqsc MY.QUEUE.MANAGER < MQJMS_PSQ.mqsc
```

If an error occurs, check that you typed the queue manager name correctly and that the queue manager is running.

For a broker running on a remote queue manager

For operation with a broker running on a remote queue manager, further setup is required.

1. Define a transmission queue on the remote queue manager with a queue name matching the local queue manager. These names must match for correct routing of messages by WebSphere MQ.
2. Define a sender channel on the remote queue manager and a receiver channel on the local queue manager. The sender channel should use the transmission queue defined in step 1.
3. Set up the local queue manager for communication with the remote broker:
 - a. Define a local transmission queue with the same name as the queue manager running the remote broker.
 - b. Define local sender and remote receiver channels to the remote broker queue manager. The sender channel must use the transmission queue defined in step 3a.
4. To operate the remote broker, take the following steps:
 - a. Start the remote broker queue manager.
 - b. Start a listener for the remote broker queue manager (TCP/IP channels).
 - c. Start the sender and receiver channels to the local queue manager.
 - d. Start the broker on the remote queue manager.

An example command is

```
strmqbrk -m MyBrokerMgr
```

5. To operate the local queue manager to communicate with the remote broker, take the following steps:

- a. Start the local queue manager.
- b. Start a listener for the local queue manager.
- c. Start the sender and receiver channels to the remote broker queue manager.

Queues that require authorization for non-privileged users

Non-privileged users need authorization granted to access the queues used by JMS. For details about access control in WebSphere MQ, see the chapter about protecting WebSphere MQ objects in the *WebSphere MQ System Administration Guide*.

For JMS point-to-point mode, the access control issues are similar to those for the WebSphere MQ classes for Java:

- Queues that are used by QueueSender need put authority.
- Queues that are used by QueueReceivers and QueueBrowsers need get, inq, and browse authorities.
- The QueueSession.createTemporaryQueue method needs access to the model queue that is defined in the QueueConnectionFactory temporaryModel field (by default this is SYSTEM.DEFAULT.MODEL.QUEUE).

For JMS publish/subscribe mode, the following system queues are used:

```
SYSTEM.JMS.ADMIN.QUEUE
SYSTEM.JMS.REPORT.QUEUE
SYSTEM.JMS.MODEL.QUEUE
SYSTEM.JMS.PS.STATUS.QUEUE
SYSTEM.JMS.ND.SUBSCRIBER.QUEUE
SYSTEM.JMS.D.SUBSCRIBER.QUEUE
SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE
SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE
SYSTEM.BROKER.CONTROL.QUEUE
```

Also, any application that publishes messages needs access to the STREAM queue that is specified in the topic connection factory being used. The default value for this is SYSTEM.BROKER.DEFAULT.STREAM.

If you use ConnectionConsumer, additional authorization might be needed. Queues to be read by the ConnectionConsumer must have get, inq and browse authorities. The system dead-letter queue, and any backout-queue or report queue used by the ConnectionConsumer must have put and passall authorities.

Using the sample JMS applet to verify the TCP/IP client

WebSphere MQ JMS includes an installation verification applet, test.html. You can use the applet to verify the TCP/IP connected client mode of WebSphere MQ JMS except on the z/OS and OS/390 platform, where the TCP/IP connected client mode is not supported.

The standard security settings for applets in Java 1.2 and higher require that all referenced classes are loaded from the same location as the applet you want to run. For information on how to ensure that applets using WebSphere MQ JMS work, see Appendix F, "Using WebSphere MQ Java in applets with Java 1.2 or later" on page 423.

Verifying TCP/IP client

The applet connects to a given queue manager, exercises all the WebSphere MQ calls, and produces diagnostic messages if there are any failures. If the applet does not complete successfully, follow the advice given in the diagnostic messages and run the applet again.

Using the sample applet with OS/400

The OS/400 operating system does not have a native Graphical User Interface (GUI). To run the sample applet, you need to use the Remote Abstract Window Toolkit for Java (AWT), or the Class Broker for Java (CBJ), on graphics capable hardware.

Running the sample applet

First make sure that your queue manager can accept client connections. For details of this, see “Configuring your queue manager to accept client connections” on page 15.

There are different ways of running the JMS sample applet. Each has slightly different properties because of the security restrictions on applets imposed by the Java virtual machine.

Normal Java security settings cause the appletviewer or browser to ignore your system CLASSPATH, so the WebSphere MQ base Java and WebSphere MQ JMS libraries must be present in the same location as the applet class file. For further details of applets and security settings, see Appendix F, “Using WebSphere MQ Java in applets with Java 1.2 or later” on page 423.

Running from a web server (in appletviewer or in a browser):

Invoke the applet using a command line like the following:

```
appletviewer http://<web.server.host/jmsapplet>/test.html
```

or by pointing your Java 1.3 enabled browser at this Web page. Change the string `<web.server.host/jmsapplet>` as appropriate to the URL of the Web server you are using.

Running in appletviewer from the local machine:

Invoke the applet using a command line like the following:

```
appletviewer test.html
```

Remember that the WebSphere MQ base Java and WebSphere MQ JMS libraries must be present in the same local directory as the applet class file. Also, in this case, the applet might connect only to queue managers on the local machine.

Running the applet as an application:

Use a command line like the following:

```
java JMSTestApplet
```

The JMS sample applet contains a main method that allows the applet to run as a standalone Java application.

This option requires the WebSphere MQ base Java and WebSphere MQ JMS libraries to be present in the system CLASSPATH, as for your own WebSphere MQ JMS applications. It allows you to connect to any host and queue manager to which you have TCP/IP access.

Tracing the sample as an application

To trace the sample as an application, alter the command line parameters as shown below, in the same way as you would trace your own JMS applications:

```
java -DMQJMS_TRACE_LEVEL=on JMSTestApplet
```

More details can be found in “Tracing programs” on page 38.

Running the point-to-point IVT

This section describes the point-to-point installation verification test program (IVT) that is supplied with WebSphere MQ JMS.

The IVT verifies the installation by connecting to the default queue manager on the local machine, using the WebSphere MQ JMS in bindings mode. It then sends a message to the SYSTEM.DEFAULT.LOCAL.QUEUE queue and reads it back again.

You can run the program in one of two possible modes.

With JNDI lookup of administered objects

JNDI mode forces the program to obtain its administered objects from a JNDI namespace, which is the expected operation of JMS client applications. (See “Administering JMS objects” on page 45 for a description of administered objects). This invocation method has the same prerequisites as the administration tool (see Chapter 5, “Using the WebSphere MQ JMS administration tool” on page 41).

Without JNDI lookup of administered objects

If you do not want to use JNDI, you can create the administered objects at runtime by running the IVT in non-JNDI mode. Because a JNDI-based repository is relatively complex to set up, run the IVT first without JNDI.

Point-to-point verification without JNDI

A script, named IVTRun on UNIX, or IVTRun.bat on Windows systems, is provided to run the IVT. This file is installed in the bin subdirectory of the installation.

To run the test without JNDI, issue the following command:

```
IVTRun [-t] -nojndi [-m <qmgr>]
```

For client mode, to run the test without JNDI, issue the following command:

```
IVTRun [-t] -nojndi -client -m <qmgr> -host <hostname> [-port <port>]
[-channel <channel>]
```

where:

- t** turns tracing on (by default, tracing is off)
- qmgr** is the name of the queue manager to which you want to connect
- hostname** is the host on which the queue manager is running
- port** is the TCP/IP port on which the queue manager’s listener is running (default 1414)
- channel** is the client connection channel (default SYSTEM.DEF.SVRCONN)

If the test completes successfully, you should see output similar to the following:

```
| 5648-C60, 5724-B41, 5655-F10 (c) Copyright IBM Corp. 2002. All Rights Reserved.
| Websphere MQ classes for Java(tm) Message Service 5.300
| Installation Verification Test
```

Point-to-point IVT

|      Closing Connection
|      IVT completed OK
|      IVT finished
```

Point-to-point verification with JNDI

To run the IVT with JNDI, the LDAP server must be running and must be configured to accept Java objects. If the following message occurs, it indicates that there is a connection to the LDAP server, but that the server is not correctly configured:

```
Unable to bind to object
```

This message means that either the server is not storing Java objects, or the permissions on the objects or the suffix are not correct. See “Checking your LDAP server configuration” on page 407.

Also, the following administered objects must be retrievable from a JNDI namespace:

- MQQueueConnectionFactory
- MQQueue

A script, named IVTSetup on UNIX, or IVTSetup.bat on Windows systems, is provided to create these objects automatically. Enter the command:

```
IVTSetup
```

The script invokes the WebSphere MQ JMS Administration tool (see Chapter 5, "Using the WebSphere MQ JMS administration tool" on page 41) and creates the objects in a JNDI namespace.

The MQQueueConnectionFactory is bound under the name `ivtQCF` (for LDAP, `cn=ivtQCF`). All the properties are default values:

```
TRANSPORT(BIND)
PORT(1414)
HOSTNAME(localhost)
CHANNEL(SYSTEM.DEF.SVRCONN)
VERSION(1)
CCSID(819)
TEMPMODEL(SYSTEM.DEFAULT.MODEL.QUEUE)
QMANAGER()
```

The MQQueue is bound under the name `ivtQ` (`cn=ivtQ`). The value of the `QUEUE` property becomes `QUEUE(SYSTEM.DEFAULT.LOCAL.QUEUE)`. All other properties have default values:

```
PERSISTENCE(APP)
QUEUE(SYSTEM.DEFAULT.LOCAL.QUEUE)
EXPIRY(APP)
TARGCLIENT(JMS)
ENCODING(NATIVE)
VERSION(1)
CCSID(1208)
PRIORITY(APP)
QMANAGER()
```

Once the administered objects are created in the JNDI namespace, run the `IVTRun` (`IVTRun.bat` on Windows systems) script using the following command:

```
IVTRun [ -t ] -url "<providerURL>" [ -icf <initCtxFact> ]
```

where:

-t turns tracing on (by default, tracing is off)

providerURL

Note: Enclose the *providerURL* string in quotation marks (""). This is the JNDI location of the administered objects. If the default initial context factory is in use, this is an LDAP URL of the form:

```
"ldap://hostname.company.com/contextName"
```

If a file system service provider is used, (see `initCtxFact` below), the URL is of the form:

```
"file://directorySpec"
```

initCtxFact is the classname of the initial context factory. The default is for an LDAP service provider, and has the value:

```
com.sun.jndi.ldap.LdapCtxFactory
```

If a file system service provider is used, set this parameter to:

```
com.sun.jndi.fscontext.RefFSContextFactory
```

If the test completes successfully, the output is similar to the non-JNDI output, except that the `create QueueConnectionFactory` and `Queue` lines indicate retrieval of the object from JNDI. The following shows an example.

Point-to-point IVT

```
5648-C60, 5724-B41, 5655-F10 (c) Copyright IBM Corp. 2002. All Rights Reserved.  
Websphere MQ classes for Java(tm) Message Service 5.300  
Installation Verification Test
```

Using administered objects, please ensure that these are available

```
Retrieving a QueueConnectionFactory from JNDI  
Creating a Connection  
Creating a Session  
Retrieving a Queue from JNDI  
Creating a QueueSender  
Creating a QueueReceiver  
Creating a TextMessage  
Sending the message to SYSTEM.DEFAULT.LOCAL.QUEUE  
Reading the message back again
```

```
Got message:  
JMS Message class: jms_text  
JMSType:          null  
...  
...
```

Although not strictly necessary, it is good practice to remove objects that are created by the IVTSetup script from the JNDI namespace. A script called IVTTidy (IVTTidy.bat on Windows systems) is provided for this purpose.

IVT error recovery

If the test is not successful, note the following:

- For help with any error messages involving the classpath, check that your classpath is set correctly, as described in “Post installation setup” on page 25.
- The IVT might fail with a message failed to create MQQueueManager, with an additional message including the number 2059. This indicates that WebSphere MQ failed to connect to the default local queue manager on the machine on which you ran the IVT. Check that the queue manager is running, and that it is marked as the default queue manager.
- A message failed to open MQ queue indicates that WebSphere MQ connected to the default queue manager, but could not open the SYSTEM.DEFAULT.LOCAL.QUEUE. This might indicate that either the queue does not exist on your default queue manager, or that the queue is not enabled for PUT and GET. Add or enable the queue for the duration of the test.

Table 6 lists the classes that are tested by IVT, and the package that they come from:

Table 6. Classes that are tested by IVT

Class	Jar file
WebSphere MQ JMS classes	com.ibm.mqjms.jar
com.ibm.mq.MQMessage	com.ibm.mq.jar
javax.jms.Message	jms.jar
javax.naming.InitialContext	jndi.jar
javax.resource.cci.Connection	connector.jar
javax.transaction.xa.XAException	jta.jar
com/sun/jndi/toolkit/ComponentDirContext	providerutil.jar
com.sun.jndi.ldap.LdapCtxFactory	ldap.jar

The publish/subscribe installation verification test

The publish/subscribe installation verification test (PSIVT) program is supplied only in compiled form. It is in the `com.ibm.mq.jms` package.

The test requires a broker such as the MQSeries Publish/Subscribe broker (SupportPac MA0C) or WebSphere MQ Integrator V2 to be installed and running.

The PSIVT attempts to:

1. Create a publisher, `p`, publishing on the topic `MQJMS/PSIVT/Information`
2. Create a subscriber, `s`, subscribing on the topic `MQJMS/PSIVT/Information`
3. Use `p` to publish a simple text message
4. Use `s` to receive a message waiting on its input queue

When you run the PSIVT, the publisher publishes the message, and the subscriber receives and displays the message. The publisher publishes to the broker's default stream. The subscriber is non-durable, does not perform message selection, and accepts messages from local connections. It performs a synchronous receive, waiting a maximum of 5 seconds for a message to arrive.

You can run the PSIVT, like the IVT, in either JNDI mode or standalone mode. JNDI mode uses JNDI to retrieve a `TopicConnectionFactory` and a `Topic` from a JNDI namespace. If JNDI is not used, these objects are created at runtime.

Publish/subscribe verification without JNDI

A script named `PSIVTRun` (`PSIVTRun.bat` on Windows systems) is provided to run PSIVT. The file is in the `bin` subdirectory of the installation.

To run the test without JNDI, issue the following command:

```
PSIVTRun -nojndi [-m <qmgr>] [-bqm <broker>] [-t]
```

For client mode, to run the test without JNDI, issue the following command:

```
PSIVTRun -nojndi -client -m <qmgr> -host <hostname> [-port <port>]
[-channel <channel>] [-bqm <broker>] [-t]
```

where:

-nojndi	indicates no JNDI lookup of the administered objects
qmgr	is the name of the queue manager to which you wish to connect
hostname	is the host on which the queue manager is running
port	is the TCP/IP port on which the queue manager's listener is running (default 1414)
channel	is the client connection channel (default <code>SYSTEM.DEF.SVRCONN</code>)
broker	is the name of the remote queue manager on which the broker is running. If this is not specified, the value used for qmgr is assumed.
-t	turns tracing on (default is off)

If the test completes successfully, output is similar to the following:

```

```

Publish/subscribe verification with JNDI

To run the PSIVT in JNDI mode, two administered objects must be retrievable from a JNDI namespace:

- A TopicConnectionFactory bound under the name ivtTCF
- A Topic bound under the name ivtT

You can define these objects by using the WebSphere MQ JMS Administration Tool (see Chapter 5, “Using the WebSphere MQ JMS administration tool” on page 41) and using the following commands:

```
DEFINE TCF(ivtTCF)
```

This command defines the TopicConnectionFactory.

```
DEFINE T(ivtT) TOPIC(MQJMS/PSIVT/Information)
```

This command defines the Topic.

These definitions assume that a default queue manager, on which the broker is running, is available. For details on configuring these objects to use a non-default queue manager, see “Administering JMS objects” on page 45. These objects must reside in a context pointed to by the `-url` command-line parameter described below.

To run the test in JNDI mode, enter the following command:

```
PSIVTRun [ -t ] -url "<providerURL>" [ -icf <initCtxFact> ]
```

where:

-t means turn tracing on (by default, tracing is off)

providerURL

Note: Enclose the *providerURL* string in quotation marks ("). This is the JNDI location of the administered objects. If the default initial context factory is in use, this is an LDAP URL of the form:
"ldap://hostname.company.com/contextName"

If a file system service provider is used, (see *initCtxFact* below), the URL is of the form:
"file://directorySpec"

initCtxFact is the classname of the initial context factory. The default is for an LDAP service provider, and has the value:
com.sun.jndi.ldap.LdapCtxFactory

If a file system service provider is used, set this parameter to:
com.sun.jndi.fscontext.RefFSContextFactory

If the test completes successfully, output is similar to the non-JNDI output, except that the create QueueConnectionFactory and Queue lines indicate retrieval of the object from JNDI.

PSIVT error recovery

If the test is not successful, note the following:

- The following message:

```
*** No broker response. Please ensure broker is running. ***
```

indicates that the broker is installed on the target queue manager, but its control queue contains some outstanding messages. For instructions on how to start it, see "Additional setup for publish/subscribe mode" on page 26.

- If the following message is displayed:

```
Unable to connect to queue manager: <default>
```

ensure that your WebSphere MQ system has configured a default queue manager.

- If the following message is displayed:

```
Unable to connect to queue manager: ...
```

ensure that the administered TopicConnectionFactory that the PSIVT uses is configured with a valid queue manager name. Alternatively, if you used the `-nojndi` option, ensure that you supplied a valid queue manager (using the `-m` option).

- If the following message is displayed:

```
Unable to access broker control queue on queue manager: ...
Please ensure the broker is installed on this queue manager
```

Publish/subscribe IVT

ensure that the administered TopicConnectionFactory that the PSIVT uses is configured with the name of the queue manager on which the broker is installed. If you used the `-nojndi` option, ensure that you supplied a queue manager name (using the `-m` option).

Running your own WebSphere MQ JMS programs

For information on writing your own WebSphere MQ JMS programs, see Chapter 10, “Writing WebSphere MQ JMS programs” on page 191.

WebSphere MQ JMS includes a utility file, `runjms` (`runjms.bat` on Windows systems), to help you to run the supplied programs and programs that you have written.

The utility provides default locations for the trace and log files, and enables you to add any application runtime parameters that your application needs. The supplied script assumes that the environment variable `MQ_JAVA_INSTALL_PATH` is set to the directory in which WebSphere MQ JMS is installed. The script also assumes that the subdirectories `trace` and `log` within the directory pointed to by `MQ_JAVA_DATA_PATH` are used for trace and log output, respectively.

Use the following command to run your application:

```
runjms <classname of application> [application-specific arguments]
```

For information on writing WebSphere MQ JMS applications and applets, see Part 3, “Programming with WebSphere MQ JMS” on page 189.

Solving problems

If a program does not complete successfully, run the installation verification program, which is described in “Running the point-to-point IVT” on page 31, and follow the advice given in the diagnostic messages.

Tracing programs

The WebSphere MQ JMS trace facility is provided to help IBM staff to diagnose customer problems.

Trace is disabled by default, because the output rapidly becomes large, and is unlikely to be of use in normal circumstances.

If you are asked to provide trace output, enable it by setting the Java property `MQJMS_TRACE_LEVEL` to one of the following values:

- on** traces WebSphere MQ JMS calls only
- base** traces both WebSphere MQ JMS calls and the underlying WebSphere MQ base Java calls

For example:

```
java -DMQJMS_TRACE_LEVEL=base MyJMSProg
```

To disable trace, set `MQJMS_TRACE_LEVEL` to **off**.

By default, trace is output to a file named `mjms.trc` in the current working directory. You can redirect it to a different directory by using the Java property `MQJMS_TRACE_DIR`.

Running WebSphere MQ JMS trace

For example:

```
java -DMQJMS_TRACE_LEVEL=base -DMQJMS_TRACE_DIR=/somepath/tracedir MyJMSProg
```

The runjms utility script sets these properties by using the environment variables MQJMS_TRACE_LEVEL and MQ_JAVA_DATA_PATH, as follows:

```
| java -DMQJMS_LOG_DIR=%MQ_JAVA_DATA_PATH%\log  
| -DMQJMS_TRACE_DIR=%MQ_JAVA_DATA_PATH%\trace  
| -DMQJMS_TRACE_LEVEL=%MQJMS_TRACE_LEVEL% %1 %2 %3 %4 %5 %6 %7 %8 %9
```

This is the default; change it as required.

Logging

The WebSphere MQ JMS log facility is provided to report serious problems, particularly those that might indicate configuration errors rather than programming errors. By default, log output is sent to the System.err stream, which usually appears on the stderr of the console in which the JVM is run.

You can redirect the output to a file by using a Java property that specifies the new location, for example:

```
java -DMQJMS_LOG_DIR=/mydir/forlogs MyJMSProg
```

```
| The utility script runjms, in the bin directory of the WebSphere MQ JMS  
| installation, sets this property to:
```

```
| <MQ_JAVA_DATA_PATH>/log
```

```
| where MQ_JAVA_DATA_PATH is set, on Windows systems, to the path to your  
| WebSphere MQ Java installation. On other platforms you need to set this  
| environment variable.
```

When the log is redirected to a file, it is output in a binary form. To view the log, the utility formatLog (formatLog.bat on Windows systems) is provided, which converts the file to plain text format. The utility is stored in the bin directory of your WebSphere MQ JMS installation. Run the conversion as follows:

```
formatLog <inputfile> <outputfile>
```

Logging

Chapter 5. Using the WebSphere MQ JMS administration tool

The administration tool enables administrators to define the properties of eight types of WebSphere MQ JMS object and to store them within a JNDI namespace. Then, JMS clients can use JNDI to retrieve these administered objects from the namespace and use them.

The JMS objects that you can administer by using the tool are:

- MQQueueConnectionFactory
- MQTopicConnectionFactory
- MQQueue
- MQTopic
- MQXAQueueConnectionFactory
- MQXATopicConnectionFactory
- JMSWrapXAQueueConnectionFactory
- JMSWrapXATopicConnectionFactory

For details about these objects, refer to “Administering JMS objects” on page 45.

Note: JMSWrapXAQueueConnectionFactory and JMSWrapXATopicConnectionFactory are classes that are specific to WebSphere Application Server. They are contained in the package **com.ibm.ejs.jms.mq**.

The tool also allows administrators to manipulate directory namespace subcontexts within the JNDI. See “Manipulating subcontexts” on page 45.

Invoking the administration tool

The administration tool has a command line interface. You can use this interactively, or use it to start a batch process. The interactive mode provides a command prompt where you can enter administration commands. In the batch mode, the command to start the tool includes the name of a file that contains an administration command script.

To start the tool in interactive mode, enter the command:

```
JMSAdmin [-t] [-v] [-cfg config_filename]
```

where:

- | | |
|-----------------------------|--------------------------------------------------------------------------|
| -t | Enables trace (default is trace off) |
| -v | Produces verbose output (default is terse output) |
| -cfg config_filename | Names an alternative configuration file (see “Configuration” on page 42) |

A command prompt is displayed, which indicates that the tool is ready to accept administration commands. This prompt initially appears as:

```
InitCtx>
```

indicating that the current context (that is, the JNDI context to which all naming and directory operations currently refer) is the initial context defined in the PROVIDER_URL configuration parameter (see “Configuration” on page 42).

Invoking the Administration tool

As you traverse the directory namespace, the prompt changes to reflect this, so that the prompt always displays the current context.

To start the tool in batch mode, enter the command:

```
JMSAdmin <test.scf
```

where *test.scf* is a script file that contains administration commands (see “Administration commands” on page 44). The last command in the file must be the END command.

Configuration

Configure the administration tool with values for the following three properties:

INITIAL_CONTEXT_FACTORY

The service provider that the tool uses. There are three explicitly supported values for this property:

- `com.sun.jndi.ldap.LdapCtxFactory` (for LDAP)
- `com.sun.jndi.fscontext.RefFSContextFactory` (for file system context)
- `com.ibm.websphere.naming.WsnInitialContextFactory` (to work with WebSphere Application Server’s CosNaming repository)

On z/OS and OS/390, `com.ibm.jndi.LDAPCtxFactory` is also supported and provides access to an LDAP server. However, this is incompatible with `com.sun.jndi.ldap.LdapCtxFactory`, in that objects created using one `InitialContextFactory` cannot be read or modified using the other.

You can also use an `InitialContextFactory` that is not in the list above. See “Using an unlisted `InitialContextFactory`” on page 43 for more details.

PROVIDER_URL

The URL of the session’s initial context; the root of all JNDI operations carried out by the tool. Three forms of this property are supported:

- `ldap://hostname/contextname` (for LDAP)
- `file:[drive:]/pathname` (for file system context)
- `iiop://hostname[:port] [/TargetContext=ctx]` (to access base WebSphere Application Server CosNaming namespace)

SECURITY_AUTHENTICATION

Whether JNDI passes security credentials to your service provider. This property is used only when an LDAP service provider is used. This property can take one of three values:

- `none` (anonymous authentication)
- `simple` (simple authentication)
- `CRAM-MD5` (CRAM-MD5 authentication mechanism)

If a valid value is not supplied, the property defaults to `none`. See “Security” on page 43 for more details about security with the administration tool.

These properties are set in a configuration file. When you invoke the tool, you can specify this configuration by using the `-cfg` command-line parameter, as described in “Invoking the administration tool” on page 41. If you do not specify a configuration file name, the tool attempts to load the default configuration file (`JMSAdmin.config`). It looks for this file first in the current directory, and then in the `<MQ_JAVA_INSTALL_PATH>/bin` directory, where `<MQ_JAVA_INSTALL_PATH>` is the path

to your WebSphere MQ JMS installation.

The configuration file is a plain-text file that consists of a set of key-value pairs, separated by =. This is shown in the following example:

```
#Set the service provider
    INITIAL_CONTEXT_FACTORY=com.sun.jndi.ldap.LdapCtxFactory
#Set the initial context
    PROVIDER_URL=ldap://polaris/o=ibm_us,c=us
#Set the authentication type
    SECURITY_AUTHENTICATION=none
```

(A # in the first column of the line indicates a comment, or a line that is not used.)

The installation comes with a sample configuration file that is called JMSAdmin.config, and is found in the <MQ_JAVA_INSTALL_PATH>/bin directory. Edit this file to suit the setup of your system.

Using an unlisted InitialContextFactory

You can use the administration tool to connect to JNDI contexts other than those listed in “Configuration” on page 42 by using three parameters defined in the JMSAdmin configuration file.

To use a different InitialContextFactory:

1. Set the INITIAL_CONTEXT_FACTORY property to the required class name.
2. Define the behavior of the InitialContextFactory using the USE_INITIAL_DIR_CONTEXT, NAME_PREFIX and NAME_READABILITY_MARKER properties.

The settings for these properties are described in the sample configuration file comments.

You do not need to define the three properties listed here, if you use one of the supported INITIAL_CONTEXT_FACTORY values. However, you can give them values to override the system defaults. If you omit one or more of the three InitialContextFactory properties, the administration tool provides suitable defaults based on the values of the other properties.

Security

You need to understand the effect of the SECURITY_AUTHENTICATION property described in “Configuration” on page 42.

- If you set this parameter to none, JNDI does not pass any security credentials to the service provider, and *anonymous authentication* is performed.
- If you set the parameter to either simple or CRAM-MD5, security credentials are passed through JNDI to the underlying service provider. These security credentials are in the form of a user distinguished name (User DN) and password.

If security credentials are required, you are prompted for these when the tool initializes. Avoid this by setting the PROVIDER_USERDN and PROVIDER_PASSWORD properties in the JMSAdmin configuration file.

Note: If you do not use these properties, the text typed, *including the password*, is echoed to the screen. This may have security implications.

The tool does no authentication itself; the task is delegated to the LDAP server. The LDAP server administrator must set up and maintain access privileges to

Configuration

different parts of the directory. If authentication fails, the tool displays an appropriate error message and terminates.

More detailed information about security and JNDI is in the documentation at Sun's Java web site (<http://java.sun.com>).

Configuring for WebSphere Application Server V3.5

For the administration tool (or any client application that needs to do subsequent lookups) to work with WebSphere Application Server's CosNaming repository, you need the following configuration:

- CLASSPATH must include WebSphere Application Server's JNDI-related jar file, `<WSAppserver>\lib\ujc.jar`
- PATH must include `<WSAppserver>\jdk\jre\bin`, where `<WSAppserver>` is the install path for WebSphere Application Server

Administration commands

When the command prompt is displayed, the tool is ready to accept commands. Administration commands are generally of the following form:

`verb [param]*`

where `verb` is one of the administration verbs listed in Table 7. All valid commands consist of at least one (and only one) verb, which appears at the beginning of the command in either its standard or short form.

The parameters a verb can take depend on the verb. For example, the `END` verb cannot take any parameters, but the `DEFINE` verb can take any number of parameters. Details of the verbs that take at least one parameter are discussed in later sections of this chapter.

Table 7. Administration verbs

Verb	Short form	Description
ALTER	ALT	Change at least one of the properties of a given administered object
DEFINE	DEF	Create and store an administered object, or create a new subcontext
DISPLAY	DIS	Display the properties of one or more stored administered objects, or the contents of the current context
DELETE	DEL	Remove one or more administered objects from the namespace, or remove an empty subcontext
CHANGE	CHG	Alter the current context, allowing the user to traverse the directory namespace anywhere below the initial context (pending security clearance)
COPY	CP	Make a copy of a stored administered object, storing it under an alternative name
MOVE	MV	Alter the name under which an administered object is stored
END		Close the administration tool

Verb names are not case-sensitive.

Administration commands

Usually, to terminate commands, you press the carriage return key. However, you can override this by typing the + symbol directly before the carriage return. This enables you to enter multiline commands, as shown in the following example:

```
DEFINE Q(BookingsInputQueue) +
      QMGR(QM.POLARIS.TEST) +
      QUEUE(BOOKINGS.INPUT.QUEUE) +
      PORT(1415) +
      CCSID(437)
```

Lines beginning with one of the characters *, #, or / are treated as comments, or lines that are ignored.

Manipulating subcontexts

Use the verbs CHANGE, DEFINE, DISPLAY and DELETE to manipulate directory namespace subcontexts. Their use is described in Table 8.

Table 8. Syntax and description of commands used to manipulate subcontexts

Command syntax	Description
DEFINE CTX(ctxName)	Attempts to create a new child subcontext of the current context, having the name ctName. Fails if there is a security violation, if the subcontext already exists, or if the name supplied is not valid.
DISPLAY CTX	Displays the contents of the current context. Administered objects are annotated with a, subcontexts with [D]. The Java type of each object is also displayed.
DELETE CTX(ctxName)	Attempts to delete the current context's child context having the name ctName. Fails if the context is not found, is non-empty, or if there is a security violation.
CHANGE CTX(ctxName)	Alters the current context, so that it now refers to the child context having the name ctName. One of two special values of ctName can be supplied: =UP moves to the current context's parent =INIT moves directly to the initial context Fails if the specified context does not exist, or if there is a security violation.

Administering JMS objects

This section describes the eight types of object that the administration tool can handle. It includes details about each of their configurable properties and the verbs that can manipulate them.

Object types

Table 9 on page 46 shows the eight types of administered objects. The Keyword column shows the strings that you can substitute for *TYPE* in the commands shown in Table 10 on page 47.

Administering JMS objects

Table 9. The JMS object types that are handled by the administration tool

Object Type	Keyword	Description
MQQueueConnectionFactory	QCF	The WebSphere MQ implementation of the JMS QueueConnectionFactory interface. This represents a factory object for creating connections in the point-to-point domain of JMS.
MQTopicConnectionFactory	TCF	The WebSphere MQ implementation of the JMS TopicConnectionFactory interface. This represents a factory object for creating connections in the publish/subscribe domain of JMS.
MQQueue	Q	The WebSphere MQ implementation of the JMS Queue interface. This represents a destination for messages in the point-to-point domain of JMS.
MQTopic	T	The WebSphere MQ implementation of the JMS Topic interface. This represents a destination for messages in the publish/subscribe domain of JMS.
MQXAQueueConnectionFactory ¹	XAQCF	The WebSphere MQ implementation of the JMS XAQueueConnectionFactory interface. This represents a factory object for creating connections in the point-to-point domain of JMS that use the XA versions of JMS classes.
MQXATopicConnectionFactory ¹	XATCF	The WebSphere MQ implementation of the JMS XATopicConnectionFactory interface. This represents a factory object for creating connections in the publish/subscribe domain of JMS that use the XA versions of JMS classes.
JMSWrapXAQueueConnectionFactory ²	WSQCF	The WebSphere MQ implementation of the JMS QueueConnectionFactory interface. This represents a factory object for creating connections in the point-to-point domain of JMS that use the XA versions of JMS classes with WebSphere Application Server.
JMSWrapXATopicConnectionFactory ²	WSTCF	The WebSphere MQ implementation of the JMS TopicConnectionFactory interface. This represents a factory object for creating connections in the publish/subscribe domain of JMS that use the XA versions of JMS classes with WebSphere Application Server.
<ol style="list-style-type: none"> 1. These classes are provided for use by vendors of application servers. They are unlikely to be directly useful to application programmers. 2. Use this style of ConnectionFactory if you want your JMS sessions to participate in global transactions that are coordinated by WebSphere Application Server. 		

Verbs used with JMS objects

You can use the verbs ALTER, DEFINE, DISPLAY, DELETE, COPY, and MOVE to manipulate administered objects in the directory namespace. Table 10 summarizes their use. Substitute *TYPE* with the keyword that represents the required administered object, as listed in Table 9 on page 46.

Table 10. Syntax and description of commands used to manipulate administered objects

Command syntax	Description
ALTER <i>TYPE</i> (name) [property]*	Attempts to update the given administered object's properties with the ones supplied. Fails if there is a security violation, if the specified object cannot be found, or if the new properties supplied are not valid.
DEFINE <i>TYPE</i> (name) [property]*	Attempts to create an administered object of type <i>TYPE</i> with the supplied properties, and store it under the name name in the current context. Fails if there is a security violation, if the supplied name is not valid or already exists, or if the properties supplied are not valid.
DISPLAY <i>TYPE</i> (name)	Displays the properties of the administered object of type <i>TYPE</i> , bound under the name name in the current context. Fails if the object does not exist, or if there is a security violation.
DELETE <i>TYPE</i> (name)	Attempts to remove the administered object of type <i>TYPE</i> , having the name name, from the current context. Fails if the object does not exist, or if there is a security violation.
COPY <i>TYPE</i> (nameA) <i>TYPE</i> (nameB)	Makes a copy of the administered object of type <i>TYPE</i> , having the name nameA, naming the copy nameB. This all occurs within the scope of the current context. Fails if the object to be copied does not exist, if an object of name nameB already exists, or if there is a security violation.
MOVE <i>TYPE</i> (nameA) <i>TYPE</i> (nameB)	Moves (renames) the administered object of type <i>TYPE</i> , having the name nameA, to nameB. This all occurs within the scope of the current context. Fails if the object to be moved does not exist, if an object of name nameB already exists, or if there is a security violation.

Creating objects

Objects are created and stored in a JNDI namespace using the following command syntax:

```
DEFINE TYPE(name) [property]*
```

That is, the DEFINE verb, followed by a *TYPE*(name) administered object reference, followed by zero or more *properties* (see "Properties" on page 48).

LDAP naming considerations

To store your objects in an LDAP environment, you must give them names that comply with certain conventions. One of these is that object and subcontext names must include a prefix, such as cn= (common name), or ou= (organizational unit).

Administering JMS objects

The administration tool simplifies the use of LDAP service providers by allowing you to refer to object and context names without a prefix. If you do not supply a prefix, the tool automatically adds a default prefix to the name you supply. For LDAP this is `cn=`.

You can change the default prefix by setting the `NAME_PREFIX` property in the `JMSAdmin` configuration file, as described in “Using an unlisted `InitialContextFactory`” on page 43.

This is shown in the following example.

```
InitCtx> DEFINE Q(testQueue)

InitCtx> DISPLAY CTX

    Contents of InitCtx

    a  cn=testQueue          com.ibm.mq.jms.MQQueue

    1 Object(s)
    0 Context(s)
    1 Binding(s), 1 Administered
```

Note that, although the object name supplied (`testQueue`) does not have a prefix, the tool automatically adds one to ensure compliance with the LDAP naming convention. Likewise, submitting the command `DISPLAY Q(testQueue)` also causes this prefix to be added.

You might need to configure your LDAP server to store Java objects. Information to assist with this configuration is provided in Appendix C, “LDAP schema definition for storing Java objects” on page 407.

Properties

A property consists of a name-value pair in the format:

```
PROPERTY_NAME(property_value)
```

Property names are not case-sensitive, and are restricted to the set of recognized names shown in Table 11. This table also shows the valid property values for each property.

Table 11. Property names and valid values

Property	Short form	Valid values (defaults in bold)
BROKERCCDSUBQ	CCDSUB	<ul style="list-style-type: none">• SYSTEM.JMS.D.CC.SUBSCRIBER.QUEUE• Any string
BROKERCCSUBQ	CCSUB	<ul style="list-style-type: none">• SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE• Any string
BROKERCONQ	BCON	Any string
BROKERDURSUBQ	BDSUB	<ul style="list-style-type: none">• SYSTEM.JMS.D.SUBSCRIBER.QUEUE• Any string
BROKERPUBQ	BPUB	<ul style="list-style-type: none">• SYSTEM.BROKER.DEFAULT.STREAM• Any string
BROKERQMGR	BQM	Any string
BROKERSUBQ	BSUB	<ul style="list-style-type: none">• SYSTEM.JMS.ND.SUBSCRIBER.QUEUE• Any string

Table 11. Property names and valid values (continued)

Property	Short form	Valid values (defaults in bold)
BROKERVER	BVER	<ul style="list-style-type: none"> • V1 - To use the WebSphere MQ broker. Also to use the WebSphere MQ Integrator V2 or WebSphere MQ Event Broker brokers in compatibility mode. • V2 - To use the WebSphere MQ Integrator V2 or WebSphere MQ Event Broker brokers in native mode
CCSID	CCS	Any positive integer
CHANNEL	CHAN	Any string
CLEANUP	CL	<ul style="list-style-type: none"> • SAFE • ASPROP • NONE • STRONG
CLEANUPINT	CLINT	<ul style="list-style-type: none"> • 60000 • Any positive integer
CLIENTID	CID	Any string
DESCRIPTION	DESC	Any string
ENCODING	ENC	See “The ENCODING property” on page 54
EXPIRY	EXP	<ul style="list-style-type: none"> • APP - Expiry may be defined by the JMS application. • UNLIM - No expiry occurs. • Any positive integer representing expiry in milliseconds.
FAILIFQUIESCE	FIQ	<ul style="list-style-type: none"> • Yes - Applications return from a method call if the queue manager has entered a controlled shutdown. • No - Applications continue to carry out operations against a quiescing queue manager, preventing that queue manager’s shutdown.
HOSTNAME	HOST	<ul style="list-style-type: none"> • localhost • Any string
MSGBATCHSZ	MBS	<ul style="list-style-type: none"> • 10 • Any positive integer
MSGRETENTION	MRET	<ul style="list-style-type: none"> • Yes - Unwanted messages remain on the input queue • No - Unwanted messages are dealt with according to their disposition options
PERSISTENCE	PER	<ul style="list-style-type: none"> • APP - Persistence is defined by the JMS application. • QDEF - Persistence takes the value of the queue default. • PERS - Messages are persistent. • NON - Messages are non-persistent.

USECONNPOOLING	UCP	<ul style="list-style-type: none"> • Yes • No

Many of the properties are relevant only to a specific subset of the object types. Table 12 on page 51 shows for each property which object types are valid, and gives a brief description of each property. The object types are identified using keywords; refer to Table 9 on page 46 for an explanation of these.

Numbers refer to notes at the end of the table. See also "Property dependencies" on page 53. Appendix A, "Mapping between administration tool properties and

programmable properties” on page 403 shows the relationship between properties set by the tool and programmable properties.

Table 12. The valid combinations of property and object type

Property	QCF	TCF	Q	T	WSQCF XAQCF	WSTCF XATCF	Description
BROKERCCDSUBQ				Y			The name of the queue from which durable subscription messages are retrieved for a ConnectionConsumer
BROKERCCSUBQ		Y				Y	The name of the queue from which non-durable subscription messages are retrieved for a ConnectionConsumer
BROKERCONQ		Y				Y	Broker’s control queue name
BROKERDURSUBQ				Y			The name of the queue from which durable subscription messages are retrieved
BROKERPUBQ		Y				Y	The name of the broker input queue (stream queue)
BROKERQMGR		Y				Y	The queue manager on which the broker is running
BROKERSUBQ		Y				Y	The name of the queue from which non-durable subscription messages are retrieved
BROKERVER		Y ⁴		Y		Y	The version of the broker being used
CCSID	Y	Y	Y	Y			The coded-character-set-ID to be used on connections
CHANNEL	Y	Y					The name of the client connection channel being used
CLEANUP		Y				Y	Cleanup Level for BROKER or MIGRATE Subscription Stores
CLEANUPINT		Y				Y	The interval between background executions of the publish/subscribe cleanup utility
CLIENTID	Y	Y ⁴			Y	Y	A string identifier for the client
DESCRIPTION	Y	Y ⁴	Y	Y	Y	Y	A description of the stored object
ENCODING			Y	Y			The encoding scheme used for this destination
EXPIRY			Y	Y			The period after which messages at a destination expire
HOSTNAME ³	Y	Y ⁴					The name of the host on which the queue manager or WebSphere MQ Event Broker broker resides. A dotted-decimal TCP/IP address can also be used.
MSGBATCHSZ	Y	Y			Y	Y	The maximum number of messages to be taken from a queue in one packet when using asynchronous message delivery
MSGRETENTION	Y				Y		Whether or not the connection consumer keeps unwanted messages on the input queue

Administering JMS objects

Table 12. The valid combinations of property and object type (continued)

Property	QCF	TCF	Q	T	WSQCF XAQCF	WSTCF XATCF	Description
PERSISTENCE			Y	Y			The persistence of messages sent to a destination
PRIORITY			Y	Y			The priority for messages sent to a destination
POLLINGINT	Y	Y			Y	Y	The interval, in milliseconds, between scans of all receivers during asynchronous message delivery
PORT ³	Y	Y ⁴					The port on which the queue manager or broker listens
PUBACKINT		Y				Y	The interval, in number of messages, between publish requests that require acknowledgement from the broker
QMANAGER	Y	Y	Y		Y	Y	The name of the queue manager to connect to
QUEUE			Y				The underlying name of the queue representing this destination
RECEXIT	Y	Y					The fully-qualified class name of the receive exit being used
RECEXITINIT	Y	Y					The receive exit initialization string
SECEXIT	Y	Y					The fully-qualified class name of the security exit being used
SECEXITINIT	Y	Y					The security exit initialization string
SENDEXIT	Y	Y					The fully-qualified class name of the send exit being used
SENDEXITINIT	Y	Y					The send exit initialization string
SSLCIPHERSUITE	Y	Y					The cipher suite to use for SSL connection
SSLCRL	Y	Y					CRL servers to check for SSL certificate revocation
SSLPEERNAME	Y	Y					For SSL, a <i>distinguished name</i> skeleton that must match that provided by the queue manager
STATREFRESHINT		Y				Y	The interval, in milliseconds, between transactions to refresh publish/subscribe status
SUBSTORE		Y				Y	Where WebSphere MQ JMS should store persistent data relating to active subscriptions
SYNCPOINTALLGETS	Y	Y			Y	Y	Whether all gets should be performed under syncpoint
TARGCLIENT ²			Y	Y			Whether the WebSphere MQ RFH2 format is used to exchange information with target applications
TEMPMODEL	Y				Y		The name of the model queue from which temporary queues are created
TOPIC				Y			The underlying name of the topic representing this destination

Table 12. The valid combinations of property and object type (continued)

Property	QCF	TCF	Q	T	WSQCF XAQCF	WSTCF XATCF	Description
TRANSPORT ³	Y	Y ⁴			Y ¹	Y ¹	Whether connections use the WebSphere MQ bindings, a client connection, or WebSphere MQ Event Broker.
USECONNPOOLING	Y	Y			Y	Y	Whether to use connection pooling

Notes:

- For WSTCF, WSQCF, XATCF, and XAQCF objects, only the BIND transport type is allowed.
- The TARGCLIENT property indicates whether the WebSphere MQ RFH2 format is used to exchange information with target applications.
The MQJMS_CLIENT_JMS_COMPLIANT constant indicates that the RFH2 format is used to send information. Applications that use WebSphere MQ JMS understand the RFH2 format. Set the MQJMS_CLIENT_JMS_COMPLIANT constant when you exchange information with a target WebSphere MQ JMS application.
The MQJMS_CLIENT_NONJMS_MQ constant indicates that the RFH2 format is not used to send information. Typically, this value is used for an existing WebSphere MQ application (that is, one that does not handle RFH2).
- HOSTNAME, PORT, and TRANSPORT are also used to identify if you are connecting to WebSphere MQ Event Broker and the broker’s IP hostname and listening port.
For more information about using WebSphere MQ Event Broker, see Chapter 11, “Programming publish/subscribe applications” on page 205.
- Only the BROKERVER, CLIENTID, DESCRIPTION, HOSTNAME, PORT, and TRANSPORT properties are supported for a TopicConnectionFactory used with a direct connection across TCP/IP to WebSphere MQ Event Broker.

Property dependencies

Some properties have dependencies on each other. This might mean that it is meaningless to supply a property unless another property is set to a particular value. The specific property groups where this can occur are

- Client properties
- Properties for connecting to WebSphere MQ Event Broker
- Exit initialization strings

Client properties

Some properties are only relevant to a connection with the TRANSPORT property set to the value CLIENT. If this property is not explicitly set on a connection factory to one of the values CLIENT or DIRECT, the transport used on connections provided by the factory is WebSphere MQ Bindings. Consequently, none of the client properties on this connection factory can be configured. These are:

- HOST
- PORT
- CHANNEL
- CCSID
- RECEXIT
- RECEXITINIT
- SECEXIT
- SECEXITINIT
- SENDEXIT

Administering JMS objects

- SENDEXITINIT
- SSLCIPHERSUITE
- SSLCRL
- SSLPEERNAME

It is an error to set any of these properties without setting the `TRANSPORT` property to `CLIENT` (or, for some, `DIRECT`; see “Properties for connecting to WebSphere MQ Event Broker”).

Properties for connecting to WebSphere MQ Event Broker

The only properties used with a direct connection to WebSphere MQ Event Broker are `BROKERVER`, `CLIENTID`, `DESCRIPTION`, `HOSTNAME`, `PORT`, and `TRANSPORT`.

The default values for `PORT` and `BROKERVER` are set by the definition of `TRANSPORT`:

1. Defining a connection factory with `TRANSPORT` as `CLIENT` sets:
 - `BROKERVER` to V1
 - `PORT` to 1414
2. Defining a connection factory with `TRANSPORT` as `DIRECT` sets:
 - `BROKERVER` to V2
 - `PORT` to 1506

If you explicitly set the value of `PORT` or `BROKERVER`, a later change to the value of `TRANSPORT` does not override your choices.

Exit initialization strings

Do not set any of the exit initialization strings without supplying the corresponding exit name. The exit initialization properties are:

- RESEXITINIT
- SESEXITINIT
- SENDEXITINIT

For example, specifying `RESEXITINIT(myString)` without specifying `RESEXIT(some.exit.classname)` causes an error.

The ENCODING property

The valid values that the `ENCODING` property can take are constructed from three sub-properties:

integer encoding	Either normal or reversed
decimal encoding	Either normal or reversed
floating-point encoding	IEEE normal, IEEE reversed, or z/OS.

The `ENCODING` is expressed as a three-character string with the following syntax:

`{N|R}{N|R}{N|R|3}`

In this string:

- N denotes normal
- R denotes reversed
- 3 denotes z/OS
- The first character represents *integer encoding*
- The second character represents *decimal encoding*

- The third character represents *floating-point encoding*

This provides a set of twelve possible values for the ENCODING property.

There is an additional value, the string NATIVE, which sets appropriate encoding values for the Java platform.

The following examples show valid combinations for ENCODING:

```
ENCODING(NNR)
ENCODING(NATIVE)
ENCODING(RR3)
```

SSL properties

When you specify TRANSPORT(CLIENT), you can enable Secure Sockets Layer (SSL) encrypted communication using the SSLCIPHERSUITE property. Set this property to a valid CipherSuite provided by your JSSE provider; it must match the CipherSpec named on the SVRCONN channel named by the CHANNEL property.

However, CipherSpecs (as specified on the SVRCONN channel) and CipherSuites (as specified on ConnectionFactory objects) use different naming schemes to represent the same SSL encryption algorithms. If a recognized CipherSpec name is specified on the SSLCIPHERSUITE property, JMSAdmin issues a warning and maps the CipherSpec to its equivalent CipherSuite. See Appendix H, “SSL CipherSuites supported by WebSphere MQ” on page 429 for a list of CipherSpecs recognized by WebSphere MQ and JMSAdmin.

The SSLPEERNAME matches the format of the SSLPEER parameter, which can be set on channel definitions. It is a list of attribute name and value pairs separated by commas or semicolons. For example:

```
SSLPEERNAME(CN=QMGR.*, OU=IBM, OU=WEBSPPHERE)
```

The set of names and values makes up a *distinguished name*. For more details about distinguished names and their use with WebSphere MQ, see the *WebSphere MQ Security* book.

The example given checks the identifying certificate presented by the server at connect-time. For the connection to succeed, the certificate must have a Common Name beginning QMGR., and must have at least two Organizational Unit names, the first of which is IBM and the second WEBSPPHERE. Checking is case-insensitive.

If SSLPEERNAME is not set, no such checking is performed. SSLPEERNAME is ignored if SSLCIPHERSUITE is not specified.

The SSLCRL property specifies zero or more CRL (Certificate Revocation List) servers. Use of this property requires a JVM at Java 2 v1.4. This is a space-delimited list of entries of the form:

```
ldap://hostname:[port]
```

optionally followed by a single /. If *port* is omitted, the default LDAP port of 389 is assumed. At connect-time, the SSL certificate presented by the server is checked against the specified CRL servers. See the *WebSphere MQ Security* book for more about CRL security.

If SSLCRL is not set, no such checking is performed. SSLCRL is ignored if SSLCIPHERSUITE is not specified.

Administering JMS objects

Sample error conditions

This section provides examples of the error conditions that might arise while creating an object.

CipherSpec mapped to CipherSuite

```
InitCtx/cn=Trash> DEFINE QCF(testQCF) SSLCIPHERSUITE(RC4_MD5_US)
WARNING: Converting CipherSpec RC4_MD5_US to
CipherSuite SSL_RSA_WITH_RC4_128_MD5
```

Invalid property for object

```
InitCtx/cn=Trash> DEFINE QCF(testQCF) PRIORITY(4)
Unable to create a valid object, please check the parameters supplied
Invalid property for a QCF: PRI
```

Invalid type for property value

```
InitCtx/cn=Trash> DEFINE QCF(testQCF) CCSID(english)
Unable to create a valid object, please check the parameters supplied
Invalid value for CCS property: English

Chapter 6. Introduction for programmers

This chapter contains general information for programmers. For more detailed information about writing programs, see Chapter 7, “Writing WebSphere MQ base Java programs” on page 63.

Why should I use the Java interface?

The WebSphere MQ classes for Java programming interface makes the many benefits of Java available to you as a developer of WebSphere MQ applications:

- The Java programming language is **easy to use**.

There is no need for header files, pointers, structures, unions, and operator overloading. Programs written in Java are easier to develop and debug than their C and C++ equivalents.

- Java is **object-oriented**.

The object-oriented features of Java are comparable to those of C++, but there is no multiple inheritance. Instead, Java uses the concept of an interface.

- Java is inherently **distributed**.

The Java class libraries contain a library of routines for coping with TCP/IP protocols like HTTP and FTP. Java programs can access URLs as easily as accessing a file system.

- Java is **robust**.

Java puts a lot of emphasis on early checking for possible problems, dynamic (runtime) checking, and the elimination of situations that are error prone. Java uses a concept of references that eliminates the possibility of overwriting memory and corrupting data.

- Java is **secure**.

Java is intended to be run in networked or distributed environments, and a lot of emphasis has been placed on security. Java programs cannot overrun their runtime stack and cannot corrupt memory outside their process space. When Java programs are downloaded from the Internet, they cannot even read or write local files.

- Java programs are **portable**.

There are no implementation-dependent aspects of the Java specification. The Java compiler generates an architecture-neutral object file format. The compiled code is executable on many processors, as long as the Java runtime system is present.

If you write your application using WebSphere MQ classes for Java, users can download the Java byte codes (called *applets*) for your program from the Internet. Users can then run these applets on their own machines. This means that users with access to your Web server can load and run your application with no prior installation needed on their machines.

When an update to the program is required, you update the copy on the Web server. The next time that users access the applet, they automatically receive the latest version. This can significantly reduce the costs involved in installing and updating traditional client applications where a large number of desktops are involved.

Advantages of Java

If you place your applet on a Web server that is accessible outside the corporate firewall, anyone on the Internet can download and use your application. This means that you can get messages into your WebSphere MQ system from anywhere on the Internet. This opens the door to building a whole new set of Internet accessible service, support, and electronic commerce applications.

The WebSphere MQ classes for Java interface

The procedural WebSphere MQ application programming interface is built around the following verbs:

```
MQBACK, MQBEGIN, MQCLOSE, MQCMIT, MQCONN, MQCONNX,  
MQDISC, MQGET, MQINQ, MQOPEN, MQPUT, MQPUT1, MQSET
```

These verbs all take, as a parameter, a handle to the WebSphere MQ object on which they are to operate. Because Java is object-oriented, the Java programming interface turns this round. Your program consists of a set of WebSphere MQ objects, which you act upon by calling methods on those objects.

When you use the procedural interface, you disconnect from a queue manager by using the call `MQDISC(Hconn, CompCode, Reason)`, where *Hconn* is a handle to the queue manager.

In the Java interface, the queue manager is represented by an object of class `MQQueueManager`. You disconnect from the queue manager by calling the `disconnect()` method on that class.

```
// declare an object of type queue manager  
MQQueueManager queueManager=new MQQueueManager();  
...  
// do something...  
...  
// disconnect from the queue manager  
queueManager.disconnect();
```

Java Development Kit

Before you can compile any applets or applications that you write, you must have access to a Java Development Kit (JDK) for your development platform. The JDK contains all the standard Java classes, variables, constructors, and interfaces on which the WebSphere MQ classes for Java classes depend. It also contains the tools required to compile and run the applets and programs on each supported platform.

You can download IBM Developer Kits for Java from the IBM Software Download Catalog, which is available on the World Wide Web at location:

<http://www.ibm.com/developerworks/java>

To compile Java applications on the iSeries and AS/400 platforms, you must first install:

- The AS/400 Developer Kit for Java, 5769-JV1
- The Qshell Interpreter, OS/400 (5769-SS1) Option 30

WebSphere MQ classes for Java class library

WebSphere MQ classes for Java is a set of Java classes that enable Java applets and applications to interact with WebSphere MQ.

The following classes are provided:

- MQChannelDefinition
- MQChannelExit
- MQDistributionList
- MQDistributionListItem
- MQEnvironment
- MQException
- MQGetMessageOptions
- MQManagedObject
- MQMessage
- MQMessageTracker
- MQPoolServices
- MQPoolServicesEvent
- MQPoolToken
- MQPutMessageOptions
- MQProcess
- MQQueue
- MQQueueManager
- MQSimpleConnectionManager

The following Java interfaces are provided:

- MQC
- MQPoolServicesEventListener
- MQReceiveExit
- MQSecurityExit
- MQSendExit

Implementation of the following Java interfaces is also provided. However, these interfaces are not intended for direct use by applications:

- MQConnectionManager
- javax.resource.spi.ManagedConnection
- javax.resource.spi.ManagedConnectionFactory
- javax.resource.spi.ManagedConnectionMetaData

In Java, a *package* is a mechanism for grouping sets of related classes together. The WebSphere MQ classes and interfaces are shipped as a Java package called `com.ibm.mq`. To include the WebSphere MQ classes for Java package in your program, add the following line at the top of your source file:

```
import com.ibm.mq.*;
```

WebSphere MQ base Java class library

Chapter 7. Writing WebSphere MQ base Java programs

To use WebSphere MQ classes for Java to access WebSphere MQ queues, you write Java programs that contain calls that put messages onto, and get messages from, WebSphere MQ queues. The programs can take the form of Java *applets*, Java *servlets*, or Java *applications*.

This chapter provides information to assist with writing Java applets, servlets, and applications to interact with WebSphere MQ systems. For details of individual classes, see Chapter 9, “The WebSphere MQ base Java classes and interfaces” on page 97.

Should I write applets or applications?

Whether you write applets, servlets, or applications depends on the connection that you want to use and from where you want to run the programs.

The main differences between applets, servlets, and applications are:

- Applets are run with an applet viewer or in a Web browser, servlets are run in a Web application server, and applications are run standalone.
- Applets can be downloaded from a Web server to a Web browser machine, but applications and servlets are not.
- Applets run with additional security rules limiting what they can do.

See Appendix F, “Using WebSphere MQ Java in applets with Java 1.2 or later” on page 423 for more information about this.

The following general rules apply:

- If you want to run your programs from machines that do not have WebSphere MQ classes for Java installed locally, write applets.
- The native bindings mode of WebSphere MQ classes for Java does not support applets. Therefore, if you want to use your programs in all connection modes, including the native bindings mode, write servlets or applications.

Connection differences

The way you program for WebSphere MQ classes for Java has some dependencies on the connection modes you want to use.

Client connections

When WebSphere MQ classes for Java is used as a client, it is similar to the WebSphere MQ C client, but has the following differences:

- It supports only TCP/IP.
- It does not support connection tables.
- It does not read any WebSphere MQ environment variables at startup.
- Information that would be stored in a channel definition and in environment variables is stored in a class called Environment. Alternatively, this information can be passed as parameters when the connection is made.
- Error and exception conditions are written to a log specified in the MQException class. The default error destination is the Java console.

Connection differences

The WebSphere MQ classes for Java clients do not support the MQBEGIN verb or fast bindings.

For general information on WebSphere MQ clients, see the *WebSphere MQ Clients* book.

Bindings mode

The bindings mode of WebSphere MQ classes for Java differs from the client modes in the following ways:

- Most of the parameters provided by the MQEnvironment class are ignored
- The bindings support the MQBEGIN verb and fast bindings into the WebSphere MQ queue manager

Note: WebSphere MQ for iSeries and WebSphere MQ for z/OS do not support the use of MQBEGIN to initiate global units of work that are coordinated by the queue manager.

Defining which connection to use

The connection is determined by the setting of variables in the MQEnvironment class.

MQEnvironment.properties

This can contain the following key/value pairs:

- For client and bindings connections:
MQC.TRANSPORT_PROPERTY, MQC.TRANSPORT_MQSERIES

MQEnvironment.hostname

Set the value of this variable follows:

- For client connections, set this to the host name of the WebSphere MQ server to which you want to connect
- For bindings mode, set this to null

Example code fragments

This section includes two example code fragments; Figure 1 on page 65 and Figure 2 on page 68. Each one uses a particular connection and includes notes to describe the changes needed to use alternative connections.

Example applet code

The following code fragment demonstrates an applet that uses a TCP/IP connection to:

1. Connect to a queue manager
2. Put a message onto SYSTEM.DEFAULT.LOCAL.QUEUE
3. Get the message back

```

//
// Note. If you receive WebSphere MQ error 2 reason 2059 and you are sure your
// WebSphere MQ and TCP/IP setup is correct,
// you should click on the "Applet" selection in the Applet viewer window
// select properties, and change "Network access" to unrestricted.
import com.ibm.mq.*;           // Include the WebSphere MQ classes for Java package

public class MQSample extends java.applet.Applet
{

    private String hostname = "your_hostname";    // define the name of your
                                                // host to connect to
    private String channel = "server_channel";    // define name of channel
                                                // for client to use
                                                // Note. assumes WebSphere MQ Server
                                                // is listening on the default
                                                // TCP/IP port of 1414
    private String qManager = "your_Q_manager";   // define name of queue
                                                // manager object to
                                                // connect to.

    private MQQueueManager qMgr;                 // define a queue manager object

    // When the class is called, this initialization is done first.

    public void init()
    {
        // Set up WebSphere MQ environment
        MQEnvironment.hostname = hostname;        // Could have put the
                                                // hostname & channel
        MQEnvironment.channel = channel;         // string directly here!

        MQEnvironment.properties.put(MQC.TRANSPORT_PROPERTY, //Set TCP/IP or server
        MQC.TRANSPORT_MQSERIES); //Connection

    } // end of init
}

```

Figure 1. WebSphere MQ classes for Java example applet (Part 1 of 3)

Example code

```
public void start()
{
    try {
        // Create a connection to the queue manager
        qMgr = new MQQueueManager(qManager);

        // Set up the options on the queue we wish to open...
        // Note. All WebSphere MQ Options are prefixed with MQC in Java.
        int openOptions = MQC.MQOO_INPUT_AS_Q_DEF |
            MQC.MQOO_OUTPUT;
        // Now specify the queue that we wish to open, and the open options...

        MQQueue system_default_local_queue =
            qMgr.accessQueue("SYSTEM.DEFAULT.LOCAL.QUEUE",
                openOptions);

        // Define a simple WebSphere MQ message, and write some text in UTF format..

        MQMessage hello_world = new MQMessage();
        hello_world.writeUTF("Hello World!");

        // specify the message options...

        MQPutMessageOptions pmo = new MQPutMessageOptions(); // accept the defaults,
                                                                // same as
                                                                // MQPMO_DEFAULT
                                                                // constant

        // put the message on the queue

        system_default_local_queue.put(hello_world,pmo);

        // get the message back again...
        // First define a WebSphere MQ message buffer to receive the message into..

        MQMessage retrievedMessage = new MQMessage();
        retrievedMessage.messageId = hello_world.messageId;

        // Set the get message options..

        MQGetMessageOptions gmo = new MQGetMessageOptions(); // accept the defaults
                                                                // same as
                                                                // MQGMO_DEFAULT

        // get the message off the queue..

        system_default_local_queue.get(retrievedMessage, gmo);

        // And prove we have the message by displaying the UTF message text

        String msgText = retrievedMessage.readUTF();
        System.out.println("The message is: " + msgText);

        // Close the queue

        system_default_local_queue.close();

        // Disconnect from the queue manager

        qMgr.disconnect();
    }

    // If an error has occurred in the above, try to identify what went wrong.
    // Was it a WebSphere MQ error?
}
```

```
catch (MQException ex)
{
    System.out.println("A WebSphere MQ error occurred : Completion code " +
        ex.completionCode +
        " Reason code " + ex.reasonCode);
}
// Was it a Java buffer space error?
catch (java.io.IOException ex)
{
    System.out.println("An error occurred whilst writing to the
message buffer: " + ex);
}
} // end of start
} // end of sample
```

Figure 1. WebSphere MQ classes for Java example applet (Part 3 of 3)

Example application code

The following code fragment demonstrates an application that uses bindings mode to:

1. Connect to a queue manager
2. Put a message onto SYSTEM.DEFAULT.LOCAL.QUEUE
3. Get the message back again

```

// put the message on the queue

system_default_local_queue.put(hello_world,pmo);

// get the message back again...
// First define a WebSphere MQ message buffer to receive the message into..

MQMessage retrievedMessage = new MQMessage();
retrievedMessage.messageId = hello_world.messageId;

// Set the get message options...

MQGetMessageOptions gmo = new MQGetMessageOptions(); // accept the defaults
                                                    // same as MQGMO_DEFAULT
// get the message off the queue...

system_default_local_queue.get(retrievedMessage, gmo);

// And prove we have the message by displaying the UTF message text

String msgText = retrievedMessage.readUTF();
System.out.println("The message is: " + msgText);
// Close the queue...
system_default_local_queue.close();
// Disconnect from the queue manager

qMgr.disconnect();
}
// If an error has occurred in the above, try to identify what went wrong
// Was it a WebSphere MQ error?
catch (MQException ex)
{
    System.out.println("A WebSphere MQ error occurred : Completion code " +
        ex.completionCode + " Reason code " + ex.reasonCode);
}
// Was it a Java buffer space error?
catch (java.io.IOException ex)
{
    System.out.println("An error occurred whilst writing to the message buffer: " + ex);
}
}
} // end of sample

```

Figure 2. WebSphere MQ classes for Java example application (Part 2 of 2)

Operations on queue managers

This section describes how to connect to, and disconnect from, a queue manager using WebSphere MQ classes for Java.

Setting up the WebSphere MQ environment

Note: This step is not necessary when using WebSphere MQ classes for Java in bindings mode. In that case, go directly to “Connecting to a queue manager” on page 70. Before you use the client connection to connect to a queue manager, you must set up the MQEnvironment.

The C based WebSphere MQ clients rely on environment variables to control the behavior of the MQCONN call. Because Java applets have no access to environment variables, the Java programming interface includes a class MQEnvironment. This class allows you to specify the following details that are to be used during the connection attempt:

Queue manager operations

- Channel name
- Host name
- Port number
- User ID
- Password

To specify the channel name and host name, use the following code:

```
MQEnvironment.hostname = "host.domain.com";
MQEnvironment.channel = "java.client.channel";
```

This is equivalent to an MQSERVER environment variable setting of:

```
"java.client.channel/TCP/host.domain.com".
```

By default, the Java clients attempt to connect to a WebSphere MQ listener at port 1414. To specify a different port, use the code:

```
MQEnvironment.port = nnnn;
```

The user ID and password default to blanks. To specify a non-blank user ID or password, use the code:

```
MQEnvironment.userID = "uid"; // equivalent to env var MQ_USER_ID
MQEnvironment.password = "pwd"; // equivalent to env var MQ_PASSWORD
```

Connecting to a queue manager

You are now ready to connect to a queue manager by creating a new instance of the `MQQueueManager` class:

```
MQQueueManager queueManager = new MQQueueManager("qMgrName");
```

To disconnect from a queue manager, call the `disconnect()` method on the queue manager:

```
queueManager.disconnect();
```

If you call the `disconnect` method, all open queues and processes that you have accessed through that queue manager are closed. However, it is good programming practice to close these resources explicitly when you finish using them. To do this, use the `close()` method.

The `commit()` and `backout()` methods on a queue manager replace the `MQCMIT` and `MQBACK` calls that are used with the procedural interface.

Accessing queues and processes

To access queues and processes, use the `MQQueueManager` class. The `MQOD` (object descriptor structure) is collapsed into the parameters of these methods. For example, to open a queue on a queue manager called `queueManager`, use the following code:

```
MQQueue queue = queueManager.accessQueue("qName",
                                          MQC.MQOO_OUTPUT,
                                          "qMgrName",
                                          "dynamicQName",
                                          "altUserId");
```

The *options* parameter is the same as the `Options` parameter in the `MQOPEN` call.

The `accessQueue` method returns a new object of class `MQQueue`.

When you have finished using the queue, use the `close()` method to close it, as in the following example:

```
queue.close();
```

With WebSphere MQ classes for Java, you can also create a queue by using the `MQQueue` constructor. The parameters are exactly the same as for the `accessQueue` method, with the addition of a queue manager parameter. For example:

```
MQQueue queue = new MQQueue(queueManager,
                             "qName",
                             MQC.MQOO_OUTPUT,
                             "qMgrName",
                             "dynamicQName",
                             "altUserId");
```

Constructing a queue object in this way enables you to write your own subclasses of `MQQueue`.

To access a process, use the `accessProcess` method in place of `accessQueue`. This method does not have a *dynamic queue name* parameter, because this does not apply to processes.

The `accessProcess` method returns a new object of class `MQProcess`.

When you have finished using the process object, use the `close()` method to close it, as in the following example:

```
process.close();
```

With WebSphere MQ classes for Java, you can also create a process by using the `MQProcess` constructor. The parameters are exactly the same as for the `accessProcess` method, with the addition of a queue manager parameter. Constructing a process object in this way enables you to write your own subclasses of `MQProcess`.

Handling messages

Put messages onto queues using the `put()` method of the `MQQueue` class. You get messages from queues using the `get()` method of the `MQQueue` class. Unlike the procedural interface, where `MQPUT` and `MQGET` put and get arrays of bytes, the Java programming language puts and gets instances of the `MQMessage` class. The `MQMessage` class encapsulates the data buffer that contains the actual message data, together with all the `MQMD` (message descriptor) parameters that describe that message.

To build a new message, create a new instance of the `MQMessage` class, and use the `writeXXX` methods to put data into the message buffer.

When the new message instance is created, all the `MQMD` parameters are automatically set to their default values, as defined in the *WebSphere MQ Application Programming Reference*. The `put()` method of `MQQueue` also takes an instance of the `MQPutMessageOptions` class as a parameter. This class represents the `MQPMO` structure. The following example creates a message and puts it onto a queue:

```
// Build a new message containing my age followed by my name
MQMessage myMessage = new MQMessage();
myMessage.writeInt(25);
```

```
String name = "Charlie Jordan";
```

Message handling

```
myMessage.writeInt(name.length());
myMessage.writeBytes(name);

// Use the default put message options...
MQPutMessageOptions pmo = new MQPutMessageOptions();

// put the message!
queue.put(myMessage,pmo);
```

The `get()` method of `MQQueue` returns a new instance of `MQMessage`, which represents the message just taken from the queue. It also takes an instance of the `MQGetMessageOptions` class as a parameter. This class represents the `MQGMO` structure.

You do not need to specify a maximum message size, because the `get()` method automatically adjusts the size of its internal buffer to fit the incoming message. Use the `readXXX` methods of the `MQMessage` class to access the data in the returned message.

The following example shows how to get a message from a queue:

```
// Get a message from the queue
MQMessage theMessage = new MQMessage();
MQGetMessageOptions gmo = new MQGetMessageOptions();
queue.get(theMessage,gmo); // has default values

// Extract the message data
int age = theMessage.readInt();
int strLen = theMessage.readInt();
byte[] strData = new byte[strLen];
theMessage.readFully(strData,0,strLen);
String name = new String(strData,0);
```

You can alter the number format that the read and write methods use by setting the *encoding* member variable.

You can alter the character set to use for reading and writing strings by setting the *characterSet* member variable.

See “`MQMessage`” on page 121 for more details.

Note: The `writeUTF()` method of `MQMessage` automatically encodes the length of the string as well as the Unicode bytes it contains. When your message will be read by another Java program (using `readUTF()`), this is the simplest way to send string information.

Handling errors

Methods in the Java interface do not return a completion code and reason code. Instead, they throw an exception whenever the completion code and reason code resulting from a WebSphere MQ call are not both zero. This simplifies the program logic so that you do not have to check the return codes after each call to WebSphere MQ. You can decide at which points in your program you want to deal with the possibility of failure. At these points, you can surround your code with try and catch blocks, as in the following example:

```
try {
    myQueue.put(messageA,putMessageOptionsA);
    myQueue.put(messageB,putMessageOptionsB);
}
catch (MQException ex) {
```

```

// This block of code is only executed if one of
// the two put methods gave rise to a non-zero
// completion code or reason code.
System.out.println("An error occurred during the put operation:" +
    "CC = " + ex.completionCode +
    "RC = " + ex.reasonCode);
System.out.println("Cause exception:" + ex.getCause() );
}

```

The WebSphere MQ call reason codes reported back in Java exceptions are documented in a chapter called “Return Codes” in the *WebSphere MQ Application Programming Reference*.

Sometimes the reason code does not convey all details associated with the error. This can occur if WebSphere MQ uses services provided by another product (for example, a JSSE implementation) that throws an Exception to WebSphere MQ. In this case, the method `MQException.getCause()` retrieves the underlying Exception which caused the error.

Getting and setting attribute values

For many of the common attributes, the classes `MQManagedObject`, `MQQueue`, `MQProcess`, and `MQQueueManager` contain `getXXX()` and `setXXX()` methods. These methods allow you to get and set their attribute values. Note that for `MQQueue`, the methods work only if you specify the appropriate inquire and set flags when you open the queue.

For less common attributes, the `MQQueueManager`, `MQQueue`, and `MQProcess` classes all inherit from a class called `MQManagedObject`. This class defines the `inquire()` and `set()` interfaces.

When you create a new queue manager object by using the `new` operator, it is automatically opened for inquire. When you use the `accessProcess()` method to access a process object, that object is automatically opened for inquire. When you use the `accessQueue()` method to access a queue object, that object is *not* automatically opened for either inquire or set operations. This is because adding these options automatically can cause problems with some types of remote queues. To use the `inquire`, `set`, `getXXX`, and `setXXX` methods on a queue, you must specify the appropriate inquire and set flags in the `openOptions` parameter of the `accessQueue()` method.

The `inquire` and `set` methods take three parameters:

- selectors array
- `intAttrs` array
- `charAttrs` array

You do not need the `SelectorCount`, `IntAttrCount`, and `CharAttrLength` parameters that are found in `MQINQ`, because the length of an array in Java is always known. The following example shows how to make an inquiry on a queue:

```

// inquire on a queue
final static int MQIA_DEF_PRIORITY = 6;
final static int MQCA_Q_DESC = 2013;
final static int MQ_Q_DESC_LENGTH = 64;

int[] selectors = new int[2];
int[] intAttrs = new int[1];
byte[] charAttrs = new byte[MQ_Q_DESC_LENGTH]

selectors[0] = MQIA_DEF_PRIORITY;

```

Using attribute values

```
selectors[1] = MQCA_Q_DESC;

queue.inquire(selectors,intAttrs,charAttrs);

System.out.println("Default Priority = " + intAttrs[0]);
System.out.println("Description : " + new String(charAttrs,0));
```

Multithreaded programs

Multithreaded programs are hard to avoid in Java. Consider a simple program that connects to a queue manager and opens a queue at startup. The program displays a single button on the screen. When a user presses that button, the program fetches a message from the queue.

The Java runtime environment is inherently multithreaded. Therefore, your application initialization occurs in one thread, and the code that executes in response to the button press executes in a separate thread (the user interface thread).

With the C based WebSphere MQ client, this would cause a problem, because handles cannot be shared across multiple threads. WebSphere MQ classes for Java relaxes this constraint, allowing a queue manager object (and its associated queue and process objects) to be shared across multiple threads.

The implementation of WebSphere MQ classes for Java ensures that, for a given connection (MQQueueManager object instance), all access to the target WebSphere MQ queue manager is synchronized. A thread that wants to issue a call to a queue manager is blocked until all other calls in progress for that connection are complete. If you require simultaneous access to the same queue manager from multiple threads within your program, create a new MQQueueManager object for each thread that requires concurrent access. (This is equivalent to issuing a separate MQCONN call for each thread.)

Writing user exits

WebSphere MQ classes for Java allows you to provide your own send, receive, and security exits.

To implement an exit, you define a new Java class that implements the appropriate interface. Three exit interfaces are defined in the WebSphere MQ package:

- MQSendExit
- MQReceiveExit
- MQSecurityExit

Note: User exits are supported for client connections only; they are not supported for bindings connections.

Any SSL encryption defined for a connection is performed *after* the send exit has been invoked. Similarly, decryption is performed *before* the receive or security exits are invoked.

The following sample defines a class that implements all three:

```
class MyMQExits implements MQSendExit, MQReceiveExit, MQSecurityExit {

    // This method comes from the send exit
    public byte[] sendExit(MQChannelExit channelExitParms,
                          MQChannelDefinition channelDefParms,
```

```

        byte agentBuffer[])
    {
        // fill in the body of the send exit here
    }

    // This method comes from the receive exit
    public byte[] receiveExit(MQChannelExit channelExitParms,
                             MQChannelDefinition channelDefParms,
                             byte agentBuffer[])
    {
        // fill in the body of the receive exit here
    }

    // This method comes from the security exit
    public byte[] securityExit(MQChannelExit channelExitParms,
                               MQChannelDefinition channelDefParms,
                               byte agentBuffer[])
    {
        // fill in the body of the security exit here
    }
}

```

Each exit is passed an `MQChannelExit` and an `MQChannelDefinition` object instance. These objects represent the MQCXP and MQCD structures defined in the procedural interface.

For a Send exit, the *agentBuffer* parameter contains the data that is about to be sent. For a Receive exit or a Security exit, the *agentBuffer* parameter contains the data that has just been received. You do not need a length parameter, because the expression `agentBuffer.length` indicates the length of the array.

For the Send and Security exits, your exit code should return the byte array that you want to send to the server. For a Receive exit, your exit code must return the modified data that you want WebSphere MQ classes for Java to interpret.

The simplest possible exit body is:

```

{
    return agentBuffer;
}

```

If your program is to run as a downloaded Java applet, the security restrictions that apply mean that you cannot read or write any local files. If your exit needs a configuration file, you can place the file on the Web and use the `java.net.URL` class to download it and examine its contents.

Connection pooling

WebSphere MQ classes for Java provides additional support for applications that deal with multiple connections to WebSphere MQ queue managers. When a connection is no longer required, instead of destroying it, it can be pooled and later reused. This can provide a substantial performance enhancement for applications and middleware that connect serially to arbitrary queue managers.

WebSphere MQ provides a default connection pool. Applications can activate or deactivate this connection pool by registering and deregistering tokens through the `MQEnvironment` class. If the pool is active when WebSphere MQ base Java constructs an `MQQueueManager` object, it searches this default pool and reuses

Connection pooling

any suitable connection. When an `MQQueueManager.disconnect()` call occurs, the underlying connection is returned to the pool.

Alternatively, applications can construct an `MQSimpleConnectionManager` connection pool for a particular use. Then, the application can either specify that pool during construction of an `MQQueueManager` object, or pass that pool to `MQEnvironment` for use as the default connection pool.

Also, WebSphere MQ base Java provides a partial implementation of the Java 2 Platform Enterprise Edition (J2EE) Connector Architecture. Applications running under a Java 2 v1.3 JVM with JAAS 1.0 (Java Authentication and Authorization Service) can provide their own connection pool by implementing the `javax.resource.spi.ConnectionManager` interface. Again, this interface can be specified on the `MQQueueManager` constructor, or specified as the default connection pool.

Controlling the default connection pool

Consider the following example application, `MQApp1`:

```
import com.ibm.mq.*;
public class MQApp1
{
    public static void main(String[] args) throws MQException
    {
        for (int i=0; i<args.length; i++) {
            MQQueueManager qmgr=new MQQueueManager(args[i]);
            :
            : (do something with qmgr)
            :
            qmgr.disconnect();
        }
    }
}
```

`MQApp1` takes a list of local queue managers from the command line, connects to each in turn, and performs some operation. However, when the command line lists the same queue manager many times, it is more efficient to connect only once, and to reuse that connection many times.

WebSphere MQ base Java provides a default connection pool that you can use to do this. To enable the pool, use one of the `MQEnvironment.addConnectionPoolToken()` methods. To disable the pool, use `MQEnvironment.removeConnectionPoolToken()`.

The following example application, `MQApp2`, is functionally identical to `MQApp1`, but connects only once to each queue manager.

```
import com.ibm.mq.*;
public class MQApp2
{
    public static void main(String[] args) throws MQException
    {
        MQPoolToken token=MQEnvironment.addConnectionPoolToken();

        for (int i=0; i<args.length; i++) {
            MQQueueManager qmgr=new MQQueueManager(args[i]);
            :
            : (do something with qmgr)
            :
            qmgr.disconnect();
        }
    }
}
```

```

MQEnvironment.removeConnectionPoolToken(token);
    }
}

```

The first bold line activates the default connection pool by registering an MQPoolToken object with MQEnvironment.

The MQQueueManager constructor now searches this pool for an appropriate connection and only creates a connection to the queue manager if it cannot find an existing one. The qmgr.disconnect() call returns the connection to the pool for later reuse. These API calls are the same as the sample application MQApp1.

The second highlighted line deactivates the default connection pool, which destroys any queue manager connections stored in the pool. This is important because otherwise the application would terminate with a number of live queue manager connections in the pool. This situation could cause errors that would appear in the queue manager logs.

The default connection pool stores a maximum of ten unused connections, and keeps unused connections active for a maximum of five minutes. The application can alter this (for details, see “Supplying a different connection pool” on page 78).

Instead of using MQEnvironment to supply an MQPoolToken, the application can construct its own:

```

MQPoolToken token=new MQPoolToken();
MQEnvironment.addConnectionPoolToken(token);

```

Some applications or middleware vendors provide subclasses of MQPoolToken in order to pass information to a custom connection pool. They can be constructed and passed to addConnectionPoolToken() in this way so that extra information can be passed to the connection pool.

The default connection pool and multiple components

MQEnvironment holds a static set of registered MQPoolToken objects. To add or remove MQPoolTokens from this set, use the following methods:

- MQEnvironment.addConnectionPoolToken()
- MQEnvironment.removeConnectionPoolToken()

An application might consist of many components that exist independently and perform work using a queue manager. In such an application, each component should add an MQPoolToken to the MQEnvironment set for its lifetime.

For example, the example application MQApp3 creates ten threads and starts each one. Each thread registers its own MQPoolToken, waits for a length of time, then connects to the queue manager. After the thread disconnects, it removes its own MQPoolToken.

The default connection pool remains active while there is at least one token in the set of MQPoolTokens, so it will remain active for the duration of this application. The application does not need to keep a master object in overall control of the threads.

```

import com.ibm.mq.*;
public class MQApp3
{
    public static void main(String[] args)

```

Connection pooling

```
    {
        for (int i=0; i<10; i++) {
            MQApp3_Thread thread=new MQApp3_Thread(i*60000);
            thread.start();
        }
    }
}

class MQApp3_Thread extends Thread
{
    long time;

    public MQApp3_Thread(long time)
    {
        this.time=time;
    }

    public synchronized void run()
    {
        MQPoolToken token=MQEnvironment.addConnectionPoolToken();
        try {
            wait(time);
            MQQueueManager qmgr=new MQQueueManager("my.qmgr.1");
            :
            : (do something with qmgr)
            :
            qmgr.disconnect();
        }
        catch (MQException mqe) {System.err.println("Error occurred!");}
        catch (InterruptedException ie) {}

        MQEnvironment.removeConnectionPoolToken(token);
    }
}
```

Supplying a different connection pool

This section describes how to use the class **com.ibm.mq.MQSimpleConnectionManager** to supply a different connection pool. This class provides basic facilities for connection pooling, and applications can use this class to customize the behavior of the pool.

Once it is instantiated, an **MQSimpleConnectionManager** can be specified on the **MQQueueManager** constructor. The **MQSimpleConnectionManager** then manages the connection that underlies the constructed **MQQueueManager**. If the **MQSimpleConnectionManager** contains a suitable pooled connection, that connection is reused and returned to the **MQSimpleConnectionManager** after an **MQQueueManager.disconnect()** call.

The following code fragment demonstrates this behavior:

```
MQSimpleConnectionManager myConnMan=new MQSimpleConnectionManager();
myConnMan.setActive(MQSimpleConnectionManager.MODE_ACTIVE);
MQQueueManager qmgr=new MQQueueManager("my.qmgr.1", myConnMan);
:
: (do something with qmgr)
:
qmgr.disconnect();

MQQueueManager qmgr2=new MQQueueManager("my.qmgr.1", myConnMan);
:
: (do something with qmgr2)
:
qmgr2.disconnect();
myConnMan.setActive(MQSimpleConnectionManager.MODE_INACTIVE);
```

Connection pooling

The connection that is forged during the first `MQQueueManager` constructor is stored in `myConnMan` after the `qmgr.disconnect()` call. The connection is then reused during the second call to the `MQQueueManager` constructor.

The second line enables the `MQSimpleConnectionManager`. The last line disables `MQSimpleConnectionManager`, destroying any connections held in the pool. An `MQSimpleConnectionManager` is, by default, in `MODE_AUTO`, which is described later in this section.

An `MQSimpleConnectionManager` allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes, or if there are more than ten unused connections in the pool. You can alter these values using:

- `MQSimpleConnectionManager.setTimeout()`
- `MQSimpleConnectionManager.setHighThreshold()`

You can also set up an `MQSimpleConnectionManager` for use as the default connection pool, to be used when no Connection Manager is supplied on the `MQQueueManager` constructor.

The following application demonstrates this:

```
import com.ibm.mq.*;
public class MQApp4
{
    public static void main(String[] args)
    {
        MQSimpleConnectionManager myConnMan=new MQSimpleConnectionManager();
        myConnMan.setActive(MQSimpleConnectionManager.MODE_AUTO);
        myConnMan.setTimeout(3600000);
        myConnMan.setHighThreshold(50);
        MQEnvironment.setDefaultConnectionFactory(myConnMan);
        MQApp3.main(args);
    }
}
```

The bold lines set up an `MQSimpleConnectionManager`. This is set to:

- Destroy connections that have not been used for an hour
- Limit the number of unused connections held in the pool to 50
- `MODE_AUTO` (the default). This means that the pool is active only if it is the default connection manager, and there is at least one token in the set of `MQPoolTokens` held by `MQEnvironment`.

The new `MQSimpleConnectionManager` is then set as the default connection manager.

In the last line, the application calls `MQApp3.main()`. This runs a number of threads, where each thread uses WebSphere MQ independently. These threads use `myConnMan` when they forge connections.

Connection pooling

Supplying your own ConnectionManager

Under Java 2 v1.3, with JAAS 1.0 installed, applications and middleware providers can provide alternative implementations of connection pools. WebSphere MQ base Java provides a partial implementation of the J2EE Connector Architecture. Implementations of `javax.resource.spi.ConnectionManager` can either be used as the default Connection Manager or be specified on the `MQQueueManager` constructor.

WebSphere MQ base Java complies with the Connection Management contract of the J2EE Connector Architecture. Read this section in conjunction with the Connection Management contract of the J2EE Connector Architecture (refer to Sun's Web site at <http://java.sun.com>).

The `ConnectionManager` interface defines only one method:

```
package javax.resource.spi;
public interface ConnectionManager {
    Object allocateConnection(ManagedConnectionFactory mcf,
                             ConnectionRequestInfo cxRequestInfo);
}
```

The `MQQueueManager` constructor calls `allocateConnection` on the appropriate `ConnectionManager`. It passes appropriate implementations of `ManagedConnectionFactory` and `ConnectionRequestInfo` as parameters to describe the connection required.

The `ConnectionManager` searches its pool for a `javax.resource.spi.ManagedConnection` object that has been created with identical `ManagedConnectionFactory` and `ConnectionRequestInfo` objects. If the `ConnectionManager` finds any suitable `ManagedConnection` objects, it creates a `java.util.Set` that contains the candidate `ManagedConnections`. Then, the `ConnectionManager` calls the following:

```
ManagedConnection mc=mcf.matchManagedConnections(connectionSet, subject,
cxRequestInfo);
```

The WebSphere MQ implementation of `ManagedConnectionFactory` ignores the `subject` parameter. This method selects and returns a suitable `ManagedConnection` from the set, or returns null if it does not find a suitable `ManagedConnection`. If there is not a suitable `ManagedConnection` in the pool, the `ConnectionManager` can create one by using:

```
ManagedConnection mc=mcf.createManagedConnection(subject, cxRequestInfo);
```

Again, the `subject` parameter is ignored. This method connects to a WebSphere MQ queue manager and returns an implementation of `javax.resource.spi.ManagedConnection` that represents the newly-forged connection. Once the `ConnectionManager` has obtained a `ManagedConnection` (either from the pool or freshly created), it creates a connection handle using:

```
Object handle=mc.getConnection(subject, cxRequestInfo);
```

This connection handle can be returned from `allocateConnection()`.

A `ConnectionManager` must register an interest in the `ManagedConnection` through:

```
mc.addConnectionEventListener()
```

The `ConnectionEventListener` is notified if a severe error occurs on the connection, or when `MQQueueManager.disconnect()` is called. When `MQQueueManager.disconnect()` is called, the `ConnectionEventListener` can do either of the following:

- Reset the `ManagedConnection` using the `mc.cleanup()` call, then return the `ManagedConnection` to the pool
- Destroy the `ManagedConnection` using the `mc.destroy()` call

If the `ConnectionManager` is the default `ConnectionManager`, it can also register an interest in the state of the `MQEnvironment`-managed set of `MQPoolTokens`. To do so, first construct an `MQPoolServices` object, then register an `MQPoolServicesEventListener` object with the `MQPoolServices` object:

```
MQPoolServices mqs=new MQPoolServices();  
mqs.addMQPoolServicesEventListener(listener);
```

The listener is notified when an `MQPoolToken` is added or removed from the set, or when the default `ConnectionManager` changes. The `MQPoolServices` object also provides a way to query the current size of the set of `MQPoolTokens`.

JTA/JDBC coordination using WebSphere MQ base Java

WebSphere MQ base Java supports the `MQQueueManager.begin()` method, which allows WebSphere MQ to act as a coordinator for a database which provides a JDBC 2 compliant driver. Currently this support is available on Solaris, AIX, and Windows systems with Oracle or DB2 databases.

Installation

In order to use the XA-JTA support, you must use the special JTA switch library. The method for using this library varies depending on whether you are using Windows systems or one of the other platforms.

Installation on Windows systems

On Windows systems, the new XA library is supplied as a complete DLL. The name of this DLL is `jdbcxxx.dll` where `xxx` indicates the database for which the switch library has been compiled. This library is in the `java/lib/jdbc` directory of your WebSphere MQ base Java installation.

Installation on other platforms

The switch file is supplied as an object file that you must link yourself using the supplied makefile. This is necessary because certain libraries required by the switch library might be in different locations on different systems. Because the switch library is loaded by the queue manager, which runs in a setuid environment, you cannot use the dynamic library path variable to locate these libraries. You therefore need to put the full path names to these libraries in the switch library itself.

The object files are called `jdbcxxx.o` where `xxx` indicates which database the object file is for. When linked, a switch file called `jdbcxxx` is produced; add this to the `qm.ini` file in the same manner as the standard switch libraries.

To create the switch library, go into the `java/lib/jdbc` subdirectory of your WebSphere MQ base Java installation and run `make` with your target database as a parameter. Currently supported targets for XA-JTA are `oracle` and `db2`. For example:

```
make db2
```

JTA/JDBC coordination

The makefiles are set up to link against the databases and JDKs in their standard installed location. The exception to this is Oracle, which can be installed anywhere on the system. The makefile uses Oracle's ORACLE_HOME environment variable to link the library correctly. If your JDK is in a non-standard location, you can override the default directory with the JAVA_HOME definition:

```
make JAVA_HOME=/usr/my_jdk13 oracle
```

The above command produces a switch file named jdbcora, which is used in the same way as a standard switch library, including using the same XAOpenString. If you have previously configured an XAResourceManager in your qm.ini, replace the SwitchFile line with a reference to the new JTA-specific switch file. If you have not previously used an XA switch file, refer to the *WebSphere MQ System Administration Guide* for of configuring the XAResourceManager stanza for different databases, remembering to replace the standard switch file with the Java-specific one.

Once you have updated the qm.ini, restart the queue manager. Ensure that all appropriate database environment variables have been set before calling strmqm.

Usage

The basic sequence of API calls for a user application is:

```
qMgr = new MQQueueManager("QM1")
Connection con = qMgr.getJDBCConnection( xads );
qMgr.begin()
```

< Perform MQ and DB operations to be grouped in a unit of work >

```
qMgr.commit() or qMgr.backout();
con.close()
qMgr.disconnect()
```

xads in the getJDBCConnection call is a database-specific implementation of the XADataSource interface, which defines the details of the database to connect to. See the documentation for your database to determine how to create an appropriate XADataSource object to pass into getJDBCConnection.

You also need to update your CLASSPATH with the appropriate database-specific jar files for performing JDBC work.

If you need to connect to multiple databases, you might have to call getJDBCConnection several times to perform the transaction across several different connections.

There are two forms of the getJDBCConnection, reflecting the two forms of XADataSource.getXAConnection:

```
public java.sql.Connection getJDBCConnection(javax.sql.XADataSource xads)
    throws MQException, SQLException, Exception

public java.sql.Connection getJDBCConnection(XADataSource dataSource,
    String userid, String password)
    throws MQException, SQLException, Exception
```

These methods declare Exception in their throws clauses to avoid problems with the JVM verifier for customers who are not using the JTA functionality. The actual exception thrown is javax.transaction.xa.XAException. which requires the jta.jar file to be added to the classpath for programs that did not previously require it.

Known problems and limitations

Because this support makes calls to JDBC drivers, the implementation of those JDBC drivers can have significant impact on the system behavior. In particular, tested JDBC drivers behave differently when the database is shut down while an application is running. **Always** avoid abruptly shutting down a database while there are applications holding open connections to it.

Oracle 8.1.7

Calling the JDBC `Connection.close()` method after `MQQueueManager.disconnect()` generates an `SQLException`. Either call `Connection.close()` before `MQQueueManager.disconnect()`, or omit the call to `Connection.close()`.

DB2® Sometimes DB2 returns a `SQL0805N` error. This problem can be resolved with the following CLP command:

```
DB2 bind @db2cli.lst blocking all grant public
```

Refer to the DB2 documentation for more information.

Solaris and JDK 1.3

When running on Solaris with JDK 1.3, attempting to start the queue manager from a user ID other than root or mqm is likely to fail to load the `jdbcora` switch file with the following message being put to the error log:

```
AMQ6175: The system could not dynamically load the library /opt/mqm/java/lib/jdbcora.
The error message was ld.so.1: amqzma0: fatal: libverify.so: open failed:
No such file or directory. The Queue Manager will continue without this module.
```

The problem arises because of a dependency between two libraries in JDK1.3 that cannot be resolved by the dynamic linker when the invoking program has the `setuid` bit set (as `strmqm` does).

Under these circumstances, start the queue manager from the `mqm` user ID; if this is not practical, make a symbolic link for `libverify` into `/usr/lib`. For example:

```
ln -s /usr/j2se/jre/lib/sparc/libverify.so /usr/lib/libverify.so
```

Solaris and multiple XAResourceManager stanzas

When attempting to use multiple `XAResourceManager` stanzas on any given queue manager on Solaris, the commit call might fail. Treat this as an unsupported combination; it does not affect queue managers with a single `XAResourceManager` stanza.

Windows systems

The JDBC libraries supplied with WebSphere MQ Java (`jdbcdb2.dll` and `jdbcora.dll`) have a dependency on `jvm.dll`, which is supplied with the JVM. However, depending on the JVM used, this DLL might be in a subdirectory that is not on the path; for example, `jre/bin/classic/jvm.dll`.

If `jvm.dll` cannot be found when the queue manager starts, the queue manager produces a message like the following (this example is for DB2):

```
AMQ6174: The library C:\Program Files\IBM\MQSeries\Java\lib\jdbc\jdbcdb2.dll
was not found. The queue manager will continue without this module.
```

In fact, the file not found is `jvm.dll`. The solution is to either copy `jvm.dll` to somewhere already on the path or update the path to include the location of `jvm.dll`.

Secure Sockets Layer (SSL) support

WebSphere MQ base Java client applications and WebSphere MQ JMS connections using TRANSPORT(CLIENT) support Secure Sockets Layer (SSL) encryption. SSL provides communication encryption, authentication, and message integrity. It is typically used to secure communications between any two peers on the Internet or within an intranet.

WebSphere MQ classes for Java uses Java Secure Socket Extension (JSSE) to handle SSL encryption, and so requires a JSSE provider. J2SE v1.4 JVMs have a JSSE provider built in. Details of how to manage and store certificates can vary from provider to provider. For information about this, refer to your JSSE provider's documentation.

This section assumes that your JSSE provider is correctly installed and configured, and that suitable certificates have been installed and made available to your JSSE provider.

Enabling SSL

SSL is supported only for client connections. To enable SSL, you must specify the CipherSuite to use when communicating with the queue manager, and this must match the CipherSpec set on the target channel. Additionally, the named CipherSuite must be supported by your JSSE provider. However, CipherSuites are distinct from CipherSpecs and so have different names. Appendix H, "SSL CipherSuites supported by WebSphere MQ" on page 429 contains a table mapping the CipherSpecs supported by WebSphere MQ to their equivalent CipherSuites as known to JSSE.

To enable SSL, specify the CipherSuite using the sslCipherSuite static member variable of MQEnvironment. The following example attaches to a SVRCONN channel named SECURE.SVRCONN.CHANNEL, which has been set up to require SSL with a CipherSpec of RC4_MD5_EXPORT:

```
MQEnvironment.hostname      = "your_hostname";
MQEnvironment.channel       = "SECURE.SVRCONN.CHANNEL";
MQEnvironment.sslCipherSuite = "SSL_RSA_EXPORT_WITH_RC4_40_MD5";
MQQueueManager qmgr = new MQQueueManager("your_Q_manager");
```

Note that, although the channel has a CipherSpec of RC4_MD5_EXPORT, the Java application must specify a CipherSuite of SSL_RSA_EXPORT_WITH_RC4_40_MD5. For more information about CipherSpecs and CipherSuites, see the *WebSphere MQ Security* book. See Appendix H, "SSL CipherSuites supported by WebSphere MQ" on page 429 for a list of mappings between CipherSpecs and CipherSuites.

The sslCipherSuite property can also be set using the MQC.SSL_CIPHER_SUITE_PROPERTY in the Hash table of connection properties.

To successfully connect using SSL, the JSSE TrustStore must be set up with Certificate Authority root certificates from which the certificate presented by the queue manager can be authenticated. Similarly, if SSLClientAuth on the SVRCONN channel has been set to MQSSL_CLIENT_AUTH_REQUIRED, the JSSE KeyStore must contain an identifying certificate that is trusted by the queue manager.

Using the distinguished name of the queue manager

The queue manager identifies itself using an SSL certificate, which contains a *Distinguished Name* (DN). A WebSphere MQ Java client application can use this DN

to ensure that it is communicating with the correct queue manager. A DN pattern is specified using the `sslPeerName` variable of `MQEnvironment`. For example, setting:

```
MQEnvironment.sslPeerName = "CN=QMGR.*, OU=IBM, OU=WEBSPPHERE";
```

allows the connection to succeed only if the queue manager presents a certificate with a Common Name beginning `QMGR.`, and at least two Organizational Unit names, the first of which must be `IBM` and the second `WEBSPPHERE`.

The `sslPeerName` property can also be set using the `MQC.SSL_PEER_NAME_PROPERTY` in the hash table of connection properties. For more information about distinguished names, refer to *WebSphere MQ Security*.

If `sslPeerName` is set, connections succeed only if it is set to a valid pattern and the queue manager presents a matching certificate.

Using certificate revocation lists

A certificate revocation list (CRL) is a set of certificates that have been revoked, either by the issuing Certificate Authority or by the local organization. CRLs are typically hosted on LDAP servers. With Java 2 v1.4, a CRL server can be specified at connect-time and the certificate presented by the queue manager is checked against the CRL before the connection is allowed. For more information about certificate revocation lists and WebSphere MQ, see *WebSphere MQ Security*.

Note: To use a `CertStore` successfully with a CRL hosted on an LDAP server, make sure that your Java Software Development Kit (SDK) is compatible with the CRL. Some SDKs require that the CRL conforms to RFC 2587, which defines a schema for LDAP v2. Most LDAP v3 servers use RFC 2256 instead.

The CRLs to use are specified through the `java.security.cert.CertStore` class. Refer to documentation on this class for full details of how to obtain instances of `CertStore`. To create a `CertStore` based on an LDAP server, first create an `LDAPCertStoreParameters` instance, initialized with the server and port settings to use. For example:

```
import java.security.cert.*;
CertStoreParameters csp = new LDAPCertStoreParameters("crl_server", 389);
```

Having created a `CertStoreParameters` instance, use the static constructor on `CertStore` to create a `CertStore` of type LDAP:

```
CertStore cs = CertStore.getInstance("LDAP", csp);
```

Other `CertStore` types (for example, `Collection`) are also supported. Commonly there are several CRL servers set up with identical CRL information to give redundancy. Once you have a `CertStore` object for each of these CRL servers, place them all in a suitable `Collection`. The following example shows the `CertStore` objects placed in an `ArrayList`:

```
import java.util.ArrayList;
Collection crls = new ArrayList();
crls.add(cs);
```

This `Collection` can be set into the `MQEnvironment` static variable, `sslCertStores`, before connecting to enable CRL checking:

```
MQEnvironment.sslCertStores = crls;
```

SSL support

The certificate presented by the queue manager when a connection is being set up is validated as follows:

1. The first CertStore object in the Collection identified by `sslCertStores` is used to identify a CRL server.
2. An attempt is made to contact the CRL server.
3. If the attempt is successful, the server is searched for a match for the certificate.
 - a. If the certificate is found to be revoked, the search process is over and the connection request fails with reason code `MQRC_SSL_CERTIFICATE_REVOKED`.
 - b. If the certificate is not found, the search process is over and the connection is allowed to proceed.
4. If the attempt to contact the server is unsuccessful, the next CertStore object is used to identify a CRL server and the process repeats from step 2.
If this was the last CertStore in the Collection, or if the Collection contains no CertStore objects, the search process has failed and the connection request fails with reason code `MQRC_SSL_CERT_STORE_ERROR`.

The Collection object determines the order in which CertStores are used.

The Collection of CertStores can also be set using the `MQC.SSL_CERT_STORE_PROPERTY`. As a convenience, this property also allows a single CertStore to be specified without needing to be a member of a Collection.

If `sslCertStores` is set to null, no CRL checking is performed. This property is ignored if `sslCipherSuite` is not set.

Supplying a customized SSLSocketFactory

Different JSSE implementations can provide different features. For example, a specialized JSSE implementation could allow configuration of a particular model of encryption hardware. Additionally, some JSSE providers allow customization of KeyStores and TrustStores by program, or allow the choice of identity certificate from the KeyStore to be altered. In JSSE, all these customizations are abstracted into a factory class, `javax.net.ssl.SSLSocketFactory`.

Refer to your JSSE documentation for details of how to create a customized `SSLSocketFactory` implementation. The details vary from provider to provider, but a typical sequence of steps might be:

1. Create an `SSLContext` object using a static method on `SSLContext`
2. Initialize this `SSLContext` with appropriate `KeyManagers` and `TrustManager` implementations (created from their own factory classes)
3. Create an `SSLSocketFactory` from the `SSLContext`

When you have an `SSLSocketFactory` object, set the `MQEnvironment.sslSocketFactory` to the customized factory object. For example:

```
javax.net.ssl.SSLSocketFactory sf = sslContext.getSocketFactory();  
MQEnvironment.sslSocketFactory = sf;
```

WebSphere MQ classes for Java then use this `SSLSocketFactory` to connect to the WebSphere MQ queue manager. This property can also be set using the `MQC.SSL_SOCKET_FACTORY_PROPERTY`. If `sslSocketFactory` is set to null, the JVM's default `SSLSocketFactory` is used. This property is ignored if `sslCipherSuite` is not set.

Error handling when using SSL

The following reason codes can be issued by WebSphere MQ classes for Java when connecting to a queue manager using SSL:

MQRC_SSL_NOT_ALLOWED

The `sslCipherSuite` property was set, but `bindings connect` was used. Only client connect supports SSL.

MQRC_JSSE_ERROR

The JSSE provider reported an error that could not be handled by WebSphere MQ. This could be caused by a configuration problem with JSSE, or because the certificate presented by the queue manager could not be validated. The exception produced by JSSE can be retrieved using the `getCause()` method on `MQException`.

MQRC_SSL_PEER_NAME_MISMATCH

The DN pattern specified in the `sslPeerName` property did not match the DN presented by the queue manager.

MQRC_SSL_PEER_NAME_ERROR

The DN pattern specified in the `sslPeerName` property was not valid.

MQRC_UNSUPPORTED_CIPHER_SUITE

The `CipherSuite` named in `sslCipherSuite` was not recognized by the JSSE provider. A full list of `CipherSuites` supported by the JSSE provider can be obtained by a program using the `SSLConnectionFactory.getSupportedCipherSuites()` method. A list of `CipherSuites` that can be used to communicate with WebSphere MQ can be found in Appendix H, "SSL CipherSuites supported by WebSphere MQ" on page 429.

MQRC_SSL_CERTIFICATE_REVOKED

The certificate presented by the queue manager was found in a CRL specified with the `sslCertStores` property. Update the queue manager to use trusted certificates.

MQRC_SSL_CERT_STORE_ERROR

None of the supplied `CertStores` could be searched for the certificate presented by the queue manager. The `MQException.getCause()` method returns the error that occurred while searching the first `CertStore` attempted. If the causal exception is `NoSuchElementException`, `ClassCastException`, or `NullPointerException`, check that the `Collection` specified on the `sslCertStores` property contains at least one valid `CertStore` object.

Compiling and testing WebSphere MQ base Java programs

Before compiling WebSphere MQ base Java programs, you must ensure that your WebSphere MQ classes for Java installation directory is in your `CLASSPATH` environment variable, as described in Chapter 2, "Installation" on page 9.

To compile a class called `MyClass.java`, use the command:

```
javac MyClass.java
```

Running WebSphere MQ base Java applets

Running WebSphere MQ base Java applets

If you write an applet (subclass of `java.applet.Applet`), you must create an HTML file referencing your class before you can run it. A sample HTML file might look as follows:

```
<html>
<body>
<applet code="MyClass.class" width=200 height=400>
</applet>
</body>
</html>
```

Run your applet either by loading this HTML file into a Java-enabled Web browser, or by using the `appletviewer` that comes with the Java Development Kit (JDK).

To use the applet viewer, enter the command:

```
appletviewer myclass.html
```

Running WebSphere MQ base Java applications

If you write an application (a class that contains a `main()` method), using either the client or the bindings mode, run your program using the Java interpreter. Use the command:

```
java MyClass
```

Note: The `.class` extension is omitted from the class name.

Tracing WebSphere MQ base Java programs

WebSphere MQ base Java includes a trace facility, which you can use to produce diagnostic messages if you suspect that there might be a problem with the code. (You normally need to use this facility only at the request of IBM service.)

Tracing is controlled by the `enableTracing` and `disableTracing` methods of the `MQEnvironment` class. For example:

```
MQEnvironment.enableTracing(2); // trace at level 2
... // these commands will be traced
MQEnvironment.disableTracing(); // turn tracing off again
```

The trace is written to the Java console (`System.err`).

If your program is an application, or if you run it from your local disk using the `appletviewer` command, you can also redirect the trace output to a file of your choice. The following code fragment shows an example of how to redirect the trace output to a file called `myapp.trc`:

```
import java.io.*;

try {
    FileOutputStream
    traceFile = new FileOutputStream("myapp.trc");
    MQEnvironment.enableTracing(2,traceFile);
}
catch (IOException ex) {
    // couldn't open the file,
    // trace to System.err instead
    MQEnvironment.enableTracing(2);
}
```

There are five different levels of tracing:

Tracing WebSphere MQ base Java programs

1. Provides entry, exit, and exception tracing
2. Provides parameter information in addition to 1
3. Provides transmitted and received WebSphere MQ headers and data blocks in addition to 2
4. Provides transmitted and received user message data in addition to 3
5. Provides tracing of methods in the Java Virtual Machine in addition to 4

To trace methods in the Java Virtual Machine with trace level 5:

- For an application, run it by issuing the command `java_g` (instead of `java`)
- For an applet, run it by issuing the command `appletviewer_g` (instead of `appletviewer`)

Note: `java_g` is not supported on OS/400, but similar function is provided by using `OPTION(*VERBOSE)` on the `RUNJAVA` command.

Chapter 8. Environment-dependent behavior

WebSphere MQ classes for Java allow you to create applications that can run against different versions of WebSphere MQ and MQSeries. This chapter describes the behavior of the Java classes dependent on these different versions.

WebSphere MQ classes for Java provides a core of classes, which provide consistent function and behavior in all the environments. Features outside this core depend on the capability of the queue manager to which the application is connected.

Except where noted here, the behavior exhibited is as described in the Application Programming Reference book appropriate to the queue manager.

Core details

WebSphere MQ classes for Java contains the following core set of classes, which can be used in all environments with only the minor variations listed in “Restrictions and variations for core classes” on page 92.

- MQEnvironment
- MQException
- MQGetMessageOptions
 - Excluding:
 - MatchOptions
 - GroupStatus
 - SegmentStatus
 - Segmentation
- MQManagedObject
 - Excluding:
 - inquire()
 - set()
- MQMessage
 - Excluding:
 - groupId
 - messageFlags
 - messageSequenceNumber
 - offset
 - originalLength
- MQPoolServices
- MQPoolServicesEvent
- MQPoolServicesEventListener
- MQPoolToken
- MQPutMessageOptions
 - Excluding:
 - knownDestCount
 - unknownDestCount
 - invalidDestCount
 - recordFields
- MQProcess
- MQQueue
- MQQueueManager

Core details

Excluding:

- begin()
- accessDistributionList()
- MQSimpleConnectionManager
- MQC

Notes:

1. Some constants are not included in the core (see “Restrictions and variations for core classes” for details); do not use them in completely portable programs.
2. Some platforms do not support all connection modes. On these platforms, you can use only the core classes and options that relate to the supported modes. (See Table 1 on page 5.)

Restrictions and variations for core classes

The core classes generally behave consistently across all environments, even if the equivalent MQI calls normally have environment differences. The behavior is as if a Windows or UNIX WebSphere MQ queue manager is used, except for the following minor restrictions and variations.

MQGMO_* values

The following MQGMO_* values are not supported by all queue managers, and their use might throw MQException from an MQQueue.get():

MQGMO_SYNCPOINT_IF_PERSISTENT
MQGMO_MARK_SKIP_BACKOUT
MQGMO_BROWSE_MSG_UNDER_CURSOR
MQGMO_LOCK
MQGMO_UNLOCK
MQGMO_LOGICAL_ORDER
MQGMO_COMPLETE_MESSAGE
MQGMO_ALL_MSGS_AVAILABLE
MQGMO_ALL_SEGMENTS_AVAILABLE

Additionally, MQGMO_SET_SIGNAL is not supported when used from Java.

MQPMRF_* values

These are used only when putting messages to a distribution list, and are supported only by queue managers supporting distribution lists. For example, z/OS and OS/390 queue managers do not support distribution lists.

MQPMO_* values

The following MQPMO_* values are not supported by all queue managers, and their use might throw MQException from an MQQueue.put() or an MQQueueManager.put():

MQPMO_NEW_MESSAGE_ID
MQPMO_NEW_CORREL_ID
MQPMO_LOGICAL_ORDER

MQCNO_FASTPATH_BINDING

This value is ignored on queue managers that do not support it, or when using a TCP/IP client connection.

MQRO_* values

The following report options can be set but are ignored by some queue managers. This can affect applications connected to a queue manager that honors the report options when the report message is generated by a remote queue manager that does not. Avoid relying on these options if there is a possibility that a queue manager involved does not support them.

MQRO_EXCEPTION_WITH_FULL_DATA
 MQRO_EXPIRATION_WITH_FULL_DATA
 MQRO_COA_WITH_FULL_DATA
 MQRO_COD_WITH_FULL_DATA
 MQRO_DISCARD_MSG

Miscellaneous differences with z/OS and OS/390

Message priority

When a message is put with a priority greater than MaxPriority, a z/OS or OS/390 queue manager rejects the put with MQCC_FAILED and MQRC_PRIORITY_ERROR. Other platforms complete the put with MQCC_WARNING and MQRC_PRIORITY_EXCEEDS_MAXIMUM, and treat the message as if it were put with MaxPriority.

BackoutCount

A z/OS or OS/390 queue manager returns a maximum BackoutCount of 255, even if the message has been backed out more than 255 times.

Default dynamic queue prefix

When connected to a z/OS or OS/390 queue manager using a bindings connection, the default dynamic queue prefix is CSQ.*. Otherwise, the default dynamic queue prefix is AMQ.*.

MQQueueManager constructor

Client connect is not supported on z/OS and OS/390. Attempting to connect with client options results in an MQException with MQCC_FAILED and MQRC_ENVIRONMENT_ERROR. The MQQueueManager constructor might also fail with MQRC_CHAR_CONVERSION_ERROR (if it fails to initialize conversion between the IBM-1047 and ISO8859-1 code pages), or MQRC_UCS2_CONVERSION_ERROR (if it fails to initialize conversion between the queue manager's code page and Unicode). If your application fails with one of these reason codes, ensure that the National Language Resources component of Language Environment[®] is installed, and ensure that the correct conversion tables are available.

Conversion tables for Unicode are installed as part of the OS/390 C/C++ optional feature. See the *OS/390: C/C++ Programming Guide* (SC09-2362) for more information about enabling UCS-2 conversions.

Features outside the core

The WebSphere MQ classes for Java contain the following functions that are specifically designed to use API extensions that are not supported by all queue managers. This section describes how they behave when using a queue manager that does *not* support them.

MQQueueManager constructor option

The MQQueueManager constructor includes an optional integer argument. This maps onto the MQI's MQCNO options field, and is used to switch between normal and fast path connection. This extended form of the constructor is accepted in all environments, provided that the only options used are MQCNO_STANDARD_BINDING or MQCNO_FASTPATH_BINDING. Any other options cause the constructor to fail with MQRC_OPTIONS_ERROR. The fast path option MQC.MQCNO_FASTPATH_BINDING is honored only when with a bindings connection to a queue manager that supports it. In other environments, it is ignored.

MQQueueManager.begin() method

This can be used only against a WebSphere MQ queue manager on UNIX or Windows systems in bindings mode. Otherwise, it fails with MQRC_ENVIRONMENT_ERROR. See "JTA/JDBC coordination using WebSphere MQ base Java" on page 81 for more details.

MQGetMessageOptions fields

When using a queue manager that does not support the Version 2 MQGMO structure, leave the following fields set to their default values:

- GroupStatus
- SegmentStatus
- Segmentation

Also, the MatchOptions field support only MQMO_MATCH_MSG_ID and MQMO_MATCH_CORREL_ID. If you put unsupported values into these fields, the subsequent MQQueue.get() fail with MQRC_GMO_ERROR. If the queue manager does not support the Version 2 MQGMO structure, these fields are not updated after a successful MQQueue.get().

Distribution lists

The following classes are used to create distribution lists:

- MQDistributionList
- MQDistributionListItem
- MQMessageTracker

You can create and populate MQDistributionLists and MQDistributionListItems in any environment, but not all queue managers allow you to open an MQDistributionList. In particular, z/OS and OS/390 queue managers do not support distribution lists. Attempting to open an MQDistributionList when using such a queue manager results in MQRC_OD_ERROR.

MQPutMessageOptions fields

Four fields in the MQPMO are rendered as the following member variables in the MQPutMessageOptions class:

- knownDestCount

```

|         unknownDestCount
|         invalidDestCount
|         recordFields

```

These fields are primarily intended for use with distribution lists. However, a queue manager that supports distribution lists also fills in the DestCount fields after an MQPUT to a single queue. For example, if the queue resolves to a local queue, knownDestCount is set to 1 and the other two count fields are set to 0.

If the queue manager does not support distribution lists, these values are simulated as follows:

- If the put() succeeds, unknownDestCount is set to 1, and the others are set to 0.
- If the put() fails, invalidDestCount is set to 1, and the others are set to 0.

The recordFields variable is used with distribution lists. A value can be written into recordFields at any time, regardless of the environment. It is ignored if the MQPutMessageOptions object is used on a subsequent MQQueue.put() or MQQueueManager.put(), rather than MQDistributionList.put().

MQMD fields

The following MQMD fields are largely concerned with message segmentation:

```

|         GroupId
|         MsgSeqNumber
|         Offset
|         MsgFlags
|         OriginalLength

```

If an application sets any of these MQMD fields to values other than their defaults, and then does a put() or get() on a queue manager that does not support these, the put() or get() raises an MQException with MQRC_MD_ERROR. A successful put() or get() with such a queue manager always leaves the MQMD fields set to their default values. Do not send a grouped or segmented message to a Java application that runs against a queue manager that does not support message grouping and segmentation.

If a Java application attempts to get() a message from a queue manager that does not support these fields, and the physical message to be retrieved is part of a group of segmented messages (that is, it has non-default values for the MQMD fields), it is retrieved without error. However, the MQMD fields in the MQMessage are not updated, the MQMessage format property is set to MQFMT_MD_EXTENSION, and the true message data is prefixed with an MQMDE structure that contains the values for the new fields.

Chapter 9. The WebSphere MQ base Java classes and interfaces

This chapter describes all the WebSphere MQ classes for Java classes and interfaces. It includes details of the variables, constructors, and methods in each class and interface.

The following classes are described:

- MQChannelDefinition
- MQChannelExit
- MQDistributionList
- MQDistributionListItem
- MQEnvironment
- MQException
- MQGetMessageOptions
- MQManagedObject
- MQMessage
- MQMessageTracker
- MQPoolServices
- MQPoolServicesEvent
- MQPoolToken
- MQPutMessageOptions
- MQProcess
- MQQueue
- MQQueueManager
- MQSimpleConnectionManager

The following interfaces are described:

- MQC
- MQPoolServicesEventListener
- MQConnectionManager
- MQReceiveExit
- MQSecurityExit
- MQSendExit
- ManagedConnection
- ManagedConnectionFactory
- ManagedConnectionMetaData

MQChannelDefinition

```
java.lang.Object
└── com.ibm.mq.MQChannelDefinition
```

```
public class MQChannelDefinition
extends Object
```

Use the MQChannelDefinition class to pass information concerning the connection to the queue manager to the send, receive, and security exits.

Note: This class does not apply when connecting directly to WebSphere MQ in bindings mode.

Variables

channelName

```
public String channelName
```

The name of the channel through which the connection is established.

connectionName

```
public String connectionName
```

The TCP/IP hostname of the machine on which the queue manager resides.

maxMessageLength

```
public int maxMessageLength
```

The maximum length of message that can be sent to the queue manager.

queueManagerName

```
public String queueManagerName
```

The name of the queue manager to which the connection is made.

receiveUserData

```
public String receiveUserData
```

A storage area for the receive exit to use. Information placed here is preserved across invocations of the receive exit, and is also available to the send and security exits.

remotePassword

```
public String remotePassword
```

The password used to establish the connection.

remoteUserId

```
public String remoteUserId
```

The user id used to establish the connection.

securityUserData

```
public String securityUserData
```

A storage area for the security exit to use. Information placed here is preserved across invocations of the security exit, and is also available to the send and receive exits.

sendUserData

```
public String sendUserData
```

MQChannelDefinition

A storage area for the send exit to use. Information placed here is preserved across invocations of the send exit, and is also available to the security and receive exits.

```
| sslPeerName  
|     public String sslPeerName  
  
|     If SSL is used to encrypt data on the wire, this is set to the Distinguished  
|     Name presented by the queue manager during connection. If SSL is not  
|     used, it is left at null.
```

Constructors

```
MQChannelDefinition  
    public MQChannelDefinition()
```

MQChannelExit

```
java.lang.Object
└─ com.ibm.mq.MQChannelExit
```

```
public class MQChannelExit
extends Object
```

This class defines context information passed to the send, receive, and security exits when they are invoked. The exit must set the `exitResponse` member variable to indicate what action the WebSphere MQ Client for Java should take next.

Note: This class does not apply when connecting directly to WebSphere MQ in bindings mode.

Variables

```
MQXCC_CLOSE_CHANNEL
    public final static int MQXCC_CLOSE_CHANNEL

MQXCC_OK
    public final static int MQXCC_OK

MQXCC_SUPPRESS_FUNCTION
    public final static int MQXCC_SUPPRESS_FUNCTION

MQXCC_SEND_AND_REQUEST_SEC_MSG
    public final static int MQXCC_SEND_AND_REQUEST_SEC_MSG

MQXCC_SEND_SEC_MSG
    public final static int MQXCC_SEND_SEC_MSG

MQXCC_SUPPRESS_EXIT
    public final static int MQXCC_SUPPRESS_EXIT

MQXR_INIT
    public final static int MQXR_INIT

MQXR_INIT_SEC
    public final static int MQXR_INIT_SEC

MQXR_SEC_MSG
    public final static int MQXR_SEC_MSG

MQXR_TERM
    public final static int MQXR_TERM

MQXR_XMIT
    public final static int MQXR_XMIT

MQXT_CHANNEL_SEC_EXIT
    public final static int MQXT_CHANNEL_SEC_EXIT

MQXT_CHANNEL_SEND_EXIT
    public final static int MQXT_CHANNEL_SEND_EXIT

MQXT_CHANNEL_RCV_EXIT
    public final static int MQXT_CHANNEL_RCV_EXIT

capabilityFlags
    public static final int capabilityFlags
```

Indicates the capability of the queue manager.

Only the MQC.MQCF_DIST_LISTS flag is supported.

exitID public int exitID

The type of exit that has been invoked. For an MQSecurityExit this is always MQXT_CHANNEL_SEC_EXIT; for an MQSendExit this is always MQXT_CHANNEL_SEND_EXIT; for an MQReceiveExit this is always MQXT_CHANNEL_RCV_EXIT.

exitReason

public int exitReason

The reason for invoking the exit. Possible values are:

MQXR_INIT

Exit initialization; called after the channel connection conditions have been negotiated, but before any security flows have been sent.

MQXR_INIT_SEC

Indicates that the exit is to initiate the security dialog with the queue manager.

MQXR_SEC_MSG

Indicates to the security exit that a security message has been received from the queue manager.

MQXR_TERM

Exit termination; called after the disconnect flows have been sent but before the socket connection is destroyed.

MQXR_XMIT

For a send exit, indicates that data is to be transmitted to the queue manager.

For a receive exit, indicates that data has been received from the queue manager.

exitResponse

public int exitResponse

Set by the exit to indicate the action that WebSphere MQ classes for Java should take next. Valid values are:

MQXCC_CLOSE_CHANNEL

Set by any exit to indicate that the connection to the queue manager should be closed.

MQXCC_OK

Set by the security exit to indicate that security exchanges are complete.

Set by send exit to indicate that the returned data is to be transmitted to the queue manager.

Set by the receive exit to indicate that the returned data is available for processing by the WebSphere MQ Client for Java.

MQXCC_SEND_AND_REQUEST_SEC_MSG

Set by the security exit to indicate that the returned data is to be transmitted to the queue manager, and that a response is expected from the queue manager.

MQChannelExit

MQXCC_SEND_SEC_MSG

Set by the security exit to indicate that the returned data is to be transmitted to the queue manager, and that no response is expected.

MQXCC_SUPPRESS_EXIT

Set by any exit to indicate that it should no longer be called.

MQXCC_SUPPRESS_FUNCTION

Set by the security exit to indicate that communications with the queue manager should be shut down.

exitUserArea

```
public byte exitUserArea[]
```

A storage area available for the exit to use.

Any data placed in the exitUserArea is preserved by the WebSphere MQ Client for Java across exit invocations with the same exitID. (That is, the send, receive, and security exits each have their own, independent, user areas.)

fapLevel

```
public static final int fapLevel
```

The negotiated Format and Protocol (FAP) level.

maxSegmentLength

```
public int maxSegmentLength
```

The maximum length for any one transmission to a queue manager.

If the exit returns data that is to be sent to the queue manager, the length of the returned data must not exceed this value.

Constructors

MQChannelExit

```
public MQChannelExit()
```

MQDistributionList

```

java.lang.Object
├── com.ibm.mq.MQManagedObject
│   └── com.ibm.mq.MQDistributionList

```

```

public class MQDistributionList
extends MQManagedObject (See page 118.)

```

Create an `MQDistributionList` using the `MQDistributionList` constructor or the `accessDistributionList` method for `MQQueueManager`.

A distribution list represents a set of open queues to which messages can be sent using a single call to the `put()` method. (See "Distribution lists" in the *WebSphere MQ Application Programming Guide*.)

Constructors

`MQDistributionList`

```

public MQDistributionList(MQQueueManager qMgr,
                        MQDistributionListItem[] litems,
                        int openOptions,
                        String alternateUserId)
    throws MQException

```

`qMgr` is the queue manager where the list is to be opened.

`litems` are the items to be included in the distribution list.

See "accessDistributionList" on page 161 for details of the remaining parameters.

Methods

`getFirstDistributionListItem`

```

public MQDistributionListItem getFirstDistributionListItem()

```

Returns the first item in the distribution list, or *null* if the list is empty.

`getInvalidDestinationCount`

```

public int getInvalidDestinationCount()

```

Returns the number of items in the distribution list that failed to open successfully.

`getValidDestinationCount`

```

public int getValidDestinationCount()

```

Returns the number of items in the distribution list that were opened successfully.

`put`

```

public synchronized void put(MQMessage message,
                             MQPutMessageOptions putMessageOptions )
    throws MQException

```

Puts a message to the queues on the distribution list.

MQDistributionList

Parameters

message

An input/output parameter containing the message descriptor information and the returned message data.

putMessageOptions

Options that control the action of MQPUT. (See “MQPutMessageOptions” on page 147 for details.)

Throws MQException if the put fails.

MQDistributionListItem

```

java.lang.Object
├── com.ibm.mq.MQMessageTracker
│   └── com.ibm.mq.MQDistributionListItem

```

```

public class MQDistributionListItem
extends MQMessageTracker (See page 139.)

```

An MQDistributionListItem represents a single item (queue) within a distribution list.

Variables

completionCode

```
public int completionCode
```

The completion code resulting from the last operation on this item. If this was the construction of an MQDistributionList, the completion code relates to the opening of the queue. If it was a put operation, the completion code relates to the attempt to put a message onto this queue.

The initial value is 0.

queueManagerName

```
public String queueManagerName
```

The name of the queue manager on which the queue is defined.

The initial value is "".

queueName

```
public String queueName
```

The name of a queue you want to use with a distribution list. This cannot be the name of a model queue.

The initial value is "".

reasonCode

```
public int reasonCode
```

The reason code resulting from the last operation on this item. If this was the construction of an MQDistributionList, the reason code relates to the opening of the queue. If it was a put operation, the reason code relates to the attempt to put a message onto this queue.

The initial value is 0.

Constructors

MQDistributionListItem

```
public MQDistributionListItem()
```

Construct a new MQDistributionListItem object.

MQEnvironment

```
java.lang.Object
└── com.ibm.mq.MQEnvironment
```

```
public class MQEnvironment
extends Object
```

Note: All the methods and attributes of this class apply to the WebSphere MQ classes for Java client connections, but only `enableTracing`, `disableTracing`, `properties`, and `version_notice` apply to bindings connections.

MQEnvironment contains static member variables that control the environment in which an MQQueueManager object (and its corresponding connection to WebSphere MQ) is constructed.

Values set in the MQEnvironment class take effect when the MQQueueManager constructor is called, so set the values in the MQEnvironment class before you construct an MQQueueManager instance.

Variables

Note: Variables marked with * do not apply when connecting directly to WebSphere MQ in bindings mode.

CCSID*

```
public static int CCSID
```

The CCSID used by the client.

Changing this value affects the way that the queue manager you connect to translates information in the WebSphere MQ headers. All data in WebSphere MQ headers is drawn from the invariant part of the ASCII codeset, except for the data in the `applicationIdData` and the `putApplicationName` fields of the `MQMessage` class. (See “MQMessage” on page 121.)

If you avoid using characters from the variant part of the ASCII codeset for these two fields, you are then safe to change the CCSID from 819 to any other ASCII codeset.

If you change the client’s CCSID to be the same as that of the queue manager to which you are connecting, you gain a performance benefit at the queue manager because it does not attempt to translate the message headers.

The default value is 819.

channel*

```
public static String channel
```

The name of the channel to connect to on the target queue manager. You *must* set this member variable, or the corresponding property, before constructing an MQQueueManager instance for use in client mode.

hostname*

```
public static String hostname
```

The TCP/IP hostname of the machine on which the WebSphere MQ server resides. If the hostname is not set, and no overriding properties are set, bindings mode is used to connect to the local queue manager.

password*

```
public static String password
```

Equivalent to the WebSphere MQ environment variable MQ_PASSWORD.

If a security exit is not defined for this client, the value of password is transmitted to the server and is available to the server security exit when it is invoked. Use the value to verify the identity of the WebSphere MQ client.

The default value is "".

port*

```
public static int port
```

The port to connect to. This is the port on which the WebSphere MQ server is listening for incoming connection requests. The default value is 1414.

properties

```
public static java.util.Hashtable properties
```

A set of key/value pairs defining the WebSphere MQ environment.

This hash table allows you to set environment properties as key/value pairs rather than as individual variables.

The properties can also be passed as a Hashtable in a parameter on the MQQueueManager constructor. Properties passed on the constructor take precedence over values set with this properties variable, but they are otherwise interchangeable. The order of precedence of finding properties is:

1. properties parameter on MQQueueManager constructor
2. MQEnvironment.properties
3. Other MQEnvironment variables
4. Constant default values

The possible key/value pairs are shown in the following table:

Key	Value
MQC.CCSID_PROPERTY	Integer (overrides MQEnvironment.CCSID)
MQC.CHANNEL_PROPERTY	String (overrides MQEnvironment.channel)
MQC.CONNECT_OPTIONS_PROPERTY	Integer, defaults to MQC.MQCNO_NONE
MQC.HOST_NAME_PROPERTY	String (overrides MQEnvironment.hostname)
MQC.ORB_PROPERTY	org.omg.CORBA.ORB (optional)
MQC.PASSWORD_PROPERTY	String (overrides MQEnvironment.password)
MQC.PORT_PROPERTY	Integer (overrides MQEnvironment.port)
MQC.RECEIVE_EXIT_PROPERTY	MQReceiveExit (overrides MQEnvironment.receiveExit)
MQC.SECURITY_EXIT_PROPERTY	MQSecurityExit (overrides MQEnvironment.securityExit)
MQC.SEND_EXIT_PROPERTY	MQSendExit (overrides MQEnvironment.sendExit)

MQEnvironment

Key	Value
MQC.SSL_CERT_STORE_PROPERTY	java.util.Collection, or java.security.cert.CertStore (overrides MQEnvironment.sslCertStores)
MQC.SSL_CIPHER_SUITE_PROPERTY	String (overrides MQEnvironment.sslCipherSuite)
MQC.SSL_PEER_NAME_PROPERTY	String (overrides MQEnvironment.sslPeerName)
MQC.SSL_SOCKET_FACTORY_PROPERTY	javax.net.ssl.SSLSocketFactory (overrides MQEnvironment.sslSocketFactory)
MQC.TRANSPORT_PROPERTY	MQC.TRANSPORT_MQSERIES_BINDINGS or MQC.TRANSPORT_MQSERIES_CLIENT or MQC.TRANSPORT_MQSERIES (the default, which selects bindings or client, based on the value of hostname.)
MQC.USER_ID_PROPERTY	String (overrides MQEnvironment.userID.)

receiveExit*

```
public static MQReceiveExit receiveExit
```

A receive exit allows you to examine, and possibly alter, data received from a queue manager. It is normally used in conjunction with a corresponding send exit at the queue manager.

To provide your own receive exit, define a class that implements the `MQReceiveExit` interface, and assign `receiveExit` to an instance of that class. Otherwise, you can leave `receiveExit` set to null, in which case no receive exit is called.

See also “`MQReceiveExit`” on page 176.

securityExit*

```
public static MQSecurityExit securityExit
```

A security exit allows you to customize the security flows that occur when an attempt is made to connect to a queue manager.

To provide your own security exit, define a class that implements the `MQSecurityExit` interface, and assign `securityExit` to an instance of that class. Otherwise, you can leave `securityExit` set to null, in which case no security exit is called.

See also “`MQSecurityExit`” on page 178.

sendExit*

```
public static MQSendExit sendExit
```

A send exit allows you to examine, and possibly alter, the data sent to a queue manager. It is normally used in conjunction with a corresponding receive exit at the queue manager.

To provide your own send exit, define a class that implements the `MQSendExit` interface, and assign `sendExit` to an instance of that class. Otherwise, you can leave `sendExit` set to null, in which case no send exit is called.

See also “`MQSendExit`” on page 180.

sslCertStores*

```
public static java.util.Collection sslCertStores
```

A Collection of CertStore objects used for certificate revocation checking. Use of this variable requires a JVM at Java 2 v1.4 or later. If sslCipherSuite is set, this variable can be used to ensure that the queue manager's certificate has not become revoked. Each CertStore in the Collection represents an identical copy of the certificate revocation list (CRL). For more information on the behaviour of sslCertStores, refer to "Using certificate revocation lists" on page 85. If set to null (default), the certificate presented by the queue manager is not checked against any certificate revocation list. This variable is ignored if sslCipherSuite is null.

sslCipherSuite*

```
public static String sslCipherSuite
```

If set, SSL is enabled for the connection. Set the sslCipherSuite to the CipherSuite name matching the CipherSpec set on the SVRCONN channel. If set to null (default), no SSL encryption is performed.

sslPeerName*

```
public static String sslPeerName
```

A distinguished name pattern. If sslCipherSuite is set, this variable can be used to ensure the correct queue manager is used. For a description of the format for this value, see "Using the distinguished name of the queue manager" on page 84. If set to null (default), no checking of the queue manager's DN is performed. This variable is ignored if sslCipherSuite is null.

sslSocketFactory*

```
public static javax.net.ssl.SSLSocketFactory sslSocketFactory
```

The factory to use when connecting with SSL encryption. If sslCipherSuite is set, this variable can be used to customize all aspects of the SSL connection. For more information on constructing and customizing SSLSocketFactory instances, refer to your JSSE provider; for information regarding the use of this variable, refer to "Supplying a customized SSLSocketFactory" on page 86. If set to null (default) and SSL encryption is requested, the default SSLSocketFactory is used. This variable is ignored if sslCipherSuite is null.

userID*

```
public static String userID
```

Equivalent to the WebSphere MQ environment variable MQ_USER_ID.

If a security exit is not defined for this client, the value of userID is transmitted to the server and is available to the server security exit when it is invoked. Use the value to verify the identity of the WebSphere MQ client.

The default value is "".

version_notice

```
public final static String version_notice
```

The current version of WebSphere MQ classes for Java.

MQEnvironment

Constructors

MQEnvironment
`public MQEnvironment()`

Methods

addConnectionPoolToken

`public static void addConnectionPoolToken(MQPoolToken token)`

Adds the supplied MQPoolToken to the set of tokens. A default ConnectionManager can use this as a hint; typically, it is enabled only while there is at least one token in the set.

Parameters:

token The MQPoolToken to add to the set of tokens.

addConnectionPoolToken

`public static MQPoolToken addConnectionPoolToken()`

Constructs an MQPoolToken and adds it to the set of tokens. The MQPoolToken is returned to the application to be passed later into removeConnectionPoolToken().

disableTracing

`public static void disableTracing()`

Turns off the WebSphere MQ Client for Java trace facility.

enableTracing

`public static void enableTracing(int level)`

Turns on the WebSphere MQ Client for Java trace facility.

Parameters

level The level of tracing required, from 1 to 5 (5 being the most detailed).

enableTracing

`public static void enableTracing(int level,
OutputStream stream)`

Turns on the WebSphere MQ Client for Java trace facility.

Parameters:

level The level of tracing required, from 1 to 5 (5 being the most detailed).

stream The stream to which the trace is written.

getDefaultConnectionManager

`public static javax.resource.spi.ConnectionManager
getDefaultConnectionManager()`

Returns the default ConnectionManager. If the default ConnectionManager is actually an MQConnectionManager, returns null.

getVersionNotice()

```
public static final String getVersionNotice()
```

Returns the current version of the WebSphere MQ base Java.

removeConnectionPoolToken

```
public static void removeConnectionPoolToken(MQPoolToken token)
```

Removes the specified MQPoolToken from the set of tokens. If that MQPoolToken is not in the set, there is no action.

Parameters:

token The MQPoolToken to remove from the set of tokens.

setDefaultConnectionManager

```
public static void setDefaultConnectionManager(
    MQConnectionManager cxManager)
```

Sets the supplied MQConnectionManager to be the default ConnectionManager. The default ConnectionManager is used when there is no ConnectionManager specified on the MQQueueManager constructor. This method also empties the set of MQPoolTokens.

Parameters:

cxManager
The MQConnectionManager to be the default ConnectionManager.

setDefaultConnectionManager

```
public static void setDefaultConnectionManager
    (javax.resource.spi.ConnectionManager cxManager)
```

Sets the default ConnectionManager, and empties the set of MQPoolTokens. The default ConnectionManager is used when there is no ConnectionManager specified on the MQQueueManager constructor.

This method requires a JVM at Java 2 v1.3 or later, with JAAS 1.0 or later installed.

Parameters:

cxManager
The default ConnectionManager (which implements the javax.resource.spi.ConnectionManager interface).

MQException

```

public class MQException
  extends Exception
  
```

An MQException is thrown whenever a WebSphere MQ error occurs. You can change the output stream for the exceptions that are logged by setting the value of MQException.log. The default value is System.err. This class contains definitions of completion code and error code constants. Constants beginning MQCC_ are WebSphere MQ completion codes, and constants beginning MQRC_ are WebSphere MQ reason codes. The *WebSphere MQ Application Programming Reference* contains a full description of these errors and their probable causes.

Variables

completionCode

```
public int completionCode
```

WebSphere MQ completion code giving rise to the error. The possible values are:

- MQException.MQCC_WARNING
- MQException.MQCC_FAILED

exceptionSource

```
public Object exceptionSource
```

The object instance that threw the exception. You can use this as part of your diagnostics when determining the cause of an error.

```
log public static java.io.OutputStreamWriter log
```

Stream to which exceptions are logged. (The default is System.err.) If you set this to null, no logging occurs.

reasonCode

```
public int reasonCode
```

WebSphere MQ reason code describing the error. For a full explanation of the reason codes, refer to the *WebSphere MQ Application Programming Reference*.

Constructors

MQException

```
public MQException(int completionCode,
                  int reasonCode,
                  Object source)
```

Construct a new MQException object.

Parameters

completionCode

The WebSphere MQ completion code.

reasonCode

The WebSphere MQ reason code.

source The object in which the error occurred.

Methods

getCause

```
public Throwable getCause()
```

Returns the cause of this MQException, or null if the cause is nonexistent or unknown. Note that this method is available on MQException even under JVMs before Java 2 v1.4.

initCause

```
public Throwable initCause(Throwable cause)
```

Initializes the cause of this MQException to the specified value. Throws `IllegalArgumentException` if the cause is this MQException or `IllegalStateException` if the cause has already been set. Returns this MQException. Note that this method is available on MQException even under JVMs before Java 2 v1.4. Applications do not normally use this method.

MQGetMessageOptions

```
java.lang.Object
└─ com.ibm.mq.MQGetMessageOptions
```

```
public class MQGetMessageOptions
extends Object
```

This class contains options that control the behavior of `MQQueue.get()`.

Note: The behavior of some of the options available in this class depends on the environment in which they are used. These elements are marked with a *. See Chapter 8, “Environment-dependent behavior” on page 91 for details.

Variables

groupStatus*

```
public char groupStatus
```

This is an output field that indicates whether the retrieved message is in a group, and if it is, whether it is the last in the group. Possible values are:

MQC.MQGS_LAST_MSG_IN_GROUP

Message is the last in the group. This is also the value returned if the group consists of only one message.

MQC.MQGS_MSG_IN_GROUP

Message is in a group, but is not the last in the group.

MQC.MQGS_NOT_IN_GROUP

Message is not in a group.

matchOptions*

```
public int matchOptions
```

Selection criteria that determine which message is retrieved. The following match options can be set:

MQC.MQMO_MATCH_CORREL_ID

Correlation id to be matched.

MQC.MQMO_MATCH_GROUP_ID

Group id to be matched.

MQC.MQMO_MATCH_MSG_ID

Message id to be matched.

MQC.MQMO_MATCH_MSG_SEQ_NUMBER

Match message sequence number.

MQC.MQMO_NONE

No matching required.

options

```
public int options
```

Options that control the action of `MQQueue.get`. Any or none of the following values can be specified. If more than one option is required, the values can be added together or combined using the bitwise OR operator.

MQC.MQMO_ACCEPT_TRUNCATED_MSG

Allow truncation of message data.

MQC.MQGMO_BROWSE_FIRST

Browse from start of queue.

MQC.MQGMO_BROWSE_MSG_UNDER_CURSOR*

Browse message under browse cursor.

MQC.MQGMO_BROWSE_NEXT

Browse from the current position in the queue.

MQC.MQGMO_CONVERT

Request the application data to be converted, to conform to the characterSet and encoding attributes of the MQMessage, before the data is copied into the message buffer. Because data conversion is also applied as the data is retrieved from the message buffer, applications do not usually set this option.

Using this option can cause problems when converting from single byte character sets to double byte character sets. Instead, do the conversion using the readString, readLine, and writeString methods after the message has been delivered.

MQC.MQGMO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing.

MQC.MQGMO_LOCK*

Lock the message that is browsed.

MQC.MQGMO_MARK_SKIP_BACKOUT*

Allow a unit of work to be backed out without reinstating the message on the queue.

MQC.MQGMO_MSG_UNDER_CURSOR

Get message under browse cursor.

MQC.MQGMO_NONE

No other options have been specified; all options assume their default values.

MQC.MQGMO_NO_SYNCPOINT

Get message without syncpoint control.

MQC.MQGMO_NO_WAIT

Return immediately if there is no suitable message.

MQC.MQGMO_SYNCPOINT

Get the message under syncpoint control; the message is marked as being unavailable to other applications, but it is deleted from the queue only when the unit of work is committed. The message is made available again if the unit of work is backed out.

MQC.MQGMO_SYNCPOINT_IF_PERSISTENT*

Get message with syncpoint control if message is persistent.

MQC.MQGMO_UNLOCK*

Unlock a previously locked message.

MQC.MQGMO_WAIT

Wait for a message to arrive.

Segmenting and grouping WebSphere MQ messages can be sent or received as a single entity, can be split into several segments for sending and receiving, and can also be linked to other messages in a group.

MQGetMessageOptions

Each piece of data that is sent is known as a *physical* message, which can be a complete *logical* message, or a segment of a longer logical message.

Each physical message usually has a different `MsgId`. All the segments of a single logical message have the same `groupId` value and `MsgSeqNumber` value, but the `Offset` value is different for each segment. The `Offset` field gives the offset of the data in the physical message from the start of the logical message. The segments usually have different `MsgId` values, because they are individual physical messages.

Logical messages that form part of a group have the same `groupId` value, but each message in the group has a different `MsgSeqNumber` value. Messages in a group can also be segmented.

The following options can be used for dealing with segmented or grouped messages:

MQC.MQGMO_ALL_MSGS_AVAILABLE*

Retrieve messages from a group only when all the messages in the group are available.

MQC.MQGMO_ALL_SEGMENTS_AVAILABLE*

Retrieve the segments of a logical message only when all the segments in the group are available.

MQC.MQGMO_COMPLETE_MSG*

Retrieve only complete logical messages.

MQC.MQGMO_LOGICAL_ORDER*

Return messages in groups, and segments of logical messages, in logical order.

resolvedQueueName

```
public String resolvedQueueName
```

This is an output field that the queue manager sets to the local name of the queue from which the message was retrieved. This is different from the name used to open the queue if an alias queue or model queue was opened.

segmentation*

```
public char segmentation
```

This is an output field that indicates whether or not segmentation is allowed for the retrieved message. Possible values are:

MQC.MQSEG_INHIBITED

Segmentation not allowed.

MQC.MQSEG_ALLOWED

Segmentation allowed.

segmentStatus*

```
public char segmentStatus
```

This is an output field that indicates whether the retrieved message is a segment of a logical message. If the message is a segment, the flag indicates whether or not it is the last segment. Possible values are:

MQC.MQSS_LAST_SEGMENT

Message is the last segment of the logical message. This is also the value returned if the logical message consists of only one segment.

MQC.MQSS_NOT_A_SEGMENT

Message is not a segment.

MQC.MQSS_SEGMENT

Message is a segment, but is not the last segment of the logical message.

waitInterval

```
public int waitInterval
```

The maximum time (in milliseconds) that an MQQueue.get call waits for a suitable message to arrive (used in conjunction with MQC.MQGMO_WAIT). A value of MQC.MQWI_UNLIMITED indicates that an unlimited wait is required.

Constructors

MQGetMessageOptions

```
public MQGetMessageOptions()
```

Construct a new MQGetMessageOptions object with options set to MQC.MQGMO_NO_WAIT, a wait interval of zero, and a blank resolved queue name.

MQManagedObject

```
java.lang.Object
└─ com.ibm.mq.MQManagedObject
```

```
public class MQManagedObject
extends Object
```

MQManagedObject is a superclass for MQQueueManager, MQQueue, and MQProcess. It provides the ability to inquire and set attributes of these resources.

Variables

alternateUserId

```
public String alternateUserId
```

The alternate user ID (if any) specified when this resource was opened. Setting this attribute has no effect.

closeOptions

```
public int closeOptions
```

Set this attribute to control the way the resource is closed. The default value is MQC.MQCO_NONE, and this is the only permissible value for all resources other than permanent dynamic queues, and temporary dynamic queues that are being accessed by the objects that created them. For these queues, the following additional values are permissible:

MQC.MQCO_DELETE

Delete the queue if there are no messages.

MQC.MQCO_DELETE_PURGE

Delete the queue, purging any messages on it.

connectionReference

```
public MQQueueManager connectionReference
```

The queue manager to which this resource belongs. Setting this attribute has no effect.

isOpen

```
public boolean isOpen
```

Indicates whether this resource is currently open. This attribute is *deprecated* and setting it has no effect.

```
name public String name
```

The name of this resource (either the name supplied on the access method, or the name allocated by the queue manager for a dynamic queue). Setting this attribute has no effect.

openOptions

```
public int openOptions
```

The options specified when this resource was opened. Setting this attribute has no effect.

Constructors

MQManagedObject

```
protected MQManagedObject()
```

Constructor method.

Methods

close

```
public synchronized void close()
```

Throws MQException.

Closes the object. No further operations against this resource are permitted after this method has been called. To change the behavior of the close method, set the closeOptions attribute.

Throws MQException if the WebSphere MQ call fails.

getDescription

```
public String getDescription()
```

Throws MQException.

Returns the description of this resource as held at the queue manager.

If this method is called after the resource has been closed, an MQException is thrown.

inquire

```
public void inquire(int selectors[],
                   int intAttrs[],
                   byte charAttrs[])
```

Throws MQException.

Returns an array of integers and a set of character strings containing the attributes of an object (queue, process, or queue manager).

The attributes to be queried are specified in the selectors array. Refer to the *WebSphere MQ Application Programming Reference* for details of the permissible selectors and their corresponding integer values.

Many of the more common attributes can be queried using the getXXX() methods defined in MQManagedObject, MQQueue, MQQueueManager, and MQProcess.

Parameters

selectors

Integer array identifying the attributes with values to be inquired on.

intAttrs

The array in which the integer attribute values are returned. Integer attribute values are returned in the same order as the integer attribute selectors in the selectors array.

MQManagedObject

charAttrs

The buffer in which the character attributes are returned, concatenated. Character attributes are returned in the same order as the character attribute selectors in the selectors array. The length of each attribute string is fixed for each attribute.

Throws MQException if the inquire fails.

isOpen

```
public boolean isOpen()
```

Returns the value of the isOpen variable.

set

```
public synchronized void set(int selectors[],
                             int intAttrs[],
                             byte charAttrs[])
```

Throws MQException.

Sets the attributes defined in the selector's vector.

The attributes to be set are specified in the selectors array. Refer to the *WebSphere MQ Application Programming Reference* for details of the permissible selectors and their corresponding integer values.

Some queue attributes can be set using the setXXX() methods defined in MQQueue.

Parameters

selectors

Integer array identifying the attributes with values to be set.

intAttrs

The array of integer attribute values to be set. These values must be in the same order as the integer attribute selectors in the selectors array.

charAttrs

The buffer in which the character attributes to be set are concatenated. These values must be in the same order as the character attribute selectors in the selectors array. The length of each character attribute is fixed.

Throws MQException if the set fails.

MQMessage

```
java.lang.Object
└── com.ibm.mq.MQMessage
```

```
public class MQMessage
implements DataInput, DataOutput
```

MQMessage represents both the message descriptor and the data for a WebSphere MQ message. There is group of readXXX methods for reading data from a message, and a group of writeXXX methods for writing data into a message. The format of numbers and strings used by these read and write methods can be controlled by the encoding and characterSet member variables. The remaining member variables contain control information that accompanies the application message data when a message travels between sending and receiving applications. The application can set values into the member variable before putting a message to a queue and can read values after retrieving a message from a queue.

Variables

accountingToken

```
public byte accountingToken[]
```

Part of the identity context of the message; it allows an application to charge for work done as a result of the message.

The default value is MQC.MQACT_NONE.

applicationIdData

```
public String applicationIdData
```

Part of the identity context of the message; it is information that is defined by the application suite, and can be used to provide additional information about the message or its originator.

The default value is "".

applicationOriginData

```
public String applicationOriginData
```

Information defined by the application that can be used to provide additional information about the origin of the message.

The default value is "".

backoutCount

```
public int backoutCount
```

A count of the number of times the message has previously been returned by an MQQueue.get() call as part of a unit of work, and subsequently backed out.

The default value is zero.

characterSet

```
public int characterSet
```

The coded character set identifier of character data in the application message data. The behavior of the readString, readLine, and writeString methods is altered accordingly.

MQMessage

The default value for this field is MQC.MQCCSI_Q_MGR. If the default value is used, CharacterSet 819 (iso-8859-1/latin/ibm819) is assumed. The character set values you can use depend upon the JVM you use. Table 13 shows coded character set identifiers and the characterSet values to use:

Table 13. Character set identifiers

characterSet	Description
37	ibm037
437	ibm437 / PC Original
500	ibm500
819	iso-8859-1 / latin1 / ibm819
1200	Unicode
1208	UTF-8

1251	Windows Cyrillic
1252	Windows Latin 1
1253	Windows Greek
1254	Windows Turkish
1255	Windows Hebrew
1256	Windows Arabic
1257	Windows Baltic
1258	Windows Vietnamese
1381	ibm1381
1383	ibm1383
2022	JIS
5601	ksc-5601 Korean
33722	ibm33722

correlationId

```
public byte correlationId[]
```

For an MQQueue.get() call, the correlation identifier of the message to be retrieved. Normally the queue manager returns the first message with a message identifier and correlation identifier that match those specified. The special value MQC.MQCI_NONE allows *any* correlation identifier to match.

For an MQQueue.put() call, this specifies the correlation identifier to use.

The default value is MQC.MQCI_NONE.

encoding

```
public int encoding
```

MQMessage

The representation used for numeric values in the application message data; this applies to binary, packed decimal, and floating point data. The behavior of the read and write methods for these numeric formats is altered accordingly.

The following encodings are defined for binary integers:

MQC.MQENC_INTEGER_NORMAL

Big-endian integers, as in Java

MQC.MQENC_INTEGER_REVERSED

Little-endian integers, as used by PCs.

The following encodings are defined for packed-decimal integers:

MQC.MQENC_DECIMAL_NORMAL

Big-endian packed-decimal, as used by z/OS.

MQC.MQENC_DECIMAL_REVERSED

Little-endian packed-decimal.

The following encodings are defined for floating-point numbers:

MQC.MQENC_FLOAT_IEEE_NORMAL

Big-endian IEEE floats, as in Java.

MQC.MQENC_FLOAT_IEEE_REVERSED

Little-endian IEEE floats, as used by PCs.

MQC.MQENC_FLOAT_S390

z/OS format floating points.

Construct a value for the encoding field by adding together one value from each of these three sections (or using the bitwise OR operator). The default value is:

```
MQC.MQENC_INTEGER_NORMAL |  
MQC.MQENC_DECIMAL_NORMAL |  
MQC.MQENC_FLOAT_IEEE_NORMAL
```

For convenience, this value is also represented by `MQC.MQENC_NATIVE`. This setting causes `writeInt()` to write a big-endian integer, and `readInt()` to read a big-endian integer. If you set the flag `MQC.MQENC_INTEGER_REVERSED` instead, `writeInt()` writes a little-endian integer, and `readInt()` reads a little-endian integer.

A loss in precision can occur when converting from IEEE format floating points to zSeries[®] format floating points.

expiry public int expiry

An expiry time expressed in tenths of a second, set by the application that puts the message. After a message's expiry time has elapsed, it is eligible to be discarded by the queue manager. If the message specified one of the `MQC.MQRO_EXPIRATION` flags, a report is generated when the message is discarded.

The default value is `MQC.MQEI_UNLIMITED`, meaning that the message never expires.

feedback
public int feedback

Used with a message of type MQC.MQMT_REPORT to indicate the nature of the report. The following feedback codes are defined by the system:

- MQC.MQFB_EXPIRATION
- MQC.MQFB_COA
- MQC.MQFB_COD
- MQC.MQFB_QUIT
- MQC.MQFB_PAN
- MQC.MQFB_NAN
- MQC.MQFB_DATA_LENGTH_ZERO
- MQC.MQFB_DATA_LENGTH_NEGATIVE
- MQC.MQFB_DATA_LENGTH_TOO_BIG
- MQC.MQFB_BUFFER_OVERFLOW
- MQC.MQFB_LENGTH_OFF_BY_ONE
- MQC.MQFB_IH_ERROR

Application-defined feedback values in the range MQC.MQFB_APPL_FIRST to MQC.MQFB_APPL_LAST can also be used.

The default value of this field is MQC.MQFB_NONE, indicating that no feedback is provided.

format

public String format

A format name used by the sender of the message to indicate the nature of the data in the message to the receiver. You can use your own format names, but names beginning with the letters MQ have meanings that are defined by the queue manager. The queue manager built-in formats are:

MQC.MQFMT_ADMIN

Command server request/reply message.

MQC.MQFMT_COMMAND_1

Type 1 command reply message.

MQC.MQFMT_COMMAND_2

Type 2 command reply message.

MQC.MQFMT_DEAD_LETTER_HEADER

Dead-letter header.

MQC.MQFMT_EVENT

Event message.

MQC.MQFMT_NONE

No format name.

MQC.MQFMT_PCF

User-defined message in programmable command format.

MQC.MQFMT_STRING

Message consisting entirely of characters.

MQC.MQFMT_TRIGGER

Trigger message

MQC.MQFMT_XMIT_Q_HEADER

Transmission queue header.

The default value is MQC.MQFMT_NONE.

MQMessage

groupId

```
public byte[] groupId
```

A byte string that identifies the message group to which the physical message belongs.

The default value is MQC.MQGI_NONE.

messageFlags

```
public int messageFlags
```

Flags controlling the segmentation and status of a message.

messageId

```
public byte messageId[]
```

For an MQQueue.get() call, this field specifies the message identifier of the message to be retrieved. Normally, the queue manager returns the first message with a message identifier and correlation identifier that match those specified. The special value MQC.MQMI_NONE allows *any* message identifier to match.

For an MQQueue.put() call, this specifies the message identifier to use. If MQC.MQMI_NONE is specified, the queue manager generates a unique message identifier when the message is put. The value of this member variable is updated after the put, to indicate the message identifier that was used.

The default value is MQC.MQMI_NONE.

messageSequenceNumber

```
public int messageSequenceNumber
```

The sequence number of a logical message within a group.

messageType

```
public int messageType
```

Indicates the type of the message. The following values are currently defined by the system:

- MQC.MQMT_DATAGRAM
- MQC.MQMT_REPLY
- MQC.MQMT_REPORT
- MQC.MQMT_REQUEST

Application-defined values can also be used, in the range MQC.MQMT_APPL_FIRST to MQC.MQMT_APPL_LAST.

The default value of this field is MQC.MQMT_DATAGRAM.

offset `public int offset`

In a segmented message, the offset of data in a physical message from the start of a logical message.

originalLength

```
public int originalLength
```

The original length of a segmented message.

persistence

```
public int persistence
```

Message persistence. The following values are defined:

- MQC.MQPER_NOT_PERSISTENT

- MQC.MQPER_PERSISTENT
- MQC.MQPER_PERSISTENCE_AS_Q_DEF

The default value is MQC.MQPER_PERSISTENCE_AS_Q_DEF, which takes the persistence for the message from the default persistence attribute of the destination queue.

priority

```
public int priority
```

The message priority. The special value MQC.MQPRI_PRIORITY_AS_Q_DEF can also be set in outbound messages, in which case the priority for the message is taken from the default priority attribute of the destination queue.

The default value is MQC.MQPRI_PRIORITY_AS_Q_DEF.

putApplicationName

```
public String putApplicationName
```

The name of the application that put the message. The default value is "".

putApplicationType

```
public int putApplicationType
```

The type of application that put the message. This can be a system-defined or user-defined value. The following values are defined by the system:

- MQC.MQAT_AIX
- MQC.MQAT_CICS
- MQC.MQAT_DOS
- MQC.MQAT_IMS
- MQC.MQAT_MVS
- MQC.MQAT_OS2
- MQC.MQAT_OS400
- MQC.MQAT_QMGR
- MQC.MQAT_UNIX
- MQC.MQAT_WINDOWS
- MQC.MQAT_JAVA

The default value is the special value MQC.MQAT_NO_CONTEXT, which indicates that no context information is present in the message.

putDateTime

```
public GregorianCalendar putDateTime
```

The time and date that the message was put.

replyToQueueManagerName

```
public String replyToQueueManagerName
```

The name of the queue manager to which reply or report messages should be sent.

The default value is "".

If the value is "" on an MQQueue.put() call, the QueueManager fills in the value.

replyToQueueName

```
public String replyToQueueName
```

MQMessage

The name of the message queue to which the application that issued the get request for the message should send MQC.MQMT_REPLY and MQC.MQMT_REPORT messages.

The default value is "".

report public int report

A report is a message about another message. This member variable enables the application sending the original message to specify which report messages are required, whether the application message data is to be included in them, and how to set the message and correlation identifiers in the report or reply. Any, all, or none of the following report types can be requested:

- Exception
- Expiration
- Confirm on arrival
- Confirm on delivery

For each type, only one of the three corresponding values below should be specified, depending on whether the application message data is to be included in the report message.

Note: Values marked with ** in the following list are not supported by z/OS™ queue managers; do not use them if your application is likely to access a z/OS queue manager, regardless of the platform on which the application is running.

The valid values are:

- MQC.MQRO_COA
- MQC.MQRO_COA_WITH_DATA
- MQC.MQRO_COA_WITH_FULL_DATA**
- MQC.MQRO_COD
- MQC.MQRO_COD_WITH_DATA
- MQC.MQRO_COD_WITH_FULL_DATA**
- MQC.MQRO_EXCEPTION
- MQC.MQRO_EXCEPTION_WITH_DATA
- MQC.MQRO_EXCEPTION_WITH_FULL_DATA**
- MQC.MQRO_EXPIRATION
- MQC.MQRO_EXPIRATION_WITH_DATA
- MQC.MQRO_EXPIRATION_WITH_FULL_DATA**

You can specify one of the following to control how the message Id is generated for the report or reply message:

- MQC.MQRO_NEW_MSG_ID
- MQC.MQRO_PASS_MSG_ID

You can specify one of the following to control how the correlation Id of the report or reply message is to be set:

- MQC.MQRO_COPY_MSG_ID_TO_CORREL_ID
- MQC.MQRO_PASS_CORREL_ID

You can specify one of the following to control the disposition of the original message when it cannot be delivered to the destination queue:

- MQC.MQRO_DEAD_LETTER_Q
- MQC.MQRO_DISCARD_MSG **

If no report options are specified, the default is:

```
MQC.MQRO_NEW_MSG_ID |
MQC.MQRO_COPY_MSG_ID_TO_CORREL_ID |
MQC.MQRO_DEAD_LETTER_Q
```

You can specify one or both of the following to request that the receiving application sends a positive action or negative action report message.

- MQRO_PAN
- MQRO_NAN

userId public String userId

Part of the identity context of the message; it identifies the user that originated this message.

The default value is "".

Constructors

MQMessage

```
public MQMessage()
```

Creates a new message with default message descriptor information and an empty message buffer.

Methods

clearMessage

```
public void clearMessage()
```

Throws IOException.

Discards any data in the message buffer and set the data offset back to zero.

getDataLength

```
public int getDataLength()
```

Throws MQException.

The number of bytes of message data remaining to be read.

getDataOffset

```
public int getDataOffset()
```

Throws IOException.

Returns the current cursor position within the message data (the point at which read and write operations take effect).

getMessageLength

```
public int getMessageLength
```

Throws IOException.

The number of bytes of message data in this MQMessage object.

getTotalMessageLength

```
public int getTotalMessageLength()
```

MQMessage

The total number of bytes in the message as stored on the message queue from which this message was retrieved. When an MQQueue.get() method fails with a message-truncated error code, this method tells you the total size of the message on the queue.

See also “MQQueue.get” on page 151.

getVersion

```
public int getVersion()
```

Returns the version of the structure in use.

readBoolean

```
public boolean readBoolean()
```

Throws IOException.

Reads a (signed) byte from the current position in the message buffer.

readChar

```
public char readChar()
```

Throws IOException, EOFException.

Reads a Unicode character from the current position in the message buffer.

readDecimal2

```
public short readDecimal2()
```

Throws IOException, EOFException.

Reads a 2-byte packed decimal number (-999 to 999). The behavior of this method is controlled by the value of the encoding member variable. A value of MQC.MQENC_DECIMAL_NORMAL reads a big-endian packed decimal number; a value of MQC.MQENC_DECIMAL_REVERSED reads a little-endian packed decimal number.

readDecimal4

```
public int readDecimal4()
```

Throws IOException, EOFException.

Reads a 4-byte packed decimal number (-9999999 to 9999999). The behavior of this method is controlled by the value of the encoding member variable. A value of MQC.MQENC_DECIMAL_NORMAL reads a big-endian packed decimal number; a value of MQC.MQENC_DECIMAL_REVERSED reads a little-endian packed decimal number.

readDecimal8

```
public long readDecimal8()
```

Throws IOException, EOFException.

Reads an 8-byte packed decimal number (-9999999999999999 to 9999999999999999). The behavior of this method is controlled by the encoding member variable. A value of MQC.MQENC_DECIMAL_NORMAL reads a big-endian packed decimal number; a value of MQC.MQENC_DECIMAL_REVERSED reads a little-endian packed decimal number.

readDouble

```
public double readDouble()
```

Throws IOException, EOFException.

Reads a double from the current position in the message buffer. The value of the encoding member variable determines the behavior of this method.

Values of MQC.MQENC_FLOAT_IEEE_NORMAL and MQC.MQENC_FLOAT_IEEE_REVERSED read IEEE standard doubles in big-endian and little-endian formats respectively.

A value of MQC.MQENC_FLOAT_S390 reads a System/390 format floating point number.

readFloat

```
public float readFloat()
```

Throws IOException, EOFException.

Reads a float from the current position in the message buffer. The value of the encoding member variable determines the behavior of this method.

Values of MQC.MQENC_FLOAT_IEEE_NORMAL and MQC.MQENC_FLOAT_IEEE_REVERSED read IEEE standard floats in big-endian and little-endian formats respectively.

A value of MQC.MQENC_FLOAT_S390 reads a System/390 format floating point number.

readFully

```
public void readFully(byte b[])
```

Throws Exception, EOFException.

Fills the byte array *b* with data from the message buffer.

readFully

```
public void readFully(byte b[],
                    int off,
                    int len)
```

Throws IOException, EOFException.

Fills *len* elements of the byte array *b* with data from the message buffer, starting at offset *off*.

readInt

```
public int readInt()
```

Throws IOException, EOFException.

Reads an integer from the current position in the message buffer. The value of the encoding member variable determines the behavior of this method.

MQMessage

A value of `MQC.MQENC_INTEGER_NORMAL` reads a big-endian integer; a value of `MQC.MQENC_INTEGER_REVERSED` reads a little-endian integer.

readInt2

```
public short readInt2()
```

Throws `IOException`, `EOFException`.

Synonym for `readShort()`, provided for cross-language WebSphere MQ API compatibility.

readInt4

```
public int readInt4()
```

Throws `IOException`, `EOFException`.

Synonym for `readInt()`, provided for cross-language WebSphere MQ API compatibility.

readInt8

```
public long readInt8()
```

Throws `IOException`, `EOFException`.

Synonym for `readLong()`, provided for cross-language WebSphere MQ API compatibility.

readLine

```
public String readLine()
```

Throws `IOException`.

Converts from the codeset identified in the `characterSet` member variable to Unicode, and then reads in a line that has been terminated by `\n`, `\r`, `\r\n`, or EOF.

readLong

```
public long readLong()
```

Throws `IOException`, `EOFException`.

Reads a long from the current position in the message buffer. The value of the `encoding` member variable determines the behavior of this method.

A value of `MQC.MQENC_INTEGER_NORMAL` reads a big-endian long; a value of `MQC.MQENC_INTEGER_REVERSED` reads a little-endian long.

readObject

```
public Object readObject()
```

Throws `OptionalDataException`, `ClassNotFoundException`, `IOException`.

Reads an object from the message buffer. The class of the object, the signature of the class, and the value of the non-transient and non-static fields of the class are all read.

readShort

```
public short readShort()
```

Throws IOException, EOFException.

Reads a short from the current position in the message buffer. The value of the encoding member variable determines the behavior of this method.

A value of MQC.MQENC_INTEGER_NORMAL reads a big-endian short; a value of MQC.MQENC_INTEGER_REVERSED reads a little-endian short.

readString

```
public String readString(int length)
```

Throws IOException, EOFException.

Reads a string in the codeset identified by the characterSet member variable, and convert it into Unicode.

Parameters:

length The number of characters to read (which may differ from the number of bytes according to the codeset, because some codesets use more than one byte per character).

readUInt2

```
public int readUInt2()
```

Throws IOException, EOFException.

Synonym for readUnsignedShort(), provided for cross-language WebSphere MQ API compatibility.

readUnsignedByte

```
public int readUnsignedByte()
```

Throws IOException, EOFException.

Reads an unsigned byte from the current position in the message buffer.

readUnsignedShort

```
public int readUnsignedShort()
```

Throws IOException, EOFException.

Reads an unsigned short from the current position in the message buffer. The value of the encoding member variable determines the behavior of this method.

A value of MQC.MQENC_INTEGER_NORMAL reads a big-endian unsigned short; a value of MQC.MQENC_INTEGER_REVERSED reads a little-endian unsigned short.

readUTF

```
public String readUTF()
```

Throws IOException.

MQMessage

Reads a UTF string, prefixed by a 2-byte length field, from the current position in the message buffer.

resizeBuffer

```
public void resizeBuffer(int size)
```

Throws IOException.

A hint to the MQMessage object about the size of buffer that might be required for subsequent get operations. If the message currently contains message data, and the new size is less than the current size, the message data is truncated.

seek

```
public void seek(int pos)
```

Throws IOException.

Moves the cursor to the absolute position in the message buffer given by *pos*. Subsequent reads and writes act at this position in the buffer.

Throws EOFException if *pos* is outside the message data length.

setDataOffset

```
public void setDataOffset(int offset)
```

Throws IOException.

Moves the cursor to the absolute position in the message buffer. This method is a synonym for `seek()`, and is provided for cross-language compatibility with the other WebSphere MQ APIs.

setVersion

```
public void setVersion(int version)
```

Specifies which version of the structure to use. Possible values are:

- MQC.MQMD_VERSION_1
- MQC.MQMD_VERSION_2

You do not need to call this method unless you want to force the client to use a version 1 structure when connected to a queue manager that is capable of handling version 2 structures. In all other situations, the client determines the correct version of the structure to use by querying the queue manager's capabilities.

skipBytes

```
public int skipBytes(int n)
```

Throws IOException, EOFException.

Moves forward *n* bytes in the message buffer.

This method blocks until one of the following occurs:

- All the bytes are skipped
- The end of message buffer is detected
- An exception is thrown

Returns the number of bytes skipped, which is always *n*.

write

```
public void write(int b)
```

Throws IOException.

Writes a byte into the message buffer at the current position.

write

```
public void write(byte b[])
```

Throws IOException.

Writes an array of bytes into the message buffer at the current position.

write

```
public void write(byte b[],
                  int off,
                  int len)
```

Throws IOException.

Writes a series of bytes into the message buffer at the current position. *len* bytes are written, taken from offset *off* in the array *b*.

writeBoolean

```
public void writeBoolean(boolean v)
```

Throws IOException.

Writes a boolean into the message buffer at the current position.

writeByte

```
public void writeByte(int v)
```

Throws IOException.

Writes a byte into the message buffer at the current position.

writeBytes

```
public void writeBytes(String s)
```

Throws IOException.

Writes the string to the message buffer as a sequence of bytes. Each character in the string is written in sequence by discarding its high eight bits.

writeChar

```
public void writeChar(int v)
```

Throws IOException.

Writes a Unicode character into the message buffer at the current position.

writeChars

```
public void writeChars(String s)
```

Throws IOException.

MQMessage

Writes a string as a sequence of Unicode characters into the message buffer at the current position.

writeDecimal2

```
public void writeDecimal2(short v)
```

Throws IOException.

Writes a 2-byte packed decimal format number into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

A value of MQC.MQENC_DECIMAL_NORMAL writes a big-endian packed decimal; a value of MQC.MQENC_DECIMAL_REVERSED writes a little-endian packed decimal.

Parameters

v can be in the range -999 to 999.

writeDecimal4

```
public void writeDecimal4(int v)
```

Throws IOException.

Writes a 4-byte packed decimal format number into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

A value of MQC.MQENC_DECIMAL_NORMAL writes a big-endian packed decimal; a value of MQC.MQENC_DECIMAL_REVERSED writes a little-endian packed decimal.

Parameters

v can be in the range -9999999 to 9999999.

writeDecimal8

```
public void writeDecimal8(long v)
```

Throws IOException.

Writes an 8-byte packed decimal format number into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

A value of MQC.MQENC_DECIMAL_NORMAL writes a big-endian packed decimal; a value of MQC.MQENC_DECIMAL_REVERSED writes a little-endian packed decimal.

Parameters:

v can be in the range -9999999999999999 to 9999999999999999.

writeDouble

```
public void writeDouble(double v)
```

Throws IOException

Writes a double into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

Values of `MQC.MQENC_FLOAT_IEEE_NORMAL` and `MQC.MQENC_FLOAT_IEEE_REVERSED` write IEEE standard floats in big-endian and little-endian formats respectively.

A value of `MQC.MQENC_FLOAT_S390` writes a System/390 format floating point number. Note that the range of IEEE doubles is greater than the range of S/390[®] double precision floating point numbers, so very large numbers cannot be converted.

writeFloat

```
public void writeFloat(float v)
```

Throws `IOException`.

Writes a float into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

Values of `MQC.MQENC_FLOAT_IEEE_NORMAL` and `MQC.MQENC_FLOAT_IEEE_REVERSED` write IEEE standard floats in big-endian and little-endian formats respectively.

A value of `MQC.MQENC_FLOAT_S390` writes a System/390 format floating point number.

writeInt

```
public void writeInt(int v)
```

Throws `IOException`.

Writes an integer into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

A value of `MQC.MQENC_INTEGER_NORMAL` writes a big-endian integer; a value of `MQC.MQENC_INTEGER_REVERSED` writes a little-endian integer.

writeInt2

```
public void writeInt2(int v)
```

Throws `IOException`.

Synonym for `writeShort()`, provided for cross-language WebSphere MQ API compatibility.

writeInt4

```
public void writeInt4(int v)
```

Throws `IOException`.

Synonym for `writeInt()`, provided for cross-language WebSphere MQ API compatibility.

writeInt8

```
public void writeInt8(long v)
```

MQMessage

Throws IOException.

Synonym for writeLong(), provided for cross-language WebSphere MQ API compatibility.

writeLong

```
public void writeLong(long v)
```

Throws IOException.

Writes a long into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

A value of MQC.MQENC_INTEGER_NORMAL writes a big-endian long; a value of MQC.MQENC_INTEGER_REVERSED writes a little-endian long.

writeObject

```
public void writeObject(Object obj)
```

Throws IOException.

Writes the specified object to the message buffer. The class of the object, the signature of the class, and the values of the non-transient and non-static fields of the class and all its supertypes are all written.

writeShort

```
public void writeShort(int v)
```

Throws IOException.

Writes a short into the message buffer at the current position. The value of the encoding member variable determines the behavior of this method.

A value of MQC.MQENC_INTEGER_NORMAL writes a big-endian short; a value of MQC.MQENC_INTEGER_REVERSED writes a little-endian short.

writeString

```
public void writeString(String str)
```

Throws IOException.

Writes a string into the message buffer at the current position, converting it to the codeset identified by the characterSet member variable.

writeUTF

```
public void writeUTF(String str)
```

Throws IOException.

Writes a UTF string, prefixed by a 2-byte length field, into the message buffer at the current position.

MQMessageTracker

```
java.lang.Object
└─ com.ibm.mq.MQMessageTracker
```

```
public abstract class MQMessageTracker
extends Object
```

Note: You can use this class only when connected to a WebSphere MQ queue manager.

This class is inherited by MQDistributionListItem (on page 105) where it is used to tailor message parameters for a given destination in a distribution list.

Variables

accountingToken

```
public byte accountingToken[]
```

Part of the identity context of the message. It allows an application to charge for work done as a result of the message.

The default value is MQC.MQACT_NONE.

correlationId

```
public byte correlationId[]
```

The correlation identifier to use when the message is put.

The default value is MQC.MQCI_NONE.

feedback

```
public int feedback
```

Used with a message of type MQC.MQMT_REPORT to indicate the nature of the report. The following feedback codes are defined by the system:

- MQC.MQFB_BUFFER_OVERFLOW
- MQC.MQFB_COA
- MQC.MQFB_COD
- MQC.MQFB_DATA_LENGTH_NEGATIVE
- MQC.MQFB_DATA_LENGTH_TOO_BIG
- MQC.MQFB_DATA_LENGTH_ZERO
- MQC.MQFB_EXPIRATION
- MQC.MQFB_IIH_ERROR
- MQC.MQFB_LENGTH_OFF_BY_ONE
- MQC.MQFB_NAN
- MQC.MQFB_NONE
- MQC.MQFB_PAN
- MQC.MQFB_QUIT

Application-defined feedback values in the range MQC.MQFB_APPL_FIRST to MQC.MQFB_APPL_LAST can also be used.

The default value of this field is MQC.MQFB_NONE, indicating that no feedback is provided.

groupId

```
public byte[] groupId
```

MQMessageTracker

A byte string that identifies the message group to which the physical message belongs.

The default value is MQC.MQGI_NONE.

messageId

```
public byte messageId[]
```

The message identifier to use when the message is put. If MQC.MQMI_NONE is specified, the queue manager generates a unique message identifier when the message is put. The value of this member variable is updated after the put to indicate the message identifier that was used.

The default value is MQC.MQMI_NONE.

MQPoolServices

```
java.lang.Object
└─ com.ibm.mq.MQPoolServices
```

```
public class MQPoolServices
extends Object
```

Note: Normally, applications do not use this class.

The MQPoolServices class can be used by implementations of ConnectionManager that are intended for use as the default ConnectionManager for WebSphere MQ connections.

A ConnectionManager can construct an MQPoolServices object and, through it, register a listener. This listener receives events that relate to the set of MQPoolTokens that MQEnvironment manages. The ConnectionManager can use this information to perform any necessary startup or cleanup work.

See also “MQPoolServicesEvent” on page 142 and “MQPoolServicesEventListener” on page 174.

Constructors

MQPoolServices

```
public MQPoolServices()
```

Construct a new MQPoolServices object.

Methods

addMQPoolServicesEventListener

```
public void addMQPoolServicesEventListener
(MQPoolServicesEventListener listener)
```

Adds an MQPoolServicesEventListener. The listener receives an event whenever a token is added or removed from the set of MQPoolTokens that MQEnvironment controls, or whenever the default ConnectionManager changes.

getTokenCount

```
public int getTokenCount()
```

Returns the number of MQPoolTokens that are currently registered with MQEnvironment.

removeMQPoolServicesEventListener

```
public void removeMQPoolServicesEventListener
(MQPoolServicesEventListener listener)
```

Removes an MQPoolServicesEventListener.

MQPoolServicesEvent

```
java.lang.Object
├── java.util.EventObject
│   └── com.ibm.mq.MQPoolServicesEvent
```

Note: Normally, applications do not use this class.

An MQPoolServicesEvent is generated whenever an MQPoolToken is added to, or removed from, the set of tokens that MQEnvironment controls. An event is also generated when the default ConnectionManager is changed.

See also “MQPoolServices” on page 141 and “MQPoolServicesEventListener” on page 174.

Variables

DEFAULT_POOL_CHANGED

```
public static final int DEFAULT_POOL_CHANGED
```

The event ID used when the default ConnectionManager changes.

ID protected int ID

The event ID. Valid values are:

```
TOKEN_ADDED
```

```
TOKEN_REMOVED
```

```
DEFAULT_POOL_CHANGED
```

TOKEN_ADDED

```
public static final int TOKEN_ADDED
```

The event ID used when an MQPoolToken is added to the set.

TOKEN_REMOVED

```
public static final int TOKEN_REMOVED
```

The event ID used when an MQPoolToken is removed from the set.

token protected MQPoolToken token

The token. When the event ID is DEFAULT_POOL_CHANGED, this is null.

Constructors

MQPoolServicesEvent

```
public MQPoolServicesEvent(Object source, int eid)
```

Constructs an MQPoolServicesEvent based on the event ID.

MQPoolServicesEvent

```
public MQPoolServicesEvent(Object source, int eid, MQPoolToken token)
```

Constructs an MQPoolServicesEvent based on the event ID and the token.

Methods

getId public int getId()

Gets the event ID.

Returns

The event ID, with one of the following values:

 DEFAULT_POOL_CHANGED

 TOKEN_ADDED

 TOKEN_REMOVED

getToken

public MQPoolToken getToken()

Returns the token that was added to, or removed from, the set. If the event ID is DEFAULT_POOL_CHANGED, this is null.

MQPoolToken

```
java.lang.Object
└── com.ibm.mq.MQPoolToken
```

```
public class MQPoolToken
extends Object
```

Use an MQPoolToken to enable the default connection pool. MQPoolTokens are registered with the MQEnvironment class before an application component connects to WebSphere MQ. Later, they are deregistered when the component has finished using WebSphere MQ. Typically, the default ConnectionManager is active while the set of registered MQPoolTokens is not empty.

MQPoolToken provides no methods or variables. ConnectionManager providers can choose to extend MQPoolToken so that hints can be passed to the ConnectionManager.

See “MQEnvironment.addConnectionPoolToken” on page 110 and “MQEnvironment.removeConnectionPoolToken” on page 111.

Constructors

MQPoolToken

```
public MQPoolToken()
```

Construct a new MQPoolToken object.

MQProcess

```

java.lang.Object
├── com.ibm.mq.MQManagedObject
│   └── com.ibm.mq.MQProcess

```

public class **MQProcess**
 extends **MQManagedObject**. (See page 118.)

MQProcess provides inquire operations for WebSphere MQ processes.

Constructors

MQProcess

```

public MQProcess(MQQueueManager qMgr,
                 String processName,
                 int openOptions,
                 String queueManagerName,
                 String alternateUserId)
    throws MQException

```

Access a process on the queue manager qMgr. See accessProcess in the “MQQueueManager” on page 158 for details of the remaining parameters.

Methods

close

```
public synchronized void close()
```

Throws MQException.

Overrides “MQManagedObject.close” on page 119.

getApplicationId

```
public String getApplicationId()
```

A character string that identifies the application to be started. This information is for use by a trigger monitor application that processes messages on the initiation queue; the information is sent to the initiation queue as part of the trigger message.

Throws MQException if you call this method after you have closed the process.

getApplicationType

```
public int getApplicationType()
```

Throws MQException (see page 112).

Identifies the nature of the program to be started in response to the receipt of a trigger message. The application type can take any value, but the following values are recommended for standard types:

- MQC.MQAT_AIX
- MQC.MQAT_CICS
- MQC.MQAT_DOS
- MQC.MQAT_IMS
- MQC.MQAT_MVS
- MQC.MQAT_OS2

MQProcess

- MQC.MQAT_OS400
- MQC.MQAT_UNIX
- MQC.MQAT_WINDOWS
- MQC.MQAT_WINDOWS_NT
- MQC.MWQAT_USER_FIRST (lowest value for user-defined application type)
- MQC.MQAT_USER_LAST (highest value for user-defined application type)

getEnvironmentData

```
public String getEnvironmentData()
```

Throws MQException.

A string containing environment-related information pertaining to the application to be started.

getUserData

```
public String getUserData()
```

Throws MQException.

A string containing user information relevant to the application to be started.

MQPutMessageOptions

```
java.lang.Object
└── com.ibm.mq.MQPutMessageOptions
```

```
public class MQPutMessageOptions
extends Object
```

This class contains options that control the behavior of MQQueue.put().

Note: The behavior of some of the options available in this class depends on the environment in which they are used. These elements are marked with a *. See Chapter 8, “Environment-dependent behavior” on page 91 for more details.

Variables

contextReference

```
public MQQueue contextReference
```

An input field that indicates the source of the context information.

If the options field includes MQC.MQPMO_PASS_IDENTITY_CONTEXT, or MQC.MQPMO_PASS_ALL_CONTEXT, set this field to refer to the MQQueue from which to take the context information.

The initial value of this field is null.

invalidDestCount *

```
public int invalidDestCount
```

An output field set by the queue manager to the number of messages that could not be sent to queues in a distribution list. The count includes queues that failed to open as well as queues that were opened successfully, but for which the put operation failed. This field is also set when opening a single queue that is not part of a distribution list.

knownDestCount *

```
public int knownDestCount
```

An output field set by the queue manager to the number of messages that the current call has sent successfully to queues that resolve to local queues. This field is also set when opening a single queue that is not part of a distribution list.

options

```
public int options
```

Options that control the action of MQQueue.put. Any or none of the following values can be specified. If more than one option is required, the values can be added together or combined using the bitwise OR operator.

MQC.MQPMO_DEFAULT_CONTEXT

Associate default context with the message.

MQC.MQPMO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing.

MQC.MQPMO_LOGICAL_ORDER*

Put logical messages and segments in message groups into their logical order.

MQPutMessageOptions

MQC.MQPMO_NEW_CORREL_ID*

Generate a new correlation id for each sent message.

MQC.MQPMO_NEW_MSG_ID*

Generate a new message id for each sent message.

MQC.MQPMO_NONE

No options specified. Do not use in conjunction with other options.

MQC.MQPMO_NO_CONTEXT

No context is to be associated with the message.

MQC.MQPMO_NO_SYNCPOINT

Put a message without syncpoint control. Note that, if the syncpoint control option is not specified, a default of no syncpoint is assumed. This applies to all supported platforms.

MQC.MQPMO_PASS_ALL_CONTEXT

Pass all context from an input queue handle.

MQC.MQPMO_PASS_IDENTITY_CONTEXT

Pass identity context from an input queue handle.

MQC.MQPMO_SET_ALL_CONTEXT

Set all context from the application.

MQC.MQPMO_SET_IDENTITY_CONTEXT

Set identity context from the application.

MQC.MQPMO_SYNCPOINT

Put a message with syncpoint control. The message is not visible outside the unit of work until the unit of work is committed. If the unit of work is backed out, the message is deleted.

recordFields *

```
public int recordFields
```

Flags indicating which fields are to be customized in each queue when putting a message to a distribution list. One or more of the following flags can be specified:

MQC.MQPMRF_ACCOUNTING_TOKEN

Use the accountingToken attribute in the MQDistributionListItem.

MQC.MQPMRF_CORREL_ID

Use the correlationId attribute in the MQDistributionListItem.

MQC.MQPMRF_FEEDBACK

Use the feedback attribute in the MQDistributionListItem.

MQC.MQPMRF_GROUP_ID

Use the groupId attribute in the MQDistributionListItem.

MQC.MQPMRF_MSG_ID

Use the messageId attribute in the MQDistributionListItem.

The special value MQC.MQPMRF_NONE indicates that no fields are to be customized.

resolvedQueueManagerName

```
public String resolvedQueueManagerName
```

An output field set by the queue manager to the name of the queue manager that owns the queue specified by the remote queue name. This

MQPutMessageOptions

might be different from the name of the queue manager from which the queue was accessed if the queue is a remote queue.

resolvedQueueName

```
public String resolvedQueueName
```

An output field that is set by the queue manager to the name of the queue on which the message is placed. This might be different from the name used to open the queue if the opened queue was an alias or model queue.

unknownDestCount *

```
public int unknownDestCount
```

An output field set by the queue manager to the number of messages that the current call has sent successfully to queues that resolve to remote queues. This field is also set when opening a single queue that is not part of a distribution list.

Constructors

MQPutMessageOptions

```
public MQPutMessageOptions()
```

Construct a new MQPutMessageOptions object with no options set, and a blank resolvedQueueName and resolvedQueueManagerName.

MQQueue

```

java.lang.Object
├── com.ibm.mq.MQManagedObject
│   └── com.ibm.mq.MQQueue

```

public class **MQQueue**
 extends **MQManagedObject**. (See page 118.)

MQQueue provides inquire, set, put, and get operations for WebSphere MQ queues. The inquire and set capabilities are inherited from MQ.MQManagedObject.

See also “MQQueueManager.accessQueue” on page 163.

Constructors

MQQueue

```

public MQQueue(MQQueueManager qMgr, String queueName, int openOptions,
               String queueManagerName, String dynamicQueueName,
               String alternateUserId )
    throws MQException

```

Access a queue on the queue manager qMgr.

See “MQQueueManager.accessQueue” on page 163 for details of the remaining parameters.

Methods

close

```
public synchronized void close()
```

Throws MQException.

Overrides “MQManagedObject.close” on page 119.

get

```

public synchronized void get(MQMessage message,
                             MQGetMessageOptions getMessageOptions,
                             int MaxMsgSize)

```

Throws MQException.

Retrieves a message from the queue, up to a maximum specified message size.

This method takes an MQMessage object as a parameter. It uses some of the fields in the object as input parameters, in particular the messageId and correlationId, so it is important to ensure that these are set as required. (See “Message” on page 309.)

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor (member variables) and message data portions of the MQMessage are completely replaced with the message descriptor and message data from the incoming message.

All calls to WebSphere MQ from a given MQQueueManager are synchronous. Therefore, if you perform a `get` with `wait`, all other threads using the same MQQueueManager are blocked from making further WebSphere MQ calls until the `get` completes. If you need multiple threads to access WebSphere MQ simultaneously, each thread must create its own MQQueueManager object.

Parameters

message

An input/output parameter containing the message descriptor information and the returned message data.

getMessageOptions

Options controlling the action of the `get`. (See “MQGetMessageOptions” on page 114.)

Using option `MQC.MQGMO_CONVERT` might result in an exception with reason code `MQException.MQRC_CONVERTED_STRING_TOO_BIG` when converting from single byte character codes to double byte codes. In this case, the message is copied into the buffer but remains encoded using its original character set.

MaxMsgSize

The largest message this call can receive. If the message on the queue is larger than this size, one of two things occurs:

1. If the `MQC.MQGMO_ACCEPT_TRUNCATED_MSG` flag is set in the options member variable of the `MQGetMessageOptions` object, the message is filled with as much of the message data as will fit in the specified buffer size, and an exception is thrown with completion code `MQException.MQCC_WARNING` and reason code `MQException.MQRC_TRUNCATED_MSG_ACCEPTED`.
2. If the `MQC.MQGMO_ACCEPT_TRUNCATED_MSG` flag is not set, the message is left on the queue and an `MQException` is raised with completion code `MQException.MQCC_WARNING` and reason code `MQException.MQRC_TRUNCATED_MSG_FAILED`.

Throws `MQException` if the `get` fails.

get

```
public synchronized void get(MQMessage message,
                             MQGetMessageOptions getMessageOptions)
```

Throws `MQException`.

Retrieves a message from the queue, regardless of the size of the message. For large messages, the `get` method might have to issue two calls to WebSphere MQ on your behalf, one to establish the required buffer size and one to get the message data itself.

This method takes an `MQMessage` object as a parameter. It uses some of the fields in the object as input parameters, in particular the `messageId` and `correlationId`, so it is important to ensure that these are set as required. (See “Message” on page 309.)

MQQueue

If the get fails, the MQMessage object is unchanged. If it succeeds, the message descriptor (member variables) and message data portions of the MQMessage are completely replaced with the message descriptor and message data from the incoming message.

All calls to WebSphere MQ from a given MQQueueManager are synchronous. Therefore, if you perform a get with wait, all other threads using the same MQQueueManager are blocked from making further WebSphere MQ calls until the get completes. If you need multiple threads to access WebSphere MQ simultaneously, each thread must create its own MQQueueManager object.

Parameters

message

An input/output parameter containing the message descriptor information and the returned message data.

getMessageOptions

Options controlling the action of the get. (See "MQGetMessageOptions" on page 114 for details.)

Throws MQException if the get fails.

get

```
public synchronized void get(MQMessage message)
```

A simplified version of the get method previously described.

Parameters

MQMessage

An input/output parameter containing the message descriptor information and the returned message data.

This method uses a default instance of MQGetMessageOptions to do the get. The message option used is MQGMO_NOWAIT.

getCreationDateTime

```
public GregorianCalendar getCreationDateTime()
```

Throws MQException.

The date and time that this queue was created.

getQueueType

```
public int getQueueType()
```

Throws MQException

Returns

The type of this queue with one of the following values:

- MQC.MQQT_ALIAS
- MQC.MQQT_LOCAL
- MQC.MQQT_REMOTE
- MQC.MQQT_CLUSTER

getCurrentDepth

```
public int getCurrentDepth()
```

Throws MQException.

Gets the number of messages currently on the queue. This value is incremented during a put call, and during backout of a get call. It is decremented during a non-browse get and during backout of a put call.

getDefinitionType

```
public int getDefinitionType()
```

Throws MQException.

How the queue was defined.

Returns

One of the following:

- MQC.MQODT_PREDEFINED
- MQC.MQODT_PERMANENT_DYNAMIC
- MQC.MQODT_TEMPORARY_DYNAMIC

getInhibitGet

```
public int getInhibitGet()
```

Throws MQException.

Whether get operations are allowed for this queue.

Returns

The possible values are:

- MQC.MQQA_GET_INHIBITED
- MQC.MQQA_GET_ALLOWED

getInhibitPut

```
public int getInhibitPut()
```

Throws MQException.

Whether put operations are allowed for this queue.

Returns

One of the following:

- MQC.MQQA_PUT_INHIBITED
- MQC.MQQA_PUT_ALLOWED

getMaximumDepth

```
public int getMaximumDepth()
```

Throws MQException.

The maximum number of messages that can exist on the queue at any one time. An attempt to put a message to a queue that already contains this many messages fails with reason code MQException.MQRC_Q_FULL.

getMaximumMessageLength

```
public int getMaximumMessageLength()
```

Throws MQException.

MQQueue

The maximum length of the application data that can exist in each message on this queue. An attempt to put a message larger than this value fails with reason code MQException.MQRC_MSG_TOO_BIG_FOR_Q.

getOpenInputCount

```
public int getOpenInputCount()
```

Throws MQException.

The number of handles that are currently valid for removing messages from the queue. This is the *total* number of such handles known to the local queue manager, not just those created by the WebSphere MQ classes for Java (using `accessQueue`).

getOpenOutputCount

```
public int getOpenOutputCount()
```

Throws MQException.

The number of handles that are currently valid for adding messages to the queue. This is the *total* number of such handles known to the local queue manager, not just those created by the WebSphere MQ classes for Java (using `accessQueue`).

getShareability

```
public int getShareability()
```

Throws MQException.

Whether the queue can be opened for input multiple times.

Returns

One of the following:

- MQC.MQQA_SHAREABLE
- MQC.MQQA_NOT_SHAREABLE

getTriggerControl

```
public int getTriggerControl()
```

Throws MQException.

Whether trigger messages are written to an initiation queue, to start an application to service the queue.

Returns

The possible values are:

- MQC.MQTC_OFF
- MQC.MQTC_ON

getTriggerData

```
public String getTriggerData()
```

Throws MQException.

The free-format data that the queue manager inserts into the trigger message when a message arriving on this queue causes a trigger message to be written to the initiation queue.

getTriggerDepth

```
public int getTriggerDepth()
```

Throws MQException.

The number of messages that have to be on the queue before a trigger message is written when trigger type is set to MQC.MQTT_DEPTH.

getTriggerMessagePriority

```
public int getTriggerMessagePriority()
```

Throws MQException.

The message priority below which messages do not contribute to the generation of trigger messages (that is, the queue manager ignores these messages when deciding whether to generate a trigger). A value of zero causes all messages to contribute to the generation of trigger messages.

getTriggerType

```
public int getTriggerType()
```

Throws MQException.

The conditions under which trigger messages are written as a result of messages arriving on this queue.

Returns

The possible values are:

- MQC.MQTT_NONE
- MQC.MQTT_FIRST
- MQC.MQTT_EVERY
- MQC.MQTT_DEPTH

put

```
public synchronized void put(MQMessage message,
                             MQPutMessageOptions putMessageOptions)
```

Throws MQException.

Places a message onto the queue.

Note: For simplicity and performance, if you want to put just a single message to a queue, use the put() method on your MQQueueManager object. For this you do not need to have an MQQueue object. See “MQQueueManager.put” on page 169.

This method takes an MQMessage object as a parameter. The message descriptor properties of this object can be altered as a result of this method. The values that they have immediately after the completion of this method are the values that were put onto the WebSphere MQ queue.

Modifications to the MQMessage object after the put has completed do not affect the actual message on the WebSphere MQ queue.

A put updates the messageId and correlationId. Consider this when making further calls to put/get using the same MQMessage object. Also, calling put does not clear the message data, so:

MQQueue

```
msg.writeString("a");
q.put(msg,pmo);
msg.writeString("b");
q.put(msg,pmo);
```

puts two messages. The first contains a and the second ab.

Parameters

message

Message Buffer containing the Message Descriptor data and message to be sent.

putMessageOptions

Options controlling the action of the put. (See "MQPutMessageOptions" on page 147)

Throws MQException if the put fails.

put

```
public synchronized void put(MQMessage message)
```

A simplified version of the put method previously described.

Parameters

MQMessage

Message Buffer containing the Message Descriptor data and message to be sent.

This method uses a default instance of MQPutMessageOptions to do the put.

setInhibitGet

```
public void setInhibitGet(int inhibit)
```

Throws MQException.

Controls whether get operations are allowed for this queue. The permissible values are:

- MQC.MQQA_GET_INHIBITED
- MQC.MQQA_GET_ALLOWED

setInhibitPut

```
public void setInhibitPut(int inhibit)
```

Throws MQException.

Controls whether put operations are allowed for this queue. The permissible values are:

- MQC.MQQA_PUT_INHIBITED
- MQC.MQQA_PUT_ALLOWED

setTriggerControl

```
public void setTriggerControl(int trigger)
```

Throws MQException.

Controls whether trigger messages are written to an initiation queue to start an application to service the queue. The permissible values are:

- MQC.MQTC_OFF
- MQC.MQTC_ON

setTriggerData

```
public void setTriggerData(String data)
```

Throws MQException.

Sets the free-format data that the queue manager inserts into the trigger message when a message arriving on this queue causes a trigger message to be written to the initiation queue. The maximum permissible length of the string is given by MQC.MQ_TRIGGER_DATA_LENGTH.

setTriggerDepth

```
public void setTriggerDepth(int depth)
```

Throws MQException.

Sets the number of messages that have to be on the queue before a trigger message is written when trigger type is set to MQC.MQTT_DEPTH.

setTriggerMessagePriority

```
public void setTriggerMessagePriority(int priority)
```

Throws MQException.

Sets the message priority below which messages do not contribute to the generation of trigger messages (that is, the queue manager ignores these messages when deciding whether a trigger should be generated). A value of zero causes all messages to contribute to the generation of trigger messages.

setTriggerType

```
public void setTriggerType(int type)
```

Throws MQException.

Sets the conditions under which trigger messages are written as a result of messages arriving on this queue. The possible values are:

- MQC.MQTT_NONE
- MQC.MQTT_FIRST
- MQC.MQTT EVERY
- MQC.MQTT_DEPTH

MQQueueManager

```
java.lang.Object
├── com.ibm.mq.MQManagedObject
│   └── com.ibm.mq.MQQueueManager
```

```
public class MQQueueManager
extends MQManagedObject. (See page 118.)
```

Note: The behavior of some of the options available in this class depends on the environment in which they are used. These elements are marked with a *. See Chapter 8, “Environment-dependent behavior” on page 91 for details.

Variables

```
isConnected
public boolean isConnected

True if the connection to the queue manager is still open.
```

Constructors

```
MQQueueManager
public MQQueueManager(String queueManagerName)
```

Throws MQException.

Creates a connection to the named queue manager.

Note: When using WebSphere MQ classes for Java, the hostname, channel name, and port to use during the connection request are specified in the MQEnvironment class. This must be done *before* calling this constructor.

The following example shows a connection to a queue manager MYQM, running on a machine with hostname fred.mq.com.

```
MQEnvironment.hostname = "fred.mq.com"; // host to connect to
MQEnvironment.port      = 1414;         // port to connect to.
                                        // If I don't set this,
                                        // it defaults to 1414
                                        // (the default WebSphere MQ port)
MQEnvironment.channel  = "channel.name"; // the CASE-SENSITIVE
                                        // name of the
                                        // SVR CONN channel on
                                        // the queue manager
MQQueueManager qMgr    = new MQQueueManager("MYQM");
```

If the queue manager name is left blank (null or ""), a connection is made to the default queue manager.

See also “MQEnvironment” on page 106.

MQQueueManager

```
public MQQueueManager(String queueManagerName,
                      MQConnectionFactory cxManager)
```

Throws MQException.

Connects to the specified Queue Manager, using the properties in MQEnvironment. The specified MQConnectionFactory manages the connection.

MQQueueManager

```
public MQQueueManager(String queueManagerName,
                      ConnectionManager cxManager)
```

Throws MQException.

Connects to the specified Queue Manager, using the properties in MQEnvironment. The specified ConnectionManager manages the connection.

This constructor requires a JVM at at least Java 2 v1.3, with at least JAAS 1.0 installed.

MQQueueManager

```
public MQQueueManager(String queueManagerName,
                      int options)
```

Throws MQException.

This version of the constructor is intended for use only in bindings mode. It uses the extended connection API (MQCONNEX) to connect to the queue manager. The *options* parameter allows you to choose fast or normal bindings. Possible values are:

- MQC.MQCNO_FASTPATH_BINDING for fast bindings *
- MQC.MQCNO_STANDARD_BINDING for normal bindings.

MQQueueManager

```
public MQQueueManager(String queueManagerName,
                      int options,
                      MQConnectionFactory cxManager)
```

Throws MQException.

Performs an MQCONNEX, passing the supplied options. The specified MQConnectionFactory manages the connection.

MQQueueManager

```
public MQQueueManager(String queueManagerName,
                      int options,
                      ConnectionManager cxManager)
```

Throws MQException.

Performs an MQCONNEX, passing the supplied options. The specified ConnectionManager manages the connection.

This constructor requires a JVM at at least Java 2 v1.3, with at least JAAS 1.0 installed.

MQQueueManager

MQQueueManager

```
public MQQueueManager(String queueManagerName,  
                      java.util.Hashtable properties)
```

The properties parameter takes a series of key/value pairs that describe the WebSphere MQ environment for this particular queue manager. These properties, where specified, override the values set by the MQEnvironment class, and allow the individual properties to be set on a queue manager by queue manager basis. See "MQEnvironment.properties" on page 107.

MQQueueManager

```
public MQQueueManager(String queueManagerName,  
                      Hashtable properties,  
                      MQConnectionFactory cxManager)
```

Throws MQException.

This constructor connects to the named Queue Manager, using the supplied hash table of properties to override those in MQEnvironment. The specified MQConnectionFactory manages the connection.

MQQueueManager

```
public MQQueueManager(String queueManagerName,  
                      Hashtable properties,  
                      ConnectionManager cxManager)
```

Throws MQException.

Connects to the named Queue Manager, using the supplied hash table of properties to override those in MQEnvironment. The specified ConnectionManager manages the connection.

This constructor requires a JVM at at least Java 2 v1.3, with at least JAAS 1.0 installed.

Methods

accessDistributionList

```
public synchronized MQDistributionList accessDistributionList
    (MQDistributionListItem[] litems, int openOptions,
     String alternateUserId)
```

Throws MQException.

Parameters

litems The items to be included in the distribution list.

openOptions

Options that control the opening of the distribution list.

alternateUserId

If MQOO_ALTERNATE_USER_AUTHORITY is specified in the openOptions parameter, specifies the alternate user identifier that is used to check the authorization for the open. If MQOO_ALTERNATE_USER_AUTHORITY is not specified, this parameter can be left blank (or null).

Returns

A newly-created MQDistributionList, which is open and ready for put operations.

Throws MQException if the open fails.

See also “MQQueueManager.accessQueue” on page 163.

accessDistributionList

This is a simplified version of the AccessDistributionList method previously described.

```
public synchronized MQDistributionList accessDistributionList
    (MQDistributionListItem[] litems,
     int openOptions)
```

Throws MQException.

Parameters

litems The items to be included in the distribution list.

openOptions

Options that control the opening of the distribution list.

See the full description of “accessDistributionList” above for details of the other parameters.

alternateUserId is set to “”.

MQQueueManager

accessProcess

```
public synchronized MQProcess accessProcess  
    (String processName,  
     int openOptions,  
     String queueManagerName,  
     String alternateUserId)
```

Throws MQException.

Establishes access to a WebSphere MQ process on this queue manager to inquire about the process attributes.

Parameters

processName

Name of process to open.

openOptions

Options that control the opening of the process. Inquire is automatically added to the options specified, so there is no need to specify it explicitly.

Valid options are:

MQC.MQOO_ALTERNATE_USER_AUTHORITY

Validate with the specified user ID

MQC.MQOO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing

If more than one option is required, the values can be added together or combined using the bitwise OR operator. See the *WebSphere MQ Application Programming Reference* for a fuller description of these options.

queueManagerName

Name of the queue manager on which the process is defined. Applications should leave this parameter blank or null.

alternateUserId

If MQOO_ALTERNATE_USER_AUTHORITY is specified in the openOptions parameter, this parameter specifies the alternate user identifier that is used to check the authorization for the open. If MQOO_ALTERNATE_USER_AUTHORITY is not specified, this parameter can be left blank (or null).

accessProcess

This is a simplified version of the AccessProcess method previously described.

```
public synchronized MQProcess accessProcess  
    (String processName,  
     int openOptions)
```

Parameters*processName*

The name of the process to open.

openOptions

Options that control the opening of the process.

See the full description of “accessProcess” on page 162 above for details of the other options.

queueManagerName and *alternateUserId* are set to “”.

accessQueue

```
public synchronized MQQueue accessQueue
    (String queueName, int openOptions,
     String queueManagerName,
     String dynamicQueueName,
     String alternateUserId)
```

Throws MQException.

Establishes access to a WebSphere MQ queue on this queue manager to get or browse messages, put messages, inquire about the attributes of the queue or set the attributes of the queue.

If the queue named is a model queue, a dynamic local queue is created. The name of the created queue can be determined from the name attribute of the returned MQQueue object.

Parameters*queueName*

Name of queue to open.

openOptions

Options that control the opening of the queue. Valid options are:

MQC.MQOO_ALTERNATE_USER_AUTHORITY

Validate with the specified user identifier.

MQC.MQOO_BIND_AS_QDEF

Use default binding for queue.

MQC.MQOO_BIND_NOT_FIXED

Do not bind to a specific destination.

MQC.MQOO_BIND_ON_OPEN

Bind handle to destination when queue is opened.

MQC.MQOO_BROWSE

Open to browse message.

MQC.MQOO_FAIL_IF QUIESCING

Fail if the queue manager is quiescing.

MQC.MQOO_INPUT_AS_Q_DEF

Open to get messages using queue-defined default.

MQC.MQOO_INPUT_SHARED

Open to get messages with shared access.

MQQueueManager

MQC.MQOO_INPUT_EXCLUSIVE

Open to get messages with exclusive access.

MQC.MQOO_INQUIRE

Open for inquiry - required if you wish to query properties.

MQC.MQOO_OUTPUT

Open to put messages.

MQC.MQOO_PASS_ALL_CONTEXT

Allow all context to be passed.

MQC.MQOO_PASS_IDENTITY_CONTEXT

Allow identity context to be passed.

MQC.MQOO_SAVE_ALL_CONTEXT

Save context when message retrieved*.

MQC.MQOO_SET

Open to set attributes.

MQC.MQOO_SET_ALL_CONTEXT

Allows all context to be set.

MQC.MQOO_SET_IDENTITY_CONTEXT

Allows identity context to be set.

If more than one option is required, the values can be added together or combined using the bitwise OR operator. See the *WebSphere MQ Application Programming Reference* for a fuller description of these options.

queueManagerName

Name of the queue manager on which the queue is defined. A name that is entirely blank or null denotes the queue manager to which this MQQueueManager object is connected.

dynamicQueueName

This parameter is ignored unless *queueName* specifies the name of a model queue. If it does, this parameter specifies the name of the dynamic queue to be created. A blank or null name is not valid if *queueName* specifies the name of a model queue. If the last non-blank character in the name is an asterisk (*), the queue manager replaces the asterisk with a string of characters that guarantees that the name generated for the queue is unique on this queue manager.

alternateUserId

If **MQOO_ALTERNATE_USER_AUTHORITY** is specified in the *openOptions* parameter, this parameter specifies the alternate user identifier that is used to check the authorization for the open. If **MQOO_ALTERNATE_USER_AUTHORITY** is not specified, this parameter can be left blank (or null).

Returns

MQQueue that has been successfully opened.

Throws MQException if the open fails.

accessQueue

```
public synchronized MQQueue accessQueue
    (String queueName,
     int openOptions)
```

Throws MQException if you call this method after disconnecting from the queue manager.

Parameters

queueName

Name of queue to open

openOptions

Options that control the opening of the queue

See the description of “MQQueueManager.accessQueue” on page 163 for details of the parameters.

For this version of the method, *queueManagerName*, *dynamicQueueName*, and *alternateUserId* are set to “”.

Returns

MQProcess that has been successfully opened.

Throws MQException if the open fails.

backout

```
public synchronized void backout()
```

Throws MQException.

Calling this method indicates to the queue manager that all the message gets and puts that have occurred since the last syncpoint are to be backed out. Messages put as part of a unit of work (with the MQC.MQPMO_SYNCPOINT flag set in the options field of MQPutMessageOptions) are deleted; messages retrieved as part of a unit of work (with the MQC.MQGMO_SYNCPOINT flag set in the options field of MQGetMessageOptions) are reinstated on the queue.

See also the description of the commit method.

begin* (bindings connection only)

```
public synchronized void begin()
```

Throws MQException.

This method is supported only by the WebSphere MQ classes for Java in bindings mode. It signals to the queue manager that a new unit of work is starting. For a complete description of using this method, see “JTA/JDBC coordination using WebSphere MQ base Java” on page 81.

Do not use this method for applications that use local one-phase transactions.

MQQueueManager

commit

```
public synchronized void commit()
```

Throws MQException.

Calling this method indicates to the queue manager that the application has reached a syncpoint, and that all the message gets and puts that have occurred since the last syncpoint are to be made permanent. Messages put as part of a unit of work (with the MQC.MQPMO_SYNCPOINT flag set in the options field of MQPutMessageOptions) are made available to other applications. Messages retrieved as part of a unit of work (with the MQC.MQGMO_SYNCPOINT flag set in the options field of MQGetMessageOptions) are deleted.

See also the description of the backout method.

disconnect

```
public synchronized void disconnect()
```

Throws MQException.

Terminates the connection to the queue manager. All open queues and processes accessed by this queue manager are closed, and become unusable. When you have disconnected from a queue manager, the only way to reconnect is to create a new MQQueueManager object.

Normally, any work performed as part of a unit of work is committed. However, if this connection is managed by a ConnectionManager, rather than an MQConnectionManager, the unit of work might be rolled back.

getCharacterSet

```
public int getCharacterSet()
```

Throws MQException.

Returns the CCSID (Coded Character Set Identifier) of the queue manager's codeset. This defines the character set used by the queue manager for all character string fields in the application programming interface.

Throws MQException if you call this method after disconnecting from the queue manager.

getCommandInputQueueName

```
public String getCommandInputQueueName()
```

Throws MQException.

Returns the name of the command input queue defined on the queue manager. This is a queue to which applications can send commands, if authorized to do so.

Throws MQException if you call this method after disconnecting from the queue manager.

getCommandLevel

```
public int getCommandLevel()
```

Throws MQException.

Indicates the level of system control commands supported by the queue manager. The set of system control commands that correspond to a particular command level varies according to the architecture of the platform on which the queue manager is running. See the WebSphere MQ documentation for your platform for further details.

Throws MQException if you call this method after disconnecting from the queue manager.

Returns

One of the MQC.MQCMDL_LEVEL_xxx constants

getDistributionListCapable

```
public boolean getDistributionListCapable()
```

Indicates whether the queue manager supports distribution lists.

getJDBCConnection

```
public java.sql.Connection getJDBCConnection(XADataSource dataSource,
                                             String userid, String password)
    throws MQException, SQLException, Exception
```

Returns a Connection object for use with the JTA-JDBC support.

This method declares Exception in its throws clause to avoid problems with the JVM verifier for customers who are not using the JTA functionality. The actual exception thrown is javax.transaction.xa.XAException, which requires the jta.jar file to be added to the classpath for programs that did not previously require it.

Parameters*dataSource*

A database-specific implementation of the XADataSource interface that defines the details of the database to connect to. See the documentation for your database to determine how to create an appropriate XADataSource object to pass into getJDBCConnection.

userid

The user ID to use for this connection to the database. This is passed to the underlying XADataSource.getXAConnection method.

password

The password to use for this connection to the database. This is passed to the underlying XADataSource.getXAConnection method.

MQQueueManager

getJDBCConnection

```
public java.sql.Connection getJDBCConnection(javax.sql.XADataSource xads)
    throws MQException, SQLException, Exception
```

Returns a Connection object for use with the JTA-JDBC support.

This method declares Exception in its throws clause to avoid problems with the JVM verifier for customers who are not using the JTA functionality. The actual exception thrown is javax.transaction.xa.XAException, which requires the jta.jar file to be added to the classpath for programs that did not previously require it.

Parameters

xads A database-specific implementation of the XADataSource interface that defines the details of the database to connect to. See the documentation for your database to determine how to create an appropriate XADataSource object to pass into getJDBCConnection.

getMaximumMessageLength

```
public int getMaximumMessageLength()
```

Throws MQException.

Returns the maximum length of a message (in bytes) that can be handled by the queue manager. No queue can be defined with a maximum message length greater than this.

Throws MQException if you call this method after disconnecting from the queue manager.

getMaximumPriority

```
public int getMaximumPriority()
```

Throws MQException.

Returns the maximum message priority supported by the queue manager. Priorities range from zero (lowest) to this value.

Throws MQException if you call this method after disconnecting from the queue manager.

getSyncpointAvailability

```
public int getSyncpointAvailability()
```

Throws MQException.

Indicates whether the queue manager supports units of work and syncpointing with the MQQueue.get and MQQueue.put methods.

Returns

- MQC.MQSP_AVAILABLE if syncpointing is available.
- MQC.MQSP_NOT_AVAILABLE if syncpointing is not available.

Throws MQException if you call this method after disconnecting from the queue manager.

isConnected

```
public boolean isConnected()
```

Returns the value of the isConnected variable.

put

```
public synchronized void put(String qName,
                             String qmName,
                             MQMessage msg,
                             MQPutMessageOptions pmo,
                             String altUserId)
```

Throws MQException.

Places a single message onto a queue without having to create an MQQueue object first.

The qName (queue name) and qmName (queue manager name) parameters identify where the message is placed. If the queue is a model queue, an MQException is thrown.

In other respects, this method behaves like the put method on the MQQueue object. It is an implementation of the MQPUT1 MQI call. See "MQQueue.put" on page 155.

Parameters

qName The name of the queue onto which to place the message.

qmName

The name of the queue manager on which the queue is defined.

msg The message to send.

pmo Options controlling the actions of the put. See "MQPutMessageOptions" on page 147 for more details.

altUserId

Specifies an alternative user identifier used to check authorization when placing the message on a queue. If you do **not** specify MQPMO_ALTERNATE_USER, this parameter is ignored.

put

```
public synchronized void put(String qName,
                             String qmName,
                             MQMessage msg,
                             MQPutMessageOptions pmo)
```

Throws MQException.

Places a single message onto a queue without having to create an MQQueue object first.

MQQueueManager

This version of the method allows you to omit the altUserid parameter. See the fully-specified method (“MQQueueManager.put” on page 169) for details of the parameters.

put

```
public synchronized void put(String qName,  
                             String qmName,  
                             MQMessage msg)
```

Throws MQException.

Places a single message onto a queue without having to create an MQQueue object first.

This version of the method allows you to omit the put message options (pmo) and altUserid parameters. See the fully-specified method (“MQQueueManager.put” on page 169) for details of the parameters.

put

```
public synchronized void put(String qName,  
                             MQMessage msg,  
                             MQPutMessageOptions pmo)
```

Throws MQException.

Places a single message onto a queue without having to create an MQQueue object first.

This version of the method allows you to omit the qmName and altUserid parameters. See the fully-specified method (“MQQueueManager.put” on page 169) for details of the parameters.

put

```
public synchronized void put(String qName,  
                             MQMessage msg)
```

Throws MQException.

Places a single message onto a queue without having to create an MQQueue object first.

This version of the method allows you to omit the qmName, put message options (pmo), and altUserid parameters. See the fully-specified method (“MQQueueManager.put” on page 169) for details of the parameters.

MQSimpleConnectionManager

```

java.lang.Object      com.ibm.mq.MQConnectionManager
    |
    | com.ibm.mq.MQSimpleConnectionManager

```

```

public class MQSimpleConnectionManager
implements MQConnectionManager (See page 175.)

```

An MQSimpleConnectionManager provides basic connection pooling functionality. You can use an MQSimpleConnectionManager either as the default Connection Manager, or as a parameter to an MQQueueManager constructor. When an MQQueueManager is constructed, the most-recently-used connection in the pool is used.

Connections are destroyed (by a separate thread) when they are unused for a specified period, or when there are more than a specified number of unused connections in the pool. You can specify the timeout period and the maximum number of unused connections.

Variables

MODE_ACTIVE

```
public static final int MODE_ACTIVE. See "setActive" on page 172.
```

MODE_AUTO

```
public static final int MODE_AUTO. See "setActive" on page 172.
```

MODE_INACTIVE

```
public static final int MODE_INACTIVE. See "setActive" on page 172.
```

Constructors

MQSimpleConnectionManager

```
public MQSimpleConnectionManager()
```

Constructs an MQSimpleConnectionManager.

Methods

getActive

```
public int getActive()
```

Gets the mode of the connection pool.

Returns

The current active mode of the connection pool, with one of the following values (see "setActive" on page 172):

```
MODE_ACTIVE
```

```
MODE_AUTO
```

```
MODE_INACTIVE
```

getHighThreshold

```
public int getHighThreshold ()
```

Returns the HighThreshold value.

getTimeout

```
public long getTimeout()
```

MQSimpleConnectionManager

Returns the Timeout value.

setActive

```
public void setActive(int mode)
```

Sets the active mode of the connection pool.

Parameters

mode The required active mode of the connection pool. Valid values are:

MODE_ACTIVE

The connection pool is always active. When MQQueueManager.disconnect() is called, the underlying connection is pooled, and potentially reused the next time that an MQQueueManager object is constructed. Connections are destroyed by a separate thread if they are unused for longer than the Timeout period, or if the size of the pool exceeds HighThreshold.

MODE_AUTO

The connection pool is active while the Connection Manager is the default Connection Manager and there is at least one token in the set of MQPoolTokens held by MQEnvironment. This is the default mode.

MODE_INACTIVE

The connection pool is always inactive. When this mode is entered, the pool of connections to WebSphere MQ is cleared. When MQQueueManager.disconnect() is called, the connection that underlies any active MQQueueManager object is destroyed.

setHighThreshold

```
public void setHighThreshold(int threshold)
```

Sets the HighThreshold. If the number of unused connections in the pool exceeds this value, the oldest unused connection in the pool is destroyed.

Parameters

threshold

The maximum number of unused connections in the pool.

setTimeout

```
public void setTimeout(long timeout)
```

Sets the Timeout value, where connections that remain unused for this length of time are destroyed by a separate thread.

Parameters

timeout

The value of the timeout in milliseconds.

MQC

```
public interface MQC
extends Object
```

The MQC interface defines all the constants used by the WebSphere MQ Java programming interface (except for completion code constants and error code constants). To refer to one of these constants from within your programs, prefix the constant name with MQC.. For example, you can set the close options for a queue as follows:

```
MQQueue queue;
...
queue.closeOptions = MQC.MQCO_DELETE; // delete the
// queue when
// it is closed
...
```

A full description of these constants is in the *WebSphere MQ Application Programming Reference*.

Completion code and error code constants are defined in the MQException class. See "MQException" on page 112.

MQPoolServicesEventListener

```
public interface MQPoolServicesEventListener
extends Object
```

Note: Normally, applications do not use this interface.

MQPoolServicesEventListener is for implementation by providers of default ConnectionManagers. When an MQPoolServicesEventListener is registered with an MQPoolServices object, the event listener receives an event whenever an MQPoolToken is added to, or removed from, the set of MQPoolTokens that MQEnvironment manages. It also receives an event whenever the default ConnectionManager changes.

See also “MQPoolServices” on page 141 and “MQPoolServicesEvent” on page 142.

Methods

defaultConnectionManagerChanged

```
public void defaultConnectionManagerChanged(MQPoolServicesEvent event)
```

Called when the default ConnectionManager is set. The set of MQPoolTokens is cleared.

tokenAdded

```
public void tokenAdded(MQPoolServicesEvent event)
```

Called when an MQPoolToken is added to the set.

tokenRemoved

```
public void tokenRemoved(MQPoolServicesEvent event)
```

Called when an MQPoolToken is removed from the set.

MQConnectionManager

This is a private interface that cannot be implemented by applications. WebSphere MQ classes for Java supplies an implementation of this interface (`MQSimpleConnectionManager`), which you can specify on the `MQQueueManager` constructor, or through `MQEnvironment.setDefaultConnectionManager`.

See “`MQSimpleConnectionManager`” on page 171.

Applications or middleware that want to provide their own `ConnectionManager` must implement `javax.resource.spi.ConnectionManager`. This requires Java 2 v1.3 with JAAS 1.0 installed.

MQReceiveExit

```
public interface MQReceiveExit
extends Object
```

The receive exit interface allows you to examine and possibly alter the data received from the queue manager by the WebSphere MQ classes for Java.

Note: This interface does not apply when connecting directly to WebSphere MQ in bindings mode.

To provide your own receive exit, define a class that implements this interface. Create a new instance of your class and assign the `MQEnvironment.receiveExit` variable to it before constructing your `MQQueueManager` object. For example:

```
// in MyReceiveExit.java
class MyReceiveExit implements MQReceiveExit {
    // you must provide an implementation
    // of the receiveExit method
    public byte[] receiveExit(
        MQChannelExit      channelExitParms,
        MQChannelDefinition channelDefinition,
        byte[]              agentBuffer)
    {
        // your exit code goes here...
    }
}
// in your main program...
MQEnvironment.receiveExit = new MyReceiveExit();
... // other initialization
MQQueueManager qMgr      = new MQQueueManager("");
```

Methods

receiveExit

```
public abstract byte[] receiveExit(MQChannelExit channelExitParms,
                                   MQChannelDefinition channelDefinition,
                                   byte agentBuffer[])
```

The receive exit method that your class must provide. This method is invoked whenever the WebSphere MQ classes for Java receives some data from the queue manager.

Parameters

channelExitParms

Contains information regarding the context in which the exit is being invoked. The `exitResponse` member variable is an output parameter that you use to tell the WebSphere MQ classes for Java what action to take next. See “MQChannelExit” on page 100 for further details.

channelDefinition

Contains details of the channel through which all communications with the queue manager take place.

agentBuffer

If the `channelExitParms.exitReason` is `MQChannelExit.MQXR_XMIT`, `agentBuffer` contains the data received from the queue manager; otherwise `agentBuffer` is null.

Returns

If the exit response code (in `channelExitParms`) is set so that the WebSphere MQ classes for Java can now process the data (`MQXCC_OK`), your receive exit method must return the data to be processed. The simplest receive exit, therefore, consists of the single line return `agentBuffer;`.

See also:

- “MQC” on page 173
- “MQChannelDefinition” on page 98

MQSecurityExit

```
public interface MQSecurityExit
extends Object
```

The security exit interface allows you to customize the security flows that occur when an attempt is made to connect to a queue manager.

Note: This interface does not apply when connecting directly to WebSphere MQ in bindings mode.

To provide your own security exit, define a class that implements this interface. Create a new instance of your class and assign the `MQEnvironment.securityExit` variable to it before constructing your `MQQueueManager` object. For example:

```
// in MySecurityExit.java
class MySecurityExit implements MQSecurityExit {
    // you must provide an implementation
    // of the securityExit method
    public byte[] securityExit(
        MQChannelExit      channelExitParms,
        MQChannelDefinition channelDefinition,
        byte[]              agentBuffer)
    {
        // your exit code goes here...
    }
}
// in your main program...
MQEnvironment.securityExit = new MySecurityExit();
... // other initialization
MQQueueManager qMgr      = new MQQueueManager("");
```

Methods

securityExit

```
public abstract byte[] securityExit(MQChannelExit channelExitParms,
                                    MQChannelDefinition channelDefinition,
                                    byte agentBuffer[])
```

The security exit method that your class must provide.

Parameters

channelExitParms

Contains information regarding the context in which the exit is being invoked. The `exitResponse` member variable is an output parameter that you use to tell the WebSphere MQ Client for Java what action to take next. See the “MQChannelExit” on page 100 for further details.

channelDefinition

Contains details of the channel through which all communications with the queue manager take place.

agentBuffer

If the `channelExitParms.exitReason` is `MQChannelExit.MQXR_SEC_MSG`, `agentBuffer` contains the security message received from the queue manager; otherwise `agentBuffer` is null.

Returns

If the exit response code (in `channelExitParms`) is set so that a message is to be transmitted to the queue manager, your security exit method must return the data to be transmitted.

See also:

- “MQC” on page 173
- “MQChannelDefinition” on page 98

MQSendExit

```
public interface MQSendExit
extends Object
```

The send exit interface allows you to examine and possibly alter the data sent to the queue manager by the WebSphere MQ Client for Java.

Note: This interface does not apply when connecting directly to WebSphere MQ in bindings mode.

To provide your own send exit, define a class that implements this interface. Create a new instance of your class and assign the `MQEnvironment.sendExit` variable to it before constructing your `MQQueueManager` object. For example:

```
// in MySendExit.java
class MySendExit implements MQSendExit {
    // you must provide an implementation of the sendExit method
    public byte[] sendExit(
        MQChannelExit    channelExitParms,
        MQChannelDefinition channelDefinition,
        byte[]            agentBuffer)
    {
        // your exit code goes here...
    }
}
// in your main program...
MQEnvironment.sendExit = new MySendExit();
... // other initialization
MQQueueManager qMgr    = new MQQueueManager("");
```

Methods

sendExit

```
public abstract byte[] sendExit(MQChannelExit channelExitParms,
                               MQChannelDefinition channelDefinition,
                               byte agentBuffer[])
```

The send exit method that your class must provide. This method is invoked whenever the WebSphere MQ classes for Java wishes to transmit some data to the queue manager.

Parameters

channelExitParms

Contains information regarding the context in which the exit is being invoked. The `exitResponse` member variable is an output parameter that you use to tell the WebSphere MQ classes for Java what action to take next. See “MQChannelExit” on page 100 for further details.

channelDefinition

Contains details of the channel through which all communications with the queue manager take place.

agentBuffer

If the `channelExitParms.exitReason` is `MQChannelExit.MQXR_XMIT`, `agentBuffer` contains the data to be transmitted to the queue manager; otherwise `agentBuffer` is null.

Returns

If the exit response code (in `channelExitParms`) is set so that a message is to be transmitted to the queue manager (`MQXCC_OK`), your send exit method must return the data to be transmitted. The simplest send exit, therefore, consists of the single line `return agentBuffer;`

- “MQC” on page 173
- “MQChannelDefinition” on page 98

ManagedConnection

```
public interface javax.resource.spi.ManagedConnection
```

Note: Normally, applications do not use this class; it is intended for use by implementations of ConnectionManager.

WebSphere MQ classes for Java provides an implementation of ManagedConnection that is returned from ManagedConnectionFactory.createManagedConnection. This object represents a connection to a WebSphere MQ Queue Manager. For more details about this interface, see the J2EE Connector Architecture specification (refer to Sun's Web site at <http://java.sun.com>).

Methods

addConnectionEventListener

```
public void addConnectionEventListener(ConnectionEventListener listener)
```

Adds a ConnectionEventListener to the ManagedConnection instance.

The listener is notified if a severe error occurs on the ManagedConnection, or when MQQueueManager.disconnect() is called on a connection handle that is associated with this ManagedConnection. The listener is not notified about local transaction events (see "getLocalTransaction" on page 183).

associateConnection

```
public void associateConnection(Object connection)
```

Throws ResourceException.

WebSphere MQ classes for Java does not currently support this method. A javax.resource.NotSupportedException is thrown.

cleanup

```
public void cleanup()
```

Throws ResourceException.

Closes all open connection handles, and resets the physical connection to an initial state ready to be pooled. Any pending local transaction is rolled back. For more details, see "getLocalTransaction" on page 183.

destroy

```
public void destroy()
```

Throws ResourceException.

Destroys the physical connection to the WebSphere MQ Queue Manager. Any pending local transaction is committed. For more details, see "getLocalTransaction" on page 183.

getConnection

```
public Object getConnection(javax.security.auth.Subject subject,  
                             ConnectionRequestInfo cxRequestInfo)
```

Throws ResourceException.

ManagedConnection

Creates a new connection handle for the physical connection represented by the ManagedConnection object. For WebSphere MQ classes for Java, this returns an MQQueueManager object. The ConnectionManager normally returns this object from allocateConnection.

The subject parameter is ignored. If the cxRequestInfo parameter is not suitable, a ResourceException is thrown. Multiple connection handles can be used simultaneously for each single ManagedConnection.

getLocalTransaction

```
public LocalTransaction getLocalTransaction()
```

Throws ResourceException.

WebSphere MQ classes for Java does not currently support this method. A javax.resource.NotSupportedException is thrown.

Currently, a ConnectionManager cannot manage the WebSphere MQ local transaction, and registered ConnectionEventListeners are not informed about events relating to the local transaction. When cleanup() occurs, any ongoing unit of work is rolled back. When destroy() occurs, any ongoing unit of work is committed.

Existing API behavior is that an ongoing unit of work is committed at MQQueueManager.disconnect(). This existing behavior is preserved only when an MQConnectionManager (rather than a ConnectionManager) manages the connection.

getLogWriter

```
public java.io.PrintWriter getLogWriter()
```

Throws ResourceException.

Returns the log writer for this ManagedConnection.

WebSphere MQ classes for Java does not currently use the log writer. See "MQException.log" on page 112 for more information about logging.

getMetaData

```
public ManagedConnectionMetaData getMetaData()
```

Throws ResourceException.

Gets the meta data information for the underlying Queue Manager. See "ManagedConnectionMetaData" on page 187.

getXAResource

```
public javax.transaction.xa.XAResource getXAResource()
```

Throws ResourceException.

WebSphere MQ classes for Java does not currently support this method. A javax.resource.NotSupportedException is thrown.

removeConnectionEventListener

```
public void removeConnectionEventListener(ConnectionEventListener listener)
```

Removes a registered ConnectionEventListener.

ManagedConnection

setLogWriter

```
public void setLogWriter(java.io.PrintWriter out)
```

Throws `ResourceException`.

Sets the log writer for this `ManagedConnection`. When a `ManagedConnection` is created, it inherits the log writer from its `ManagedConnectionFactory`.

WebSphere MQ classes for Java does not currently use the log writer. See “`MQException.log`” on page 112 for more information about logging.

ManagedConnectionFactory

```
public interface javax.resource.spi.ManagedConnectionFactory
```

Note: Normally, applications do not use this class; it is intended for use by implementations of ConnectionManager.

WebSphere MQ classes for Java provides an implementation of this interface to ConnectionManagers. A ManagedConnectionFactory is used to construct ManagedConnections and to select suitable ManagedConnections from a set of candidates. For more details about this interface, see the J2EE Connector Architecture specification (refer to Sun's Web site at <http://java.sun.com>).

Methods

createConnectionFactory

```
public Object createConnectionFactory()
```

Throws ResourceException.

WebSphere MQ classes for Java does not currently support the createConnectionFactory methods. This method throws a javax.resource.NotSupportedException.

createConnectionFactory

```
public Object createConnectionFactory(ConnectionManager cxManager)
```

Throws ResourceException.

WebSphere MQ classes for Java does not currently support the createConnectionFactory methods. This method throws a javax.resource.NotSupportedException.

createManagedConnection

```
public ManagedConnection createManagedConnection
    (javax.security.auth.Subject subject,
     ConnectionRequestInfo cxRequestInfo)
```

Throws ResourceException.

Creates a new physical connection to a WebSphere MQ Queue Manager, and returns a ManagedConnection object that represents this connection. WebSphere MQ ignores the subject parameter.

equals

```
public boolean equals(Object other)
```

Checks whether this ManagedConnectionFactory is equal to another ManagedConnectionFactory. Returns true if both ManagedConnectionFactories describe the same target Queue Manager.

getLogWriter

```
public java.io.PrintWriter getLogWriter()
```

Throws ResourceException.

Returns the log writer for this ManagedConnectionFactory.

ManagedConnectionFactory

WebSphere MQ classes for Java does not currently use the log writer. See "MQException.log" on page 112 for more information about logging.

hashCode

```
public int hashCode()
```

Returns the hash code for this ManagedConnectionFactory.

matchManagedConnection

```
public ManagedConnection matchManagedConnection  
(java.util.Set connectionSet,  
  javax.security.auth.Subject subject,  
  ConnectionRequestInfo cxRequestInfo)
```

Throws ResourceException.

Searches the supplied set of candidate ManagedConnections for an appropriate ManagedConnection. Returns either null, or a suitable ManagedConnection from the set that meets the criteria for connection.

setLogWriter

```
public void setLogWriter(java.io.PrintWriter out)
```

Throws ResourceException.

Sets the log writer for this ManagedConnectionFactory. When a ManagedConnection is created, it inherits the log writer from its ManagedConnectionFactory.

WebSphere MQ classes for Java does not currently use the log writer. See "MQException.log" on page 112 for more information about logging.

ManagedConnectionMetaData

```
public interface javax.resource.spi.ManagedConnectionMetaData
```

Note: Normally, applications do not use this interface; it is intended for use by implementations of ConnectionManager.

A ConnectionManager can use this interface to retrieve meta data that is related to an underlying physical connection to a Queue Manager. An implementation of this interface is returned from ManagedConnection.getMetaData(). For more details about this interface, see the J2EE Connector Architecture specification (refer to Sun's Web site at <http://java.sun.com>).

Methods

getEISProductName

```
public String getEISProductName()
```

Throws ResourceException.

Returns IBM WebSphere MQ.

getMaxConnections

```
public int getMaxConnections()
```

Throws ResourceException.

Returns 0.

getProductVersion

```
public String getProductVersion()
```

Throws ResourceException.

Returns a string that describes the command level of the WebSphere MQ queue manager to which the ManagedConnection is connected.

getUserName

```
public String getUserName()
```

Throws ResourceException.

If the ManagedConnection represents a client connection to a queue manager, this returns the user ID used for the connection. Otherwise, it returns an empty string.

ManagedConnectionMetaData

Part 3. Programming with WebSphere MQ JMS

Chapter 10. Writing WebSphere MQ JMS

programs	191
The JMS model	191
Building a connection	192
Retrieving the factory from JNDI	192
Using the factory to create a connection	193
Creating factories at runtime	193
Starting the connection	193
Choosing client or bindings transport	194
Obtaining a session	195
Sending a message	195
Setting properties with the set method	197
Message types	197
Receiving a message	198
Message selectors	199
Asynchronous delivery	199
Closing down	200
Java Virtual Machine hangs at shutdown	200
Handling errors	200
Exception listener	200
User exits	200
Using Secure Sockets Layer (SSL)	201
SSL administrative properties	201
SSLCIPHERSUITE object property	201
SSLPEERNAME object property	201
SSLCERTSTORES object property	202
SSLConnectionFactory object property	203

Chapter 11. Programming publish/subscribe applications

Introduction	205
Getting started with WebSphere MQ JMS and publish/subscribe	205
Choosing a broker	205
Setting up the broker to run the WebSphere MQ JMS	206
Connecting to your broker using WebSphere MQ	206
Connecting to your broker directly	207
Writing a simple publish/subscribe application connecting through WebSphere MQ	207
Import required packages	209
Obtain or create JMS objects	209
Publish messages	211
Receive subscriptions	211
Close down unwanted resources	211
TopicConnectionFactory administered objects	212
Topic administered objects	212
Using topics	213
Topic names	213
Creating topics at runtime	214
Subscriber options	216
Creating non-durable subscribers	216
Creating durable subscribers	216
Using message selectors	216
Suppressing local publications	216

Combining the subscriber options	217
Configuring the base subscriber queue	217
Default configuration	217
Configuring non-durable subscribers	218
Configuring durable subscribers	218
Subscription stores	219
Migration and coexistence considerations	221
Solving publish/subscribe problems	221
Incomplete publish/subscribe close down	221
Subscriber cleanup utility	222
Manual cleanup	224
Cleanup from within a program	225
Handling broker reports	225

Chapter 12. JMS messages

Message selectors	227
Mapping JMS messages onto WebSphere MQ messages	231
The MQRFH2 header	232
JMS fields and properties with corresponding MQMD fields	235
Mapping JMS fields onto WebSphere MQ fields (outgoing messages)	236
Mapping JMS header fields at send() or publish()	238
Mapping JMS property fields	239
Mapping JMS provider-specific fields	240
Mapping WebSphere MQ fields onto JMS fields (incoming messages)	241
Mapping JMS to a native WebSphere MQ application	243
Message body	243

Chapter 13. WebSphere MQ JMS Application Server Facilities

ASF classes and functions	247
ConnectionConsumer	247
Planning an application	248
General principles for point-to-point messaging	248
General principles for publish/subscribe messaging	249
Handling poison messages	250
Removing messages from the queue	251
Error handling	252
Recovering from error conditions	252
Reason and feedback codes	253
Application server sample code	253
MyServerSession.java	255
MyServerSessionPool.java	255
MessageListenerFactory.java	256
Examples of ASF use	257

Chapter 10. Writing WebSphere MQ JMS programs

This chapter provides information to help with writing WebSphere MQ JMS applications. It gives a brief introduction to the JMS model, and detailed information on programming some common tasks that application programs are likely to need to perform.

The JMS model

JMS defines a generic view of a message passing service. The generic JMS model is based around the following interfaces that are defined in Sun's `javax.jms` package:

Connection

Provides access to the underlying transport, and is used to create *Sessions*.

Session

Provides a context for producing and consuming messages, including the methods used to create *MessageProducers* and *MessageConsumers*.

MessageProducer

Used to send messages.

MessageConsumer

Used to receive messages.

A *Connection* is thread safe, but *Sessions*, *MessageProducers*, and *MessageConsumers* are not. The recommended strategy is to use one *Session* per application thread.

In WebSphere MQ terms:

Connection

Provides a scope for temporary queues. Also, it provides a place to hold the parameters that control how to connect to WebSphere MQ. Examples of these parameters are the name of the queue manager, and the name of the remote host if you use the WebSphere MQ Java client connectivity.

Session

Contains an *HCONN* and therefore defines a transactional scope.

MessageProducer and MessageConsumer

Contain an *HOBJ* that defines a particular queue for writing to or reading from.

Note that normal WebSphere MQ rules apply:

- Only a single operation can be in progress per *HCONN* at any given time. Therefore, the *MessageProducers* or *MessageConsumers* associated with a *Session* cannot be called concurrently. This is consistent with the JMS restriction of a single thread per *Session*.
- *PUTs* can use remote queues, but *GETs* can only be applied to queues on the local queue manager.

The generic JMS interfaces are subclassed into more specific versions for point-to-point and publish/subscribe behavior.

The point-to-point versions are:

JMS model

- QueueConnection
- QueueSession
- QueueSender
- QueueReceiver

When using JMS, always write application programs that use only references to the interfaces in `javax.jms`. All vendor-specific information is encapsulated in implementations of:

- QueueConnectionFactory
- TopicConnectionFactory
- Queue
- Topic

These are known as *administered objects*, that is, objects that can be built using a vendor-supplied administration tool and stored in a JNDI namespace. A JMS application can retrieve these objects from the namespace and use them without needing to know which vendor provided the implementation.

Building a connection

Connections are not created directly, but are built using a connection factory. Factory objects can be stored in a JNDI namespace, insulating the JMS application from provider-specific information. Details of how to create and store factory objects are in Chapter 5, “Using the WebSphere MQ JMS administration tool” on page 41.

If you do not have a JNDI namespace available, see “Creating factories at runtime” on page 193.

Retrieving the factory from JNDI

To retrieve an object from a JNDI namespace, set up an initial context, as shown in this fragment taken from the IVTRun sample file:

```
import javax.jms.*;
import javax.naming.*;
import javax.naming.directory.*;
.
.
.
java.util.Hashtable environment = new java.util.Hashtable();
environment.put(Context.INITIAL_CONTEXT_FACTORY, icf);
environment.put(Context.PROVIDER_URL, url);
Context ctx = new InitialDirContext( environment );
```

where:

icf defines a factory class for the initial context

url defines a context specific URL

For more details about JNDI usage, see Sun’s JNDI documentation.

Note: Some combinations of the JNDI packages and LDAP service providers can result in an LDAP error 84. To resolve the problem, insert the following line before the call to `InitialDirContext`.

```
environment.put(Context.REFERRAL, "throw");
```

Once an initial context is obtained, objects are retrieved from the namespace by using the `lookup()` method. The following code retrieves a `QueueConnectionFactory` named `ivtQCF` from an LDAP-based namespace:

```
QueueConnectionFactory factory;  
factory = (QueueConnectionFactory)ctx.lookup("cn=ivtQCF");
```

Using the factory to create a connection

The `createQueueConnection()` method on the factory object is used to create a `Connection`, as shown in the following code:

```
QueueConnection connection;  
connection = factory.createQueueConnection();
```

Creating factories at runtime

If a JNDI namespace is not available, it is possible to create factory objects at runtime. However, using this method reduces the portability of the JMS application because it requires references to WebSphere MQ specific classes.

The following code creates a `QueueConnectionFactory` with all default settings:

```
factory = new com.ibm.mq.jms.MQQueueConnectionFactory();
```

(You can omit the `com.ibm.mq.jms.` prefix if you import the `com.ibm.mq.jms` package instead.)

A connection created from the above factory uses the Java bindings to connect to the default queue manager on the local machine. The set methods shown in Table 14 on page 194 can be used to customize the factory with WebSphere MQ specific information.

The only way to create a `TopicConnectionFactory` object at runtime is to construct it using the `MQTopicConnectionFactory` constructor. For example:

```
MQTopicConnectionFactory fact = new MQTopicConnectionFactory();
```

This creates a default `TopicConnectionFactory` object with the bindings `transportType` and all other default settings.

It is possible to change the `transportType` for the `TopicConnectionFactory` using its `setTransportType()` method. For example:

```
fact.setTransportType(JMSC.MQJMS_TP_BINDINGS_MQ); // Bindings mode  
fact.setTransportType(JMSC.MQJMS_TP_CLIENT_MQ_TCPIP); // Client mode  
fact.setTransportType(JMSC.MQJMS_TP_DIRECT_TCPIP); // Direct TCP/IP mode
```

The full JMS `TopicConnectionFactory` interface has been implemented. Refer to “`TopicConnectionFactory`” on page 371 for more details. Note that certain combinations of property settings are not valid for `TopicConnectionFactory` objects. See “`Properties`” on page 48 for more details.

Starting the connection

The JMS specification defines that connections should be created in the *stopped* state. Until the connection starts, `MessageConsumers` that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
connection.start();
```

Building a connection

Table 14. Set methods on *MQQueueConnectionFactory*

Method	Description
<code>setCCSID(int)</code>	Used to set the <code>MQEnvironment.CCSID</code> property
<code>setChannel(String)</code>	The name of the channel for a client connection
<code>setFailIfQuiesce(int)</code>	Defines the behavior an application exhibits when making calls (for example, send and receive) against a quiescing queue manager. The options are: <ul style="list-style-type: none">• <code>JMSC.MQJMS_FIQ_NO</code>• <code>JMSC.MQJMS_FIQ_YES</code> (the default)
<code>setHostName(String)</code>	The name of the host for a client connection
<code>setPort(int)</code>	The port for a client connection
<code>setQueueManager(String)</code>	The name of the queue manager
<code>setTemporaryModel(String)</code>	The name of a model queue used to generate a temporary destination as a result of a call to <code>QueueSession.createTemporaryQueue()</code> . Make this the name of a temporary dynamic queue, rather than a permanent dynamic queue.
<code>setTransportType(int)</code>	How to connect to WebSphere MQ. The options are: <ul style="list-style-type: none">• <code>JMSC.MQJMS_TP_BINDINGS_MQ</code> (the default)• <code>JMSC.MQJMS_TP_CLIENT_MQ_TCPIP</code>• <code>JMSC.MQJMS_TP_DIRECT_TCPIP</code> <p>JMSC is in the package <code>com.ibm.mq.jms</code></p>
<code>setReceiveExit(String)</code> <code>setSecurityExit(String)</code> <code>setSendExit(String)</code> <code>setReceiveExitInit(String)</code> <code>setSecurityExitInit(String)</code> <code>setSendExitInit(String)</code>	Allow the use of the send, receive, and security exits provided by the underlying WebSphere MQ Classes for Java. The <code>set*Exit</code> methods take the name of a class that implements the relevant exit methods. (See the WebSphere MQ product documentation for details.) The class must implement a constructor with a single <code>String</code> parameter. This string provides any initialization data required by the exit, and is set to the value provided in the corresponding <code>set*ExitInit</code> method.

Choosing client or bindings transport

WebSphere MQ JMS can communicate with WebSphere MQ using either the client or bindings transports. (However, client transport is not supported on the z/OS and OS/390 platforms.) If you use the Java bindings, the JMS application and the WebSphere MQ queue manager must be located on the same machine. If you use the client, the queue manager can be on a different machine from the application.

The contents of the connection factory object determine which transport to use. Chapter 5, “Using the WebSphere MQ JMS administration tool” on page 41 describes how to define a factory object for use with client or bindings transport.

The following code fragment illustrates how you can define the transport within an application:

```
String HOSTNAME = "machine1";
String QMGRNAME = "machine1.QM1";
String CHANNEL = "SYSTEM.DEF.SVRCONN";

factory = new MQQueueConnectionFactory();
```

```
factory.setTransportType(JMSC.MQJMS_TP_CLIENT_MQ_TCPIP);
factory.setQueueManager(QMGRNAME);
factory.setHostName(HOSTNAME);
factory.setChannel(CHANNEL);
```

Obtaining a session

Once a connection is made, use the `createQueueSession` method on the `QueueConnection` to obtain a session.

The method takes two parameters:

1. A boolean that determines whether the session is *transacted* or *non-transacted*.
2. A parameter that determines the *acknowledge* mode.

The simplest case is that of the non-transacted session with `AUTO_ACKNOWLEDGE`, as shown in the following code fragment:

```
QueueSession session;

boolean transacted = false;
session = connection.createQueueSession(transacted,
                                       Session.AUTO_ACKNOWLEDGE);
```

Note: A connection is thread safe, but sessions (and objects that are created from them) are not. The recommended practice for multithreaded applications is to use a separate session for each thread.

Sending a message

Messages are sent using a `MessageProducer`. For point-to-point this is a `QueueSender` that is created using the `createSender` method on `QueueSession`. A `QueueSender` is normally created for a specific queue, so that all messages sent using that sender are sent to the same destination. The destination is specified using a `Queue` object. `Queue` objects can be either created at runtime, or built and stored in a JNDI namespace.

`Queue` objects are retrieved from JNDI in the following way:

```
Queue ioQueue;
ioQueue = (Queue)ctx.lookup( qLookup );
```

WebSphere MQ JMS provides an implementation of `Queue` in `com.ibm.mq.jms.MQQueue`. It contains properties that control the details of WebSphere MQ specific behavior, but in many cases it is possible to use the default values. JMS defines a standard way to specify the destination that minimizes the WebSphere MQ specific code in the application. This mechanism uses the `QueueSession.createQueue` method, which takes a string parameter describing the destination. The string itself is still in a vendor-specific format, but this is a more flexible approach than directly referring to the vendor classes.

WebSphere MQ JMS accepts two forms for the string parameter of `createQueue()`.

- The first is the name of the WebSphere MQ queue, as illustrated in the following fragment taken from the `IVTRun` program in the `samples` directory:

```
public static final String QUEUE = "SYSTEM.DEFAULT.LOCAL.QUEUE" ;
.
.
.
ioQueue = session.createQueue( QUEUE );
```

Sending a message

- The second, and more powerful, form is based on *uniform resource identifiers* (URIs). This form allows you to specify remote queues (queues on a queue manager other than the one to which you are connected). It also allows you to set the other properties contained in a `com.ibm.mq.jms.MQQueue` object.

The URI for a queue begins with the sequence `queue://`, followed by the name of the queue manager on which the queue resides. This is followed by a further `/`, the name of the queue, and optionally, a list of name-value pairs that set the remaining Queue properties. For example, the URI equivalent of the previous example is:

```
ioQueue = session.createQueue("queue:///SYSTEM.DEFAULT.LOCAL.QUEUE");
```

The name of the queue manager is omitted. This is interpreted as the queue manager to which the owning `QueueConnection` is connected at the time when the `Queue` object is used.

Note: When sending a message to a cluster, leave the Queue Manager field in the JMS Queue object blank. This enables an MQOPEN to be performed in `BIND_NOT_FIXED` mode, which allows the queue manager to be determined. Otherwise an exception is returned reporting that the queue object cannot be found. This applies when using JNDI or defining queues at runtime.

The following example connects to queue Q1 on queue manager HOST1.QM1, and causes all messages to be sent as non-persistent and priority 5:

```
ioQueue = session.createQueue("queue://HOST1.QM1/Q1?persistence=1&priority=5");
```

Table 15 lists the names that can be used in the name-value part of the URI. A disadvantage of this format is that it does not support symbolic names for the values, so where appropriate, the table also indicates *special* values, which might change. (See “Setting properties with the set method” on page 197 for an alternative way of setting properties.)

Table 15. Property names for queue URIs

Property	Description	Values
expiry	Lifetime of the message in milliseconds	0 for unlimited, positive integers for timeout (ms)
priority	Priority of the message	0 through 9, -1=QDEF, -2=APP
persistence	Whether the message should be <i>hardened</i> to disk	1=non-persistent, 2=persistent, -1=QDEF, -2=APP
CCSID	Character set of the destination	integers - valid values listed in base WebSphere MQ documentation
targetClient	Whether the receiving application is JMS compliant	0=JMS, 1=MQ
encoding	How to represent numeric fields	An integer value as described in the base WebSphere MQ documentation
The special values are:		
QDEF	Determine the property from the configuration of the WebSphere MQ queue.	
APP	The JMS application can control this property.	

Sending a message

Once the Queue object is obtained (either using `createQueue` as above or from JNDI), it must be passed into the `createSender` method to create a `QueueSender`:

```
QueueSender queueSender = session.createSender(ioQueue);
```

The resulting `queueSender` object is used to send messages by using the `send` method:

```
queueSender.send(outMessage);
```

Setting properties with the set method

You can set Queue properties by first creating an instance of `com.ibm.mq.jms.MQQueue` using the default constructor. Then you can fill in the required values by using public set methods. This method means that you can use symbolic names for the property values. However, because these values are vendor-specific, and are embedded in the code, the applications become less portable.

The following code fragment shows the setting of a queue property with a set method.

```
com.ibm.mq.jms.MQQueue q1 = new com.ibm.mq.jms.MQQueue();
q1.setBaseQueueManagerName("HOST1.QM1");
q1.setBaseQueueName("Q1");
q1.setPersistence(DeliveryMode.NON_PERSISTENT);
q1.setPriority(5);
```

Table 16 shows the symbolic property values that are supplied with WebSphere MQ JMS for use with the set methods.

Table 16. Symbolic values for queue properties

Property	Admin tool keyword	Values
expiry	UNLIM APP	JMSC.MQJMS_EXP_UNLIMITED JMSC.MQJMS_EXP_APP
priority	APP QDEF	JMSC.MQJMS_PRI_APP JMSC.MQJMS_PRI_QDEF
persistence	APP QDEF PERS NON	JMSC.MQJMS_PER_APP JMSC.MQJMS_PER_QDEF JMSC.MQJMS_PER_PER JMSC.MQJMS_PER_NON
targetClient	JMS MQ	JMSC.MQJMS_CLIENT_JMS_COMPLIANT JMSC.MQJMS_CLIENT_NONJMS_MQ
encoding	Integer(N) Integer(R) Decimal(N) Decimal(R) Float(N) Float(R) Native	JMSC.MQJMS_ENCODING_INTEGER_NORMAL JMSC.MQJMS_ENCODING_INTEGER_REVERSED JMSC.MQJMS_ENCODING_DECIMAL_NORMAL JMSC.MQJMS_ENCODING_DECIMAL_REVERSED JMSC.MQJMS_ENCODING_FLOAT_IEEE_NORMAL JMSC.MQJMS_ENCODING_FLOAT_IEEE_REVERSED JMSC.MQJMS_ENCODING_NATIVE

See “The ENCODING property” on page 54 for a discussion of encoding.

Message types

JMS provides several message types, each of which embodies some knowledge of its content. To avoid referring to the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

Sending a message

In the sample program, a text message is created in the following manner:

```
System.out.println( "Creating a TextMessage" );
TextMessage outMessage = session.createTextMessage();
System.out.println("Adding Text");
outMessage.setText(outString);
```

The message types that can be used are:

- BytesMessage
- MapMessage
- ObjectMessage
- StreamMessage
- TextMessage

Details of these types are in Chapter 14, “JMS interfaces and classes” on page 265.

Receiving a message

Messages are received using a `QueueReceiver`. This is created from a `Session` by using the `createReceiver()` method. This method takes a `Queue` parameter that defines from where the messages are received. See “Sending a message” on page 195 for details of how to create a `Queue` object.

The sample program creates a receiver and reads back the test message with the following code:

```
QueueReceiver queueReceiver = session.createReceiver(ioQueue);
Message inMessage = queueReceiver.receive(1000);
```

The parameter in the `receive` call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. You can omit this parameter, in which case, the call blocks indefinitely. If you do not want any delay, use the `receiveNowait()` method.

The `receive` methods return a message of the appropriate type. For example, if a `TextMessage` is put on a queue, when the message is received the object that is returned is an instance of `TextMessage`.

To extract the content from the body of the message, it is necessary to cast from the generic `Message` class (which is the declared return type of the `receive` methods) to the more specific subclass, such as `TextMessage`. If the received message type is not known, you can use the `instanceof` operator to determine which type it is. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

The following code illustrates the use of `instanceof`, and extraction of the content from a `TextMessage`:

```
if (inMessage instanceof TextMessage) {
    String replyString = ((TextMessage) inMessage).getText();
    .
    .
} else {
    // Print error message if Message was not a TextMessage.
    System.out.println("Reply message was not a TextMessage");
}
```

Message selectors

JMS provides a mechanism to select a subset of the messages on a queue so that this subset is returned by a receive call. When creating a `QueueReceiver`, you can provide a string that contains an SQL (Structured Query Language) expression to determine which messages to retrieve. The selector can refer to fields in the JMS message header as well as fields in the message properties (these are effectively application-defined header fields). Details of the header field names, as well as the syntax for the SQL selector, are in Chapter 12, "JMS messages" on page 227.

The following example shows how to select for a user-defined property named `myProp`:

```
queueReceiver = session.createReceiver(ioQueue, "myProp = 'blue'");
```

Note: The JMS specification does not permit the selector associated with a receiver to be changed. Once a receiver is created, the selector is fixed for the lifetime of that receiver. This means that, if you require different selectors, you must create new receivers.

Asynchronous delivery

An alternative to making calls to `QueueReceiver.receive()` is to register a method that is called automatically when a suitable message is available. The following fragment illustrates the mechanism:

```
import javax.jms.*;

public class MyClass implements MessageListener
{
    // The method that will be called by JMS when a message
    // is available.
    public void onMessage(Message message)
    {
        System.out.println("message is "+message);

        // application specific processing here
        .
        .
    }
}

// In Main program (possibly of some other class)
MyClass listener = new MyClass();
queueReceiver.setMessageListener(listener);

// main program can now continue with other application specific
// behavior.
```

Note: Use of asynchronous delivery with a `QueueReceiver` marks the entire Session as asynchronous. It is an error to make an explicit call to the receive methods of a `QueueReceiver` that is associated with a Session that is using asynchronous delivery.

Closing down

Garbage collection alone cannot release all WebSphere MQ resources in a timely manner, especially if the application needs to create many short-lived JMS objects at the Session level or lower. It is therefore important to call the `close()` methods of the various classes (`QueueConnection`, `QueueSession`, `QueueSender`, and `QueueReceiver`) when the resources are no longer required.

Java Virtual Machine hangs at shutdown

If an application using WebSphere MQ JMS finishes without calling `Connection.close()`, some JVMs appear to hang. If this problem occurs, either edit the application to include a call to `Connection.close()`, or terminate the JVM using the `Ctrl-C` keys.

Handling errors

Any runtime errors in a JMS application are reported by exceptions. The majority of methods in JMS throw `JMSEExceptions` to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

A `JMSEException` can contain a further exception embedded in it. For JMS, this can be a valuable way to pass important detail from the underlying transport. In the case of WebSphere MQ JMS, when WebSphere MQ raises an `MQException`, this exception is usually included as the embedded exception in a `JMSEException`.

The implementation of `JMSEException` does not include the embedded exception in the output of its `toString()` method. Therefore, it is necessary to check explicitly for an embedded exception and print it out, as shown in the following fragment:

```
try {
    .
    . code which may throw a JMSEException
    .
} catch (JMSEException je) {
    System.err.println("caught "+je);
    Exception e = je.getLinkedException();
    if (e != null) {
        System.err.println("linked exception: "+e);
    }
}
```

Exception listener

For asynchronous message delivery, the application code cannot catch exceptions raised by failures to receive messages. This is because the application code does not make explicit calls to `receive()` methods. To cope with this situation, it is possible to register an `ExceptionListener`, which is an instance of a class that implements the `onException()` method. When a serious error occurs, this method is called with the `JMSEException` passed as its only parameter. Further details are in Sun's JMS documentation.

User exits

WebSphere MQ JMS allows you to code and use implementations of the WebSphere MQ base Java `send`, `receive`, and `security` exits. For WebSphere MQ JMS, ensure that your exit has a constructor that takes a single string argument. See the description of exit-related `set` methods in Table 14 on page 194 and "Property dependencies" on page 53.

Using Secure Sockets Layer (SSL)

WebSphere MQ base Java client applications and WebSphere MQ JMS connections using TRANSPORT(CLIENT) support Secure Sockets Layer (SSL) encryption. SSL provides communication encryption, authentication, and message integrity. It is typically used to secure communications between any two peers on the Internet or within an intranet.

WebSphere MQ classes for Java uses Java Secure Socket Extension (JSSE) to handle SSL encryption, and so requires a JSSE provider. J2SE v1.4 JVMs have a JSSE provider built in. Details of how to manage and store certificates can vary from provider to provider. For information about this, refer to your JSSE provider's documentation.

This section assumes that your JSSE provider is correctly installed and configured, and that suitable certificates have been installed and made available to your JSSE provider.

SSL administrative properties

This section introduces the SSL administrative properties, as follows:

- "SSLCIPHERSUITE object property"
- "SSLPEERNAME object property"
- "SSLCERTSTORES object property" on page 202
- "SSLConnectionFactory object property" on page 203

SSLCIPHERSUITE object property

To enable SSL encryption on a ConnectionFactory, use JMSAdmin to set the SSLCIPHERSUITE property to a CipherSuite supported by your JSSE provider. This must match the CipherSpec set on the target channel. However, CipherSuites are distinct from CipherSpecs and so have different names. Appendix H, "SSL CipherSuites supported by WebSphere MQ" on page 429 contains a table mapping the CipherSpecs supported by WebSphere MQ to their equivalent CipherSuites as known to JSSE. Additionally, the named CipherSuite must be supported by your JSSE provider. For more information about CipherSpecs and CipherSuites with WebSphere MQ, see the *WebSphere MQ Security* book.

For example, to set a QueueConnectionFactory to connect to an SSL-enabled SVRCONN channel using a CipherSpec of RC4_MD5_EXPORT, issue the following command to JMSAdmin:

```
ALTER QCF(my.qcf) SSLCIPHERSUITE(SSL_RSA_EXPORT_WITH_RC4_40_MD5)
```

This can also be set from a program, using the setSSLCipherSuite() method on MQConnectionFactory.

For convenience, if a CipherSpec is specified on the SSLCIPHERSUITE property, JMSAdmin attempts to map the CipherSpec to an appropriate CipherSuite and issues a warning. This attempt to map is not made if the property is specified by a program.

SSLPEERNAME object property

A JMS application can ensure that it has connected to the correct queue manager, by specifying a distinguished name (DN) pattern. The connection succeeds only if the queue manager presents a DN that matches the pattern. For more details of the format of this pattern, refer to *WebSphere MQ Security* or the *WebSphere MQ Script (MQSC) Command Reference*.

Using SSL

The DN is set using the `SSLPEERNAME` property of `ConnectionFactory`. For example, the following `JMSAdmin` command sets the `ConnectionFactory` to expect the queue manager to identify itself with a Common Name beginning `QMGR.` with at least two Organizational Unit names, the first of which must be `IBM` and the second `WEBSHERE`:

```
ALTER QCF(my.qcf) SSLPEERNAME(CN=QMGR.*, OU=IBM, OU=WEBSHERE)
```

Checking is case-insensitive, and semicolons can be used in place of the commas. This can also be set from a program, using the `setSSLPeerName()` method on `MQConnectionFactory`. If this property is not set, no checking is performed on the Distinguished Name supplied by the queue manager. This property is ignored if no `CipherSuite` is set.

SSLCERTSTORES object property

It is common to use a certificate revocation list (CRL) to manage revocation of certificates that have become untrusted. These are typically hosted on LDAP servers; JMS allows an LDAP server to be specified for CRL checking under Java 2 v1.4 or later. The following `JMSAdmin` example directs JMS to use a CRL hosted on an LDAP server named `cr11.ibm.com`:

```
ALTER QCF(my.qcf) SSLCRL(ldap://cr11.ibm.com)
```

Note: To use a `CertStore` successfully with a CRL hosted on an LDAP server, make sure that your Java Software Development Kit (SDK) is compatible with the CRL. Some SDKs require that the CRL conforms to RFC 2587, which defines a schema for LDAP v2. Most LDAP v3 servers use RFC 2256 instead.

If your LDAP server is not running on the default port of 389, the port can be specified by appending a colon and the port number to the host name. If the certificate presented by the queue manager is present in the CRL hosted on `cr11.ibm.com`, the connection does not complete. To avoid single-point-of-failure, JMS allows multiple LDAP servers to be supplied, by supplying a space-delimited list of LDAP servers. For example:

```
ALTER QCF(my.qcf) SSLCRL(ldap://cr11.ibm.com ldap://cr12.ibm.com)
```

When multiple LDAP servers are specified, JMS tries each one in turn until it finds a server with which it can successfully verify the queue manager's certificate. Each server must contain identical information.

A string of this format can be supplied by a program on the `MQConnectionFactory.setSSLCertStores()` method. Alternatively, the application can create one or more `java.security.cert.CertStore` objects, place these in a suitable `Collection` object, and supply this `Collection` to the `setSSLCertStores()` method. In this way, the application can customize CRL checking. Refer to your JSSE documentation for details on constructing and using `CertStore` objects.

The certificate presented by the queue manager when a connection is being set up is validated as follows:

1. The first `CertStore` object in the `Collection` identified by `sslCertStores` is used to identify a CRL server.
2. An attempt is made to contact the CRL server.
3. If the attempt is successful, the server is searched for a match for the certificate.
 - a. If the certificate is found to be revoked, the search process is over and the connection request fails with reason code `MQRC_SSL_CERTIFICATE_REVOKED`.

- b. If the certificate is not found, the search process is over and the connection is allowed to proceed.
- 4. If the attempt to contact the server is unsuccessful, the next CertStore object is used to identify a CRL server and the process repeats from step 2.
If this was the last CertStore in the Collection, or if the Collection contains no CertStore objects, the search process has failed and the connection request fails with reason code MQRC_SSL_CERT_STORE_ERROR.

The Collection object determines the order in which CertStores are used.

If your application uses `setSSLCertStores()` to set a Collection of CertStore objects, the `MQConnectionFactory` can no longer be bound into a JNDI namespace. Attempting to do so causes an exception. If the `sslCertStores` property is not set, no revocation checking is performed on the certificate provided by the queue manager. This property is ignored if no Ciphersuite is set.

SSLSocketFactory object property

You might want to customize other aspects of the SSL connection for an application. For example, you might want to initialize cryptographic hardware or change the KeyStore and TrustStore in use. To do this, the application must first create a `javax.net.ssl.SSLSocketFactory` instance customized accordingly. Refer to your JSSE documentation for information on how to do this, as the customizable features vary from provider to provider. Once a suitable `SSLSocketFactory` has been obtained, use the `MQConnectionFactory.setSSLSocketFactory()` method to configure JMS to use the customized `SSLSocketFactory`.

If your application uses `setSSLSocketFactory()` to set a customized `SSLSocketFactory`, the `MQConnectionFactory` can no longer be bound into a JNDI namespace. Attempting to do so causes an exception. If this property is not set, the default `SSLSocketFactory` is used; refer to your JSSE documentation for details on the behavior of the default `SSLSocketFactory`. This property is ignored if no Ciphersuite is set.

Important: Do not assume that use of the SSL properties ensures security when the `ConnectionFactory` is retrieved from a JNDI namespace that is not itself secure. Specifically, the standard LDAP implementation of JNDI is not secure; an attacker can imitate the LDAP server, misleading a JMS application into connecting to the wrong server without noticing. With suitable security arrangements in place, other implementations of JNDI (such as the `fscontext` implementation) are secure.

Using SSL

Chapter 11. Programming publish/subscribe applications

You can write applications with WebSphere MQ JMS using two programming models:

- Point-to-point
- Publish/subscribe

This section considers publish/subscribe and how publish/subscribe messaging is implemented in WebSphere MQ JMS.

Introduction

With publish/subscribe messaging, one message producer can send messages to many message consumers at one time. The message producer need know nothing about the consumers receiving its messages, it needs to know only about the common destination. Similarly, the message consumers need to know only about the common destination. This common destination is called a *topic*.

A message producer that sends messages to a topic is a *publisher* and a message consumer that receives messages from a topic is a *subscriber*.

A message consumer receives messages on all topics to which it has subscribed. To receive messages from a topic, a message consumer must first subscribe to that topic. All messages sent to a topic are forwarded to all the message consumers subscribed to that topic at that time. Each consumer receives its own copy of each message.

JMS clients can establish durable subscriptions that allow consumers to disconnect and later reconnect and collect messages published while they were disconnected.

The connection between messages issued by publishers and the subscribers is made, in WebSphere MQ, by the publish/subscribe *broker*. The broker (sometimes referred to as the message broker) has a record of all the subscribers registered to a topic. When a message is published to a topic, the broker manages the forwarding of that message to the topic's subscribers.

To run a WebSphere MQ JMS publish/subscribe application, you must be able to connect to a message broker.

Getting started with WebSphere MQ JMS and publish/subscribe

Before you can start developing publish/subscribe applications, you need to choose the broker to use and set that broker up to run the WebSphere MQ JMS.

Choosing a broker

WebSphere MQ offers a choice of three brokers:

- The MQSeries Publish/Subscribe broker uses WebSphere MQ and a SupportPac.

The SupportPac MA0C is available for download from:

<http://www.ibm.com/software/ts/mqseries/txppacs>

Getting started with publish/subscribe

If you want to use the broker-based subscription store, you must use WebSphere MQ with the MQSeries Publish/Subscribe broker. No other combination of queue manager and broker supports this store.

- WebSphere MQ Integrator provides a broker that can be run in one of two modes. Compatibility mode, which provides a broker of equivalent functionality to the MQSeries Publish/Subscribe broker; and native mode, which provides additional functionality. WebSphere MQ JMS can connect to WebSphere MQ Integrator in native mode with JMS Version 5.2.1 and later. With earlier JMS versions, it can connect to WebSphere MQ Integrator in compatibility mode only.
- WebSphere MQ Event Broker provides a broker that can be connected to in two different ways:

Using message queues and WebSphere MQ

With this connection, you can run the broker in either compatibility mode or native mode.

Directly using a TCP/IP socket

With this connection, you can run the broker only in native mode. Also there is no support for:

- Persistent messages
- Transacted messages
- Durable subscriptions

This has implications for the implementation of the JMS specification for direct connections to the WebSphere MQ Event Broker:

- Because there are no persistent messages, `JMSDeliveryMode` is always `NON_PERSISTENT` and `JMSExpiration` has no meaning on messages received on direct connections.
- Because there are no transacted messages, `JMSRedelivered` has no meaning on messages received on direct connections.

Refer to Chapter 14, “JMS interfaces and classes” on page 265 for specific information on each publish and subscribe interface.

Setting up the broker to run the WebSphere MQ JMS

Broker setup depends on the broker you intend to use and how you intend to use it. Each broker provides its own documentation describing installation and setup. However, for convenience and because of WebSphere MQ JMS requirements, some setup instructions are given here.

Connecting to your broker using WebSphere MQ

This section applies to the MQSeries Publish/Subscribe broker and the broker in WebSphere MQ Integrator. It also applies to the WebSphere MQ Event Broker when you choose to connect to it using WebSphere MQ.

Each broker requires its own queue manager. Refer to the broker’s documentation regarding installation and setup.

For the WebSphere MQ JMS publish/subscribe implementation to work correctly, a number of system queues must be created on the queue manager on which the broker is running. Create these message queues on each queue manager for each broker you want to run WebSphere MQ JMS. WebSphere MQ JMS provides a script that creates these queues (see “Create the WebSphere MQ JMS system queues” on page 27).

Getting started with publish/subscribe

Run the script to create the system queues. If you are using the MQSeries Publish/Subscribe broker, your broker is now fully configured. To check that the broker is correctly configured, run the publish/subscribe verification as described in "Publish/subscribe verification without JNDI" on page 35.

If you are using the broker provided by WebSphere MQ Integrator or WebSphere MQ Event Broker, configure a publish/subscribe message flow in the broker for messages to be correctly routed. The method for creating the required message flow is similar in both cases. Refer to Appendix D, "Connecting with other products" on page 413 for details.

Connecting to your broker directly

This is only possible when you use the broker provided in WebSphere MQ Event Broker. Because the connection to this broker is made directly, no system queues are required. However, you must set up a publish/subscribe message flow in the broker for messages to be correctly routed. Refer to Appendix D, "Connecting with other products" on page 413 for details.

Writing a simple publish/subscribe application connecting through WebSphere MQ

This section provides a walkthrough of a simple WebSphere MQ JMS application.

Here is the complete example. Individual sections are discussed after.

```
/**
 * Basic pub/sub example
 *
 * A TopicConnectionFactory object is retrieved from LDAP; this is used
 * to create a TopicConnection. The TopicConnection is used to create
 * a TopicSession, which creates two publishers and two subscribers.
 * Both publishers subscribe to a topic; both subscribers then receive.
 */

import javax.jms.*;           // JMS interfaces
import javax.naming.*;       // Used for JNDI lookup of
import javax.naming.directory.*; // administered objects

import java.io.*;            // Java IO classes
import java.util.*;          // Java Util classes

class PubSubSample {

    // using LDAP
    String icf = "com.sun.jndi.ldap.LdapCtxFactory"; // initial context factory
    String url = "ldap://server.company.com/o=company_us,c=us"; //url

    private String tcfLookup = "cn=testTCF"; // TopicConnectionFactory (TCF) lookup
    private String tLookup = "cn=testT"; // topic lookup

    // Pub/Sub objects used by this program
    private TopicConnectionFactory fact = null;
    private Topic topic = null;

    public static void main(String args[])
    {
        // Initialise JNDI properties
        Hashtable env = new Hashtable();
        env.put( Context.INITIAL_CONTEXT_FACTORY, icf );
        env.put( Context.PROVIDER_URL, url );
        env.put( Context.REFERRAL, "throw" );

        Context ctx = null;
    }
}
```

Writing publish/subscribe application

```
try {
    System.out.print( "Initialising JNDI... " );
    ctx = new InitialDirContext( env );
    System.out.println( "Done!" );
} catch ( NamingException nx ) {
    System.out.println( "ERROR: " + nx );
    System.exit(-1);
}

// Lookup TCF
try {
    System.out.print( "Obtaining TCF from JNDI... " );
    fact = (TopicConnectionFactory)ctx.lookup( tcfLookup );
    System.out.println( "Done!" );
} catch ( NamingException nx ) {
    System.out.println( "ERROR: " + nx );
    System.exit(-1);
}

// Lookup Topic
try {
    System.out.print( "Obtaining topic T from JNDI... " );
    topic = (Topic)ctx.lookup( tLookup );
    System.out.println( "Done!" );
} catch ( NamingException nx ) {
    System.out.println( "ERROR: " + nx );
    System.exit(-1);
}

try {
    ctx.close();
} catch ( NamingException nx ) {
    // Just ignore an exception on closing the context
}

try {
    // Create connection
    TopicConnection conn = fact.createTopicConnection();
    // Start connection
    conn.start();

    // Session
    TopicSession sess = conn.createTopicSession(false,
        Session.AUTO_ACKNOWLEDGE);

    // Create a topic dynamically
    Topic t = sess.createTopic("myTopic");

    // Publisher
    TopicPublisher pub = sess.createPublisher(t);
    // Subscriber
    TopicSubscriber sub = sess.createSubscriber(t);
    // Publisher
    TopicPublisher pubA = sess.createPublisher(topic);
    // Subscriber
    TopicSubscriber subA = sess.createSubscriber(topic);

    // Publish "Hello World"
    TextMessage hello = sess.createTextMessage();
    hello.setText("Hello World");
    pub.publish(hello);
    hello.setText("Hello World 2");
    pubA.publish(hello);

    // Receive message
    TextMessage m = (TextMessage) sub.receive();
```

Writing publish/subscribe application

```
System.out.println("Message Text = " + m.getText());
m = (TextMessage) subA.receive();
System.out.println("Message Text = " + m.getText());

// Close publishers and subscribers
pub.close();
pubA.close();
sub.close();
subA.close();

// Close session and connection
sess.close();
conn.close();

System.exit(0);
}

catch ( JMSEException je ) {
    System.out.println("ERROR: " + je);
    System.out.println("LinkedException: " +
        je.getLinkedException());
    System.exit(-1);
}
}
```

Import required packages

The import statements for an application using WebSphere MQ classes for Java Message Service must include at least the following:

```
import javax.jms.*;           // JMS interfaces
import javax.naming.*;       // Used for JNDI lookup of
import javax.naming.directory.*; // administered objects
```

Obtain or create JMS objects

The next step is to obtain or create a number of JMS objects:

1. Obtain a TopicConnectionFactory
2. Create a TopicConnection
3. Create a TopicSession
4. Obtain a Topic from JNDI
5. Create TopicPublishers and TopicSubscribers

Many of these processes are similar to those that are used for point-to-point, as shown in the following:

Obtain a TopicConnectionFactory

The preferred way to do this is to use JNDI lookup, to maintain portability of the application code. The following code initializes a JNDI context:

```
String icf = "com.sun.jndi.ldap.LdapCtxFactory"; // initial context factory
String url = "ldap://server.company.com/o=company_us,c=us"; // url

// Initialise JNDI properties
Java.util.Hashtable env = new Hashtable();
env.put( Context.INITIAL_CONTEXT_FACTORY, icf );
env.put( Context.PROVIDER_URL, url );
env.put( Context.REFERRAL, "throw" );

Context ctx = null;
try {
    System.out.print( "Initialising JNDI... " );
    ctx = new InitialDirContext( env );
}
```

Writing publish/subscribe application

```
        System.out.println( "Done!" );
    } catch ( NamingException nx ) {
        System.out.println( "ERROR: " + nx );
        System.exit(-1);
    }
}
```

Note: Change the `icf` and `url` variables to suit your installation and your JNDI service provider.

The properties required by JNDI initialization are in a `Hashtable`, which is passed to the `InitialDirContext` constructor. If this connection fails, an exception is thrown to indicate that the administered objects required later in the application are not available.

Obtain a `TopicConnectionFactory` using a lookup key that the administrator has defined:

```
// LOOKUP TCF
try {
    System.out.print( "Obtaining TCF from JNDI... " );
    fact = (TopicConnectionFactory)ctx.lookup( tcfLookup );
    System.out.println( "Done!" );
} catch ( NamingException nx ) {
    System.out.println( "ERROR: " + nx );
    System.exit(-1);
}
```

If a JNDI namespace is not available, you can create a `TopicConnectionFactory` at runtime. You create a new `com.ibm.mq.jms.MQTopicConnectionFactory` as described in “Creating factories at runtime” on page 193.

Create a TopicConnection

This is created from the `TopicConnectionFactory` object. Connections are always initialized in a stop state and must be started with the following code:

```
// create connection
TopicConnection conn = fact.createTopicConnection();
//start connection
conn.start();
```

Create a TopicSession

This is created using the `TopicConnection`. This method takes two parameters: one to signify whether the session is transacted, and one to specify the acknowledgement mode:

```
TopicSession sess = conn.createTopicSession(false,
                                             Session.AUTO_ACKNOWLEDGE);
```

Obtain a Topic

This object can be obtained from JNDI, for use with `TopicPublishers` and `TopicSubscribers` that are created later. The following code retrieves a `Topic`:

```
Topic topic = null;
try {
    System.out.print( "Obtaining topic T from JNDI... " );
    topic = (Topic)ctx.lookup( tLookup );
    System.out.println( "Done!" );
}
catch ( NamingException nx ) {
    System.out.println( "ERROR: " + nx );
    System.exit(-1);
}
```

Writing publish/subscribe application

If a JNDI namespace is not available, you can create a Topic at runtime, as described in “Creating topics at runtime” on page 214.

The following code creates a Topic at runtime:

```
// topic
Topic t = sess.createTopic("myTopic");
```

Create consumers and producers of publications

Depending on the nature of the JMS client application that you write, a subscriber, a publisher, or both must be created. Use the `createPublisher` and `createSubscriber` methods as follows:

```
// publisher
TopicPublisher pub = sess.createPublisher(t);
// subscriber
TopicSubscriber sub = sess.createSubscriber(t);
// publisher
TopicPublisher pubA = sess.createPublisher(topic);
// subscriber
TopicSubscriber subA = sess.createSubscriber(topic);
```

Publish messages

The `TopicPublisher` object, `pub`, is used to publish messages, rather like a `QueueSender` is used in the point-to-point domain. The following fragment creates a `TextMessage` using the session, and then publishes the message:

```
// publish "hello world"
TextMessage hello = sess.createTextMessage();
hello.setText("Hello World");
pub.publish(hello);
hello.setText("Hello World 2");
pubA.publish(hello);
```

Receive subscriptions

Subscribers must be able to read the subscriptions that are delivered to them, as in the following code:

```
// receive message
TextMessage m = (TextMessage) sub.receive();
System.out.println("Message Text = " + m.getText());
m = (TextMessage) subA.receive();
System.out.println("Message Text = " + m.getText());
```

This fragment of code performs a *get-with-wait*, which means that the receive call blocks until a message is available. Alternative versions of the receive call are available (such as `receiveNoWait`). For details, see “`TopicSubscriber`” on page 386.

Close down unwanted resources

It is important to free up all the resources used by the application when it terminates. Use the `close()` method on objects that can be closed (publishers, subscribers, sessions, and connections):

```
// close publishers and subscribers
pub.close();
pubA.close();
sub.close();
subA.close();
sess.close();

// close session and connection
sess.close();
conn.close();
```

Writing publish/subscribe application

TopicConnectionFactory administered objects

In the example, the TopicConnectionFactory object is obtained from JNDI name space. The TopicConnectionFactory in this case is an administered object that has been created and administered using the JMSAdmin tool. Use this method of obtaining TopicConnectionFactory objects because it ensures code portability.

The TopicConnectionFactory in the example is testTCF in JMSAdmin. Create testTCF in JMSAdmin **before** running the application. You must also create a Topic in JMSAdmin; see “Topic administered objects”.

To create a TopicConnectionFactory object, invoke the JMSAdmin tool, as described in “Invoking the administration tool” on page 41, and execute one of the following commands, depending on the type of connection you want to make to the broker:

Bindings connection

```
InitCtx> def tcf(testTCF) transport(bind)
```

or, because this is the default transport type for TopicConnectionFactory objects:

```
InitCtx> def tcf(testTCF)
```

This creates a TopicConnectionFactory with default settings for bindings transport, connecting to the default queue manager.

Client connection

```
InitCtx> def tcf(testTCF) transport(client)
```

This creates a TopicConnectionFactory with default settings for the client transport type, connecting to localhost, on port 1414, using channel SYSTEM.DEF.SVRCONN.

Direct TCP/IP connection to WebSphere MQ Event Broker

```
InitCtx> def tcf(testTCF) transport(direct)
```

This creates a TopicConnectionFactory to make direct connections to a WebSphere MQ Event Broker, connecting to localhost on port 1506.

Topic administered objects

In the example, one of the Topic objects has been obtained from JNDI name space. This Topic is an administered object that has been created and administered in the JMSAdmin tool. Use this method of obtaining Topic objects because it ensures code portability.

To run the example application above, create the Topic called testT in JMSAdmin **before** running the application.

To create a Topic object, invoke the JMSAdmin tool, as described in “Invoking the administration tool” on page 41, and execute one of the following commands, depending on the type of connection you want to make to the broker:

Compatibility mode, or MQSeries Publish/Subscribe (SupportPac MA0C)

```
InitCtx> def t(testT) bver(V1) topic(test/topic)
```

Native mode, or direct to WebSphere MQ Event Broker

```
InitCtx> def t(testT) bver(V2) topic(test/topic)
```

Using topics

This section discusses the use of JMS Topic objects in WebSphere MQ classes for Java Message Service applications.

Topic names

This section describes the use of topic names within WebSphere MQ classes for Java Message Service.

Note: The JMS specification does not specify exact details about the use and maintenance of topic hierarchies. Therefore, this area can vary from one provider to the next.

Topic names in WebSphere MQ JMS are arranged in a tree-like hierarchy, an example of which is shown in Figure 3.

Figure 3. WebSphere MQ classes for Java Message Service topic name hierarchy

In a topic name, levels in the tree are separated by the / character. This means that the Signings node in Figure 3 is identified by the topic name:

Sport/Football/Spurs/Signings

A powerful feature of the topic system in WebSphere MQ classes for Java Message Service is the use of wildcards. These allow subscribers to subscribe to more than one topic at a time. Different brokers use different wildcard characters and different rules for their substitution. Use the broker version property of the topic (BROKERVER) to define which type of wildcards apply.

Note: The broker version of a topic must match the broker version of the topic connection factory you are using.

Broker Version 1 wildcards

The * wildcard matches zero or more characters; the ? wildcard matches a single character.

If a subscriber subscribes to the topic represented by the following topic name:

Sport/Football/*/Results

it receives publications on topics including:

- Sport/Football/Spurs/Results

Using topics

- Sport/Football/Arsenal/Results

If the subscription topic is:

Sport/Football/Spurs/*

it receives publications on topics including:

- Sport/Football/Spurs/Results
- Sport/Football/Spurs/Signings

If the subscription topic is:

Sport/Football/*

it receives publications on topics including:

- Sport/Football/Arsenal/Results
- Sport/Football/Spurs/Results
- Sport/Football/Spurs/Signings

Broker Version 2 wildcards

The # wildcard matches multiple levels in a topic; the + wildcard matches a single level.

These wildcards can be used only to stand for complete levels within a topic; that is they can be preceded only by / or start-of-string, and they can be followed only by / or end-of-string.

If a subscriber subscribes to the topic represented by the following topic name:

Sport/Football+/Results

it receives publications on topics including:

- Sport/Football/Spurs/Results
- Sport/Football/Arsenal/Results

If a subscriber subscribes to the topic represented by the following topic name:

Sport/#/Results

it receives publications on topics including:

- Sport/Football/Spurs/Results
- Sport/Football/Arsenal/Results

Although Sport/Football/Spur*/Results works with broker Version 1, there is no equivalent for broker Version 2, which does not support single character substitutions.

There is no need to administer the topic hierarchies that you use on the broker-side of your system explicitly. When the first publisher or subscriber on a given topic comes into existence, the broker automatically creates the state of the topics currently being published on, and subscribed to.

Note: A publisher cannot publish on a topic whose name contains wildcards.

Creating topics at runtime

There are four ways to create Topic objects at runtime:

1. Construct a topic using the one-argument `MQTopic` constructor

2. Construct a topic using the default `MQTopic` constructor, and then call the `setBaseTopicName(..)` method
3. Use the session's `createTopic(..)` method
4. Use the session's `createTemporaryTopic()` method

Method 1: Using `MQTopic(..)`

This method requires a reference to the WebSphere MQ implementation of the JMS Topic interface, and therefore renders the code non-portable.

The constructor takes one argument, which must be a uniform resource identifier (URI). For WebSphere MQ classes for Java Message Service Topics, this must be of the form:

```
topic://TopicName[?property=value[&property=value]*]
```

For further details on URIs and the permitted name-value pairs, see "Sending a message" on page 195.

The following code creates a topic for non-persistent, priority 5 messages:

```
// Create a Topic using the one-argument MQTopic constructor
String tSpec = "Sport/Football/Spurs/Results?persistence=1&priority=5";
Topic rtTopic = new MQTopic( "topic://" + tSpec );
```

Method 2: Using `MQTopic()`, then `setBaseTopicName(..)`

This method uses the default `MQTopic` constructor, and therefore renders the code non-portable.

After the object is created, set the `baseTopicName` property using the `setBaseTopicName` method, passing in the required topic name.

Note: The topic name used here is the non-URI form, and cannot include name-value pairs. Set these by using the set methods, as described in "Setting properties with the set method" on page 197. The following code uses this method to create a topic:

```
// Create a Topic using the default MQTopic constructor
Topic rtTopic = new MQTopic();

// Set the object properties using the setter methods
((MQTopic)rtTopic).setBaseTopicName( "Sport/Football/Spurs/Results" );
((MQTopic)rtTopic).setPersistence(1);
((MQTopic)rtTopic).setPriority(5);
```

Method 3: Using `session.createTopic(..)`

You can also create a Topic object using the `createTopic` method of `TopicSession`, which takes a topic URI as follows:

```
// Create a Topic using the session factory method
Topic rtTopic = session.createTopic( "topic://Sport/Football/Spurs/Results" );
```

Although the `createTopic` method is in the JMS specification, the format of the string argument is vendor-specific. Therefore, using this method might make your code non-portable.

Method 4: Using `session.createTemporaryTopic()`

A `TemporaryTopic` is a Topic that can be consumed only by subscribers that are created by the same `TopicConnection`. A `TemporaryTopic` is created as follows:

```
// Create a TemporaryTopic using the session factory method
Topic rtTopic = session.createTemporaryTopic();
```

Subscriber options

There are a number of different ways to use JMS subscribers. This section describes some examples of their use.

JMS provides two types of subscribers:

Non-durable subscribers

These subscribers receive messages on their chosen topic, only if the messages are published while the subscriber is active.

Durable subscribers

These subscribers receive all the messages published on a topic, including those that are published while the subscriber is inactive.

Creating non-durable subscribers

The subscriber created in “Create consumers and producers of publications” on page 210 is non-durable and is created with the following code:

```
// Create a subscriber, subscribing on the given topic
TopicSubscriber sub = session.createSubscriber( topic );
```

Creating durable subscribers

Durable subscribers cannot be configured with a direct connection to WebSphere MQ Event Broker.

Creating a durable subscriber is very similar to creating a non-durable subscriber, but you must also provide a name that uniquely identifies the subscriber:

```
// Create a durable subscriber, supplying a uniquely-identifying name
TopicSubscriber sub = session.createDurableSubscriber( topic, "D_SUB_000001" );
```

Non-durable subscribers automatically deregister themselves when their `close()` method is called (or when they fall out of scope). However, if you want to terminate a durable subscription, you must explicitly notify the system. To do this, use the session’s `unsubscribe()` method and pass in the unique name that created the subscriber:

```
// Unsubscribe the durable subscriber created above
session.unsubscribe( "D_SUB_000001" );
```

A durable subscriber is created at the queue manager specified in the `MQTopicConnectionFactory` queue manager parameter. If there is a subsequent attempt to create a durable subscriber with the same name at a different queue manager, a new and completely independent durable subscriber is returned.

Using message selectors

You can use message selectors to filter out messages that do not satisfy given criteria. For details about message selectors, see “Message selectors” on page 199. Message selectors are associated with a subscriber as follows:

```
// Associate a message selector with a non-durable subscriber
String selector = "company = 'IBM'";
TopicSubscriber sub = session.createSubscriber( topic, selector, false );
```

Suppressing local publications

You can create a subscriber that ignores publications that are published on the subscriber’s own connection. Set the third parameter of the `createSubscriber` call to true, as follows:

```
// Create a non-durable subscriber with the noLocal option set
TopicSubscriber sub = session.createSubscriber( topic, null, true );
```

Combining the subscriber options

You can combine the subscriber variations, so that you can create a durable subscriber that applies a selector and ignores local publications. The following code fragment shows the use of the combined options:

```
// Create a durable, noLocal subscriber with a selector applied
String selector = "company = 'IBM'";
TopicSubscriber sub = session.createDurableSubscriber( topic, "D_SUB_000001",
                                                    selector, true );
```

Configuring the base subscriber queue

Subscriber queues cannot be configured for a direct connection to WebSphere MQ Event Broker.

There are two ways in which you can configure subscribers:

- Multiple queue approach
Each subscriber has an exclusive queue assigned to it, from which it retrieves all its messages. JMS creates a new queue for each subscriber. This is the only approach available with WebSphere MQ JMS V1.1.
- Shared queue approach
A subscriber uses a shared queue, from which it, and other subscribers, retrieve their messages. This approach requires only one queue to serve multiple subscribers. This is the default approach used with WebSphere MQ JMS.

You can choose which approach to use, and configure which queues to use.

In general, the shared queue approach gives a modest performance advantage. For systems with a high throughput, there are also large architectural and administrative advantages, because of the significant reduction in the number of queues required.

In some situations, there are still good reasons for using the multiple queue approach:

- The theoretical physical capacity for message storage is greater.
A WebSphere MQ queue cannot hold more than 640000 messages, and in the shared queue approach, this must be divided between all the subscribers that share the queue. This issue is more significant for durable subscribers, because the lifetime of a durable subscriber is usually much longer than that of a non-durable subscriber. Therefore, more messages might accumulate for a durable subscriber.
- External administration of subscription queues is easier.
For certain application types, administrators might want to monitor the state and depth of particular subscriber queues. This task is much simpler when there is one to one mapping between a subscriber and a queue.

Default configuration

The default configuration uses the following shared subscription queues:

- SYSTEM.JMS.ND.SUBSCRIBER.QUEUE for non-durable subscriptions
- SYSTEM.JMS.D.SUBSCRIBER.QUEUE for durable subscriptions

These are created for you when you run the MQJMS_PSQ.MQSC script.

Subscriber options

If required, you can specify alternative physical queues. You can also change the configuration to use the multiple queue approach.

Configuring non-durable subscribers

You can set the non-durable subscriber queue name property in either of the following ways:

- Use the WebSphere MQ JMS administration tool (for JNDI retrieved objects) to set the BROKERSUBQ property
- Use the `setBrokerSubQueue()` method in your program

For non-durable subscriptions, the queue name you provide should start with the following characters:

```
SYSTEM.JMS.ND.
```

To select a shared queue approach, specify an explicit queue name, where the named queue is the one to use for the shared queue. The queue that you specify must already physically exist before you create the subscription.

To select the multiple queue approach, specify a queue name that ends with the `*` character. Subsequently, each subscriber that is created with this queue name creates an appropriate dynamic queue, for exclusive use by that particular subscriber. MQ JMS uses its own internal model queue to create such queues. Therefore, with the multiple queue approach, all required queues are created dynamically.

When you use the multiple queue approach, you cannot specify an explicit queue name. However, you can specify the queue prefix. This enables you to create different subscriber queue domains. For example, you could use:

```
SYSTEM.JMS.ND.MYDOMAIN.*
```

The characters that precede the `*` character are used as the prefix, so that all dynamic queues that are associated with this subscription have queue names that start with `SYSTEM.JMS.ND.MYDOMAIN`.

Configuring durable subscribers

As discussed earlier, there might still be good reasons to use the multiple queue approach for durable subscriptions. Durable subscriptions are likely to have a longer life span, so it is possible that a large number of unretrieved messages could accumulate on the queue.

Therefore, the durable subscriber queue name property is set in the Topic object (that is, at a more manageable level than `TopicConnectionFactory`). This enables you to specify a number of different subscriber queue names, without needing to re-create multiple objects starting from the `TopicConnectionFactory`.

You can set the durable subscriber queue name in either of the following ways:

- Use the WebSphere MQ JMS administration tool (for JNDI retrieved objects) to set the BROKERDURSUBQ property
- Use the `setBrokerDurSubQueue()` method in your program:

```
// Set the MQTopic durable subscriber queue name using
// the multi-queue approach
sportsTopic.setBrokerDurSubQueue("SYSTEM.JMS.D.FOOTBALL.*");
```

Once the Topic object is initialized, it is passed into the `TopicSession.createDurableSubscriber()` method to create the specified subscription:

Subscriber options

```
// Create a durable subscriber using our earlier Topic
TopicSubscriber sub = new session.createDurableSubscriber
    (sportsTopic, "D_SUB_SPORT_001");
```

For durable subscriptions, the queue name you provide must start with the following characters:

```
SYSTEM.JMS.D.
```

To select a shared queue approach, specify an explicit queue name, where the named queue is the one to use for the shared queue. The queue that you specify must already physically exist before you create the subscription.

To select the multiple queue approach, specify a queue name that ends with the * character. Subsequently, each subscriber that is created with this queue name creates an appropriate dynamic queue, for exclusive use by that subscriber. MQ JMS uses its own internal model queue to create such queues. Therefore, with the multiple queue approach, all required queues are created dynamically.

When you use the multiple queue approach, you cannot specify an explicit queue name. However, you can specify the queue prefix. This enables you to create different subscriber queue domains. For example, you could use:

```
SYSTEM.JMS.D.MYDOMAIN.*
```

The characters that precede the * character are used as the prefix, so that all dynamic queues that are associated with this subscription have queue names that start with SYSTEM.JMS.D.MYDOMAIN.

You cannot change the queue used by a durable subscriber. To do so, for example to move from the multiple queue approach to the single queue approach, first delete the old subscriber (using the unsubscribe() method) and create the subscription again from new. This removes any unconsumed messages on the durable subscription.

Subscription stores

There is no subscription store with a direct connection to WebSphere MQ Event Broker.

WebSphere MQ JMS maintains a persistent store of subscription information, used to resume durable subscriptions and cleanup after failed non-durable subscribers. This information can be managed by the publish/subscribe broker.

See the README provided with WebSphere MQ JMS for information about suitable levels of queue manager and broker.

The choice of subscription store is based on the SUBSTORE property of the TopicConnectionFactory. This takes one of three values: QUEUE, BROKER, or MIGRATE.

SUBSTORE(QUEUE)

Subscription information is stored on SYSTEM.JMS.ADMIN.QUEUE and SYSTEM.JMS.PS.STATUS.QUEUE on the local queue manager.

WebSphere MQ JMS maintains an extra connection for a long-running transaction used to detect failed subscribers. There is a connection to each

Subscriber options

queue manager in use. In a busy system, this might cause the queue manager logs to fill up, resulting in errors from both the queue manager and its applications.

If you experience these problems, the system administrator can add extra log files or datasets to the queue manager. Alternatively, reduce the `STATREFRESHINT` property on the `TopicConnectionFactory`. This causes the long-running transaction to be refreshed more frequently, allowing the logs to reset themselves.

After a non-durable subscriber has failed:

- Information is left on the two `SYSTEM.JMS` queues, which allows a later JMS application to clean up after the failed subscriber. See “Subscriber cleanup utility” on page 222 for more information.
- Messages continue to be delivered to the subscriber until a later JMS application is executed.

`SUBSTORE(Queue)` is provided for compatibility with versions of MQSeries JMS.

SUBSTORE(BROKER)

Subscription information is stored by the publish/subscribe broker used by the application. This option requires recent levels of queue manager and publish/subscribe broker. See the README provided with WebSphere MQ JMS for information about suitable levels of queue manager and broker. This subscription store requires recent levels of both queue manager and publish/subscribe broker. It is designed to provide improved resilience.

When a non-durable subscriber fails, the subscription is deregistered from the broker as soon as possible. The broker adds a response to this deregistration onto the `SYSTEM.JMS.REPORT.QUEUE`, which is used to clean up after the failed subscriber. With `SUBSTORE(BROKER)`, a separate cleanup thread is run regularly in the background of each JMS publish/subscribe application.

Cleanup is run once every 10 minutes by default, but you can change this using the `CLEANUPINT` property on the `TopicConnectionFactory`. To customize the actions performed by cleanup, use the `CLEANUP` property on the `TopicConnectionFactory`.

See “Subscriber cleanup utility” on page 222 for more information about the different behaviors of cleanup with `SUBSTORE(BROKER)`.

SUBSTORE(MIGRATE)

`MIGRATE` is the default value for `SUBSTORE`.

This option dynamically selects the queue-based or broker-based subscription store based on the levels of queue manager and publish/subscribe broker installed. If both queue manager and broker are capable of supporting `SUBSTORE(BROKER)`, this behaves as `SUBSTORE(BROKER)`; otherwise it behaves as `SUBSTORE(Queue)`. Additionally, `SUBSTORE(MIGRATE)` transfers durable subscription information from the queue-based subscription store to the broker-based store.

This provides an easy migration path from older versions of WebSphere MQ JMS, WebSphere MQ, and publish/subscribe broker. This migration occurs the first time the durable subscription is opened when both queue manager and broker are capable of supporting the broker-based

subscription store. Only information relating to the subscription being opened is migrated; information relating to other subscriptions is left in the queue-based subscription store.

Migration and coexistence considerations

Except when `SUBSTORE(MIGRATE)` is used, the two subscription stores are entirely independent.

A durable subscription is created in the store specified by the `TopicConnectionFactory`. If there is a subsequent attempt to create a durable subscriber with the same name and `ClientID` but with the other subscription store, a new durable subscription is created.

When a connection uses `SUBSTORE(MIGRATE)`, subscription information is automatically transferred from the queue-based subscription store to the broker-based subscription store when `createDurableSubscriber()` is called. If a durable subscription with matching name and `ClientID` already exists in the broker-based subscription store, this migration cannot complete and an exception is thrown from `createDurableSubscriber()`.

Once a subscription has been migrated, it is important not to access the subscription from an application using an older version of WebSphere MQ JMS, or an application running with `SUBSTORE(Queue)`. This would create a subscription in the queue-based subscription store, and prevent an application running with `SUBSTORE(MIGRATE)` from using the subscription.

To recover from this situation, either use `SUBSTORE(Broker)` from your application or unsubscribe from the subscription with `SUBSTORE(Queue)`.

For `SUBSTORE(Broker)` to function, or for `SUBSTORE(MIGRATE)` to use the broker-based subscription store, suitable versions of both queue manager and broker need to be available to WebSphere MQ JMS. Refer to the README for information regarding suitable levels.

Solving publish/subscribe problems

This section describes some problems that can occur when you develop JMS client applications that use the publish/subscribe domain. It discusses problems that are specific to the publish/subscribe domain. Refer to “Handling errors” on page 200 and “Solving problems” on page 38 for more general troubleshooting guidance.

Incomplete publish/subscribe close down

It is important that JMS client applications surrender all external resources when they terminate. To do this, call the `close()` method on all objects that can be closed once they are no longer required. For the publish/subscribe domain, these objects are:

- `TopicConnection`
- `TopicSession`
- `TopicPublisher`
- `TopicSubscriber`

The WebSphere MQ classes for Java Message Service implementation eases this task by using a *cascading close*. With this process, a call to `close` on a `TopicConnection` results in calls to `close` on each of the `TopicSessions` it created. This in turn results in calls to `close` on all `TopicSubscribers` and `TopicPublishers` the sessions created.

Publish/subscribe problems

To ensure the proper release of external resources, call `connection.close()` for each of the connections that an application creates.

There are some circumstances where this close procedure might not complete. These include:

- Loss of a WebSphere MQ client connection
- Unexpected application termination

In these circumstances, the `close()` is not called, and external resources remain open on the terminated application's behalf. The main consequences of this are:

Broker state inconsistency

The WebSphere MQ Message Broker might contain registration information for subscribers and publishers that no longer exist. This means that the broker might continue forwarding messages to subscribers that will never receive them.

Subscriber messages and queues remain

Part of the subscriber deregistration procedure is the removal of subscriber messages. If appropriate, the underlying WebSphere MQ queue that was used to receive subscriptions is also removed. If normal closure has not occurred, these messages and queues remain. If there is broker state inconsistency, the queues continue to fill up with messages that will never be read.

Additionally, if the broker resides on a queue manager other than the application's local queue manager, correct operation of WebSphere MQ JMS depends on the communication channels between the two queue managers. If these channels fail for any reason, problems such as the above can occur until the channels restart. When diagnosing problems relating to channels, be careful not to lose WebSphere MQ JMS control messages on the transmission queue.

Subscriber cleanup utility

To avoid the problems associated with non-graceful closure of subscriber objects, WebSphere MQ JMS includes a subscriber cleanup utility that attempts to detect any earlier WebSphere MQ JMS publish/subscribe problems that could have resulted from other applications. This utility runs transparently in the background and should not affect other WebSphere MQ JMS operations. If a large number of problems are detected against a given queue manager, you might see some performance degradation while resources are cleaned up.

Note: Close all subscriber objects gracefully whenever possible, to avoid a buildup of subscriber problems.

The exact behavior of the utility depends on the subscription store in use:

Subscriber cleanup with SUBSTORE(Queue)

When using the queue-based subscription store, cleanup runs on a queue manager when the first `TopicConnection` to use that physical queue manager initializes.

If all the `TopicConnections` on a given queue manager close, when the next `TopicConnection` initializes for that queue manager, the utility runs again.

The cleanup utility uses information found on the `SYSTEM.JMS.ADMIN.QUEUE` and `SYSTEM.JMS.PS.STATUS.QUEUE` to detect previously failed subscribers. If any are found, it cleans up

Publish/subscribe problems

associated resources by deregistering the subscriber from the broker, and cleaning up any unconsumed messages or temporary queues associated with the subscription.

Subscriber cleanup with SUBSTORE(BROKER)

With the broker-based subscription store, cleanup runs regularly on a background thread while there is an open `TopicConnection` to a particular physical queue manager. One instance of the cleanup thread is created for each physical queue manager to which a `TopicConnection` exists within the JVM.

The cleanup utility uses information found on the `SYSTEM.JMS.REPORT.QUEUE` (typically responses from the publish/subscribe broker) to remove unconsumed messages and temporary queues associated with a failed subscriber. It can be a few seconds after the subscriber fails before the cleanup routine can remove the messages and queues.

Two properties on the `TopicConnectionFactory` control behavior of this cleanup thread: `CLEANUP` and `CLEANUPINT`. `CLEANUPINT` determines how often (in milliseconds) cleanup is executed against any given queue manager. `CLEANUP` takes one of four possible values:

CLEANUP(SAFE)

This is the default value.

The cleanup thread tries to remove unconsumed subscription messages or temporary queues for failed subscriptions. This mode of cleanup does not interfere with the operation of other JMS applications.

CLEANUP(STRONG)

The cleanup thread performs as `CLEANUP(SAFE)`, but also clears the `SYSTEM.JMS.REPORT.QUEUE` of any unrecognized messages.

This mode of cleanup can interfere with the operation of JMS applications running with later versions of WebSphere MQ JMS. If multiple JMS applications are using the same queue manager, but using different versions of WebSphere MQ JMS, only clients using the most recent version of WebSphere MQ JMS must use this option.

CLEANUP(NONE)

In this special mode, no cleanup is performed, and no cleanup thread exists. Additionally, if the application is using the single-queue approach, unconsumed messages can be left on the queue.

This option can be useful if the application is distant from the queue manager, and especially if it only publishes rather than subscribes. However, one application must clean up the queue manager to deal with any unconsumed messages. This can be a JMS application with `CLEANUP(SAFE)` or `CLEANUP(STRONG)`, or the manual cleanup utility described in “Manual cleanup” on page 224.

CLEANUP(ASPROP)

The style of cleanup to use is determined by the system property `com.ibm.mq.jms.cleanup`, which is queried at JVM startup.

Publish/subscribe problems

This property can be set on the Java command-line using the `-D` option, to `NONE`, `SAFE`, or `STRONG`. Any other value causes an exception. If not set, the property defaults to `SAFE`.

This allows easy JVM-wide change to the cleanup level without updating every `TopicConnectionFactory` used by the system. This is useful for applications or application servers that use multiple `TopicConnectionFactory` objects.

Where multiple `TopicConnections` exist within a JVM against the same queue manager, but with differing values for `CLEANUP` and `CLEANUPINT`, the following rules are used to determine behavior:

1. A `TopicConnection` with `CLEANUP(NONE)` does not attempt to clean up immediately after its subscription has closed. However, if another `TopicConnection` is using `SAFE` or `STRONG` cleanup, the cleanup thread eventually cleans up after the subscription.
2. If any `TopicConnection` is using `STRONG` Cleanup, the cleanup thread operates at `STRONG` level. Otherwise, if any `TopicConnection` uses `SAFE` Cleanup, the cleanup thread operates at `SAFE` level. Otherwise, there is no cleanup thread.
3. The smallest value of `CLEANUPINT` for those `TopicConnections` with `SAFE` or `STRONG` Cleanup is used.

Manual cleanup

If you use the broker-based subscription store, you can operate cleanup manually from the command-line. The syntax for bindings attach is:

```
Cleanup [-m <qmgr>] [-r <interval>]
          [SAFE | STRONG | FORCE | NONDUR] [-t]
```

or, for client attach:

```
Cleanup -client [-m <qmgr>] -host <hostname> [-port <port>]
          [-channel <channel>] [-r <interval>]
          [SAFE | STRONG | FORCE | NONDUR] [-t]
```

Where:

- `qmgr`, `hostname`, `port`, and `channel` determine connection settings for the queue manager to clean up.
- `-r` sets the interval between executions of cleanup, in minutes. If not set, cleanup is performed once.
- `-t` enables tracing, to the `mjms.trc` file.
- `SAFE`, `STRONG`, `FORCE`, and `NONDUR` set the cleanup level, as follows:
 - `SAFE` and `STRONG` cleanup behave like the `CLEANUP(SAFE)` and `CLEANUP(STRONG)` options discussed in “Subscriber cleanup utility” on page 222.
 - `FORCE` cleanup behaves like `STRONG` Cleanup. However, `STRONG` cleanup leaves messages that could not be processed on the `SYSTEM.JMS.REPORT.QUEUE`; `FORCE` cleanup removes all messages even if it encounters an error during processing.

Warning

This is a dangerous option that can leave an inconsistent state between the queue manager and the broker. It cannot be run while any WebSphere MQ JMS publish/subscribe application is running against the queue manager; doing so causes the cleanup utility to abort.

- NONDUR behaves like FORCE cleanup.

After clearing the SYSTEM.JMS.REPORT.QUEUE, it attempts to remove any remaining unconsumed messages sent to non-durable subscribers. If the queue manager's command server is running on any queue beginning SYSTEM.JMS.ND.*, messages are cleared and the queue itself might be deleted. Otherwise, only SYSTEM.JMS.ND.SUBSCRIBER.QUEUE and SYSTEM.JMS.ND.CC.SUBSCRIBER.QUEUE are cleared of messages.

Cleanup from within a program

You can use a programming interface to the cleanup routines for use with SUBSTORE(BROKER), through the class `com.ibm.mq.jms.Cleanup`. Instances of this class have getter/setter methods for each of the connection properties; and also for the cleanup level and interval.

It exposes two methods:

cleanup()

Executes cleanup once

run() Runs cleanup at intervals determined by the properties of the cleanup object

This class allows complete customization of publish/subscribe Cleanup, but it is intended for use by system administration programs rather than application programs.

For more details, refer to "Cleanup *" on page 278.

Handling broker reports

The WebSphere MQ JMS implementation uses report messages from the broker to confirm registration and deregistration commands. These reports are normally consumed by the WebSphere MQ classes for Java Message Service implementation, but under some error conditions, they might remain on the queue. These messages are sent to the SYSTEM.JMS.REPORT.QUEUE queue on the local queue manager.

A Java application, `PSReportDump`, is supplied with WebSphere MQ classes for Java Message Service, which dumps the contents of this queue in plain text format. The information can then be analyzed, either by you, or by IBM support staff. You can also use the application to clear the queue of messages after a problem is diagnosed or fixed.

The compiled form of the tool is installed in the `<MQ_JAVA_INSTALL_PATH>/bin` directory. To invoke the tool, change to this directory, then use the following command:

```
java PSReportDump [-m queueManager] [-clear]
```

where:

Publish/subscribe problems

-m queueManager

The name of the queue manager to use

-clear Clear the queue of messages after dumping its contents

Attention: Do not use this option if you are using the broker-based subscription store. Instead, run the manual cleanup utility at FORCE level.

Output is sent to the screen, or you can redirect it to a file.

Chapter 12. JMS messages

JMS messages are composed of the following parts:

Header	All messages support the same set of header fields. Header fields contain values that are used by both clients and providers to identify and route messages.
Properties	Each message contains a built-in facility to support application-defined property values. Properties provide an efficient mechanism to filter application-defined messages.
Body	JMS defines several types of message body that cover the majority of messaging styles currently in use.

JMS defines five types of message body:

Stream	A stream of Java primitive values. It is filled and read sequentially.
Map	A set of name-value pairs, where names are strings and values are Java primitive types. The entries can be accessed sequentially or randomly by name. The order of the entries is undefined.
Text	A message containing a <code>java.util.String</code> .
Object	a message that contains a serializable Java object
Bytes	A stream of uninterpreted bytes. This message type is for literally encoding a body to match an existing message format.

The `JMSCorrelationID` header field is used to link one message with another. It typically links a reply message with its requesting message. `JMSCorrelationID` can hold a provider-specific message ID, an application-specific `String`, or a provider-native `byte[]` value.

Message selectors

A message contains a built-in facility to support application-defined property values. In effect, this provides a mechanism to add application-specific header fields to a message. Properties allow an application, using message selectors, to have a JMS provider select or filter messages on its behalf, using application-specific criteria. Application-defined properties must obey the following rules:

- Property names must obey the rules for a message selector identifier.
- Property values can be boolean, byte, short, int, long, float, double, and string.
- The `JMSX` and `JMS_` name prefixes are reserved.

Property values are set before sending a message. When a client receives a message, the message properties are read-only. If a client attempts to set properties at this point, a `MessageNotWriteableException` is thrown. If `clearProperties` is called, the properties can now be both read from, and written to.

Message selectors

A property value might duplicate a value in a message's body. JMS does not define a policy for what should or should not be made into a property. However, application developers must be aware that JMS providers probably handle data in a message's body more efficiently than data in a message's properties. For best performance, applications must use message properties only when they need to customize a message's header. The primary reason for doing this is to support customized message selection.

A JMS message selector allows a client to specify the messages that it is interested in by using the message header. Only messages whose headers match the selector are delivered.

Message selectors cannot refer to message body values.

A message selector matches a message when the selector evaluates to true when the message's header field and property values are substituted for their corresponding identifiers in the selector.

A message selector is a String, whose syntax is based on a subset of the SQL92 conditional expression syntax. The order in which a message selector is evaluated is from left to right within a precedence level. You can use parentheses to change this order. Predefined selector literals and operator names are written here in upper case; however, they are not case-sensitive.

A selector can contain:

- Literals
 - A string literal is enclosed in single quotes. A doubled single quote represents a single quote. Examples are 'literal' and 'literal''s'. Like Java string literals, these use the Unicode character encoding.
 - An exact numeric literal is a numeric value without a decimal point, such as 57, -957, and +62. Numbers in the range of Java long are supported.
 - An approximate numeric literal is a numeric value in scientific notation, such as 7E3 or -57.9E2, or a numeric value with a decimal, such as 7., -95.7, or +6.2. Numbers in the range of Java double are supported.
 - The boolean literals TRUE and FALSE.
- Identifiers:
 - An identifier is an unlimited length sequence of Java letters and Java digits, the first of which must be a Java letter. A letter is any character for which the method `Character.isJavaLetter` returns true. This includes `_` and `$`. A letter or digit is any character for which the method `Character.isJavaLetterOrDigit` returns true.
 - Identifiers cannot be the names NULL, TRUE, or FALSE.
 - Identifiers cannot be NOT, AND, OR, BETWEEN, LIKE, IN, or IS.
 - Identifiers are either header field references or property references.
 - Identifiers are case-sensitive.
 - Message header field references are restricted to:
 - JMSDeliveryMode
 - JMSPriority
 - JMSMessageID
 - JMSTimestamp
 - JMSCorrelationID

- JMSType
- JMSMessageID, JMSTimestamp, JMSCorrelationID, and JMSType values can be null, and if so, are treated as a NULL value.
- Any name beginning with JMSX is a JMS-defined property name.
 - Any name beginning with JMS_ is a provider-specific property name.
 - Any name that does not begin with JMS is an application-specific property name. If there is a reference to a property that does not exist in a message, its value is NULL. If it does exist, its value is the corresponding property value.
- White space is the same as it is defined for Java: space, horizontal tab, form feed, and line terminator.
 - Expressions:
 - A selector is a conditional expression. A selector that evaluates to true matches; a selector that evaluates to false or unknown does not match.
 - Arithmetic expressions are composed of themselves, arithmetic operations, identifiers (whose value is treated as a numeric literal), and numeric literals.
 - Conditional expressions are composed of themselves, comparison operations, and logical operations.
 - Standard bracketing (), to set the order in which expressions are evaluated, is supported.
 - Logical operators in precedence order: NOT, AND, OR.
 - Comparison operators: =, >, >=, <, <=, <> (not equal).
 - Only values of the same type can be compared. One exception is that it is valid to compare exact numeric values and approximate numeric values. (The type conversion required is defined by the rules of Java numeric promotion.) If there is an attempt to compare different types, the selector is always false.
 - String and boolean comparison is restricted to = and <>. Two strings are equal only if they contain the same sequence of characters.
 - Arithmetic operators in precedence order:
 - +, - unary.
 - *, /, multiplication, and division.
 - +, -, addition, and subtraction.
 - Arithmetic operations on a NULL value are not supported. If they are attempted, the complete selector is always false.
 - Arithmetic operations must use Java numeric promotion.
 - arithmetic-expr1 [NOT] BETWEEN arithmetic-expr2 and arithmetic-expr3 comparison operator:
 - Age BETWEEN 15 and 19 is equivalent to age >= 15 AND age <= 19.
 - Age NOT BETWEEN 15 and 19 is equivalent to age < 15 OR age > 19.
 - If any of the expressions of a BETWEEN operation are NULL, the value of the operation is false. If any of the expressions of a NOT BETWEEN operation are NULL, the value of the operation is true.
 - identifier [NOT] IN (string-literal1, string-literal2,...) comparison operator where identifier has a String or NULL value.
 - Country IN ('UK', 'US', 'France') is true for 'UK' and false for 'Peru'. It is equivalent to the expression (Country = 'UK') OR (Country = 'US') OR (Country = 'France').
 - Country NOT IN ('UK', 'US', 'France') is false for 'UK' and true for 'Peru'. It is equivalent to the expression NOT ((Country = 'UK') OR (Country = 'US') OR (Country = 'France')).

Message selectors

- If the identifier of an IN or NOT IN operation is NULL, the value of the operation is unknown.
- identifier [NOT] LIKE pattern-value [ESCAPE escape-character] comparison operator, where identifier has a string value. pattern-value is a string literal, where _ stands for any single character and % stands for any sequence of characters (including the empty sequence). All other characters stand for themselves. The optional escape-character is a single character string literal, whose character is used to escape the special meaning of the _ and % in pattern-value.
 - phone LIKE '12%3' is true for 123 and 12993 and false for 1234.
 - word LIKE 'l_se' is true for lose and false for loose.
 - underscored LIKE '_%' ESCAPE '\' is true for _foo and false for bar.
 - phone NOT LIKE '12%3' is false for 123 and 12993 and true for 1234.
 - If the identifier of a LIKE or NOT LIKE operation is NULL, the value of the operation is unknown.
- identifier IS NULL comparison operator tests for a null header field value, or a missing property value.
 - prop_name IS NULL.
- identifier IS NOT NULL comparison operator tests for the existence of a non-null header field value or a property value.
 - prop_name IS NOT NULL.

The following message selector selects messages with a message type of car, color of blue, and weight greater than 2500 lbs:

```
"JMSType = 'car' AND color = 'blue' AND weight > 2500"
```

As noted above, property values can be NULL. The evaluation of selector expressions that contain NULL values is defined by SQL 92 NULL semantics. The following is a brief description of these semantics:

- SQL treats a NULL value as unknown.
- Comparison or arithmetic with an unknown value always yields an unknown value.
- The IS NULL and IS NOT NULL operators convert an unknown value into the respective TRUE and FALSE values.

Although SQL supports fixed decimal comparison and arithmetic, JMS message selectors do not. This is why exact numeric literals are restricted to those without a decimal. It is also why there are numerics with a decimal as an alternate representation for an approximate numeric value.

SQL comments are not supported.

Mapping JMS messages onto WebSphere MQ messages

This section describes how the JMS message structure that is described in the first part of this chapter is mapped onto a WebSphere MQ message. It is of interest to programmers who want to transmit messages between JMS and traditional WebSphere MQ applications. It is also of interest to people who want to manipulate messages transmitted between two JMS applications, for example, in a message broker implementation.

This section does not apply when you use a direct connection to WebSphere MQ Event Broker.

WebSphere MQ messages are composed of three components:

- The WebSphere MQ Message Descriptor (MQMD)
- A WebSphere MQ MQRFH2 header
- The message body.

The MQRFH2 is optional, and its inclusion in an outgoing message is governed by a flag in the JMS Destination class. You can set this flag using the WebSphere MQ JMS administration tool. Because the MQRFH2 carries JMS-specific information, always include it in the message when the sender knows that the receiving destination is a JMS application. Normally, omit the MQRFH2 when sending a message directly to a non-JMS application. This is because such an application does not expect an MQRFH2 in its WebSphere MQ message. Figure 4 shows how the structure of a JMS message is transformed to a WebSphere MQ message and back again:

Figure 4. How messages are transformed between JMS and WebSphere MQ using the MQRFH2 header

The structures are transformed in two ways:

Mapping

Where the MQMD includes a field that is equivalent to the JMS field, the JMS field is mapped onto the MQMD field. Additional MQMD fields are exposed as JMS properties, because a JMS application might need to get or set these fields when communicating with a non-JMS application.

Copying

Where there is no MQMD equivalent, a JMS header field or property is passed, possibly transformed, as a field inside the MQRFH2.

Mapping JMS messages

The MQRFH2 header

This section describes the MQRFH Version 2 header, which carries JMS-specific data that is associated with the message content. The MQRFH2 Version 2 is an extensible header, and can also carry additional information that is not directly associated with JMS. However, this section covers only its use by JMS.

There are two parts of the header, a fixed portion and a variable portion.

Fixed portion

The fixed portion is modelled on the *standard* WebSphere MQ header pattern and consists of the following fields:

StrucId (MQCHAR4)

Structure identifier.

Must be MQRFH_STRUC_ID (value: "RFH ") (initial value).

MQRFH_STRUC_ID_ARRAY (value: "R","F","H"," ") is also defined in the usual way.

Version (MQLONG)

Structure version number.

Must be MQRFH_VERSION_2 (value: 2) (initial value).

StrucLength (MQLONG)

Total length of MQRFH2, including the NameValueData fields.

The value set into StrucLength must be a multiple of 4 (the data in the NameValueData fields can be padded with space characters to achieve this).

Encoding (MQLONG)

Data encoding.

Encoding of any numeric data in the portion of the message following the MQRFH2 (the next header, or the message data following this header).

CodedCharSetId (MQLONG)

Coded character set identifier.

Representation of any character data in the portion of the message following the MQRFH2 (the next header, or the message data following this header).

Format (MQCHAR8)

Format name.

Format name for the portion of the message following the MQRFH2.

Flags (MQLONG)

Flags.

MQRFH_NO_FLAGS =0. No flags set.

NameValueCCSID (MQLONG)

The coded character set identifier (CCSID) for the NameValueData character strings contained in this header. The NameValueData can be coded in a character set that differs from the other character strings that are contained in the header (StrucID and Format).

Mapping JMS messages

If the NameValueCCSID is a 2-byte Unicode CCSID (1200, 13488, or 17584), the byte order of the Unicode is the same as the byte ordering of the numeric fields in the MQRFH2. (For example, Version, StrucLength, and NameValueCCSID itself.)

The NameValueCCSID takes values from the following table:

Table 17. Possible values for NameValueCCSID field

Value	Meaning
1200	UCS2 open-ended
1208	UTF8
13488	UCS2 2.0 subset
17584	UCS2 2.1 subset (includes Euro symbol)

Variable portion

The variable portion follows the fixed portion. The variable portion contains a variable number of MQRFH2 folders. Each folder contains a variable number of elements or properties. Folders group together related properties. The MQRFH2 headers created by JMS can contain up to three folders:

The <mcd> folder

This contains properties that describe the *shape* or *format* of the message. For example, the Msd property identifies the message as being Text, Bytes, Stream, Map, Object, or null. This folder is always present in a JMS MQRFH2.

The <jms> folder

This is used to transport JMS header fields, and JMSX properties that cannot be fully expressed in the MQMD. This folder is always present in a JMS MQRFH2.

The <usr> folder

This is used to transport any application-defined properties associated with the message. This folder is only present if the application has set some application-defined properties.

Table 18 shows a full list of property names.

Table 18. MQRFH2 folders and properties used by JMS

JMS field name	Java type	MQRFH2 folder name	Property name	Type/values
JMSDestination	Destination	jms	Dst	string
JMSExpiration	long	jms	Exp	i8
JMSPriority	int	jms	Pri	i4
JMSDeliveryMode	int	jms	Dlv	i4
JMSCorrelationID	String	jms	Cid	string
JMSReplyTo	Destination	jms	Rto	string
JMSTimestamp	long	jms	Tms	i8
JMSType	String	mcd	Type, Set, Fmt	string
JMSXGroupID	String	jms	Gid	string
JMSXGroupSeq	int	jms	Seq	i4
xxx (user defined)	Any	usr	xxx	any

Mapping JMS messages

Table 18. MQRFH2 folders and properties used by JMS (continued)

JMS field name	Java type	MQRFH2 folder name	Property name	Type/values
		mcd	Msd	jms_none jms_text jms_bytes jms_map jms_stream jms_object

The syntax used to express the properties in the variable portion is as follows:

NameValueLength (MQLONG)

Length in bytes of the NameValueData string that immediately follows this length field (it does not include its own length). The value set into NameValueLength is always a multiple of 4 (the NameValueData field is padded with space characters to achieve this).

NameValueData (MQCHARn)

A single character string, whose length in bytes is given by the preceding NameValueLength field. It contains a folder holding a sequence of properties. Each property is a name/type/value triplet, contained within an XML element whose name is the folder name, as follows:

```
<foldername> triplet1 triplet2 ..... tripletn </foldername>
```

The closing </foldername> tag can be followed by spaces as padding characters. Each triplet is encoded using an XML-like syntax:

```
<name dt='datatype'>value</name>
```

The dt='datatype' element is optional and is omitted for many properties, because the datatype is predefined. If it is included, one or more space characters must be included before the dt= tag.

name is the name of the property; see Table 18 on page 233.

datatype

must match, after folding, one of the literal datatype values in Table 19.

value is a string representation of the value to be conveyed, using the definitions in Table 19.

A null value is encoded using the following syntax:

```
<name dt="DataType" xsi:nil="true"></name>
```

Do not use xsi:nil="false".

Table 19. Property datatype values and definitions

Datatype value	Definition
string	Any sequence of characters excluding < and &
boolean	The character 0 or 1 (1 = "true")

Table 19. Property datatype values and definitions (continued)

Datatype value	Definition
bin.hex	Hexadecimal digits representing octets
i1	A number, expressed using digits 0..9, with optional sign (no fractions or exponent). Must lie in the range -128 to 127 inclusive
i2	A number, expressed using digits 0..9, with optional sign (no fractions or exponent). Must lie in the range -32768 to 32767 inclusive
i4	A number, expressed using digits 0..9, with optional sign (no fractions or exponent). Must lie in the range -2147483648 to 2147483647 inclusive
i8	A number, expressed using digits 0..9, with optional sign (no fractions or exponent). Must lie in the range -9223372036854775808 to 92233720368547750807 inclusive
int	A number, expressed using digits 0..9, with optional sign (no fractions or exponent). Must lie in the same range as i8. This can be used in place of one of the i* types if the sender does not want to associate a particular precision with the property
r4	Floating point number, magnitude $\leq 3.40282347E+38$, $\geq 1.175E-37$ expressed using digits 0..9, optional sign, optional fractional digits, optional exponent
r8	Floating point number, magnitude $\leq 1.7976931348623E+308$, $\geq 2.225E-307$ expressed using digits 0..9, optional sign, optional fractional digits, optional exponent

A string value can contain spaces. You must use the following escape sequences in a string value:

- & for the & character
- < for the < character

You can use the following escape sequences, but they are not required:

- > for the > character
- ' for the ' character
- " for the " character

JMS fields and properties with corresponding MQMD fields

Table 20 lists the JMS header fields and Table 21 on page 236 lists the JMS properties that are mapped directly to MQMD fields. Table 22 on page 236 lists the provider specific properties and the MQMD fields that they are mapped to.

Table 20. JMS header fields mapping to MQMD fields

JMS header field	Java type	MQMD field	C type
JMSDeliveryMode	int	Persistence	MQLONG
JMSExpiration	long	Expiry	MQLONG
JMSPriority	int	Priority	MQLONG
JMSMessageID	String	MessageID	MQBYTE24
JMSTimestamp	long	PutDate PutTime	MQCHAR8 MQCHAR8
JMSCorrelationID	String	CorrelId	MQBYTE24

Mapping JMS messages

Table 21. JMS properties mapping to MQMD fields

JMS property	Java type	MQMD field	C type
JMSXUserID	String	UserIdentifier	MQCHAR12
JMSXAppID	String	PutApplName	MQCHAR28
JMSXDeliveryCount	int	BackoutCount	MLONG
JMSXGroupID	String	GroupId	MQBYTE24
JMSXGroupSeq	int	MsgSeqNumber	MLONG

Table 22. JMS provider specific properties mapping to MQMD fields

JMS provider specific property	Java type	MQMD field	C type
JMS_IBM_Report_Exception	int	Report	MLONG
JMS_IBM_Report_Expiration	int	Report	MLONG
JMS_IBM_Report_COA	int	Report	MLONG
JMS_IBM_Report_COD	int	Report	MLONG

JMS_IBM_Report_Pass_Correl_ID	int	Report	MLONG
JMS_IBM_Report_Discard_Msg	int	Report	MLONG
JMS_IBM_MsgType	int	MsgType	MLONG
JMS_IBM_Feedback	int	Feedback	MLONG
JMS_IBM_Format	String	Format	MQCHAR8
JMS_IBM_PutApplType	int	PutApplType	MLONG
JMS_IBM_Encoding	int	Encoding	MLONG
JMS_IBM_Character_Set	String	CodedCharacterSetId	MLONG
JMS_IBM_PutDate	String	PutDate	MQCHAR8
JMS_IBM_PutTime	String	PutTime	MQCHAR8
JMS_IBM_Last_Msg_In_Group	boolean	MsgFlags	MLONG

Mapping JMS fields onto WebSphere MQ fields (outgoing messages)

Table 23 on page 237 shows how the JMS header fields are mapped into MQMD/RFH2 fields at send() or publish() time. Table 24 on page 237 shows how JMS properties and Table 25 on page 237 shows how JMS provider specific properties are mapped to MQMD fields at send() or publish() time,

For fields marked Set by Message Object, the value transmitted is the value held in the JMS message immediately before the send() or publish() operation. The value in the JMS message is left unchanged by the operation.

For fields marked Set by Send Method, a value is assigned when the send() or publish() is performed (any value held in the JMS message is ignored). The value in the JMS message is updated to show the value used.

Mapping JMS messages

Fields marked as Receive-only are not transmitted and are left unchanged in the message by send() or publish().

Table 23. Outgoing message field mapping

JMS header field name	MQMD field used for transmission	Header	Set by
JMSDestination		MQRFH2	Send Method
JMSDeliveryMode	Persistence	MQRFH2	Send Method
JMSExpiration	Expiry	MQRFH2	Send Method
JMSPriority	Priority	MQRFH2	Send Method
JMSMessageID	MessageID		Send Method
JMSTimestamp	PutDate/PutTime		Send Method
JMSCorrelationID	CorrelId	MQRFH2	Message Object
JMSReplyTo	ReplyToQ/ReplyToQMgr	MQRFH2	Message Object
JMSType		MQRFH2	Message Object
JMSRedelivered			Receive-only

Table 24. Outgoing message JMS property mapping

JMS property name	MQMD field used for transmission	Header	Set by
JMSXUserID	UserIdentifier		Send Method
JMSXAppID	PutApplName		Send Method
JMSXDeliveryCount			Receive-only
JMSXGroupID	GroupId	MQRFH2	Message Object
JMSXGroupSeq	MsgSeqNumber	MQRFH2	Message Object

Table 25. Outgoing message JMS provider specific property mapping

JMS provider specific property name	MQMD field used for transmission	Header	Set by
JMS_IBM_Report_Exception	Report		Message Object
JMS_IBM_Report_Expiration	Report		Message Object
JMS_IBM_Report_COA/COD	Report		Message Object
JMS_IBM_Report_NAN/PAN	Report		Message Object
JMS_IBM_Report_Pass_Msg_ID	Report		Message Object

JMS_IBM_Feedback	Feedback		Message Object
JMS_IBM_Format	Format		Message Object
JMS_IBM_PutApplType	PutApplType		Send Method
JMS_IBM_Encoding	Encoding		Message Object
JMS_IBM_Character_Set	CodedCharacterSetId		Message Object
JMS_IBM_PutDate	PutDate		Send Method
JMS_IBM_PutTime	PutTime		Send Method

Mapping JMS messages

Table 25. Outgoing message JMS provider specific property mapping (continued)

JMS provider specific property name	MQMD field used for transmission	Header	Set by
JMS_IBM_Last_Msg_In_Group	MsgFlags		Message Object

Mapping JMS header fields at send() or publish()

The following notes relate to the mapping of JMS fields at send() or publish():

JMSDestination to MQRFH2

This is stored as a string that serializes the salient characteristics of the destination object, so that a receiving JMS can reconstitute an equivalent destination object. The MQRFH2 field is encoded as URI (see “uniform resource identifiers” on page 196 for details of the URI notation).

JMSReplyTo to MQMD ReplyToQ, ReplyToQMgr, MQRFH2

The queue and queue manager name are copied to the MQMD ReplyToQ and ReplyToQMgr fields respectively. The destination extension information (other useful details that are kept in the destination object) is copied into the MQRFH2 field. The MQRFH2 field is encoded as a URI (see “uniform resource identifiers” on page 196 for details of the URI notation).

JMSDeliveryMode to MQMD Persistence

The JMSDeliveryMode value is set by the send() or publish() Method or MessageProducer, unless the Destination Object overrides it. The JMSDeliveryMode value is mapped to the MQMD Persistence field as follows:

- JMS value PERSISTENT is equivalent to MQPER_PERSISTENT
- JMS value NON_PERSISTENT is equivalent to MQPER_NOT_PERSISTENT

If the MQQueue persistence property is not set to JMSC.MQJMS_PER_QDEF, the delivery mode value is also encoded in the MQRFH2.

JMSExpiration to/from MQMD Expiry, MQRFH2

JMSExpiration stores the time to expire (the sum of the current time and the time to live), whereas MQMD stores the time to live. Also, JMSExpiration is in milliseconds, but MQMD.expiry is in centiseconds.

- If the send() method sets an unlimited time to live, MQMD Expiry is set to MQEI_UNLIMITED, and no JMSExpiration is encoded in the MQRFH2.
- If the send() method sets a time to live that is less than 214748364.7 seconds (about 7 years), the time to live is stored in MQMD. Expiry, and the expiration time (in milliseconds), are encoded as an i8 value in the MQRFH2.
- If the send() method sets a time to live greater than 214748364.7 seconds, MQMD.Expiry is set to MQEI_UNLIMITED. The true expiration time in milliseconds is encoded as an i8 value in the MQRFH2.

JMSPriority to MQMD Priority

Directly map JMSPriority value (0-9) onto MQMD priority value (0-9). If JMSPriority is set to a non-default value, the priority level is also encoded in the MQRFH2.

JMSMessageID from MQMD MessageID

All messages sent from JMS have unique message identifiers assigned by

WebSphere MQ. The value assigned is returned in the MQMD messageId field after the MQPUT call, and is passed back to the application in the JMSMessageID field. The WebSphere MQ messageId is a 24-byte binary value, whereas the JMSMessageID is a string. The JMSMessageID is composed of the binary messageId value converted to a sequence of 48 hexadecimal characters, prefixed with the characters ID:. JMS provides a hint that can be set to disable the production of message identifiers. This hint is ignored, and a unique identifier is assigned in all cases. Any value that is set into the JMSMessageId field before a send() is overwritten.

JMSTimestamp to MQRFH2

During a send, the JMSTimestamp field is set according to the JVM's clock. This value is set into the MQRFH2. Any value that is set into the JMSTimestamp field before a send() is overwritten. See also the JMS_IBM_PutDate and JMS_IBM_PutTime properties.

JMSType to MQRFH2

This string is set into the MQRFH2 mcd.Type field. If it is in URI format, it can also affect mcd.Set and mcd.Fmt fields. See also Appendix D, "Connecting with other products" on page 413.

JMSCorrelationID to MQMD CorrelId, MQRFH2

The JMSCorrelationID can hold one of the following:

A provider specific message ID

This is a message identifier from a message previously sent or received, and so should be a string of 48 hexadecimal digits that are prefixed with ID:. The prefix is removed, the remaining characters are converted into binary, and then they are set into the MQMD CorrelId field. No CorrelId value is encoded in the MQRFH2.

A provider-native byte[] value

The value is copied into the MQMD CorrelId field - padded with nulls, or truncated to 24 bytes if necessary. No CorrelId value is encoded in the MQRFH2.

An application-specific string

The value is copied into the MQRFH2. The first 24 bytes of the string, in UTF8 format, are written into the MQMD CorrelID.

Mapping JMS property fields

These notes refer to the mapping of JMS property fields in WebSphere MQ messages:

JMSXUserID from MQMD UserIdentifier

JMSXUserID is set on return from send call.

JMSXAppID from MQMD PutApplName

JSMXAppID is set on return from send call.

JMSXGroupID to MQRFH2 (point-to-point)

For point-to-point messages, the JMSXGroupID is copied into the MQMD GroupID field. If the JMSXGroupID starts with the prefix ID:, it is converted into binary. Otherwise, it is encoded as a UTF8 string. The value is padded or truncated if necessary to a length of 24 bytes. The MQMF_MSG_IN_GROUP flag is set.

JMSXGroupID to MQRFH2 (publish/subscribe)

For publish/subscribe messages, the JMSXGroupID is copied into the MQRFH2 as a string.

Mapping JMS messages

JMSXGroupSeq MQMD MsgSeqNumber (point-to-point)

For point-to-point messages, the JMSXGroupSeq is copied into the MQMD MsgSeqNumber field. The MQMF_MSG_IN_GROUP flag is set.

JMSXGroupSeq MQMD MsgSeqNumber (publish/subscribe)

For publish/subscribe messages, the JMSXGroupSeq is copied into the MQRFH2 as an i4.

Mapping JMS provider-specific fields

The following notes refer to the mapping of JMS Provider specific fields into WebSphere MQ messages:

JMS_IBM_Report_<name> to MQMD Report

A JMS application can set the MQMD Report options, using the following JMS_IBM_Report_XXX properties. The single MQMD is mapped to several JMS_IBM_Report_XXX properties. The application must set the value of these properties to the standard WebSphere MQ MQRO_ constants (included in com.ibm.mq.MQC). So, for example, to request COD with full Data, the application must set JMS_IBM_Report_COD to the value MQC.MQRO_COD_WITH_FULL_DATA.

JMS_IBM_Report_Exception

MQRO_EXCEPTION or
MQRO_EXCEPTION_WITH_DATA or
MQRO_EXCEPTION_WITH_FULL_DATA

JMS_IBM_Report_Expiration

MQRO_EXPIRATION or
MQRO_EXPIRATION_WITH_DATA or
MQRO_EXPIRATION_WITH_FULL_DATA

JMS_IBM_Report_COA

MQRO_COA or
MQRO_COA_WITH_DATA or
MQRO_COA_WITH_FULL_DATA

JMS_IBM_Report_COD

MQRO_COD or
MQRO_COD_WITH_DATA or
MQRO_COD_WITH_FULL_DATA

JMS_IBM_Report_PAN

MQRO_PAN

JMS_IBM_Report_NAN

MQRO_NAN

JMS_IBM_Report_Pass_Msg_ID

MQRO_PASS_MSG_ID

JMS_IBM_Report_Pass_Correl_ID

MQRO_PASS_CORREL_ID

JMS_IBM_Report_Discard_Msg

MQRO_DISCARD_MSG

JMS_IBM_MsgType to MQMD MsgType

Value maps directly onto MQMD MsgType. If the application has not set

Mapping JMS messages

an explicit value of `JMS_IBM_MsgType`, a default value is used. This default value is determined as follows:

- If `JMSReplyTo` is set to a WebSphere MQ queue destination, `MsgType` is set to the value `MQMT_REQUEST`
- If `JMSReplyTo` is not set, or is set to anything other than a WebSphere MQ queue destination, `MsgType` is set to the value `MQMT_DATAGRAM`

JMS_IBM_Feedback to MQMD Feedback

Value maps directly onto MQMD Feedback.

JMS_IBM_Format to MQMD Format

Value maps directly onto MQMD Format.

JMS_IBM_Encoding to MQMD Encoding

If set, this property overrides the numeric encoding of the Destination Queue or Topic.

JMS_IBM_Character_Set to MQMD CodedCharacterSetId

If set, this property overrides the coded character set property of the Destination Queue or Topic.

JMS_IBM_PutDate from MQMD PutDate

The value of this property is set, during send, directly from the `PutDate` field in the MQMD. Any value that is set into the `JMS_IBM_PutDate` property before a send is overwritten. This field is a String of eight characters, in the WebSphere MQ Date format of `YYYYMMDD`. This property can be used in conjunction with the `JMS_IBM_PutTime` property to determine the time the message was put according to the queue manager.

JMS_IBM_PutTime from MQMD PutTime

The value of this property is set, during send, directly from the `PutTime` field in the MQMD. Any value that is set into the `JMS_IBM_PutTime` property before a send is overwritten. This field is a String of eight characters, in the WebSphere MQ Time format of `HHMMSSSTH`. This property can be used in conjunction with the `JMS_IBM_PutDate` property to determine the time the message was put according to the queue manager.

JMS_IBM_Last_Msg_In_Group to MQMD MsgFlags

For point-to-point messaging, this boolean value maps to the `MQMF_LAST_MSG_IN_GROUP` flag in the MQMD `MsgFlags` field. It is normally used in conjunction with the `JMSXGroupID` and `JMSXGroupSeq` properties to indicate to a legacy WebSphere MQ application that this is the last message in a group. This property is ignored for publish/subscribe messaging.

Mapping WebSphere MQ fields onto JMS fields (incoming messages)

Table 26 on page 242 shows how JMS header fields and Table 27 on page 242 shows how JMS property fields are mapped into MQMD/MQRFH2 fields at `send()` or `publish()` time. Table 28 on page 242 shows how JMS provider specific properties are mapped.

Mapping JMS messages

Table 26. Incoming message JMS header field mapping

1. Only set if the incoming message is a Bytes Message.

Mapping JMS to a native WebSphere MQ application

This section describes what happens if you send a message from a JMS client application to a traditional WebSphere MQ application with no knowledge of MQRFH2 headers. Figure 5 shows the mapping.

The administrator indicates that the JMS client is communicating with such an application by setting the WebSphere MQ destination's TargetClient value to JMSC.MQJMS_CLIENT_NONJMS_MQ. This indicates that no MQRFH2 field is to be produced. Note that if this is not done, the receiving application must be able to handle the MQRFH2 field.

The mapping from JMS to MQMD targeted at a native WebSphere MQ application is the same as mapping from JMS to MQMD targeted at a true JMS client. If JMS receives a WebSphere MQ message with the MQMD format field set to other than MQFMT_RFH2, data is being received from a non-JMS application. If the format is MQFMT_STRING, the message is received as a JMS text message. Otherwise, it is received as a JMS bytes message. Because there is no MQRFH2, only those JMS properties that are transmitted in the MQMD can be restored.

Figure 5. How JMS messages are transformed to WebSphere MQ messages (no MQRFH2 header)

Message body

This section discusses the encoding of the message body itself. The encoding depends on the type of JMS message:

Mapping JMS messages

ObjectMessage

is an object serialized by the Java Runtime in the normal way.

TextMessage

is an encoded string. For an outgoing message, the string is encoded in the character set given by the destination object. This defaults to UTF8 encoding (the UTF8 encoding starts with the first character of the message; there is no length field at the start). It is, however, possible to specify any other character set supported by WebSphere MQ Java. Such character sets are used mainly when you send a message to a non-JMS application.

If the character set is a double-byte set (including UTF16), the destination object's integer encoding specification determines the order of the bytes.

An incoming message is interpreted using the character set and encoding that are specified in the message itself. These specifications are in the last WebSphere MQ header (or MQMD if there are no headers). For JMS messages, the last header is usually the MQRFH2.

BytesMessage

is, by default, a sequence of bytes as defined by the JMS 1.0.2 specification and associated Java documentation.

For an outgoing message that was assembled by the application itself, the destination object's encoding property can be used to override the encodings of integer and floating point fields contained in the message. For example, you can request that floating point values are stored in S/390 rather than IEEE format).

An incoming message is interpreted using the numeric encoding specified in the message itself. This specification is in the rightmost WebSphere MQ header (or MQMD if there are no headers). For JMS messages, the rightmost header is usually the MQRFH2.

If a BytesMessage is received, and is re-sent without modification, its body is transmitted byte for byte, as it was received. The destination object's encoding property has no effect on the body. The only string-like entity that can be sent explicitly in a BytesMessage is a UTF8 string. This is encoded in Java UTF8 format, and starts with a 2-byte length field. The destination object's character set property has no effect on the encoding of an outgoing BytesMessage. The character set value in an incoming WebSphere MQ message has no effect on the interpretation of that message as a JMS BytesMessage.

Non-Java applications are unlikely to recognize the Java UTF8 encoding. Therefore, for a JMS application to send a BytesMessage that contains text data, the application itself must convert its strings to byte arrays, and write these byte arrays into the BytesMessage.

MapMessage

is a string containing a set of XML name/type/value triplets, encoded as:

```
<map><elementName1 dt='datatype'>value</elementName1>  
<elementName2 dt='datatype'>value</elementName2>.....  
</map>
```

where datatype can take one of the values described in Table 19 on page 234, and string is the default datatype, so dt='string' is omitted.

The character set used to encode or interpret the XML string that makes up the MapMessage body is determined following the rules that apply to a TextMessage.

StreamMessage

is like a map, but without element names:

```
<stream><elt dt='datatype'>value</elt>  
<elt dt='datatype'>value</elt>....</stream>
```

Every element is sent using the same tag name (elt). The default type is string, so dt='string' is omitted for string elements.

The character set used to encode or interpret the XML string that makes up the StreamMessage body is determined following the rules that apply to a TextMessage.

The MQRFH2.format field is set as follows:

MQFMT_NONE

for ObjectMessage, BytesMessage, or messages with no body.

MQFMT_STRING

for TextMessage, StreamMessage, or MapMessage.

Mapping JMS messages

Chapter 13. WebSphere MQ JMS Application Server Facilities

WebSphere MQ JMS supports the Application Server Facilities (ASF) that are specified in the Java Message Service 1.0.2 specification (see Sun's Java Web site at <http://java.sun.com>). This specification identifies three roles within this programming model:

- **The JMS provider** supplies ConnectionConsumer and advanced Session functionality.
- **The application server** supplies ServerSessionPool and ServerSession functionality.
- **The client application** uses the functionality that the JMS provider and application server supply.

This chapter does not apply if you use a direct connection to WebSphere MQ Event Broker.

The following sections contain details about how WebSphere MQ JMS implements ASF:

- "ASF classes and functions" describes how WebSphere MQ JMS implements the ConnectionConsumer class and advanced functionality in the Session class.
- "Application server sample code" on page 253 describes the sample ServerSessionPool and ServerSession code that is supplied with WebSphere MQ JMS.
- "Examples of ASF use" on page 257 describes supplied ASF samples and examples of ASF use from the perspective of a client application.

Note: The Java Message Service 1.0.2 specification for ASF also describes JMS support for distributed transactions using the X/Open XA protocol. For details of the XA support that WebSphere MQ JMS provides, see Appendix E, "JMS JTA/XA interface with WebSphere Application Server V4" on page 417.

ASF classes and functions

WebSphere MQ JMS implements the ConnectionConsumer class and advanced functionality in the Session class. For details, see:

- "ConnectionConsumer" on page 286
- "QueueConnection" on page 336
- "Session" on page 349
- "TopicConnection" on page 368

ConnectionConsumer

The JMS specification enables an application server to integrate closely with a JMS implementation by using the ConnectionConsumer interface. This feature provides concurrent processing of messages. Typically, an application server creates a pool of threads, and the JMS implementation makes messages available to these threads. A JMS-aware application server can use this feature to provide high-level messaging functionality, such as message processing beans.

ASF classes and functions

Normal applications do not use the `ConnectionConsumer`, but expert JMS clients might use it. For such clients, the `ConnectionConsumer` provides a high-performance method to deliver messages concurrently to a pool of threads. When a message arrives on a queue or a topic, JMS selects a thread from the pool and delivers a batch of messages to it. To do this, JMS runs an associated `MessageListener`'s `onMessage()` method.

You can achieve the same effect by constructing multiple `Session` and `MessageConsumer` objects, each with a registered `MessageListener`. However, the `ConnectionConsumer` provides better performance, less use of resources, and greater flexibility. In particular, fewer `Session` objects are required.

To help you develop applications that use `ConnectionConsumers`, WebSphere MQ JMS provides a fully-functioning example implementation of a pool. You can use this implementation without any changes, or adapt it to suit the specific needs of the application.

Planning an application

This section tells you how to plan an application including:

- “General principles for point-to-point messaging”
- “General principles for publish/subscribe messaging” on page 249
- “Handling poison messages” on page 250
- “Removing messages from the queue” on page 251

General principles for point-to-point messaging

When an application creates a `ConnectionConsumer` from a `QueueConnection` object, it specifies a JMS queue object and a selector string. The `ConnectionConsumer` then begins to provide messages to sessions in the associated `ServerSessionPool`. Messages arrive on the queue, and if they match the selector, they are delivered to sessions in the associated `ServerSessionPool`.

In WebSphere MQ terms, the queue object refers to either a `QLOCAL` or a `QALIAS` on the local queue manager. If it is a `QALIAS`, that `QALIAS` must refer to a `QLOCAL`. The fully-resolved WebSphere MQ `QLOCAL` is known as the *underlying QLOCAL*. A `ConnectionConsumer` is said to be *active* if it is not closed and its parent `QueueConnection` is started.

It is possible for multiple `ConnectionConsumers`, each with different selectors, to run against the same underlying `QLOCAL`. To maintain performance, unwanted messages must not accumulate on the queue. Unwanted messages are those for which no active `ConnectionConsumer` has a matching selector. You can set the `QueueConnectionFactory` so that these unwanted messages are removed from the queue (for details, see “Removing messages from the queue” on page 251). You can set this behavior in one of two ways:

- Use the JMS administration tool to set the `QueueConnectionFactory` to `MRET(NO)`.
- In your program, use:
`MQQueueConnectionFactory.setMessageRetention(JMSC.MQJMS_MRET_NO)`

If you do not change this setting, the default is to retain such unwanted messages on the queue.

It is possible that `ConnectionConsumers` that target the same underlying `QLOCAL` could be created from multiple `QueueConnection` objects. However, for

performance reasons, we recommend that multiple JVMs do not create `ConnectionConsumers` against the same underlying `QLOCAL`.

When you set up the WebSphere MQ queue manager, consider the following points:

- The underlying `QLOCAL` must be enabled for shared input. To do this, use the following MQSC command:

```
ALTER QLOCAL(your.qlocal.name) SHARE GET(ENABLED)
```

- Your queue manager must have an enabled dead-letter queue. If a `ConnectionConsumer` experiences a problem when it puts a message on the dead-letter queue, message delivery from the underlying `QLOCAL` stops. To define a dead-letter queue, use:

```
ALTER QMGR DEADQ(your.dead.letter.queue.name)
```

- The user that runs the `ConnectionConsumer` must have authority to perform `MQOPEN` with `MQOO_SAVE_ALL_CONTEXT` and `MQOO_PASS_ALL_CONTEXT`. For details, see the WebSphere MQ documentation for your specific platform.
- If unwanted messages are left on the queue, they degrade the system performance. Therefore, plan your message selectors so that between them, the `ConnectionConsumers` will remove all messages from the queue.

For details about MQSC commands, see the *WebSphere MQ Script (MQSC) Command Reference*.

General principles for publish/subscribe messaging

When an application creates a `ConnectionConsumer` from a `TopicConnection` object, it specifies a `Topic` object and a selector string. The `ConnectionConsumer` then begins to receive messages that match the selector on that `Topic`.

Alternatively, an application can create a durable `ConnectionConsumer` that is associated with a specific name. This `ConnectionConsumer` receives messages that have been published on the `Topic` since the durable `ConnectionConsumer` was last active. It receives all such messages that match the selector on the `Topic`.

For non-durable subscriptions, a separate queue is used for `ConnectionConsumer` subscriptions. The `CCSUB` configurable option on the `TopicConnectionFactory` specifies the queue to use. Normally, the `CCSUB` specifies a single queue for use by all `ConnectionConsumers` that use the same `TopicConnectionFactory`. However, it is possible to make each `ConnectionConsumer` generate a temporary queue by specifying a queue name prefix followed by a `*`.

For durable subscriptions, the `CCDSUB` property of the `Topic` specifies the queue to use. Again, this can be a queue that already exists or a queue name prefix followed by a `*`. If you specify a queue that already exists, all durable `ConnectionConsumers` that subscribe to the `Topic` use this queue. If you specify a queue name prefix followed by a `*`, a queue is generated the first time that a durable `ConnectionConsumer` is created with a given name. This queue is reused later when a durable `ConnectionConsumer` is created with the same name.

When you set up the WebSphere MQ queue manager, consider the following points:

- Your queue manager must have an enabled dead-letter queue. If a `ConnectionConsumer` experiences a problem when it puts a message on the dead-letter queue, message delivery from the underlying `QLOCAL` stops. To define a dead-letter queue, use:

ASF classes and functions

```
ALTER QMGR DEADQ(your.dead.letter.queue.name)
```

- The user that runs the ConnectionConsumer must have authority to perform MQOPEN with MQOO_SAVE_ALL_CONTEXT and MQOO_PASS_ALL_CONTEXT. For details, see the WebSphere MQ documentation for your platform.
- You can optimize performance for an individual ConnectionConsumer by creating a separate, dedicated, queue for it. This is at the cost of extra resource usage.

Handling poison messages

Sometimes, a badly-formatted message arrives on a queue. Such a message might make the receiving application fail and back out the receipt of the message. In this situation, such a message might be received, then returned to the queue, repeatedly. These messages are known as *poison messages*. The ConnectionConsumer must be able to detect poison messages and reroute them to an alternative destination.

When an application uses ConnectionConsumers, the circumstances in which a message is backed out depend on the session that the application server provides:

- When the session is non-transacted, with AUTO_ACKNOWLEDGE or DUPS_OK_ACKNOWLEDGE, a message is backed out only after a system error, or if the application terminates unexpectedly.
- When the session is non-transacted with CLIENT_ACKNOWLEDGE, unacknowledged messages can be backed out by the application server calling `Session.recover()`.

Typically, the client implementation of MessageListener or the application server calls `Message.acknowledge()`. `Message.acknowledge()` acknowledges all messages delivered on the session so far.

- When the session is transacted, the application server usually commits the session. If the application server detects an error, it may choose to back out one or more messages.
- If the application server supplies an XASession, messages are committed or backed out depending on a distributed transaction. The application server takes responsibility for completing the transaction.

The WebSphere MQ queue manager keeps a record of the number of times that each message has been backed out. When this number reaches a configurable threshold, the ConnectionConsumer requeues the message on a named backout queue. If this requeue fails for any reason, the message is removed from the queue and either requeued to the dead-letter queue, or discarded. See “Removing messages from the queue” on page 251 for more details.

On most platforms, the threshold and requeue queue are properties of the WebSphere MQ QLOCAL. For point-to-point messaging, this is the underlying QLOCAL. For publish/subscribe messaging, this is the CCSUB queue defined on the TopicConnectionFactory, or the CCDSUB queue defined on the Topic. To set the threshold and requeue queue properties, issue the following MQSC command:

```
ALTER QLOCAL(your.queue.name) BOTHRESH(threshold) BOQUEUE(your.requeue.queue.name)
```

For publish/subscribe messaging, if your system creates a dynamic queue for each subscription, these settings are obtained from the WebSphere MQ JMS model queue. To alter these settings, you can use:

```
ALTER QMODEL(SYSTEM.JMS.MODEL.QUEUE) BOTHRESH(threshold) BOQUEUE(your.requeue.queue.name)
```

If the threshold is zero, poison message handling is disabled, and poison messages remain on the input queue. Otherwise, when the backout count reaches the threshold, the message is sent to the named requeue queue. If the backout count reaches the threshold, but the message cannot go to the requeue queue, the message is sent to the dead-letter queue or discarded. This situation occurs if the requeue queue is not defined, or if the `ConnectionConsumer` cannot send the message to the requeue queue. On some platforms, you cannot specify the threshold and requeue queue properties. On these platforms, messages are sent to the dead-letter queue, or discarded, when the backout count reaches 20. See “Removing messages from the queue” for further details.

Removing messages from the queue

When an application uses `ConnectionConsumers`, JMS might need to remove messages from the queue in a number of situations:

Badly formatted message

A message might arrive that JMS cannot parse.

Poison message

A message might reach the backout threshold, but the `ConnectionConsumer` fails to requeue it on the backout queue.

No interested `ConnectionConsumer`

For point-to-point messaging, when the `QueueConnectionFactory` is set so that it does not retain unwanted messages, a message arrives that is unwanted by any of the `ConnectionConsumers`.

In these situations, the `ConnectionConsumer` attempts to remove the message from the queue. The disposition options in the report field of the message’s MQMD set the exact behavior. These options are:

`MQRO_DEAD_LETTER_Q`

The message is requeued to the queue manager’s dead-letter queue. This is the default.

`MQRO_DISCARD_MSG`

The message is discarded.

The `ConnectionConsumer` also generates a report message, and this also depends on the report field of the message’s MQMD. This message is sent to the message’s `ReplyToQ` on the `ReplyToQmgr`. If there is an error while the report message is being sent, the message is sent to the dead-letter queue instead. The exception report options in the report field of the message’s MQMD set details of the report message. These options are:

`MQRO_EXCEPTION`

A report message is generated that contains the MQMD of the original message. It does not contain any message body data.

`MQRO_EXCEPTION_WITH_DATA`

A report message is generated that contains the MQMD, any MQ headers, and 100 bytes of body data.

`MQRO_EXCEPTION_WITH_FULL_DATA`

A report message is generated that contains all data from the original message.

default

No report message is generated.

When report messages are generated, the following options are honored:

ASF classes and functions

- MQRO_NEW_MSG_ID
- MQRO_PASS_MSG_ID
- MQRO_COPY_MSG_ID_TO_CORREL_ID
- MQRO_PASS_CORREL_ID

If a `ConnectionConsumer` cannot follow the disposition options or exception report options in the message's MQMD, its action depends on the persistence of the message. If the message is non-persistent, the message is discarded and no report message is generated. If the message is persistent, delivery of all messages from the QLOCAL stops.

It is important to define a dead-letter queue, and to check it regularly to ensure that no problems occur. Particularly, ensure that the dead-letter queue does not reach its maximum depth, and that its maximum message size is large enough for all messages.

When a message is queued to the dead-letter queue, it is preceded by a WebSphere MQ dead-letter header (MQDLH). See the *WebSphere MQ Application Programming Reference* for details about the format of the MQDLH. You can identify messages that a `ConnectionConsumer` has placed on the dead-letter queue, or report messages that a `ConnectionConsumer` has generated, by the following fields:

- `PutApplType` is MQAT_JAVA (0x1C)
- `PutApplName` is "MQ JMS ConnectionConsumer"

These fields are in the MQDLH of messages on the dead-letter queue, and the MQMD of report messages. The feedback field of the MQMD, and the Reason field of the MQDLH, contain a code describing the error. For details about these codes, see "Error handling". Other fields are as described in the *WebSphere MQ Application Programming Reference*.

Error handling

This section covers various aspects of error handling, including "Recovering from error conditions" and "Reason and feedback codes" on page 253.

Recovering from error conditions

If a `ConnectionConsumer` experiences a serious error, message delivery to all `ConnectionConsumers` with an interest in the same QLOCAL stops. Typically, this occurs if the `ConnectionConsumer` cannot requeue a message to the dead-letter queue, or it experiences an error when reading messages from the QLOCAL.

When this occurs, any `ExceptionListener` that is registered with the affected `Connection` is notified.

You can use these to identify the cause of the problem. In some cases, the system administrator must intervene to resolve the problem.

There are two ways in which an application can recover from these error conditions:

- Call `close()` on all affected `ConnectionConsumers`. The application can create new `ConnectionConsumers` only after all affected `ConnectionConsumers` are closed and any system problems are resolved.
- Call `stop()` on all affected `Connections`. Once all `Connections` are stopped and any system problems are resolved, the application should be able to `start()` all `Connections` successfully.

Reason and feedback codes

To determine the cause of an error, you can use:

- The feedback code in any report messages
- The reason code in the MQDLH of any messages in the dead-letter queue

ConnectionConsumers generate the following reason codes.

MQRC_BACKOUT_THRESHOLD_REACHED (0x93A; 2362)

Cause	The message has reached the Backout Threshold defined on the QLOCAL, but no Backout Queue is defined. On platforms where you cannot define the Backout Queue, the message has reached the JMS-defined backout threshold of 20.
Action	If this is not wanted, define the Backout Queue for the relevant QLOCAL. Also look for the cause of the multiple backouts.

MQRC_MSG_NOT_MATCHED (0x93B; 2363)

Cause	In point-to-point messaging, there is a message that does not match any of the selectors for the ConnectionConsumers monitoring the queue. To maintain performance, the message is requeued to the dead-letter queue.
Action	To avoid this situation, ensure that ConnectionConsumers using the queue provide a set of selectors that deal with all messages, or set the QueueConnectionFactory to retain messages. Alternatively, investigate the source of the message.

MQRC_JMS_FORMAT_ERROR (0x93C; 2364)

Cause	JMS cannot interpret the message on the queue.
Action	Investigate the origin of the message. JMS usually delivers messages of an unexpected format as a BytesMessage or TextMessage. Occasionally, this fails if the message is very badly formatted.

Other codes that appear in these fields are caused by a failed attempt to requeue the message to a Backout Queue. In this situation, the code describes the reason that the requeue failed. To diagnose the cause of these errors, refer to the *WebSphere MQ Application Programming Reference*.

If the report message cannot be put on the ReplyToQ, it is put on the dead-letter queue. In this situation, the feedback field of the MQMD is filled in as described above. The reason field in the MQDLH explains why the report message could not be placed on the ReplyToQ.

Application server sample code

Figure 6 on page 254 summarizes the principles of ServerSessionPool and ServerSession functionality.

Application server sample code

Figure 6. ServerSessionPool and ServerSession functionality

1. The ConnectionConsumers get message references from the queue.
2. Each ConnectionConsumer selects specific message references.
3. The ConnectionConsumer buffer holds the selected message references.
4. The ConnectionConsumer requests one or more ServerSessions from the ServerSessionPool.
5. ServerSessions are allocated from the ServerSessionPool.
6. The ConnectionConsumer assigns message references to the ServerSessions and starts the ServerSession threads running.
7. Each ServerSession retrieves its referenced messages from the queue. It passes them to the onMessage method from the MessageListener that is associated with the JMS Session.
8. After it completes its processing, the ServerSession is returned to the pool.

Normally, the application server supplies `ServerSessionPool` and `ServerSession` functionality. However, WebSphere MQ JMS is supplied with a simple implementation of these interfaces, with program source. These samples are in the following directory, where `<install_dir>` is the installation directory for WebSphere MQ JMS:

```
<install_dir>/samples/jms/asf
```

These samples enable you to use the WebSphere MQ JMS ASF in a standalone environment (that is, you do not need a suitable application server). Also, they provide examples of how to implement these interfaces and take advantage of the WebSphere MQ JMS ASF. These examples are intended to aid both WebSphere MQ JMS users, and vendors of other application servers.

MyServerSession.java

This class implements the `javax.jms.ServerSession` interface. It associates a thread with a JMS session. Instances of this class are pooled by a `ServerSessionPool` (see “`MyServerSessionPool.java`”). As a `ServerSession`, it must implement the following two methods:

- `getSession()`, which returns the JMS Session associated with this `ServerSession`
- `start()`, which starts this `ServerSession`'s thread and results in the JMS Session's `run()` method being invoked

`MyServerSession` also implements the `Runnable` interface. Therefore, the creation of the `ServerSession`'s thread can be based on this class, and does not need a separate class.

The class uses a `wait()-notify()` mechanism that is based on the values of two boolean flags, `ready` and `quit`. This mechanism means that the `ServerSession` creates and starts its associated thread during its construction. However, it does not automatically execute the body of the `run()` method. The body of the `run()` method is executed only when the `ready` flag is set to true by the `start()` method. The ASF calls the `start()` method when it is necessary to deliver messages to the associated JMS session.

For delivery, the `run()` method of the JMS session is called. The WebSphere MQ JMS ASF will have already loaded the `run()` method with messages.

After delivery completes, the `ready` flag is reset to false, and the owning `ServerSessionPool` is notified that delivery is complete. The `ServerSession` then remains in a wait state until either the `start()` method is called again, or the `close()` method is invoked and ends this `ServerSession`'s thread.

MyServerSessionPool.java

This class implements the `javax.jms.ServerSessionPool` interface, creating and controlling access to a pool of `ServerSessions`.

In this implementation, the pool consists of a static array of `ServerSession` objects that are created during the construction of the pool. The following four parameters are passed into the constructor:

- `javax.jms.Connection connection`
The connection used to create JMS sessions.
- `int capacity`

The size of the array of `MyServerSession` objects.

Application server sample code

- `int ackMode`
The required acknowledge mode of the JMS sessions.
- `MessageListenerFactory mlf`
The `MessageListenerFactory` that creates the message listener that is supplied to the JMS sessions. See “`MessageListenerFactory.java`”.

The pool’s constructor uses these parameters to create an array of `MyServerSession` objects. The supplied connection is used to create JMS sessions of the given acknowledge mode and correct domain (`QueueSessions` for point-to-point and `TopicSessions` for publish/subscribe). The sessions are supplied with a message listener. Finally, the `ServerSession` objects, based on the JMS sessions, are created.

This sample implementation is a static model. That is, all the `ServerSessions` in the pool are created when the pool is created, and after this the pool cannot grow or shrink. This approach is just for simplicity. It is possible for a `ServerSessionPool` to use a sophisticated algorithm to create `ServerSessions` dynamically, as needed.

`MyServerSessionPool` keeps a record of which `ServerSessions` are currently in use by maintaining an array of boolean values called `inUse`. These booleans are all initialized to false. When the `getServerSession` method is invoked and requests a `ServerSession` from the pool, the `inUse` array is searched for the first false value. When one is found, the boolean is set to true and the corresponding `ServerSession` is returned. If there are no false values in the `inUse` array, the `getServerSession` method must `wait()` until notification occurs.

Notification occurs in either of the following circumstances:

- The pool’s `close()` method is called, indicating that the pool must be shut down.
- A `ServerSession` that is currently in use completes its workload and calls the `serverSessionFinished` method. The `serverSessionFinished` method returns the `ServerSession` to the pool, and sets the corresponding `inUse` flag to false. The `ServerSession` then becomes eligible for reuse.

MessageListenerFactory.java

In this sample, a message listener factory object is associated with each `ServerSessionPool` instance. The `MessageListenerFactory` class represents a very simple interface that is used to obtain an instance of a class that implements the `javax.jms.MessageListener` interface. The class contains a single method:

```
javax.jms.MessageListener createMessageListener();
```

An implementation of this interface is supplied when the `ServerSessionPool` is constructed. This object is used to create message listeners for the individual JMS sessions that back up the `ServerSessions` in the pool. This architecture means that each separate implementation of the `MessageListenerFactory` interface must have its own `ServerSessionPool`.

WebSphere MQ JMS includes a sample `MessageListenerFactory` implementation, which is discussed in “`CountingMessageListenerFactory.java`” on page 258.

Examples of ASF use

There is a set of classes, with their source, in the directory `<install_dir>/samples/jms/asf` (where `<install_dir>` is the installation directory for WebSphere MQ JMS). These classes use the WebSphere MQ JMS application server facilities that are described in “ASF classes and functions” on page 247, within the sample standalone application server environment that is described in “Application server sample code” on page 253.

These samples provide examples of ASF use from the perspective of a client application:

- A simple point-to-point example uses:
 - ASFClient1.java
 - Load1.java
 - CountingMessageListenerFactory.java
- A more complex point-to-point example uses:
 - ASFClient2.java
 - Load2.java
 - CountingMessageListenerFactory.java
 - LoggingMessageListenerFactory.java
- A simple publish/subscribe example uses:
 - ASFClient3.java
 - TopicLoad.java
 - CountingMessageListenerFactory.java
- A more complex publish/subscribe example uses:
 - ASFClient4.java
 - TopicLoad.java
 - CountingMessageListenerFactory.java
 - LoggingMessageListenerFactory.java
- A publish/subscribe example using a durable ConnectionConsumer uses:
 - ASFClient5.java
 - TopicLoad.java

The following sections describe each class in turn.

Load1.java

This class is a generic JMS application that loads a given queue with a number of messages, then terminates. It can either retrieve the required administered objects from a JNDI namespace, or create them explicitly, using the WebSphere MQ JMS classes that implement these interfaces. The administered objects that are required are a QueueConnectionFactory and a queue. You can use the command line options to set the number of messages with which to load the queue, and the sleep time between individual message puts.

This application has two versions of the command line syntax.

For use with JNDI, the syntax is:

```
java Load1 [-icf jndiICF] [-url jndiURL] [-qcfLookup qcfLookup]
           [-qLookup qLookup] [-sleep sleepTime] [-msgs numMsgs]
```

Examples of ASF use

For use without JNDI, the syntax is:

```
java Load1 -nojndi [-qmgr qMgrName] [-q qName]  
                [-sleep sleepTime] [-msgs numMsgs]
```

Table 29 describes the parameters and gives their defaults.

Table 29. Load1 parameters and defaults

Parameter	Meaning	Default
jndiICF	Initial context factory class used for JNDI	com.sun.jndi.ldap.LdapCtxFactory
jndiURL	Provider URL used for JNDI	ldap://localhost/o=ibm,c=us
qcfLookup	JNDI lookup key used for QueueConnectionFactory	cn=qcf
qLookup	JNDI lookup key used for Queue	cn=q
qMgrName	Name of queue manager to connect to	"" (use the default queue manager)
qName	Name of queue to load	SYSTEM.DEFAULT.LOCAL.QUEUE
sleepTime	Time (in milliseconds) to pause between message puts	0 (no pause)
numMsgs	Number of messages to put	1000

If there are any errors, an error message is displayed and the application terminates.

You can use this application to simulate message load on a WebSphere MQ queue. In turn, this message load can trigger the ASF-enabled applications described in the following sections. The messages put to the queue are simple JMS TextMessage objects. These objects do not contain user-defined message properties, which could be useful to make use of different message listeners. The source code is supplied so that you can modify this load application if necessary.

CountingMessageListenerFactory.java

This file contains definitions for two classes:

- CountingMessageListener
- CountingMessageListenerFactory

CountingMessageListener is a very simple implementation of the `javax.jms.MessageListener` interface. It keeps a record of the number of times its `onMessage` method has been invoked, but does nothing with the messages it is passed.

CountingMessageListenerFactory is the factory class for CountingMessageListener. It is an implementation of the `MessageListenerFactory` interface described in "MessageListenerFactory.java" on page 256. This factory keeps a record of all the message listeners that it produces. It also includes a method, `printStats()`, which displays usage statistics for each of these listeners.

ASFClient1.java

This application acts as a client of the WebSphere MQ JMS ASF. It sets up a single ConnectionConsumer to consume the messages in a single WebSphere MQ queue. It displays throughput statistics for each message listener that is used, and terminates after one minute.

The application can either retrieve the required administered objects from a JNDI namespace, or create them explicitly, using the WebSphere MQ JMS classes that implement these interfaces. The administered objects that are required are a QueueConnectionFactory and a queue.

This application has two versions of the command line syntax:

For use with JNDI, the syntax is:

```
java ASFClient1 [-icf jndiICF] [-url jndiURL] [-qcfLookup qcfLookup]
                [-qLookup qLookup] [-poolSize poolSize] [-batchSize batchSize]
```

For use without JNDI, the syntax is:

```
java ASFClient1 -nojndi [-qmgr qMgrName] [-q qName]
                        [-poolSize poolSize] [-batchSize batchSize]
```

Table 30 describes the parameters and gives their defaults.

Table 30. ASFClient1 parameters and defaults

Parameter	Meaning	Default
jndiICF	Initial context factory class used for JNDI	com.sun.jndi.ldap.LdapCtxFactory
jndiURL	Provider URL used for JNDI	ldap://localhost/o=ibm,c=us
qcfLookup	JNDI lookup key used for QueueConnectionFactory	cn=qcf
qLookup	JNDI lookup key used for Queue	cn=q
qMgrName	Name of queue manager to connect to	"" (use the default queue manager)
qName	Name of queue to consume from	SYSTEM.DEFAULT.LOCAL.QUEUE
poolSize	The number of ServerSessions created in the ServerSessionPool being used	5
batchSize	The maximum number of message that can be assigned to a ServerSession at a time	10

The application obtains a QueueConnection from the QueueConnectionFactory.

A ServerSessionPool, in the form of a MyServerSessionPool, is constructed using:

- The QueueConnection that was created previously
- The required poolSize
- An acknowledge mode, AUTO_ACKNOWLEDGE
- An instance of a CountingMessageListenerFactory, as described in “CountingMessageListenerFactory.java” on page 258

Examples of ASF use

The connection's `createConnectionConsumer` method is invoked, passing in:

- The queue that was obtained earlier
- A null message selector (indicating that all messages should be accepted)
- The `ServerSessionPool` that was just created
- The `batchSize` that is required

The consumption of messages is then started by invoking the connection's `start()` method.

The client application displays throughput statistics for each message listener that is used, displaying statistics every 10 seconds. After one minute, the connection is closed, the server session pool is stopped, and the application terminates.

Load2.java

This class is a JMS application that loads a given queue with a number of messages, then terminates, in a similar way to `Load1.java`. The command line syntax is also similar to that for `Load1.java` (substitute `Load2` for `Load1` in the syntax). For details, see “`Load1.java`” on page 257.

The difference is that each message contains a user property called `value`, which takes a randomly selected integer value between 0 and 100. This property means that you can apply message selectors to the messages. Consequently, the messages can be shared between the two consumers that are created in the client application described in “`ASFClient2.java`”.

LoggingMessageListenerFactory.java

This file contains definitions for two classes:

- `LoggingMessageListener`
- `LoggingMessageListenerFactory`

`LoggingMessageListener` is an implementation of the `javax.jms.MessageListener` interface. It takes the messages that are passed to it and writes an entry to the log file. The default log file is `./ASFClient2.log`. You can inspect this file and check the messages that are sent to the connection consumer that is using this message listener.

`LoggingMessageListenerFactory` is the factory class for `LoggingMessageListener`. It is an implementation of the `MessageListenerFactory` interface described in “`MessageListenerFactory.java`” on page 256.

ASFClient2.java

`ASFClient2.java` is a slightly more complicated client application than `ASFClient1.java`. It creates two `ConnectionConsumers` that feed off the same queue, but that apply different message selectors. The application uses a `CountingMessageListenerFactory` for one consumer, and a `LoggingMessageListenerFactory` for the other. Use of two different message listener factories means that each consumer must have its own server session pool.

The application displays statistics that relate to one `ConnectionConsumer` on screen, and writes statistics that relate to the other `ConnectionConsumer` to a log file.

Examples of ASF use

The command line syntax is similar to that for “ASFClient1.java” on page 259 (substitute ASFClient2 for ASFClient1 in the syntax). Each of the two server session pools contains the number of ServerSessions set by the poolSize parameter.

There should be an uneven distribution of messages. The messages loaded onto the source queue by Load2 contain a user property, where the value is between 0 and 100, evenly and randomly distributed. The message selector value>75 is applied to highConnectionConsumer, and the message selector value≤75 is applied to normalConnectionConsumer. The highConnectionConsumer’s messages (approximately 25% of the total load) are sent to a LoggingMessageListener. The normalConnectionConsumer’s messages (approximately 75% of the total load) are sent to a CountingMessageListener.

When the client application runs, statistics that relate to the normalConnectionConsumer, and its associated CountingMessageListenerFactories, are printed to screen every 10 seconds. Statistics that relate to the highConnectionConsumer, and its associated LoggingMessageListenerFactories, are written to the log file.

You can inspect the screen and the log file to see the real destination of the messages. Add the totals for each of the CountingMessageListeners. As long as the client application does not terminate before all the messages are consumed, this accounts for approximately 75% of the load. The number of log file entries accounts for the remainder of the load. (If the client application terminates before all the messages are consumed, you can increase the application timeout.)

TopicLoad.java

This class is a JMS application that is a publish/subscribe version of the Load2 queue loader described in “Load2.java” on page 260. It publishes the required number of messages under the given topic, then terminates. Each message contains a user property called value, which takes a randomly selected integer value between 0 and 100.

To use this application, ensure that the broker is running and that the required setup is complete. For details, see “Additional setup for publish/subscribe mode” on page 26.

This application has two versions of the command line syntax.

For use with JNDI, the syntax is:

```
java TopicLoad [-icf jndiICF] [-url jndiURL] [-tcfLookup tcfLookup]
               [-tLookup tLookup] [-sleep sleepTime] [-msgs numMsgs]
```

For use without JNDI, the syntax is:

```
java TopicLoad -nojndi [-qmgr qMgrName] [-t tName]
                      [-sleep sleepTime] [-msgs numMsgs]
```

Table 31 describes the parameters and gives their defaults.

Table 31. TopicLoad parameters and defaults

Parameter	Meaning	Default
jndiICF	Initial context factory class used for JNDI	com.sun.jndi.ldap.LdapCtxFactory
jndiURL	Provider URL used for JNDI	ldap://localhost/o=ibm,c=us

Examples of ASF use

Table 31. TopicLoad parameters and defaults (continued)

Parameter	Meaning	Default
tcfLookup	JNDI lookup key used for TopicConnectionFactory	cn=tcf
tLookup	JNDI lookup key used for Topic	cn=t
qMgrName	Name of queue manager to connect to, and broker queue manager to publish messages to	"" (use the default queue manager)
tName	Name of topic to publish to	MQJMS/ASF/TopicLoad
sleepTime	Time (in milliseconds) to pause between message puts	0 (no pause)
numMsgs	Number of messages to put	200

If there are any errors, an error message is displayed and the application terminates.

ASFClient3.java

ASFClient3.java is a client application that is a publish/subscribe version of "ASFClient1.java" on page 259. It sets up a single ConnectionConsumer to consume the messages published on a single Topic. It displays throughput statistics for each message listener that is used, and terminates after one minute.

This application has two versions of the command line syntax.

For use with JNDI, the syntax is:

```
java ASFClient3 [-icf jndiICF] [-url jndiURL] [-tcfLookup tcfLookup]  
                [-tLookup tLookup] [-poolsize poolSize] [-batchsize batchSize]
```

For use without JNDI, the syntax is:

```
java ASFClient3 -nojndi [-qmgr qMgrName] [-t tName]  
                        [-poolsize poolSize] [-batchsize batchSize]
```

Table 32 describes the parameters and gives their defaults.

Table 32. ASFClient3 parameters and defaults

Parameter	Meaning	Default
jndiICF	Initial context factory class used for JNDI	com.sun.jndi.ldap.LdapCtxFactory
jndiURL	Provider URL used for JNDI	ldap://localhost/o=ibm,c=us
tcfLookup	JNDI lookup key used for TopicConnectionFactory	cn=tcf
tLookup	JNDI lookup key used for Topic	cn=t
qMgrName	Name of queue manager to connect to, and broker queue manager to publish messages to	"" (use the default queue manager)
tName	Name of topic to consume from	MQJMS/ASF/TopicLoad
poolSize	The number of ServerSessions created in the ServerSessionPool being used	5

Table 32. ASFClient3 parameters and defaults (continued)

Parameter	Meaning	Default
batchSize	The maximum number of message that can be assigned to a ServerSession at a time	10

Like ASFClient1, the client application displays throughput statistics for each message listener that is used, displaying statistics every 10 seconds. After one minute, the connection is closed, the server session pool is stopped, and the application terminates.

ASFClient4.java

ASFClient4.java is a more complex publish/subscribe client application. It creates three ConnectionConsumers that all feed off the same topic, but each one applies different message selectors.

The first two consumers use *high* and *normal* message selectors, in the same way as described for the application “ASFClient2.java” on page 260. The third consumer does not use any message selector. The application uses two CountingMessageListenerFactories for the two selector-based consumers, and a LoggingMessageListenerFactory for the third consumer. Because the application uses different message listener factories, each consumer must have its own server session pool.

The application displays statistics that relate to the two selector-based consumers on screen. It writes statistics that relate to the third ConnectionConsumer to a log file.

The command line syntax is similar to that for “ASFClient3.java” on page 262 (substitute ASFClient4 for ASFClient3 in the syntax). Each of the three server session pools contains the number of ServerSessions set by the poolSize parameter.

When the client application runs, statistics that relate to the normalConnectionConsumer and the highConnectionConsumer, and their associated CountingMessageListenerFactories, are printed to screen every 10 seconds. Statistics that relate to the third ConnectionConsumer, and its associated LoggingMessageListenerFactories, are written to the log file.

You can inspect the screen and the log file to see the real destination of the messages. Add the totals for each of the CountingMessageListeners and inspect the number of log file entries.

The distribution of messages is different from the distribution obtained by a point-to-point version of the same application (ASFClient2.java). This is because, in the publish/subscribe domain, each consumer of a topic obtains its own copy of each message published on that topic. In this application, for a given topic load, the high and normal consumers receive approximately 25% and 75% of the load, respectively. The third consumer still receives 100% of the load. Therefore, the total number of messages received is greater than 100% of the load originally published on the topic.

Examples of ASF use

ASFClient5.java

This sample exercises the durable publish/subscribe `ConnectionConsumer` functionality in WebSphere MQ JMS.

You invoke it with the same command-line options as the `ASFClient4` sample, and, as with the other samples, the `TopicLoad` sample application can be used to trigger the consumer that is created. For details of `TopicLoad`, see “`TopicLoad.java`” on page 261.

When invoked, `ASFClient5` displays a menu of three options:

1. Create/reactivate a durable `ConnectionConsumer`
2. Unsubscribe a durable `ConnectionConsumer`
- X. Exit

If you choose option 1, and this is the first time this sample has been run, a new durable `ConnectionConsumer` is created using the given name. It then displays one minute’s worth of throughput statistics, rather like the other samples, before closing the connection and terminating.

Having created a durable consumer, messages published on the topic in question continues to arrive at the consumer’s destination even though the consumer is inactive.

This can be confirmed by running `ASFClient5` again, and selecting option 1. This reactivates the named durable consumer, and the statistics displayed show that any relevant messages published during the period of inactivity were subsequently delivered to the consumer.

If you run `ASFClient5` again and select option 2, this unsubscribes the named durable `ConnectionConsumer` and discards any outstanding messages delivered to it. Do this to ensure that the broker does not continue to deliver unwanted messages.

Chapter 14. JMS interfaces and classes

WebSphere MQ classes for Java Message Service consists of a number of Java classes and interfaces that are based on the Sun `javax.jms` package of interfaces and classes. Write your clients using the Sun interfaces and classes that are listed below, and that are described in detail in the following sections. The names of the WebSphere MQ objects that implement the Sun interfaces and classes have a prefix of MQ (unless stated otherwise in the object description). The descriptions include details about any deviations of the WebSphere MQ objects from the standard JMS definitions. These deviations are marked with *.

Sun Java Message Service classes and interfaces

The following tables list the JMS objects contained in the package `javax.jms`. Interfaces marked with * are implemented by applications. Interfaces marked with ** are implemented by application servers.

Table 33. Summary of interfaces in package `javax.jms`

Interface	Description
BytesMessage	Used to send a message containing a stream of uninterpreted bytes.
Connection	A client's active connection to its JMS provider.
ConnectionConsumer	For application servers, a special facility for creating a <code>ConnectionConsumer</code> .
ConnectionFactory	A set of connection configuration parameters that an administrator has defined.
ConnectionMetaData	Information that describes the <code>Connection</code> .
DeliveryMode	Delivery modes supported by JMS.
Destination	Parent interface for <code>Queue</code> and <code>Topic</code> .
ExceptionListener*	Used to receive exceptions thrown by <code>Connections</code> asynchronous delivery threads.
MapMessage	Used to send a set of name-value pairs where names are <code>Strings</code> and values are Java primitive types.
Message	Root interface of all JMS messages.
MessageConsumer	Parent interface for all message consumers.
MessageListener*	Used to receive asynchronously delivered messages.
MessageProducer	Used by a client to send messages to a destination.
ObjectMessage	Used to send a message that contains a serializable Java object.
Queue	A provider-specific queue name.
QueueBrowser	Used by a client to look at messages on a queue without removing them.
QueueConnection	An active connection to a JMS point-to-point provider.
QueueConnectionFactory	Used by a client to create <code>QueueConnections</code> with a JMS point-to-point provider.
QueueReceiver	Used by a client to receive messages that have been delivered to a queue.

Table 33. Summary of interfaces in package javax.jms (continued)

Interface	Description
QueueSender	Used by a client to send messages to a queue.
QueueSession	Provides methods to create QueueReceivers, QueueSenders, QueueBrowsers and TemporaryQueues.
ServerSession **	An object implemented by an application server.
ServerSessionPool **	An object implemented by an application server to provide a pool of ServerSessions for processing the messages of a ConnectionConsumer.
Session	A single-threaded context for producing and consuming messages.
StreamMessage	Used to send a stream of Java primitives.
TemporaryQueue	A unique queue object created for the duration of a QueueConnection.
TemporaryTopic	A unique Topic object created for the duration of a TopicConnection.
TextMessage	Used to send a message containing a java.lang.String.
Topic	A provider-specific topic name.
TopicConnection	An active connection to a JMS Publish/Subscribe provider.
TopicConnectionFactory	Used by a client to create TopicConnections with a JMS Publish/Subscribe provider.
TopicPublisher	Used by a client to publish messages on a topic.
TopicSession	Provides methods to create TopicPublishers, TopicSubscribers and TemporaryTopics.
TopicSubscriber	Used by a client to receive messages that have been published to a topic.
XAConnection	Extends the capability of Connection by providing an XASession.
XAConnectionFactory	Used by some application servers to provide support for grouping Java Transaction Service (JTS)-capable resource use into a distributed transaction.
XAQueueConnection	Provides the same create options as QueueConnection.
XAQueueConnectionFactory	Provides the same create options as a QueueConnectionFactory.
XAQueueSession	Provides a regular QueueSession that can be used to create QueueReceivers, QueueSenders and QueueBrowsers.
XASession	Extends the capability of Session by adding access to a JMS provider's support for the Java Transaction API (JTA).
XATopicConnection	Provides the same create options as TopicConnection.
XATopicConnectionFactory	Provides the same create options as TopicConnectionFactory.
XATopicSession	Provides a regular TopicSession which can be used to create TopicSubscribers and TopicPublishers.

Table 34. Summary of classes in package javax.jms

Class	Description
QueueRequestor	A helper class to simplify making service requests.
TopicRequestor	A helper class to simplify making service requests.

WebSphere MQ JMS classes

Two packages contain the WebSphere MQ classes for Java Message Service that implement the Sun interfaces. Table 35 shows the interfaces implemented by classes in the **com.ibm.mq.jms** package; Table 36 on page 269 shows the interfaces implemented by classes in the **com.ibm.jms** package.

You do not usually use the implementation classes directly; you program to the JMS interfaces. Many of the interfaces do not apply when running a publish/subscribe application on a direct connection to the IBM WebSphere MQ Event Broker. Where the names of implementation classes are listed, provider-specific methods are documented in this chapter.

Table 35. Summary of classes in package *com.ibm.mq.jms*

JMS interface	Client or bindings implementation	Direct connection to WebSphere MQ Event Broker implementation
	Cleanup	
Connection	MQConnection	Y
ConnectionConsumer	MQConnectionConsumer	
ConnectionFactory	MQConnectionFactory	
ConnectionMetaData	MQConnectionMetaData	Y
Destination	MQDestination	
MessageConsumer	MQMessageConsumer	
MessageProducer	MQMessageProducer	
Queue	MQQueue	
QueueBrowser	MQQueueBrowser	
QueueConnection	MQQueueConnection	
QueueConnectionFactory	MQQueueConnectionFactory	
	MQQueueEnumeration	
QueueReceiver	MQQueueReceiver	
QueueSender	MQQueueSender	
QueueSession	MQQueueSession	
Session	MQSession	Y
TemporaryQueue	MQTemporaryQueue	
TemporaryTopic	MQTemporaryTopic	Y
Topic	MQTopic	Y
TopicConnection	MQTopicConnection	Y
TopicConnectionFactory	MQTopicConnectionFactory	Y
TopicPublisher	MQTopicPublisher	Y
TopicSession	MQTopicSession	Y
TopicSubscriber	MQTopicSubscriber	Y
XAConnection	MQXAConnection	
XAConnectionFactory	MQXAConnectionFactory	
XAQueueConnection	MQXAQueueConnection	

WebSphere MQ JMS classes

Table 35. Summary of classes in package *com.ibm.mq.jms* (continued)

JMS interface	Client or bindings implementation	Direct connection to WebSphere MQ Event Broker implementation
XAQueueConnectionFactory	MQXAQueueConnectionFactory	
XAQueueSession	MQXAQueueSession	
XASession	MQXASession	
XATopicConnection	MQXATopicConnection	
XATopicConnectionFactory	MQXATopicConnectionFactory	
XATopicSession	MQXATopicSession	

Table 36. Summary of classes in package *com.ibm.jms*

JMS interface	Client or bindings implementation	Direct connection to WebSphere MQ Event Broker implementation
BytesMessage	Y	Y
MapMessage	Y	Y
Message	Y	Y
ObjectMessage	Y	Y
StreamMessage	Y	Y
TextMessage	Y	Y

A sample implementation of the following JMS interfaces is supplied in the WebSphere MQ classes for Java Message Service.

- ServerSession
- ServerSessionPool

See “Application server sample code” on page 253 for more information

BytesMessage

public interface **BytesMessage**
extends **Message**

WebSphere MQ class: **JMSBytesMessage**

```
java.lang.Object
|
+----com.ibm.jms.JMSMessage
      |
      +----com.ibm.jms.JMSBytesMessage
```

Use a **BytesMessage** to send a message containing a stream of uninterpreted bytes. It inherits **Message** and adds a bytes message body. The receiver of the message supplies the interpretation of the bytes.

Note: This message type is for client encoding of existing message formats. If possible, use one of the other self-defining message types instead.

See also: **MapMessage**, **Message**, **ObjectMessage**, **StreamMessage**, and **TextMessage**.

Methods

readBoolean

```
public boolean readBoolean() throws JMSEException
```

Read a boolean from the bytes message.

Returns:

the boolean value read.

Throws:

- **MessageNotReadableException** if the message is in write-only mode.
- **JMSEException** if JMS fails to read the message because of an internal JMS error.
- **MessageEOFException** if it is the end of the message bytes.

readByte

```
public byte readByte() throws JMSEException
```

Read a signed 8-bit value from the bytes message.

Returns:

The next byte from the bytes message as a signed 8-bit byte.

Throws:

- **MessageNotReadableException** if the message is in write-only mode.
- **MessageEOFException** if it is the end of the message bytes.
- **JMSEException** if JMS fails to read the message because of an internal JMS error.

readBytes

```
public int readBytes(byte[] value) throws JMSEException
```

Read a byte array from the bytes message. If there are sufficient bytes remaining in the stream, the entire buffer is filled; if not, the buffer is partially filled.

Parameters:

value: the buffer into which the data is read.

Returns:

The total number of bytes read into the buffer, or -1 if there is no more data because the end of the bytes has been reached.

Throws:

- MessageNotReadableException if the message is in write-only mode.
- JMSEException if JMS fails to read the message because of an internal JMS error.

readBytes

```
public int readBytes(byte[] value, int length)
                    throws JMSEException
```

Read a portion of the bytes message.

Parameters:

- value: the buffer into which the data is read.
- length: the number of bytes to read.

Returns:

The total number of bytes read into the buffer, or -1 if there is no more data because the end of the bytes has been reached.

Throws:

- MessageNotReadableException if the message is in write-only mode.
- IndexOutOfBoundsException if length is negative, or is less than the length of the array value
- JMSEException if JMS fails to read the message because of an internal JMS error.

readChar

```
public char readChar() throws JMSEException
```

Read a Unicode character value from the bytes message.

Returns:

The next two bytes from the bytes message as a Unicode character.

Throws:

- MessageNotReadableException if the message is in write-only mode.
- MessageEOFException if it is the end of the message bytes.
- JMSEException if JMS fails to read the message because of an internal JMS error.

BytesMessage

readDouble

`public double readDouble() throws JMSEException`

Read a double from the bytes message.

Returns:

The next eight bytes from the bytes message, interpreted as a double.

Throws:

- `MessageNotReadableException` if the message is in write-only mode.
- `MessageEOFException` if it is the end of the message bytes.
- `JMSEException` if JMS fails to read the message because of an internal JMS error.

readFloat

`public float readFloat() throws JMSEException`

Read a float from the bytes message.

Returns:

The next four bytes from the bytes message, interpreted as a float.

Throws:

- `MessageNotReadableException` if the message is in write-only mode.
- `MessageEOFException` if it is the end of the message bytes.
- `JMSEException` if JMS fails to read the message because of an internal JMS error.

readInt

`public int readInt() throws JMSEException`

Read a signed 32-bit integer from the bytes message.

Returns:

The next four bytes from the bytes message, interpreted as an int.

Throws:

- `MessageNotReadableException` if the message is in write-only mode.
- `MessageEOFException` if it is the end of the message bytes.
- `JMSEException` if JMS fails to read the message because of an internal JMS error.

readLong

`public long readLong() throws JMSEException`

Read a signed 64-bit integer from the bytes message.

Returns:

The next eight bytes from the bytes message, interpreted as a long.

Throws:

- `MessageNotReadableException` if the message is in write-only mode.
- `MessageEOFException` if it is the end of the message bytes.

- JMSEException if JMS fails to read the message because of an internal JMS error.

readShort

```
public short readShort() throws JMSEException
```

Read a signed 16-bit number from the bytes message.

Returns:

The next two bytes from the bytes message, interpreted as a signed 16-bit number.

Throws:

- MessageNotReadableException if the message is in write-only mode.
- MessageEOFException if it is the end of the message bytes.
- JMSEException if JMS fails to read the message because of an internal JMS error.

readUnsignedByte

```
public int readUnsignedByte() throws JMSEException
```

Read an unsigned 8-bit number from the bytes message.

Returns:

The next byte from the bytes message, interpreted as an unsigned 8-bit number.

Throws:

- MessageNotReadableException if the message is in write-only mode.
- MessageEOFException if it is the end of the message bytes.
- JMSEException if JMS fails to read the message because of an internal JMS error.

readUnsignedShort

```
public int readUnsignedShort() throws JMSEException
```

Read an unsigned 16-bit number from the bytes message.

Returns:

The next two bytes from the bytes message, interpreted as an unsigned 16-bit integer.

Throws:

- MessageNotReadableException if the message is in write-only mode.
- MessageEOFException if it is the end of the message bytes.
- JMSEException if JMS fails to read the message because of an internal JMS error.

BytesMessage

readUTF

```
public java.lang.String readUTF() throws JMSEException
```

Read a string that has been encoded using a modified UTF-8 format from the bytes message. The first two bytes are interpreted as a 2-byte length field.

Returns:

A Unicode string from the bytes message.

Throws:

- `MessageNotReadableException` if the message is in write-only mode.
- `MessageEOFException` if it is the end of the message bytes.
- `JMSEException` if JMS fails to read the message because of an internal JMS error.

reset

```
public void reset() throws JMSEException
```

Put the message body in read-only mode, and reposition the stream of bytes to the beginning.

Throws:

- `JMSEException` if JMS fails to reset the message because of an internal JMS error.
- `MessageFormatException` if message has an incorrect format

writeBoolean

```
public void writeBoolean(boolean value) throws JMSEException
```

Write a boolean to the bytes message as a 1-byte value. The value true is written out as the value (byte)1; the value false is written out as the value (byte)0.

Parameters:

value: the boolean value to be written.

Throws:

- `MessageNotWriteableException` if message in read-only mode.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

writeByte

```
public void writeByte(byte value) throws JMSEException
```

Write a byte to the bytes message as a 1-byte value.

Parameters:

value: the byte value to be written.

Throws:

- `MessageNotWriteableException` if message in read-only mode.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

writeBytes

```
public void writeBytes(byte[] value) throws JMSEException
```

Write a byte array to the bytes message.

Parameters:

value: the byte array to be written.

Throws:

- MessageNotWriteableException if message in read-only mode.
- JMSEException if JMS fails to write the message because of an internal JMS error.

writeBytes

```
public void writeBytes(byte[] value,
                      int length) throws JMSEException
```

Write a portion of a byte array to the bytes message.

Parameters:

- value: the byte array value to be written.
- offset: the initial offset within the byte array.
- length: the number of bytes to use.

Throws:

- MessageNotWriteableException if message in read-only mode.
- JMSEException if JMS fails to write the message because of an internal JMS error.

writeChar

```
public void writeChar(char value) throws JMSEException
```

Write a char to the bytes message as a 2-byte value, high byte first.

Parameters:

value: the char value to be written.

Throws:

- MessageNotWriteableException if message in read-only mode.
- JMSEException if JMS fails to write the message because of an internal JMS error.

writeDouble

```
public void writeDouble(double value) throws JMSEException
```

Convert the double argument to a long using `doubleToLongBits` method in class `Double`, and then write that long value to the bytes message as an 8-byte quantity.

Parameters:

value: the double value to be written.

Throws:

- MessageNotWriteableException if message in read-only mode.
- JMSEException if JMS fails to write the message because of an internal JMS error.

BytesMessage

writeFloat

```
public void writeFloat(float value) throws JMSEException
```

Convert the float argument to an int using `floatToIntBits` method in class `Float`, and then write that int value to the bytes message as a 4-byte quantity.

Parameters:

value: the float value to be written.

Throws:

- `MessageNotWriteableException` - if message in read-only mode.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

writeInt

```
public void writeInt(int value) throws JMSEException
```

Write an int to the bytes message as four bytes.

Parameters:

value: the int to be written.

Throws:

- `MessageNotWriteableException` if message in read-only mode.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

writeLong

```
public void writeLong(long value) throws JMSEException
```

Write a long to the bytes message as eight bytes,

Parameters:

value: the long to be written.

Throws:

- `MessageNotWriteableException` if message in read-only mode.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

writeObject

```
public void writeObject(java.lang.Object value)
                        throws JMSEException
```

Write a Java object to the bytes message.

Note: This method works only for the primitive object types (such as `Integer`, `Double`, and `Long`), `Strings`, and byte arrays.

Parameters:

value: the Java object to be written.

Throws:

- `MessageNotWriteableException` if message in read-only mode.
- `MessageFormatException` if object is not a valid type.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

writeShort

```
public void writeShort(short value) throws JMSEException
```

Write a short to the bytes message as two bytes.

Parameters:

value: the short to be written.

Throws:

- `MessageNotWriteableException` - if message in read-only mode.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

writeUTF

```
public void writeUTF(java.lang.String value)  
                    throws JMSEException
```

Write a string to the bytes message using UTF-8 encoding in a machine-independent manner. The UTF-8 string written to the buffer starts with a 2-byte length field.

Parameters:

value: the String value to be written.

Throws:

- `MessageNotWriteableException` if message in read-only mode.
- `JMSEException` if JMS fails to write the message because of an internal JMS error.

Cleanup *

```
public class Cleanup
implements Runnable
```

WebSphere MQ class: **Cleanup**

Cleanup contains utilities for dealing with broken non-durable subscriptions using the SUBSTATE(BROKER) option. It is not applicable if you use a direct connection to WebSphere MQ Event Broker.

See also: **ConnectionFactory**.

WebSphere MQ constructor

Cleanup

```
public Cleanup()
```

Default constructor.

Cleanup

```
public Cleanup(MQTopicConnectionFactory mqtcf) throws JMSEException
```

Constructor that copies property values from the supplied MQTopicConnectionFactory.

Methods

cleanup

```
public void cleanup() throws JMSEException
```

Executes Cleanup once. If cleanupLevel is NONE, throws an IllegalStateException.

getCCSID

```
public int getCCSID()
```

Get the character set of the queue manager.

getChannel

```
public String getChannel()
```

For client only, get the channel that was used.

getCleanupInterval

```
public long getCleanupInterval()
```

Retrieve the cleanup interval.

getCleanupLevel

```
public int getCleanupLevel()
```

Retrieve the cleanup level.

getExceptionListener

```
public ExceptionListener getExceptionListener()
```

Return the ExceptionListener.

getHostName

```
public String getHostName()
```

Retrieve the name of the host.

getPort

```
public int getPort()
```

For client connections, get the port number.

getQueueManager

```
public String getQueueManager()
```

Get the name of the queue manager.

getReceiveExit

```
public String getReceiveExit()
```

Get the name of the receive exit class.

getReceiveExitInit

```
public String getReceiveExitInit()
```

Get the initialization string that was passed to the receive exit class.

getSecurityExit

```
public String getSecurityExit()
```

Get the name of the security exit class.

getSecurityExitInit

```
public String getSecurityExitInit()
```

Get the security exit initialization string.

getSendExit

```
public String getSendExit()
```

Get the name of the send exit class.

Cleanup

getSendExitInit

```
public String getSendExitInit()
```

Get the send exit initialization string.

getTransportType

```
public int getTransportType()
```

Retrieve the transport type.

isRunning

```
public boolean isRunning()
```

Return true if the run() method is currently active.

main

```
public static void main(String args[])  
    throws java.io.UnsupportedEncodingException
```

Invoke the utility from a command line. For details of the invocation options and parameters, see “Manual cleanup” on page 224.

run

```
public void run()
```

Run this utility in the background at intervals, as determined by the cleanupLevel and cleanupInterval properties.

setCCSID

```
public void setCCSID(int x) throws JMSEException
```

Set the character set to be used when connecting to the queue manager. See Table 13 on page 122 for a list of allowed values. We recommend that you use the default value (819) for most situations.

setChannel

```
public void setChannel(String x) throws JMSEException
```

For client only, set the channel to use.

setCleanupInterval

```
public void setCleanupInterval(long interval) throws JMSEException
```

Set the cleanupInterval.

Parameters:

- interval: length of time in milliseconds between runs of the cleanup utility

Throws:

JMSEException if interval is less than 0

setCleanupLevel

```
public void setCleanupLevel(int level) throws JMSEException
```

Set the cleanup level to use. It can be one of
 JMSC.MQJMS_CLEANUP_NONE
 JMSC.MQJMS_CLEANUP_SAFE
 JMSC.MQJMS_CLEANUP_STRONG
 JMSC.MQJMS_CLEANUP_FORCE
 JMSC.MQJMS_CLEANUP_NONDUR

setExceptionListener

```
public void setExceptionListener(ExceptionListener el)
```

Set the ExceptionListener. If set, the ExceptionListener receives any exceptions caused during the run() method. Shortly after issuing the exception to the ExceptionListener, Cleanup terminates.

setHostName

```
public void setHostName(String hostname)
```

For client connections, the name of the host to connect to.

setPort

```
public void setPort(int port) throws JMSEException
```

Set the port for a client connection.

Parameters:

port: the new value to use.

Throws:

JMSEException if the port is negative.

setQueueManager

```
public void setQueueManager(String x) throws JMSEException
```

Set the name of the queue manager to connect to.

setReceiveExit

```
public void setReceiveExit(String receiveExit)
```

The name of a class that implements a receive exit.

setReceiveExitInit

```
public void setReceiveExitInit(String x)
```

Initialization string that is passed to the constructor of the receive exit class.

Cleanup

setSecurityExit

```
public void setSecurityExit(String securityExit)
```

The name of a class that implements a security exit.

setSecurityExitInit

```
public void setSecurityExitInit(String x)
```

Initialization string that is passed to the security exit constructor.

setSendExit

```
public void setSendExit(String sendExit)
```

The name of a class that implements a send exit.

setSendExitInit

```
public void setSendExitInit(String x)
```

Initialization string that is passed to the constructor of send exit.

setTransportType

```
public void setTransportType(int x) throws JMSEException
```

Set the transport type to use. It can be one of:

JMSC.MQJMS_TP_BINDINGS_MQ

JMSC.MQJMS_TP_CLIENT_MQ_TCPIP

stop

```
public void stop()
```

Stop any currently running cleanup thread. Return when cleanup has finished. Do nothing if cleanup is not running.

Connection

public interface **Connection**

Subinterfaces: **QueueConnection**, **TopicConnection**, **XAQueueConnection**, and **XATopicConnection**

WebSphere MQ class: **MQConnection**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnection
```

A JMS Connection is a client's active connection to its JMS provider.

See also: **QueueConnection**, **TopicConnection**, **XAQueueConnection**, and **XATopicConnection**

Methods

close

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a Connection, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough. There is no need to close the sessions, producers, and consumers of a closed connection.

Closing a connection causes any of its sessions' in-process transactions to be rolled back. If a session's work is coordinated by an external transaction manager, when using XASession, a session's commit and rollback methods are not used and the result of a closed session's work is determined later by a transaction manager. Closing a connection does **not** force an acknowledgement of client acknowledged sessions.

WebSphere MQ JMS keeps a pool of WebSphere MQ hConns available for use by sessions. Under some circumstances, Connection.close() clears this pool. If an application uses multiple connections sequentially, you can force the pool to remain active between JMS connections. To do this, register an MQPoolToken with com.ibm.mq.MQEnvironment for the lifetime of your JMS application. For details, see "Connection pooling" on page 75 and "MQEnvironment" on page 106.

Throws:

JMSEException if the JMS implementation fails to close the connection because of an internal error. Examples are a failure to release resources or to close a socket connection.

Connection

getClientID

```
public java.lang.String getClientID()  
                        throws JMSEException
```

Get the client identifier for this connection. The client identifier can either be preconfigured by the administrator in a `ConnectionFactory`, or assigned by calling `setClientId`.

Returns:

The unique client identifier.

Throws:

`JMSEException` if the JMS implementation fails to return the client ID for this connection because of an internal error.

getExceptionListener

```
public ExceptionListener getExceptionListener()  
                        throws JMSEException
```

Get the `ExceptionListener` for this connection.

Returns:

The `ExceptionListener` for this connection

Throws:

`JMSEException` general exception if the JMS implementation fails to get the exception listener for this connection.

getMetaData

```
public ConnectionMetaData getMetaData() throws JMSEException
```

Get the metadata for this connection.

Returns:

The connection metadata.

Throws:

`JMSEException` general exception if the JMS implementation fails to get the connection metadata for this connection.

See also:

“`ConnectionMetaData`” on page 295

setClientID

```
public void setClientID(java.lang.String clientID)  
                        throws JMSEException
```

Set the client identifier for this connection.

Note: The client identifier is ignored for point-to-point connections.

WebSphere MQ Event Broker note

This method always throws an `IllegalStateException` when you make a direct connection to WebSphere MQ Event Broker.

Parameters:

`clientID`: the unique client identifier.

Throws:

- `JMSEException` if the JMS implementation fails to set the client ID for this Connection because of an internal error.
- `InvalidClientIDException` if the JMS client specifies a non valid or duplicate client ID.
- `IllegalStateException` if attempting to set a connection's client identifier at the wrong time, or if it has been configured administratively.

setExceptionListener

```
public void setExceptionListener(ExceptionListener listener)  
                                throws JMSEException
```

Set an exception listener for this connection.

Parameters:

handler: the exception listener.

Throws:

`JMSEException` general exception if the JMS implementation fails to set the exception listener for this connection.

start

```
public void start() throws JMSEException
```

Start (or restart) a connection's delivery of incoming messages. Starting a started session is ignored. Use the stop method to stop delivery.

Throws:

`JMSEException` if the JMS implementation fails to start the message delivery because of an internal error.

stop

```
public void stop() throws JMSEException
```

Used to stop a connection's delivery of incoming messages temporarily. It can be restarted using its start method. When stopped, delivery to all the connection's message consumers is inhibited. Synchronous receives are blocked, and messages are not delivered to message listeners.

Stopping a session has no affect on its ability to send messages. Stopping a stopped session is ignored.

Throws:

`JMSEException` if the JMS implementation fails to stop the message delivery because of an internal error.

ConnectionConsumer

public interface **ConnectionConsumer**

WebSphere MQ class: **MQConnectionConsumer**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnectionConsumer
```

For application servers, Connections provide a special facility to create a ConnectionConsumer. A Destination and a Property Selector specify the messages that it is to consume. Also, a ConnectionConsumer must be given a ServerSessionPool to use to process its messages.

See also: **QueueConnection**, and **TopicConnection**.

Methods

close()

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a ConnectionConsumer, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Throws:

JMSEException if a JMS implementation fails to release resources on behalf of ConnectionConsumer, or if it fails to close the connection consumer.

getServerSessionPool()

```
public ServerSessionPool getServerSessionPool()
                                throws JMSEException
```

Get the server session associated with this connection consumer.

Returns:

The server session pool used by this connection consumer.

Throws:

JMSEException if a JMS implementation fails to get the server session pool associated with this connection consumer because of an internal error.

ConnectionFactory

public interface **ConnectionFactory**
 Subinterfaces: **QueueConnectionFactory**, **TopicConnectionFactory**,
XAQueueConnectionFactory, and **XATopicConnectionFactory**

WebSphere MQ class: **MQConnectionFactory**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnectionFactory
```

A ConnectionFactory encapsulates a set of connection configuration parameters that has been defined by an administrator. A client uses it to create a Connection with a JMS provider.

WebSphere MQ Event Broker note

For direct connections to WebSphere MQ Event Broker, properties accessed by methods marked with a § are ignored.

See also: **QueueConnectionFactory**, **TopicConnectionFactory**,
XAQueueConnectionFactory, and **XATopicConnectionFactory**

WebSphere MQ constructor

```
MQConnectionFactory
    public MQConnectionFactory()
```

Methods

```
getCCSID * §
    public int getCCSID()
```

Get the character set of the queue manager.

```
getChannel * §
    public String getChannel()
```

For client only, get the channel that was used.

```
getClientId *
    public String getClientId()
```

Get the client identifier that is used for all connections that are created using this ConnectionFactory.

ConnectionFactory

getDescription *

```
public String getDescription()
```

Retrieve the object description.

getFailIfQuiesce * §

```
public int getFailIfQuiesce()
```

Get the default behavior of applications accessing a quiescing queue manager when using destinations created using this ConnectionFactory object.

getHostName *

```
public String getHostName()
```

Retrieve the name of the host.

getMsgBatchSize * §

```
public int getMsgBatchSize()
```

Return the current value of this property.

getPollingInterval * §

```
public int getPollingInterval()
```

Return the current value of this property.

getPort *

```
public int getPort()
```

For client connections or direct TCP/IP connection to WebSphere MQ Event Broker, get the port number.

getQueueManager * §

```
public String getQueueManager()
```

Get the name of the queue manager.

getReceiveExit * §

```
public String getReceiveExit()
```

Get the name of the receive exit class.

getReceiveExitInit * §

```
public String getReceiveExitInit()
```

Get the initialization string that was passed to the receive exit class.

getSecurityExit * §

```
public String getSecurityExit()
```

Get the name of the security exit class.

getSecurityExitInit * §

```
public String getSecurityExitInit()
```

Get the security exit initialization string.

getSendExit * §

```
public String getSendExit()
```

Get the name of the send exit class.

getSendExitInit * §

```
public String getSendExitInit()
```

Get the send exit initialization string.

getSSLCertStores * §

```
public java.util.Collection getSSLCertStores()
```

Return a collection of CertStore objects. If setSSLCertStores() was used to set a collection of CertStore objects, the value returned from getSSLCertStores() is a copy of the original collection. If setSSLCertStores() was used to set a string detailing a list of LDAP URIs, this method returns a collection of CertStore objects representing the LDAP CRLs.

getSSLCertStoresAsString * §

```
public String getSSLCertStoresAsString()
    throws JMSEException
```

Return the string of LDAP URIs, set with setSSLCertStores. Throws JMSEException if a collection of CertStores was set.

getSSLCipherSuite * §

```
public String getSSLCipherSuite()
```

Return the CipherSuite used for SSL encryption.

getSSLPeerName * §

```
public String getSSLPeerName()
```

Return the distinguished name pattern used to validate the queue manager.

getSSLSocketFactory * §

```
public javax.net.ssl.SSLSocketFactory getSSLSocketFactory()
```

Return the SSLSocketFactory used with SSL encryption.

getSyncpointAllGets * §

```
public boolean getSyncpointAllGets()
```

Return the current value of this property.

ConnectionFactory

getTransportType *

```
public int getTransportType()
```

Retrieve the transport type.

getUseConnectionPooling * §

```
public boolean getUseConnectionPooling()
```

Return the current value of this property.

setCCSID * §

```
public void setCCSID(int x) throws JMSEException
```

Set the character set to be used when connecting to the queue manager. See Table 13 on page 122 for a list of allowed values. We recommend that you use the default value (819) for most situations.

setChannel * §

```
public void setChannel(String x) throws JMSEException
```

For client only, set the channel to use.

setClientId *

```
public void setClientId(String x)
```

Set the client Identifier to be used for all connections created using this connection.

WebSphere MQ Event Broker note

This method always throws an `IllegalStateException` when you make a direct connection to WebSphere MQ Event Broker.

setDescription *

```
public void setDescription(String x)
```

A short description of the object.

setFailIfQuiesce * §

```
public void setFailIfQuiesce(int fiqValue) throws JMSEException
```

Set the default behavior of applications accessing a quiescing queue manager when using destinations created using this `ConnectionFactory` object.

Takes values of:

- `JMSC.MQJMS_FIQ_YES` (default)
- `JMSC.MQJMS_FIQ_NO`

setHostName *

```
public void setHostName(String hostname)
```

For client connections or direct TCP/IP connections to WebSphere MQ Event Broker, the name of the host to connect to.

setMsgBatchSize * §

```
public void setMsgBatchSize(int x)
```

Set the maximum number of messages to be taken at once when using asynchronous delivery.

setPollingInterval * §

```
public void setPollingInterval(int x)
```

Set the interval between scans of all receivers during asynchronous message delivery. The value is a number of milliseconds.

setPort *

```
public void setPort(int port) throws JMSEException
```

Set the port for a client connection or direct TCP/IP connection to WebSphere MQ Event Broker.

Parameters:

port: the new value to use.

Throws:

JMSEException if the port is negative.

setQueueManager * §

```
public void setQueueManager(String x) throws JMSEException
```

Set the name of the queue manager to connect to.

setReceiveExit * §

```
public void setReceiveExit(String receiveExit)
```

The name of a class that implements a receive exit.

setReceiveExitInit * §

```
public void setReceiveExitInit(String x)
```

Initialization string that is passed to the constructor of the receive exit class.

setSecurityExit * §

```
public void setSecurityExit(String securityExit)
```

The name of a class that implements a security exit.

ConnectionFactory

setSecurityExitInit * §

```
public void setSecurityExitInit(String x)
```

Initialization string that is passed to the security exit constructor.

setSendExit * §

```
public void setSendExit(String sendExit)
```

The name of a class that implements a send exit.

setSendExitInit * §

```
public void setSendExitInit(String x)
```

Initialization string that is passed to the constructor of send exit.

setSSLCertStores * §

```
public void setSSLCertStores(java.util.Collection stores)
```

Provide a collection of CertStore objects used for CRL checking. The certificate provided by the queue manager is checked against one of the CertStore objects contained within the collection; if the certificate is found, the connection attempt fails. At connect-time, each CertStore in the collection is tried in turn until one is successfully used to verify the queue manager's certificate. If set to null (the default), no checking of the queue manager's certificate is performed. This property is ignored if sslCipherSuite is null. Use of this property requires Java 2 v1.4.

If CertStores are specified using this method, the MQConnectionFactory cannot be bound into a JNDI namespace. Attempting to do so will result in an exception.

Note: To use a CertStore successfully with a CRL hosted on an LDAP server, make sure that your Java Software Development Kit (SDK) is compatible with the CRL. Some SDKs require that the CRL conforms to RFC 2587, which defines a schema for LDAP v2. Most LDAP v3 servers use RFC 2256 instead.

setSSLCertStores * §

```
public void setSSLCertStores(String storeSpec)
        throws JMSEException
```

Specify a list of LDAP servers used for CRL checking. This string must consist of a sequence of space-delimited LDAP URIs of the form ldap://host[:port]. If no port is specified, the LDAP default of 389 is assumed. The certificate provided by the queue manager is checked against one of the listed LDAP CRL servers; if found, the connection fails. Each LDAP server is tried in turn until one is successfully used to verify the queue manager's certificate. If set to null (the default), no checking of the queue manager's certificate is performed. Throws JMSEException if the supplied list of LDAP URIs is not valid. This property is ignored if sslCipherSuite is null. Use of this property requires Java 2 v1.4.

Note: To use a CertStore successfully with a CRL hosted on an LDAP server, make sure that your Java Software Development Kit (SDK) is compatible with the CRL. Some SDKs require that the CRL conforms to RFC 2587, which defines a schema for LDAP v2. Most LDAP v3 servers use RFC 2256 instead.

setSSLCipherSuite * §

```
public void setSSLCipherSuite(String cipherSuite)
```

Set this to the CipherSuite matching the CipherSpec set on the SVRCONN channel. If set to null (the default), no SSL encryption is performed. See Appendix H, “SSL CipherSuites supported by WebSphere MQ” on page 429 for a list of CipherSuites and their associated CipherSpecs.

setSSLPeerName * §

```
public void setSSLPeerName(String peerName)
    throws JMSEException
```

Sets sslPeerName to a distinguished name pattern. If sslCipherSuite is set, this variable can be used to ensure the correct queue manager is used. For a description of the format for this value, see “Using the distinguished name of the queue manager” on page 84. The distinguished name provided by the queue manager must match this pattern, or the connection attempt fails. If set to null (the default), no checking of the queue manager’s DN is performed. Throws JMSEException if the supplied pattern is not valid. This property is ignored if sslCipherSuite is null.

setSSLSocketFactory * §

```
public void setSSLSocketFactory(javax.net.ssl.SSLSocketFactory sf)
```

Set the SSLSocketFactory for use with SSL encryption. Use this to customize all aspects of SSL encryption. For more information on constructing and customizing SSLSocketFactory instances, refer to your JSSE provider’s documentation. If set to null (default), the JSSE default SSLSocketFactory is used when SSL encryption is requested. This property is ignored if sslCipherSuite is null.

If a custom SSLSocketFactory is specified, the MQConnectionFactory cannot be bound into a JNDI namespace. Attempting to do so results in an exception.

setSyncpointAllGets * §

```
public void setSyncpointAllGets(boolean x)
```

Choose whether to do all GET operations within a syncpoint. The default setting for this property is false. This allows GET operations not under transaction management to perform more quickly.

setTransportType *

```
public void setTransportType(int x) throws JMSEException
```

Set the transport type to use. It can be one of:

```
JMSC.MQJMS_TP_BINDINGS_MQ
JMSC.MQJMS_TP_CLIENT_MQ_TCPIP
JMSC.MQJMS_TP_DIRECT_TCPIP
```

ConnectionFactory

setUseConnectionPooling * §

```
public void setUseConnectionPooling(boolean x)
```

| Choose whether to use connection pooling. If you set this to true, JMS
| enables connection pooling for the lifetime of any connections created
| through the ConnectionFactory. This also affects connections created with
| UseConnectionPooling set to false; to disable connection pooling
| throughout a JVM, ensure that all ConnectionFactories used within the
| JVM have ConnectionPooling set to false. The default, and recommended,
| value is true. You can disable connection pooling if, for example, your
| applications run in an environment that performs its own pooling.

ConnectionMetaData

public interface **ConnectionMetaData**

WebSphere MQ class: **MQConnectionMetaData**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnectionMetaData
```

ConnectionMetaData provides information that describes the connection.

WebSphere MQ constructor

```
MQConnectionMetaData
    public MQConnectionMetaData()
```

Methods

getJMSMajorVersion

```
public int getJMSMajorVersion() throws JMSEException
```

Get the JMS major version number.

Returns:

The JMS major version number.

Throws:

JMSEException if an internal error occurs in JMS implementation during the metadata retrieval.

getJMSMinorVersion

```
public int getJMSMinorVersion() throws JMSEException
```

Get the JMS minor version number.

Returns:

The JMS minor version number.

Throws:

JMSEException if an internal error occurs in JMS implementation during the metadata retrieval.

getJMSProviderName

```
public java.lang.String getJMSProviderName()
                                throws JMSEException
```

Get the JMS provider name.

Returns:

The JMS provider name.

Throws:

JMSEException if an internal error occurs in JMS implementation during the metadata retrieval.

getJMSVersion

```
public java.lang.String getJMSVersion() throws JMSEException
```

Get the JMS version.

ConnectionMetaData

Returns:

The JMS version.

Throws:

JMSEException if an internal error occurs in JMS implementation during the metadata retrieval.

getJMSXPropertyNames

```
public java.util.Enumeration getJMSXPropertyNames()
                                throws JMSEException
```

Get an enumeration of the names of the JMSX Properties supported by this connection.

Returns:

An enumeration of JMSX PropertyNames.

Throws:

JMSEException if an internal error occurs in JMS implementation during the property names retrieval.

getProviderMajorVersion

```
public int getProviderMajorVersion() throws JMSEException
```

Get the JMS provider major version number.

Returns:

The JMS provider major version number.

Throws:

JMSEException - if an internal error occurs in JMS implementation during the metadata retrieval.

getProviderMinorVersion

```
public int getProviderMinorVersion() throws JMSEException
```

Get the JMS provider minor version number.

Returns:

The JMS provider minor version number.

Throws:

JMSEException if an internal error occurs in JMS implementation during the metadata retrieval.

getProviderVersion

```
public java.lang.String getProviderVersion()
                                throws JMSEException
```

Get the JMS provider version.

Returns:

The JMS provider version.

Throws:

JMSEException if an internal error occurs in JMS implementation during the metadata retrieval.

toString *

```
public String toString()
```

Overrides:

toString in class Object.

DeliveryMode

public interface **DeliveryMode**

Delivery modes supported by JMS.

Fields

NON_PERSISTENT

```
public static final int NON_PERSISTENT
```

The lowest overhead delivery mode, because it does not require that the message be logged to stable storage.

PERSISTENT

```
public static final int PERSISTENT
```

Instruct the JMS provider to log the message to stable storage as part of the client's send operation.

Destination

public interface **Destination**

Subinterfaces: **Queue**, **TemporaryQueue**, **TemporaryTopic**, and **Topic**

WebSphere MQ class: **MQDestination**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQDestination
```

The Destination object encapsulates provider-specific addresses.

See also: **Queue**, **TemporaryQueue**, **TemporaryTopic**, and **Topic**

WebSphere MQ constructors

MQDestination

```
public MQDestination()
```

Methods

getCCSID *

```
public int getCCSID()
```

Get the name of the character set that is used by this destination.

getDescription *

```
public String getDescription()
```

Get the description of the object.

getEncoding *

```
public int getEncoding()
```

Get the encoding that is used for this destination.

getExpiry *

```
public int getExpiry()
```

Get the value of the expiry for this destination.

getFailIfQuiesce *

```
public int getFailIfQuiesce()
```

Get the behavior of applications accessing a quiescing queue manager with this destination.

getPersistence *

```
public int getPersistence()
```

Get the value of the persistence for this destination.

getPriority *

```
public int getPriority()
```

Get the override priority value.

getTargetClient *

```
public int getTargetClient()
```

Get the JMS compliance indicator flag.

setCCSID *

```
public void setCCSID(int x) throws JMSEException
```

Character set to be used to encode text strings in messages sent to this destination. See Table 13 on page 122 for a list of allowed values. The default value is 1208 (UTF8).

setDescription *

```
public void setDescription(String x)
```

A short description of the object.

setEncoding *

```
public void setEncoding(int x) throws JMSEException
```

The encoding to be used for numeric fields in messages sent to this destination. See Table 13 on page 122 for a list of allowed values.

setExpiry *

```
public void setExpiry(int expiry) throws JMSEException
```

Override the expiry of all messages sent to this destination.

setFailIfQuiesce *

```
public void setFailIfQuiesce(int fiqValue) throws JMSEException
```

Set the behavior of applications accessing a quiescing queue manager with this destination.

Takes values of:

- JMSC.MQJMS_FIQ_YES (default)
- JMSC.MQJMS_FIQ_NO

setPersistence *

```
public void setPersistence(int persistence)
                        throws JMSEException
```

Override the persistence of all messages sent to this destination.

setPriority *

```
public void setPriority(int priority) throws JMSEException
```

Override the priority of all messages sent to this destination.

setTargetClient *

```
public void setTargetClient(int targetClient)
                        throws JMSEException
```

Whether the remote application is JMS compliant.

ExceptionListener

```
public interface ExceptionListener
```

If a JMS provider detects a serious problem with a connection, it informs the connection's `ExceptionListener` if one has been registered. It does this by calling the listener's `onException()` method, passing it a `JMSEException` that describes the problem.

This allows a client to be asynchronously notified of a problem. Some connections only consume messages, so they have no other way to learn that their `Connection` has failed.

Exceptions are delivered when:

- There is a failure in receiving an asynchronous message
- A message throws a runtime exception

Methods

onException

```
public void onException(JMSEException exception)
```

Notify user of a JMS exception.

Parameters:

`exception`: the JMS exception. These are exceptions that result from asynchronous message delivery. Typically, they indicate a problem with receiving a message from the queue manager, or possibly an internal error in the JMS implementation.

MapMessage

```
public interface MapMessage
extends Message
```

WebSphere MQ class: **JMSMapMessage**

```
java.lang.Object
|
+----com.ibm.jms.JMSMessage
|
+----com.ibm.jms.JMSMapMessage
```

Use a `MapMessage` to send a set of name-value pairs where names are strings and values are Java primitive types. The entries can be accessed sequentially or randomly by name. The order of the entries is undefined.

See also: `BytesMessage`, `Message`, `ObjectMessage`, `StreamMessage`, and `TextMessage`

Methods

`getBoolean`

```
public boolean getBoolean(java.lang.String name) throws JMSEException
```

Return the boolean value with the given name.

Parameters:

name: the name of the boolean

Returns:

The boolean value with the given name.

Throws:

- `JMSEException` if JMS fails to read the message because of an internal JMS error.
- `MessageFormatException` if this type conversion is not valid.

`getByte`

```
public byte getByte(java.lang.String name) throws JMSEException
```

Return the byte value with the given name.

Parameters:

name: the name of the byte.

Returns:

The byte value with the given name.

Throws:

- `JMSEException` if JMS fails to read the message because of an internal JMS error.
- `MessageFormatException` if this type conversion is not valid.

MapMessage

getBytes

public byte[] **getBytes**(java.lang.String name) throws JMSEException

Return the byte array value with the given name.

Parameters:

name: the name of the byte array.

Returns:

A copy of the byte array value with the given name. If there is no item by this name, a null value is returned.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type of conversion is not valid.

getChar

public char **getChar**(java.lang.String name) throws JMSEException

Return the Unicode character value with the given name.

Parameters:

name: the name of the Unicode character.

Returns:

The Unicode character value with the given name.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getDouble

public double **getDouble**(java.lang.String name) throws JMSEException

Return the double value with the given name.

Parameters:

name: the name of the double.

Returns:

The double value with the given name.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getFloat

public float **getFloat**(java.lang.String name) throws JMSEException

Return the float value with the given name.

Parameters:

name: the name of the float.

Returns:

The float value with the given name.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getInt

public int **getInt**(java.lang.String name) throws JMSEException

Return the integer value with the given name.

Parameters:

name: the name of the integer.

Returns:

The integer value with the given name.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getLong

public long **getLong**(java.lang.String name) throws JMSEException

Return the long value with the given name.

Parameters:

name: the name of the long.

Returns:

The long value with the given name.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getMapNames

public java.util.Enumeration **getMapNames**() throws JMSEException

Return an enumeration of all the map message's names.

Returns:

An enumeration of all the names in this map message.

Throws:

JMSEException if JMS fails to read the message because of an internal JMS error.

MapMessage

getObject

```
public java.lang.Object getObject(java.lang.String name) throws JMSEException
```

Return the Java object value with the given name. This method returns in object format, a value that has been stored in the map either using the setObject method call, or the equivalent primitive set method.

Parameters:

name: the name of the Java object.

Returns:

A copy of the Java object value with the given name, in object format (if it is set as an int, an Integer is returned). If there is no item by this name, a null value is returned.

Throws:

JMSEException if JMS fails to read the message because of an internal JMS error.

getShort

```
public short getShort(java.lang.String name) throws JMSEException
```

Return the short value with the given name.

Parameters:

name: the name of the short.

Returns:

The short value with the given name.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getString

```
public java.lang.String getString(java.lang.String name) throws JMSEException
```

Return the string value with the given name.

Parameters:

name: the name of the string.

Returns:

The string value with the given name. If there is no item by this name, a null value is returned.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

itemExists

```
public boolean itemExists(java.lang.String name)
                        throws JMSEException
```

Check if an item exists in this MapMessage.

Parameters:

name: the name of the item to test.

Returns:

True if the item exists.

Throws:

JMSEException - if a JMS error occurs.

setBoolean

```
public void setBoolean(java.lang.String name,
                       boolean value) throws JMSEException
```

Set a boolean value with the given name into the map.

Parameters:

- name: the name of the boolean.
- value: the boolean value to set in the Map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

setByte

```
public void setByte(java.lang.String name,
                    byte value) throws JMSEException
```

Set a byte value with the given name into the map.

Parameters:

- name: the name of the byte.
- value: the byte value to set in the Map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error
- MessageNotWriteableException if the message is in read-only mode.

setBytes

```
public void setBytes(java.lang.String name,
                     byte[] value) throws JMSEException
```

Set a byte array value with the given name into the map.

Parameters:

- name: the name of the byte array.
- value: the byte array value to set in the map.
The array is copied, so the value in the map is not altered by subsequent modifications to the array.

MapMessage

Throws:

- `JMSEException` if JMS fails to write message due to some internal JMS error.
- `MessageNotWriteableException` if the message is in read-only mode.

setBytes

```
public void setBytes(java.lang.String name,  
                    byte[] value,  
                    int offset,  
                    int length) throws JMSEException
```

Set a portion of the byte array value with the given name into the mp.

The array is copied, so the value in the map is not altered by subsequent modifications to the array.

Parameters:

- `name`: the name of the byte array.
- `value`: the byte array value to set in the Map.
- `offset`: the initial offset within the byte array.
- `length`: the number of bytes to be copied.

Throws:

- `JMSEException` if JMS fails to write message due to some internal JMS error.
- `MessageNotWriteableException` if the message is in read-only mode.

setChar

```
public void setChar(java.lang.String name,  
                   char value) throws JMSEException
```

Set a Unicode character value with the given name into the map.

Parameters:

- `name`: the name of the Unicode character.
- `value`: the Unicode character value to set in the map.

Throws:

- `JMSEException` if JMS fails to write message due to some internal JMS error.
- `MessageNotWriteableException` if the message is in read-only mode.

setDouble

```
public void setDouble(java.lang.String name,  
                    double value) throws JMSEException
```

Set a double value with the given name into the map.

Parameters:

- `name`: the name of the double.
- `value`: the double value to set in the Map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

setFloat

```
public void setFloat(java.lang.String name,  
                    float value) throws JMSEException
```

Set a float value with the given name into the map.

Parameters:

- name: the name of the float.
- value: the float value to set in the map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

setInt

```
public void setInt(java.lang.String name,  
                  int value) throws JMSEException
```

Set an integer value with the given name into the map.

Parameters:

- name: the name of the integer.
- value: the integer value to set in the map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

setLong

```
public void setLong(java.lang.String name,  
                   long value) throws JMSEException
```

Set a long value with the given name into the map.

Parameters:

- name: the name of the long.
- value: the long value to set in the map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

MapMessage

setObject

```
public void setObject(java.lang.String name,  
                      java.lang.Object value) throws JMSEException
```

Set a Java object value with the given name into the map. This method works only for object primitive types (for example, Integer, Double, and Long), strings and byte arrays.

Parameters:

- name: the name of the Java object.
- value: the Java object value to set in the map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageFormatException if object is not valid.
- MessageNotWriteableException if the message is in read-only mode.

setShort

```
public void setShort(java.lang.String name,  
                    short value) throws JMSEException
```

Set a short value with the given name into the map.

Parameters:

- name: the name of the short.
- value: the short value to set in the map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageNotWriteableException - if the message is in read-only mode.

setString

```
public void setString(java.lang.String name,  
                     java.lang.String value) throws JMSEException
```

Set a string value with the given name into the map.

Parameters:

- name: the name of the string.
- value: the string value to set in the map.

Throws:

- JMSEException if JMS fails to write message due to some internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

Message

public interface **Message**
 Subinterfaces: **BytesMessage**, **MapMessage**, **ObjectMessage**,
StreamMessage, and **TextMessage**

WebSphere MQ class: **JMSMessage**

```
java.lang.Object
|
+----com.ibm.jms.MQJMSMessage
```

The Message interface is the root interface of all JMS messages. It defines the JMS header and the acknowledge method used for all messages.

Fields

DEFAULT_DELIVERY_MODE

```
public static final int DEFAULT_DELIVERY_MODE
```

The default delivery mode value.

DEFAULT_PRIORITY

```
public static final int DEFAULT_PRIORITY
```

The default priority value.

DEFAULT_TIME_TO_LIVE

```
public static final long DEFAULT_TIME_TO_LIVE
```

The default time-to-live value.

Methods

acknowledge

```
public void acknowledge() throws JMSEException
```

Acknowledge this and all previous messages received by the session.

Throws:

JMSEException if JMS fails to acknowledge because of an internal JMS error.

clearBody

```
public void clearBody() throws JMSEException
```

Clear out the message body. All other parts of the message are left untouched.

Throws:

JMSEException if JMS fails to because of an internal JMS error.

Message

clearProperties

```
public void clearProperties() throws JMSEException
```

Clear a message's properties. The header fields and message body are not cleared.

Throws:

JMSEException if JMS fails to clear JMS message properties because of an internal JMS error.

getBooleanProperty

```
public boolean getBooleanProperty(java.lang.String name)  
                                     throws JMSEException
```

Return the boolean property value with the given name.

Parameters:

name: the name of the boolean property.

Returns:

The boolean property value with the given name.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid

getBytesProperty

```
public byte getBytesProperty(java.lang.String name)  
                                     throws JMSEException
```

Return the byte property value with the given name.

Parameters:

name: the name of the byte property.

Returns:

The byte property value with the given name.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getDoubleProperty

```
public double getDoubleProperty(java.lang.String name)  
                                     throws JMSEException
```

Return the double property value with the given name.

Parameters:

name: the name of the double property.

Returns:

The double property value with the given name.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getFloatProperty

```
public float getFloatProperty(java.lang.String name)
                                throws JMSEException
```

Return the float property value with the given name.

Parameters:

name: the name of the float property.

Returns:

The float property value with the given name.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getIntProperty

```
public int getIntProperty(java.lang.String name)
                                throws JMSEException
```

Return the integer property value with the given name.

Parameters:

name: the name of the integer property.

Returns:

The integer property value with the given name.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getJMSCorrelationID

```
public java.lang.String getJMSCorrelationID()
                                throws JMSEException
```

Get the correlation ID for the message.

Returns:

The correlation ID of a message as a string.

Throws:

JMSEException if JMS fails to get the correlation ID because of an internal JMS error.

See also:

setJMSCorrelationID(), getJMSCorrelationIDAsBytes(),
setJMSCorrelationIDAsBytes()

Message

getJMSCorrelationIDAsBytes

```
public byte[] getJMSCorrelationIDAsBytes() throws JMSEException
```

Get the correlation ID as an array of bytes for the message.

Returns:

The correlation ID of a message as an array of bytes.

Throws:

JMSEException if JMS fails to get correlation ID because of an internal JMS error.

See also:

setJMSCorrelationID(), getJMSCorrelationID(),
setJMSCorrelationIDAsBytes()

getJMSDeliveryMode

```
public int getJMSDeliveryMode() throws JMSEException
```

Get the delivery mode for this message.

Returns:

The delivery mode of this message.

Throws:

JMSEException if JMS fails to get JMS DeliveryMode because of an internal JMS error.

See also:

setJMSDeliveryMode(), DeliveryMode

getJMSDestination

```
public Destination getJMSDestination() throws JMSEException
```

Get the destination for this message.

Returns:

The destination of this message.

Throws:

JMSEException if JMS fails to get JMS Destination because of an internal JMS error.

See also:

setJMSDestination()

getJMSExpiration

```
public long getJMSExpiration() throws JMSEException
```

Get the message's expiration value.

Returns:

The time that the message expires. It is the sum of the time-to-live value specified by the client, and the GMT at the time of the send.

Throws:

JMSEException if JMS fails to get JMS message expiration because of an internal JMS error.

See also:

setJMSExpiration()

getJMSMessageID

```
public java.lang.String getJMSMessageID()
                                throws JMSEException
```

Get the message ID.

Returns:

The message ID.

Throws:

JMSEException if JMS fails to get the message ID because of an internal JMS error.

See also:

setJMSMessageID()

getJMSPriority

```
public int getJMSPriority() throws JMSEException
```

Get the message priority.

Returns:

The message priority.

Throws:

JMSEException if JMS fails to get JMS message priority because of an internal JMS error.

See also:

setJMSPriority() for priority levels

getJMSRedelivered

```
public boolean getJMSRedelivered() throws JMSEException
```

Get an indication of whether this message is being redelivered.

If a client receives a message with the redelivered indicator set, it is likely, but not guaranteed, that this message was delivered to the client earlier, but that the client did not acknowledge its receipt at that earlier time.

Returns:

Set to true if this message is being redelivered.

Throws:

JMSEException if JMS fails to get JMS redelivered flag because of an internal JMS error.

See also:

setJMSRedelivered()

getJMSReplyTo

```
public Destination getJMSReplyTo() throws JMSEException
```

Get where a reply to this message should be sent.

Returns:

Where to send a response to this message

Throws:

JMSEException if JMS fails to get ReplyTo destination because of an internal JMS error.

Message

See also:

setJMSReplyTo()

getJMSTimestamp

public long **getJMSTimestamp()** throws JMSEException

Get the message timestamp.

Returns:

The message timestamp.

Throws:

JMSEException if JMS fails to get the timestamp because of an internal JMS error.

See also:

setJMSTimestamp()

getJMSType

public java.lang.String **getJMSType()** throws JMSEException

Get the message type.

Returns:

The message type.

Throws:

JMSEException if JMS fails to get JMS message type because of an internal JMS error.

See also:

setJMSType()

getLongProperty

public long **getLongProperty**(java.lang.String name)
throws JMSEException

Return the long property value with the given name.

Parameters:

name: the name of the long property.

Returns:

The long property value with the given name.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getObjectProperty

public java.lang.Object **getObjectProperty** (java.lang.String name)
throws JMSEException

Return the Java object property value with the given name.

Parameters:

name: the name of the Java object property.

Returns:

The Java object property value with the given name, in object format (for example, if it set as an int, an Integer is returned). If there is no property by this name, a null value is returned.

Throws:

JMSEException if JMS fails to get the property because of an internal JMS error.

getPropertyNames

```
public java.util.Enumeration getPropertyNames()  
                                throws JMSEException
```

Return an enumeration of all the property names.

Returns:

An enumeration of all the names of property values.

Throws:

JMSEException if JMS fails to get the property names because of an internal JMS error.

getShortProperty

```
public short getShortProperty(java.lang.String name)  
                                throws JMSEException
```

Return the short property value with the given name.

Parameters:

name: the name of the short property.

Returns:

The short property value with the given name.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

getStringProperty

```
public java.lang.String getStringProperty (java.lang.String name)  
                                throws JMSEException
```

Return the string property value with the given name.

Parameters:

name: the name of the string property

Returns:

The string property value with the given name. If there is no property by this name, a null value is returned.

Throws:

- JMSEException if JMS fails to get the property because of an internal JMS error.
- MessageFormatException if this type conversion is not valid.

Message

propertyExists

```
public boolean propertyExists(java.lang.String name)
                                throws JMSEException
```

Check if a property value exists.

Parameters:

name: the name of the property to test.

Returns:

True if the property does exist.

Throws:

JMSEException if JMS fails to check whether a property exists because of an internal JMS error.

setBooleanProperty

```
public void setBooleanProperty(java.lang.String name,
                                boolean value) throws JMSEException
```

Set a boolean property value with the given name into the message.

Parameters:

- name: the name of the boolean property.
- value: the boolean property value to set in the message.

Throws:

- JMSEException if JMS fails to set property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

setByteProperty

```
public void setByteProperty(java.lang.String name,
                              byte value) throws JMSEException
```

Set a byte property value with the given name into the message.

Parameters:

- name: the name of the byte property.
- value: the byte property value to set in the message.

Throws:

- JMSEException if JMS fails to set property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

setDoubleProperty

```
public void setDoubleProperty(java.lang.String name,
                                double value) throws JMSEException
```

Set a double property value with the given name into the message.

Parameters:

- name: the name of the double property.
- value: the double property value to set in the message.

Throws:

- JMSException if JMS fails to set the property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

setFloatProperty

```
public void setFloatProperty(java.lang.String name,
                             float value) throws JMSException
```

Set a float property value with the given name into the message.

Parameters:

- name: the name of the float property.
- value: the float property value to set in the message.

Throws:

- JMSException if JMS fails to set the property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

setIntProperty

```
public void setIntProperty(java.lang.String name,
                             int value) throws JMSException
```

Set an integer property value with the given name into the message.

Parameters:

- name: the name of the integer property.
- value: the integer property value to set in the message.

Throws:

- JMSException if JMS fails to set property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

setJMSCorrelationID

```
public void setJMSCorrelationID
           (java.lang.String correlationID)
           throws JMSException
```

Set the correlation ID for the message.

A client can use the JMSCorrelationID header field to link one message with another. A typical use is to link a response message with its request message.

Note: The use of a byte[] value for JMSCorrelationID is non-portable.

Parameters:

correlationID: the message ID of a message being referred to.

Throws:

JMSException if JMS fails to set the correlation ID because of an internal JMS error.

See also:

getJMSCorrelationID(), getJMSCorrelationIDAsBytes(),
setJMSCorrelationIDAsBytes()

Message

setJMSCorrelationIDAsBytes

```
public void setJMSCorrelationIDAsBytes(byte[] correlationID)
                                         throws JMSEException
```

Set the correlation ID as an array of bytes for the message. A client can use this call to set the correlationID equal either to a messageID from a previous message, or to an application-specific string. Application-specific strings must not start with the characters ID.

Parameters:

correlationID: the correlation ID as a string, or the message ID of a message being referred to.

Throws:

JMSEException if JMS fails to set the correlation ID because of an internal JMS error.

See also:

setJMSCorrelationID(), getJMSCorrelationID(),
getJMSCorrelationIDAsBytes()

setJMSDeliveryMode

```
public void setJMSDeliveryMode(int deliveryMode)
                                         throws JMSEException
```

Set the delivery mode for this message.

Any value set using this method is ignored when the message is sent, but this method can be used to change the value in a received message.

To alter the delivery mode when a message is sent, use the setDeliveryMode method on the QueueSender or TopicPublisher (this method is inherited from MessageProducer).

Parameters:

deliveryMode: the delivery mode for this message.

Throws:

JMSEException if JMS fails to set JMS DeliveryMode because of an internal JMS error.

See also:

getJMSDeliveryMode(), DeliveryMode

setJMSDestination

```
public void setJMSDestination(Destination destination)
                                         throws JMSEException
```

Set the destination for this message.

Any value set using this method is ignored when the message is sent, but this method can be used to change the value in a received message.

Parameters:

destination: the destination for this message.

Throws:

JMSEException if JMS fails to set JMS destination because of an internal JMS error.

See also:

`getJMSTDestination()`

setJMSExpiration

```
public void setJMSExpiration(long expiration)
                               throws JMSException
```

Set the message's expiration value.

Any value set using this method is ignored when the message is sent, but this method can be used to change the value in a received message.

Parameters:

expiration: the message's expiration time.

Throws:

JMSException if JMS fails to set JMS message expiration because of an internal JMS error.

See also:

`getJMSExpiration()`

setJMSMessageID

```
public void setJMSMessageID(java.lang.String id)
                               throws JMSException
```

Set the message ID.

Any value set using this method is ignored when the message is sent, but this method can be used to change the value in a received message.

Parameters:

id: the ID of the message.

Throws:

JMSException if JMS fails to set the message ID because of an internal JMS error.

See also:

`getJMSMessageID()`

setJMSPriority

```
public void setJMSPriority(int priority)
                               throws JMSException
```

Set the priority for this message.

JMS defines a ten-level priority value, with 0 as the lowest priority, and 9 as the highest. In addition, clients must consider priorities 0-4 as gradations of normal priority, and priorities 5-9 as gradations of expedited priority.

Parameters:

priority: the priority of this message.

Throws:

JMSException if JMS fails to set JMS message priority because of an internal JMS error.

See also:

`getJMSPriority()`

Message

setJMSRedelivered

```
public void setJMSRedelivered(boolean redelivered)
                                   throws JMSEException
```

Set to indicate whether this message is being redelivered.

Any value set using this method is ignored when the message is sent, but this method can be used to change the value in a received message.

Parameters:

`redelivered`: an indication of whether this message is being redelivered.

Throws:

JMSEException if JMS fails to set JMSRedelivered flag because of an internal JMS error.

See also:

`getJMSRedelivered()`

setJMSReplyTo

```
public void setJMSReplyTo(Destination replyTo)
                                   throws JMSEException
```

Set where a reply to this message should be sent.

Parameters:

`replyTo`: where to send a response to this message. A null value indicates that no reply is expected.

Throws:

JMSEException if JMS fails to set ReplyTo destination because of an internal JMS error.

See also:

`getJMSReplyTo()`

setJMSTimestamp

```
public void setJMSTimestamp(long timestamp)
                                   throws JMSEException
```

Set the message timestamp.

Any value set using this method is ignored when the message is sent, but this method can be used to change the value in a received message.

Parameters:

`timestamp`: the timestamp for this message.

Throws:

JMSEException if JMS fails to set the timestamp because of an internal JMS error.

See also:

`getJMSTimestamp()`

setJMSType

```
public void setJMSType(java.lang.String type)
                        throws JMSEException
```

Set the message type.

JMS clients must assign a value to type whether the application makes use of it or not. This ensures that it is properly set for those providers that require it.

Parameters:

type: the class of message.

Throws:

JMSEException if JMS fails to set JMS message type because of an internal JMS error.

See also:

getJMSType()

setLongProperty

```
public void setLongProperty(java.lang.String name,
                             long value) throws JMSEException
```

Set a long property value with the given name into the message.

Parameters:

- name: the name of the long property.
- value: the long property value to set in the message.

Throws:

- JMSEException if JMS fails to set property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

setObjectProperty

```
public void setObjectProperty(java.lang.String name,
                               java.lang.Object value) throws JMSEException
```

Set a property value with the given name into the message.

Parameters:

- name: the name of the Java object property.
- value: the Java object property value to set in the message.

Throws:

- JMSEException if JMS fails to set property because of an internal JMS error.
- MessageFormatException if the object is not valid.
- MessageNotWriteableException - if the properties are read-only.

Message

setShortProperty

```
public void setShortProperty(java.lang.String name,  
                             short value) throws JMSEException
```

Set a short property value with the given name into the message.

Parameters:

- name: the name of the short property.
- value: the short property value to set in the message.

Throws:

- JMSEException if JMS fails to set property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

setStringProperty

```
public void setStringProperty(java.lang.String name,  
                               java.lang.String value) throws JMSEException
```

Set a string property value with the given name into the message.

Parameters:

- name: the name of the string property.
- value: the string property value to set in the message.

Throws:

- JMSEException if JMS fails to set the property because of an internal JMS error.
- MessageNotWriteableException if the properties are read-only.

MessageConsumer

public interface **MessageConsumer**
 Subinterfaces: **QueueReceiver** and **TopicSubscriber**

WebSphere MQ class: **MQMessageConsumer**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQMessageConsumer
```

MessageConsumer is the parent interface for all message consumers. A client uses a message consumer to receive messages from a Destination.

Methods

getMessageListener

```
public MessageListener getMessageListener()
                                throws JMSEException
```

Get the message consumer's MessageListener.

Returns:

The listener for the message consumer, or null if a listener is not set.

Throws:

JMSEException if JMS fails to get the message listener because of a JMS error.

See also:

setMessageListener

getMessageSelector

```
public java.lang.String getMessageSelector()
                                throws JMSEException
```

Get this message consumer's message selector expression.

Returns:

The message consumer's message selector.

Throws:

JMSEException if JMS fails to get the message selector because of a JMS error.

receive

```
public Message receive() throws JMSEException
```

Receive the next message produced for this message consumer.

Returns:

The next message produced for this message consumer.

Throws:

JMSEException if JMS fails to receive the next message because of an error.

MessageConsumer

receive

```
public Message receive(long timeOut) throws JMSEException
```

Receive the next message that arrives within the specified timeout interval. A timeout value of zero causes the call to wait indefinitely until a message arrives.

Parameters:

timeout: the timeout value (in milliseconds).

Returns:

The next message produced for this message consumer, or null if one is not available.

Throws:

JMSEException if JMS fails to receive the next message because of an error.

receiveNoWait

```
public Message receiveNoWait() throws JMSEException
```

Receive the next message if one is immediately available.

Returns:

The next message produced for this message consumer, or null if one is not available.

Throws:

JMSEException if JMS fails to receive the next message because of an error.

setMessageListener

```
public void setMessageListener(MessageListener listener)  
                                throws JMSEException
```

Set the message consumer's MessageListener.

Parameters:

messageListener: the messages are delivered to this listener.

Throws:

JMSEException if JMS fails to set message listener because of a JMS error.

See also:

getMessageListener

close

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a MessageConsumer, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

This call blocks until a receive or message listener in progress has completed.

Throws:

JMSEException if JMS fails to close the consumer because of an error.

MessageListener

public interface **MessageListener**

Use a MessageListener to receive asynchronously delivered messages.

Methods

onMessage

public void **onMessage**(Message message)

Pass a message to the listener.

Parameters:

message: the message passed to the listener.

See also

Session.setMessageListener

MessageProducer

public interface **MessageProducer**
Subinterfaces: **QueueSender** and **TopicPublisher**

WebSphere MQ class: **MQMessageProducer**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQMessageProducer
```

A client uses a MessageProducer to send messages to a destination.

WebSphere MQ constructors

MQMessageProducer
public MQMessageProducer()

Methods

close
public void **close()** throws JMSEException

Because a provider can allocate some resources outside the JVM on behalf of a MessageProducer, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Throws:
JMSEException if JMS fails to close the producer because of an error.

getDeliveryMode
public int **getDeliveryMode()** throws JMSEException

Get the producer's default delivery mode.

Returns:
The message delivery mode for this message producer.

Throws:
JMSEException if JMS fails to get the delivery mode because of an internal error.

See also:
setDeliveryMode

getDisableMessageID
public boolean **getDisableMessageID()** throws JMSEException

Get an indication of whether message IDs are disabled.

Returns:
An indication of whether message IDs are disabled.

Throws:
JMSEException if JMS fails to get the disabled message ID because of an internal error.

getDisableMessageTimestamp

```
public boolean getDisableMessageTimestamp()  
                throws JMSEException
```

Get an indication of whether message timestamps are disabled.

Returns:

An indication of whether message IDs are disabled.

Throws:

JMSEException if JMS fails to get the disabled message timestamp because of an internal error.

getPriority

```
public int getPriority() throws JMSEException
```

Get the producer's default priority.

Returns:

The message priority for this message producer.

Throws:

JMSEException if JMS fails to get the priority because of an internal error.

See also:

setPriority

getTimeToLive

```
public long getTimeToLive() throws JMSEException
```

Get the default length of time in milliseconds from its dispatch time that the message system retains a produced message.

Returns:

The message time-to-live in milliseconds; zero is unlimited.

Throws:

JMSEException if JMS fails to get the time-to-live because of an internal error.

See also:

setTimeToLive

setDeliveryMode

```
public void setDeliveryMode(int deliveryMode)  
                throws JMSEException
```

Set the producer's default delivery mode; it is set to DeliveryMode.PERSISTENT by default.

Parameters:

deliveryMode: the message delivery mode for this message producer.

Throws:

JMSEException if JMS fails to set the delivery mode because of an internal error.

See also:

getDeliveryMode, DeliveryMode.NON_PERSISTENT, DeliveryMode.PERSISTENT

MessageProducer

setDisableMessageID

```
public void setDisableMessageID(boolean value)
                                     throws JMSEException
```

Set whether message IDs are disabled; they are enabled by default.

Note: This method is ignored in the WebSphere MQ classes for Java Message Service implementation.

Parameters:

value: indicates whether message IDs are disabled.

Throws:

JMSEException if JMS fails to set the disabled message ID because of an internal error.

setDisableMessageTimestamp

```
public void setDisableMessageTimestamp(boolean value)
                                     throws JMSEException
```

Set whether message timestamps are disabled; they are enabled by default.

Note: This method is ignored in the WebSphere MQ classes for Java Message Service implementation.

Parameters:

value: indicates whether message timestamps are disabled.

Throws:

JMSEException if JMS fails to set the disabled message timestamp because of an internal error.

setPriority

```
public void setPriority(int priority) throws JMSEException
```

Set the producer's default priority (default 4).

Parameters:

priority: the message priority for this message producer.

Throws:

JMSEException if JMS fails to set the priority because of an internal error.

See also:

getPriority

setTimeToLive

```
public void setTimeToLive(long timeToLive)
                                     throws JMSEException
```

Set the default length of time, in milliseconds from its dispatch time, that the message system retains a produced message.

Time-to-live is set to zero by default.

WebSphere MQ Event Broker note

This method throws a JMSEException if set to other than 0 when you make a direct connection to WebSphere MQ Event Broker.

Parameters:

`timeToLive`: the message time to live in milliseconds; zero is unlimited.

Throws:

`JMSEException` if JMS fails to set the time-to-live because of an internal error.

See also:

`getTimeToLive`

MQQueueEnumeration *

```
public class MQQueueEnumeration
    extends Object
    implements Enumeration
```

```
java.lang.Object
|
+----com.ibm.mq.jms.MQQueueEnumeration
```

MQQueueEnumeration enumerates messages on a queue. This class is not defined in the JMS specification; it is created by calling the `getEnumeration` method of `MQQueueBrowser`. The class contains a base `MQQueue` instance to hold the browse cursor. The queue is closed once the cursor has moved off the end of the queue.

There is no way to reset an instance of this class; it acts as a *one-shot* mechanism.

See also: `MQQueueBrowser`

Methods

hasMoreElements

```
public boolean hasMoreElements()
```

Whether another message can be returned.

nextElement

```
public Object nextElement() throws NoSuchElementException
```

Return the current message.

If `hasMoreElements()` returns true, `nextElement()` always returns a message. It is possible for the returned message to pass its expiry date between the `hasMoreElements()` and the `nextElement` calls.

ObjectMessage

```
public interface ObjectMessage
extends Message
```

WebSphere MQ class: **JMSObjectMessage**

```
java.lang.Object
|
+----com.ibm.jms.JMSMessage
|
+----com.ibm.jms.JMSObjectMessage
```

Use an `ObjectMessage` to send a message that contains a serializable Java object. It inherits from `Message` and adds a body containing a single Java reference. Only serializable Java objects can be used.

See also: `BytesMessage`, `MapMessage`, `Message`, `StreamMessage`, and `TextMessage`

Methods

`getObject`

```
public java.io.Serializable getObject()
throws JMSException
```

Get the serializable object containing this message's data. The default value is null.

Returns:

The serializable object containing this message's data.

Throws:

- `JMSException` if JMS fails to get the object because of an internal JMS error.
- `MessageFormatException` if object deserialization fails.

`setObject`

```
public void setObject(java.io.Serializable object)
throws JMSException
```

Set the serializable object containing this message's data. The `ObjectMessage` contains a snapshot of the object at the time `setObject()` is called. Subsequent modifications of the object have no effect on the `ObjectMessage` body.

Parameters:

`object`: the message's data.

Throws:

- `JMSException` if JMS fails to set the object because of an internal JMS error.
- `MessageFormatException` if object serialization fails.
- `MessageNotWriteableException` if the message is in read-only mode.

Queue

public interface **Queue**
 extends **Destination**
 Subinterfaces: **TemporaryQueue**

WebSphere MQ class: **MQQueue**

```

java.lang.Object
|
+----com.ibm.mq.jms.MQDestination
      |
      +----com.ibm.mq.jms.MQQueue
  
```

A Queue object encapsulates a provider-specific queue name. It is the way that a client specifies the identity of a queue to JMS methods.

WebSphere MQ constructors

MQQueue *

```
public MQQueue()
```

Default constructor for use by the administration tool.

MQQueue *

```
public MQQueue(String URIqueue)
```

Create a new MQQueue instance. The string takes a URI format, as described on page 196.

MQQueue *

```
public MQQueue(String queueManagerName,
               String queueName)
```

Methods

getBaseQueueManagerName *

```
public String getBaseQueueManagerName()
```

Returns:

The value of the WebSphere MQ queue manager name.

getBaseQueueName *

```
public String getBaseQueueName()
```

Returns:

The value of the WebSphere MQ queue name.

getQueueName

```
public java.lang.String getQueueName()
                               throws JMSException
```

Get the name of this queue.

Clients that depend upon the name are not portable.

Returns:

The queue name

Throws:

JMSEException if JMS implementation for queue fails to return the queue name because of an internal error.

getReference *

```
public Reference getReference() throws NamingException
```

Create a reference for this queue.

Returns:

A reference for this object.

Throws:

NamingException.

setBaseQueueManagerName *

```
public void setBaseQueueManagerName(String x) throws JMSEException
```

Set the value of the WebSphere MQ queue manager name.

Note: Only the administration tool can use this method.

setBaseQueueName *

```
public void setBaseQueueName(String x) throws JMSEException
```

Set the value of the WebSphere MQ queue name.

Note: Only the administration tool can use this method. It makes no attempt to decode queue:qmgr:queue format strings.

toString

```
public java.lang.String toString()
```

Return a well-formatted printed version of the queue name.

Returns:

The provider-specific identity values for this queue.

Overrides:

toString in class java.lang.Object

QueueBrowser

public interface **QueueBrowser**

WebSphere MQ class: **MQueueBrowser**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQueueBrowser
```

A client uses a **QueueBrowser** to look at messages on a queue without removing them.

Note: The WebSphere MQ class **MQueueEnumeration** is used to hold the browse cursor.

See also: **QueueReceiver**

Methods

close

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a **QueueBrowser**, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Throws:

JMSEException if a JMS fails to close this browser because of a JMS error.

getEnumeration

```
public java.util.Enumeration getEnumeration() throws JMSEException
```

Get an enumeration for browsing the current queue messages in the order that they are received.

Returns:

An enumeration for browsing the messages.

Throws:

JMSEException if JMS fails to get the enumeration for this browser because of a JMS error.

Note: If the browser is created for a nonexistent queue, this is not detected until the first call to **getEnumeration**.

getMessageSelector

```
public java.lang.String getMessageSelector() throws JMSEException
```

Get this queue browser's message selector expression.

Returns:

This queue browser's message selector.

Throws:

JMSEException if JMS fails to get the message selector for this browser because of a JMS error.

getQueue

public Queue **getQueue()** throws JMSEException

Get the queue associated with this queue browser.

Returns:

The queue.

Throws:

JMSEException if JMS fails to get the queue associated with this browser because of a JMS error.

QueueConnection

public interface **QueueConnection**
extends **Connection**
Subinterfaces: **XAQueueConnection**

WebSphere MQ class: **MQQueueConnection**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnection
      |
      +----com.ibm.mq.jms.MQQueueConnection
```

A `QueueConnection` is an active connection to a JMS point-to-point provider. A client uses a `QueueConnection` to create one or more `QueueSessions` for producing and consuming messages.

See also: **Connection**, **QueueConnectionFactory**, and **XAQueueConnection**

Methods

close *

```
public void close() throws JMSException
```

Overrides:

Close in class `MQConnection`.

createConnectionConsumer

```
public ConnectionConsumer createConnectionConsumer
    (Queue queue,
     java.lang.String messageSelector,
     ServerSessionPool sessionPool,
     int maxMessages)
    throws JMSException
```

Create a connection consumer for this connection. This is an expert facility that is not used by regular JMS clients.

Parameters:

- `queue`: the queue to access.
- `messageSelector`: only messages with properties that match the message selector expression are delivered.
- `sessionPool`: the server session pool to associate with this connection consumer.
- `maxMessages`: the maximum number of messages that can be assigned to a server session at one time.

Returns:

The connection consumer.

Throws:

- `JMSEException` if the JMS connection fails to create a connection consumer because of an internal error, or incorrect arguments for `sessionPool` and `messageSelector`.
- `InvalidSelectorException` if the message selector is not valid.

See also:

`ConnectionConsumer`

createQueueSession

```
public QueueSession createQueueSession(boolean transacted,
                                       int acknowledgeMode)
                                       throws JMSEException
```

Create a `QueueSession`.

Parameters:

- `transacted`: if true, the session is transacted.
- `acknowledgeMode`: indicates whether the consumer or the client acknowledges any messages it receives. Possible values are:
`Session.AUTO_ACKNOWLEDGE`
`Session.CLIENT_ACKNOWLEDGE`
`Session.DUPS_OK_ACKNOWLEDGE`

This parameter is ignored if the session is transacted.

Returns:

A newly-created queue session.

Throws:

`JMSEException` if JMS Connection fails to create a session because of an internal error, or lack of support for specific transaction and acknowledgement mode.

QueueConnectionFactory

```
public interface QueueConnectionFactory
extends ConnectionFactory
Subinterfaces: XAQueueConnectionFactory
```

WebSphere MQ class: **MQQueueConnectionFactory**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnectionFactory
      |
      +----com.ibm.mq.jms.MQQueueConnectionFactory
```

A client uses a `QueueConnectionFactory` to create `QueueConnections` with a JMS point-to-point provider.

See also: `ConnectionFactory` and `XAQueueConnectionFactory`

WebSphere MQ constructor

```
MQQueueConnectionFactory
public MQQueueConnectionFactory()
```

Methods

```
createQueueConnection
public QueueConnection createQueueConnection()
throws JMSEException
```

Create a queue connection with default user identity. The connection is created in stopped mode. No messages are delivered until `Connection.start` method is explicitly called.

Returns:

A newly-created queue connection.

Throws:

- `JMSEException` if JMS provider fails to create queue connection because of an internal error.
- `JMSSecurityException` if client authentication fails because of a non valid user name or password.

```
createQueueConnection
public QueueConnection createQueueConnection
      (java.lang.String userName,
       java.lang.String password)
      throws JMSEException
```

Create a queue connection with specified user identity.

Note: Use this method only with transport type `JMSC.MQJMS_TP_CLIENT_MQ_TCPIP` (see `ConnectionFactory`). The connection is created in stopped mode. No messages are delivered until `Connection.start` method is explicitly called.

Parameters:

- userName: the caller's user name.
- password: the caller's password.

Returns:

A newly-created queue connection.

Throws:

- JMSEException if JMS Provider fails to create queue connection because of an internal error.
- JMSSecurityException if client authentication fails because of a non valid user name or password.

getMessageRetention*

```
public int getMessageRetention()
```

Get method for messageRetention attribute.

Returns:

- JMSC.MQJMS_MRET_YES: unwanted messages remain on the input queue.
- JMSC.MQJMS_MRET_NO: unwanted messages are dealt with according to their disposition options.

getReference *

```
public Reference getReference() throws NamingException
```

Create a reference for this queue connection factory .

Returns:

A reference for this object.

Throws:

NamingException.

getTemporaryModel *

```
public String getTemporaryModel()
```

setMessageRetention*

```
public void setMessageRetention(int x) throws JMSEException
```

Set method for messageRetention attribute.

Parameters:

Valid values are:

- JMSC.MQJMS_MRET_YES: unwanted messages remain on the input queue.
- JMSC.MQJMS_MRET_NO: unwanted messages are dealt with according to their disposition options. For more information on this, see "General principles for point-to-point messaging" on page 248.

setTemporaryModel *

```
public void setTemporaryModel(String x) throws JMSEException
```

QueueReceiver

```
public interface QueueReceiver  
extends MessageConsumer
```

WebSphere MQ class: **MQQueueReceiver**

```
java.lang.Object  
|  
+----com.ibm.mq.jms.MQMessageConsumer  
|  
+----com.ibm.mq.jms.MQQueueReceiver
```

A client uses a `QueueReceiver` to receive messages that have been delivered to a queue.

See also: **MessageConsumer**

This class inherits the following methods from **MQMessageConsumer**.

- `receive`
- `receiveNoWait`
- `close`
- `getMessageListener`
- `setMessageListener`

Methods

getQueue

```
public Queue getQueue() throws JMSException
```

Get the queue associated with this queue receiver.

Returns:

The queue.

Throws:

`JMSException` if JMS fails to get queue for this queue receiver because of an internal error.

QueueRequestor

```
public class QueueRequestor
    extends java.lang.Object
```

```
java.lang.Object
|
+----jvax.jms.QueueRequestor
```

The QueueRequestor helper class simplifies making service requests. The QueueRequestor constructor is given a non-transacted QueueSession and a destination Queue. It creates a TemporaryQueue for the responses, and provides a request() method that sends the request message and waits for its reply. Users are free to create more sophisticated versions.

See also: [TopicRequestor](#)

Constructors

QueueRequestor

```
public QueueRequestor(QueueSession session,
                    Queue queue)
    throws JMSEException
```

This implementation assumes that the session parameter is non-transacted and either AUTO_ACKNOWLEDGE or DUPS_OK_ACKNOWLEDGE.

Parameters:

- session: the queue session the queue belongs to.
- queue: the queue to perform the request/reply call on.

Throws:

JMSEException if a JMS error occurs.

Methods

close

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a QueueRequestor, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Note: This method closes the session object passed to the QueueRequestor constructor.

Throws:

JMSEException if a JMS error occurs.

request

```
public Message request(Message message)
    throws JMSEException
```

Send a request and wait for a reply. The temporary queue is used for replyTo, and only one reply is expected for each request.

QueueRequestor

Parameters:

message: the message to send.

Returns:

The reply message.

Throws:

JMSEException if a JMS error occurs.

QueueSender

```
public interface QueueSender
extends MessageProducer
```

WebSphere MQ class: **MQQueueSender**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQMessageProducer
      |
      +----com.ibm.mq.jms.MQQueueSender
```

A client uses a QueueSender to send messages to a queue.

A QueueSender is normally associated with a particular queue. However, it is possible to create an unidentified QueueSender that is not associated with any given queue.

See also: **MessageProducer**

Methods

close *

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a QueueSender, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Throws:

JMSEException if JMS fails to close the producer because of some error.

Overrides:

Close in class MQMessageProducer.

getQueue

```
public Queue getQueue() throws JMSEException
```

Get the queue associated with this queue sender.

Returns:

The queue.

Throws:

JMSEException if JMS fails to get the queue for this queue sender because of an internal error.

QueueSender

send

```
public void send(Message message) throws JMSEException
```

Send a message to the queue. Use the QueueSender's default delivery mode, time-to-live, and priority.

Parameters:

message: the message to be sent.

Throws:

- JMSEException if JMS fails to send the message because of an error.
- MessageFormatException if a non valid message is specified.
- InvalidDestinationException if a client uses this method with a queue sender with a non valid queue.

send

```
public void send(Message message,
                int deliveryMode,
                int priority,
                long timeToLive) throws JMSEException
```

Send a message specifying delivery mode, priority, and time-to-live to the queue.

Parameters:

- message: the message to be sent.
- deliveryMode: the delivery mode to use.
- priority: the priority for this message.
- timeToLive: the message's lifetime (in milliseconds).

Throws:

- JMSEException if JMS fails to send the message because of an internal error.
- MessageFormatException if a non valid message is specified.
- InvalidDestinationException if a client uses this method with a queue sender with a non valid queue.

send

```
public void send(Queue queue,
                Message message) throws JMSEException
```

Send a message to the specified queue with the QueueSender's default delivery mode, time-to-live, and priority.

Note: This method can be used only with unidentified QueueSenders.

Parameters:

- queue:- the queue that this message should be sent to.
- message: the message to be sent.

Throws:

- JMSEException if JMS fails to send the message because of an internal error.
- MessageFormatException if a non valid message is specified.

- `InvalidDestinationException` if a client uses this method with a non valid queue.

send

```
public void send(Queue queue,
                Message message,
                int deliveryMode,
                int priority,
                long timeToLive) throws JMSException
```

Send a message to the specified queue with delivery mode, priority, and time-to-live.

Note: This method can be used only with unidentified `QueueSenders`.

Parameters:

- `queue`: the queue that this message should be sent to.
- `message`: the message to be sent.
- `deliveryMode`: the delivery mode to use.
- `priority`: the priority for this message.
- `timeToLive`: the message's lifetime (in milliseconds).

Throws:

- `JMSException` if JMS fails to send the message because of an internal error.
- `MessageFormatException` if a non valid message is specified.
- `InvalidDestinationException` if a client uses this method with a non valid queue.

QueueSession

public interface **QueueSession**
extends **Session**

WebSphere MQ class: **MQQueueSession**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQSession
      |
      +----com.ibm.mq.jms.MQQueueSession
```

A **QueueSession** provides methods to create **QueueReceivers**, **QueueSenders**, **QueueBrowsers**, and **TemporaryQueues**.

See also: **Session**

The following methods are inherited from **MQSession**:

- close
- commit
- rollback
- recover

Methods

createBrowser

```
public QueueBrowser createBrowser(Queue queue)
                                   throws JMSEException
```

Create a **QueueBrowser** to peek at the messages on the specified queue.

Parameters:

queue: the queue to access.

Throws:

- **JMSEException** if a session fails to create a browser because of a JMS error.
- **InvalidDestinationException** if a non valid queue is specified.

createBrowser

```
public QueueBrowser createBrowser(Queue queue,
                                   java.lang.String messageSelector)
                                   throws JMSEException
```

Create a **QueueBrowser** to peek at the messages on the specified queue.

Parameters:

- queue: the queue to access.
- messageSelector: only deliver messages with properties that match the message selector expression.

Throws:

- **JMSEException** if a session fails to create a browser because of a JMS error.
- **InvalidDestinationException** if a non valid queue is specified.
- **InvalidSelectorException** if the message selector is not valid.

createQueue

```
public Queue createQueue(java.lang.String queueName)
                        throws JMSEException
```

Create a queue with a queue name. This allows the creation of a queue with a provider-specific name. The string takes a URI format, as described on page 196.

Note: Clients that depend on this ability are not portable.

Parameters:

queueName: the name of this queue.

Returns:

A queue with the given name.

Throws:

JMSEException if a session fails to create a queue because of a JMS error.

createReceiver

```
public QueueReceiver createReceiver(Queue queue)
                        throws JMSEException
```

Create a QueueReceiver to receive messages from the specified queue.

Parameters:

queue: the queue to access.

Throws:

- JMSEException if a session fails to create a receiver because of a JMS error.
- InvalidDestinationException if a non valid queue is specified.

createReceiver

```
public QueueReceiver createReceiver(Queue queue,
                                       java.lang.String messageSelector)
                        throws JMSEException
```

Create a QueueReceiver to receive messages from the specified queue.

Parameters:

- queue: the queue to access.
- messageSelector: only messages with properties that match the message selector expression are delivered.

Throws:

- JMSEException if a session fails to create a receiver because of a JMS error.
- InvalidDestinationException if a non valid queue is specified.
- InvalidSelectorException if the message selector is not valid.

createSender

```
public QueueSender createSender(Queue queue)
                        throws JMSEException
```

Create a QueueSender to send messages to the specified queue.

QueueSession

Parameters:

queue: the queue to access, or null if this is to be an unidentified producer.

Throws:

- JMSException if a session fails to create a sender because of a JMS error.
- InvalidDestinationException if a non valid queue is specified.

createTemporaryQueue

```
public TemporaryQueue createTemporaryQueue()  
                        throws JMSException
```

Create a temporary queue. Its lifetime is that of the QueueConnection unless deleted earlier.

Returns:

A temporary queue.

Throws:

JMSException if a session fails to create a temporary queue because of a JMS error.

Session

public interface **Session**
 extends **java.lang.Runnable**
 Subinterfaces: **QueueSession**, **TopicSession**, **XAQueueSession**, **XASession**, and **XATopicSession**

WebSphere MQ class: **MQSession**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQSession
```

A JMS session is a single-threaded context for producing and consuming messages.

See also: **QueueSession**, **TopicSession**, **XAQueueSession**, **XASession**, and **XATopicSession**

Fields

AUTO_ACKNOWLEDGE

```
public static final int AUTO_ACKNOWLEDGE
```

With this acknowledgement mode, the session automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.

CLIENT_ACKNOWLEDGE

```
public static final int CLIENT_ACKNOWLEDGE
```

With this acknowledgement mode, the client acknowledges a message by calling a message's acknowledge method.

DUPS_OK_ACKNOWLEDGE

```
public static final int DUPS_OK_ACKNOWLEDGE
```

This acknowledgement mode instructs the session to lazily acknowledge the delivery of messages.

Methods

close

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a session, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Closing a transacted session rolls back any in-progress transaction. Closing a session automatically closes its message producers and consumer, so there is no need to close them individually.

Throws:

JMSEException if the JMS implementation fails to close a session because of an internal error.

Session

commit

```
public void commit() throws JMSEException
```

Commit all messages done in this transaction and release any locks currently held.

WebSphere MQ Event Broker note

This always throws a JMSEException when you have a direct connection to WebSphere MQ Event Broker.

Throws:

- JMSEException if JMS implementation fails to commit the transaction because of an internal error.
- TransactionRolledBackException if the transaction gets rolled back because of an internal error during commit.

createBytesMessage

```
public BytesMessage createBytesMessage()  
    throws JMSEException
```

Create a BytesMessage. A BytesMessage is used to send a message containing a stream of uninterpreted bytes.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

createMapMessage

```
public MapMessage createMapMessage() throws JMSEException
```

Create a MapMessage. A MapMessage is used to send a self-defining set of name-value pairs, where names are strings, and values are Java primitive types.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

createMessage

```
public Message createMessage() throws JMSEException
```

Create a message. The Message interface is the root interface of all JMS messages. It holds all the standard message header information. It can be sent when a message containing only header information is sufficient.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

createObjectMessage

```
public ObjectMessage createObjectMessage()
    throws JMSEException
```

Create an ObjectMessage. An ObjectMessage is used to send a message that contains a serializable Java object.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

createObjectMessage

```
public ObjectMessage createObjectMessage
    (java.io.Serializable object)
    throws JMSEException
```

Create an initialized ObjectMessage. An ObjectMessage is used to send a message that contains a serializable Java object.

Parameters:

object: the object to use to initialize this message.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

createStreamMessage

```
public StreamMessage createStreamMessage()
    throws JMSEException
```

Create a StreamMessage. A StreamMessage is used to send a self-defining stream of Java primitives.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

createTextMessage

```
public TextMessage createTextMessage() throws JMSEException
```

Create a TextMessage. A TextMessage is used to send a message containing a string.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

createTextMessage

```
public TextMessage createTextMessage
    (java.lang.String string)
    throws JMSEException
```

Create an initialized TextMessage. A TextMessage is used to send a message containing a string.

Parameters:

string: the string used to initialize this message.

Throws:

JMSEException if JMS fails to create this message because of an internal error.

Session

getMessageListener

```
public MessageListener getMessageListener()  
                                throws JMSEException
```

Return the session's distinguished message listener.

Returns:

The message listener associated with this session.

Throws:

JMSEException if JMS fails to get the message listener because of an internal error in the JMS Provider.

See also:

setMessageListener

getTransacted

```
public boolean getTransacted() throws JMSEException
```

Whether the session is in transacted mode.

WebSphere MQ Event Broker note

This method always returns false when you have a direct connection to WebSphere MQ Event Broker.

Returns:

True if the session is in transacted mode.

Throws:

JMSEException if JMS fails to return the transaction mode because of an internal error in JMS Provider.

recover

```
public void recover() throws JMSEException
```

Stop message delivery in this session, and restart sending messages with the oldest unacknowledged message.

WebSphere MQ Event Broker note

This always throws a JMSEException when you have a direct connection to WebSphere MQ Event Broker.

Throws:

JMSEException if the JMS implementation fails to stop message delivery and restart message send because of an internal error.

rollback

```
public void rollback() throws JMSEException
```

Roll back any messages done in this transaction and release any locks currently held.

WebSphere MQ Event Broker note

This always throws a JMSEException when you have a direct connection to WebSphere MQ Event Broker.

Throws:

JMSEException if the JMS implementation fails to roll back the transaction because of an internal error.

run

```
public void run()
```

This method is intended for use only by application servers.

WebSphere MQ Event Broker note

This always throws an IllegalStateException when you have a direct connection to WebSphere MQ Event Broker.

Specified by:

run in the interface java.lang.Runnable

See also:

ServerSession

setMessageListener

```
public void setMessageListener(MessageListener listener)
                               throws JMSEException
```

Set the session's distinguished message listener. When it is set, no other form of message receipt in the session can be used. However, all forms of sending messages are still supported.

This is an expert facility that is not used by regular JMS clients.

Parameters:

listener: the message listener to associate with this session.

Throws:

JMSEException if JMS fails to set the message listener because of an internal error in the JMS Provider.

See also:

getMessageListener, ServerSessionPool, ServerSession

StreamMessage

public interface **StreamMessage**
extends **Message**

WebSphere MQ class: **JMSStreamMessage**

```
java.lang.Object
|
+----com.ibm.jms.JMSMessage
      |
      +----com.ibm.jms.JMSStreamMessage
```

Use a `StreamMessage` to send a stream of Java primitives.

See also: **BytesMessage**, **MapMessage**, **Message**, **ObjectMessage** and **TextMessage**

Methods

readBoolean

public boolean **readBoolean()** throws `JMSException`

Read a boolean from the stream message.

Returns:

The boolean value read.

Throws:

- `JMSException` if JMS fails to read the message because of an internal JMS error.
- `MessageEOFException` if an end of message stream is received.
- `MessageFormatException` if this type conversion is not valid.
- `MessageNotReadableException` if the message is in write-only mode.

readByte

public byte **readByte()** throws `JMSException`

Read a byte value from the stream message.

Returns:

The next byte from the stream message as an 8-bit byte.

Throws:

- `JMSException` if JMS fails to read the message because of an internal JMS error.
- `MessageEOFException` if an end of message stream is received.
- `MessageFormatException` if this type conversion is not valid.
- `MessageNotReadableException` if the message is in write-only mode.

readBytes

```
public int readBytes(byte[] value)
    throws JMSException message.
```

Read a byte array field from the stream message into the specified byte[] object (the read buffer). If the buffer size is less than, or equal to, the size of the data in the message field, an application must make further calls to this method to retrieve the remainder of the data. Once the first readBytes call on a byte[] field value has been done, the full value of the field must be read before it is valid to read the next field. An attempt to read the next field before that has been done throws a MessageFormatException.

Parameters:

value: the buffer into which the data is read.

Returns:

The total number of bytes read into the buffer, or -1 if there is no more data because the end of the byte field has been reached.

Throws:

- JMSException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream is received.
- MessageFormatException if this type conversion is not valid.
- MessageNotReadableException if the message is in write-only mode.

readChar

```
public char readChar() throws JMSException
```

Read a Unicode character value from the stream message.

Returns:

A Unicode character from the stream message.

Throws:

- JMSException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream is received.
- MessageFormatException if this type conversion is not valid.
- MessageNotReadableException if the message is in write-only mode.

readDouble

```
public double readDouble() throws JMSException
```

Read a double from the stream message.

Returns:

A double value from the stream message.

Throws:

- JMSException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream is received.
- MessageFormatException if this type conversion is not valid.

StreamMessage

- MessageNotReadableException if the message is in write-only mode.

readFloat

public float **readFloat()** throws JMSEException

Read a float from the stream message.

Returns:

A float value from the stream message.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream
- MessageFormatException if this type conversion is not valid.
- MessageNotReadableException if the message is in write-only mode.

readInt

public int **readInt()** throws JMSEException

Read a 32-bit integer from the stream message.

Returns:

A 32-bit integer value from the stream message, interpreted as an int.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream is received.
- MessageFormatException if this type conversion is not valid.
- MessageNotReadableException if the message is in write-only mode.

readLong

public long **readLong()** throws JMSEException

Read a 64-bit integer from the stream message.

Returns:

A 64-bit integer value from the stream message, interpreted as a long.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream
- MessageFormatException if this type conversion is not valid.
- MessageNotReadableException if the message is in write-only mode.

readObject

```
public java.lang.Object readObject() throws JMSEException
```

Read a Java object from the stream message.

Returns:

A Java object from the stream message in object format (for example, if it was set as an int, an integer is returned).

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream is received.
- NotReadableException if the message is in write-only mode.

readShort

```
public short readShort() throws JMSEException
```

Read a 16-bit number from the stream message.

Returns:

A 16-bit number from the stream message.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream is received.
- MessageFormatException if this type conversion is not valid.
- MessageNotReadableException if the message is in write-only mode.

readString

```
public java.lang.String readString() throws JMSEException
```

Read in a string from the stream message.

Returns:

A Unicode string from the stream message.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageEOFException if an end of message stream is received.
- MessageFormatException if this type conversion is not valid.
- MessageNotReadableException if the message is in write-only mode

StreamMessage

reset

```
public void reset() throws JMSEException
```

Put the message in read-only mode, and reposition the stream to the beginning.

Throws:

- JMSEException if JMS fails to reset the message because of an internal JMS error.
- MessageFormatException if the message has an non valid format.

writeBoolean

```
public void writeBoolean(boolean value) throws JMSEException
```

Write a boolean to the stream message.

Parameters:

value: the boolean value to be written.

Throws:

- JMSEException if JMS fails to read the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

writeByte

```
public void writeByte(byte value) throws JMSEException
```

Write a byte to the stream message.

Parameters:

value: the byte value to be written.

Throws:

- JMSEException if JMS fails to write the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

writeBytes

```
public void writeBytes(byte[] value) throws JMSEException
```

Write a byte array to the stream message.

Parameters:

value: the byte array to be written.

Throws:

- JMSEException if JMS fails to write the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

writeBytes

```
public void writeBytes(byte[] value,
                       int offset,
                       int length) throws JMSEException
```

Write a portion of a byte array to the stream message.

Parameters:

- **value**: the byte array value to be written.
- **offset**: the initial offset within the byte array.
- **length**: the number of bytes to use.

Throws:

- **JMSEException** if JMS fails to write the message because of an internal JMS error.
- **MessageNotWriteableException** if the message is in read-only mode.

writeChar

```
public void writeChar(char value) throws JMSEException
```

Write a character to the stream message.

Parameters:

value: the character value to be written.

Throws:

- **JMSEException** if JMS fails to write the message because of an internal JMS error.
- **MessageNotWriteableException** if the message is in read-only mode.

writeDouble

```
public void writeDouble(double value) throws JMSEException
```

Write a double to the stream message.

Parameters:

value: the double value to be written.

Throws:

- **JMSEException** if JMS fails to write the message because of an internal JMS error.
- **MessageNotWriteableException** if the message is in read-only mode.

writeFloat

```
public void writeFloat(float value) throws JMSEException
```

Write a float to the stream message.

Parameters:

value: the float value to be written.

Throws:

- **JMSEException** if JMS fails to write the message because of an internal JMS error.

StreamMessage

- MessageNotWriteableException if the message is in read-only mode.

writeInt

```
public void writeInt(int value) throws JMSEException
```

Write an integer to the stream message.

Parameters:

value: the integer to be written.

Throws:

- JMSEException if JMS fails to write the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

writeLong

```
public void writeLong(long value) throws JMSEException
```

Write a long to the stream message.

Parameters:

value: the long to be written.

Throws:

- JMSEException if JMS fails to write the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

writeObject

```
public void writeObject(java.lang.Object value)  
                        throws JMSEException
```

Write a Java object to the stream message. This method works only for object primitive types (for example, Integer, Double, Long), strings, and byte arrays.

Parameters:

value: the Java object to be written.

Throws:

- JMSEException if JMS fails to write the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.
- MessageFormatException if the object is not valid.

writeShort

public void **writeShort**(short value) throws JMSEException

Write a short to the stream message.

Parameters:

value: the short to be written.

Throws:

- JMSEException if JMS fails to write the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

writeString

public void **writeString**(java.lang.String value)
throws JMSEException

Write a string to the stream message.

Parameters:

value: the string value to be written.

Throws:

- JMSEException if JMS fails to write the message because of an internal JMS error.
- MessageNotWriteableException if the message is in read-only mode.

TemporaryQueue

TemporaryQueue

```
public interface TemporaryQueue
extends Queue
```

WebSphere MQ class: **MQTemporaryQueue**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQDestination
      |
      +----com.ibm.mq.jms.MQQueue
            |
            +----com.ibm.mq.jms.MQTemporaryQueue
```

A `TemporaryQueue` is a unique queue object that is created for the duration of a `QueueConnection`.

Methods

delete

```
public void delete() throws JMSEException
```

Delete this temporary queue. If there are still existing senders or receivers using it, a `JMSEException` is thrown.

Throws:

`JMSEException` if JMS implementation fails to delete a `TemporaryQueue` because of an internal error.

TemporaryTopic

```
public interface TemporaryTopic
extends Topic
```

WebSphere MQ class: **MQTemporaryTopic**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQDestination
      |
      +----com.ibm.mq.jms.MQTopic
            |
            +----com.ibm.mq.jms.MQTemporaryTopic
```

A `TemporaryTopic` is a unique topic object created for the duration of a `TopicConnection` and can be consumed only by consumers of that connection.

WebSphere MQ constructor

MQTemporaryTopic

`MQTemporaryTopic()` throws `JMSEException`

Methods

delete

public void **delete**() throws `JMSEException`

Delete this temporary topic. If there are still existing publishers or subscribers using it, a `JMSEException` is thrown.

Throws:

`JMSEException` if JMS implementation fails to delete a `TemporaryTopic` because of an internal error.

TextMessage

public interface **TextMessage**
extends **Message**

WebSphere MQ class: **JMSTextMessage**

```
java.lang.Object
|
+----com.ibm.jms.JMSMessage
      |
      +----com.ibm.jms.JMSTextMessage
```

Use `TextMessage` to send a message containing a `java.lang.String`. It inherits from `Message` and adds a text message body.

See also: **BytesMessage**, **MapMessage**, **Message**, **ObjectMessage** and **StreamMessage**

Methods

getText

```
public java.lang.String getText() throws JMSEException
```

Get the string containing this message's data. The default value is null.

Returns:

The string containing the message's data.

Throws:

`JMSEException` if JMS fails to get the text because of an internal JMS error.

setText

```
public void setText(java.lang.String string)
                    throws JMSEException
```

Set the string containing this message's data.

Parameters:

`string`: the string containing the message's data.

Throws:

- `JMSEException` if JMS fails to set text because of an internal JMS error.
- `MessageNotWriteableException` if the message is in read-only mode.

Topic

public interface **Topic**
 extends **Destination**
 Subinterfaces: **TemporaryTopic**

WebSphere MQ class: **MQTopic**

```

java.lang.Object
|
+----com.ibm.mq.jms.MQDestination
      |
      +----com.ibm.mq.jms.MQTopic
  
```

A Topic object encapsulates a provider-specific topic name. It is the way that a client specifies the identity of a topic to JMS methods.

WebSphere MQ Event Broker note

For direct connections to WebSphere MQ Event Broker, properties accessed by methods marked with a § are ignored.

See also: **Destination**

WebSphere MQ constructor

MQTopic

```

public MQTopic()
public MQTopic(string URITopic)
  
```

See **TopicSession.createTopic**.

Methods

getBaseTopicName *

```
public String getBaseTopicName()
```

Get method for the underlying WebSphere MQ topic name.

getBrokerCCDurSubQueue * §

```
public String getBrokerCCDurSubQueue()
```

Get method for brokerCCDurSubQueue attribute.

Returns:

The name of the durable subscription queue (the brokerCCDurSubQueue) to use for a ConnectionConsumer.

Topic

getBrokerDurSubQueue * §

```
public String getBrokerDurSubQueue()
```

Get method for brokerDurSubQueue attribute.

Returns:

The name of the durable subscription queue (the brokerDurSubQueue) to use.

getBrokerVersion *

```
public int getBrokerVersion()
```

Get method for brokerVersion attribute.

Returns:

The broker's version number

getReference *

```
public Reference getReference()
```

Create a reference for this topic.

Returns:

A reference for this object.

Throws:

NamingException.

getTopicName

```
public java.lang.String getTopicName() throws JMSEException
```

Get the name of this topic in URI format. (URI format is described in "Creating topics at runtime" on page 214.)

Note: Clients that depend upon the name are not portable.

Returns:

The topic name.

Throws:

JMSEException if JMS implementation for topic fails to return the topic name because of an internal error.

setBaseTopicName *

```
public void setBaseTopicName(String x)
```

Set method for the underlying WebSphere MQ topic name.

setBrokerCCDurSubQueue * §

```
public void setBrokerCCDurSubQueue(String x) throws JMSEException
```

Set method for brokerCCDurSubQueue attribute.

Parameters:

brokerCCDurSubQueue: the name of the durable subscription queue to use for a ConnectionConsumer.

setBrokerDurSubQueue * §

```
public void setBrokerDurSubQueue(String x) throws JMSEException
```

Set method for brokerDurSubQueue attribute.

Parameters:

brokerDurSubQueue: the name of the durable subscription queue to use.

setBrokerVersion *

```
public void setBrokerVersion(int x) throws JMSEException
```

Set method for brokerVersion attribute.

Parameters:

An integer representing one of the valid broker version number values. These are represented by the constants:

```
JMSC.MQJMS_BROKER_V1
```

```
JMSC.MQJMS_BROKER_V2
```

toString

```
public String toString()
```

Return a well-formatted printed version of the topic name.

Returns:

The provider-specific identity values for this topic.

Overrides:

toString in class Object.

TopicConnection

public interface **TopicConnection**
extends **Connection**
Subinterfaces: **XATopicConnection**

WebSphere MQ class: **MQTopicConnection**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnection
      |
      +----com.ibm.mq.jms.MQTopicConnection
```

A **TopicConnection** is an active connection to a JMS publish/subscribe provider.

See also: **Connection**, **TopicConnectionFactory**, and **XATopicConnection**

Methods

createConnectionConsumer

```
public ConnectionConsumer createConnectionConsumer
    (Topic topic,
     java.lang.String messageSelector,
     ServerSessionPool sessionPool,
     int maxMessages)
    throws JMSEException
```

Create a connection consumer for this connection. This is an expert facility that is not used by regular JMS clients.

WebSphere MQ Event Broker note

For a direct connection to WebSphere MQ Event Broker, this method throws a **JMSEException**.

Parameters:

- **topic**: the topic to access.
- **messageSelector**: only deliver messages with properties that match the message selector expression.
- **sessionPool**: the server session pool to associate with this connection consumer.
- **maxMessages**: the maximum number of messages that can be assigned to a server session at one time.

Returns:

The connection consumer.

Throws:

- **JMSEException** if the JMS Connection fails to create a connection consumer because of an internal error, or because of incorrect arguments for **sessionPool**.
- **InvalidSelectorException** if the message selector is not valid.

See also:

ConnectionConsumer

createDurableConnectionConsumer

```
public ConnectionConsumer createDurableConnectionConsumer
    (Topic topic,
     java.lang.String subscriptionName,
     java.lang.String messageSelector,
     ServerSessionPool sessionPool,
     int maxMessages)
    throws JMSEException
```

Create a durable connection consumer for this connection. This is an expert facility that is not used by regular JMS clients.

WebSphere MQ Event Broker note

For a direct connection to WebSphere MQ Event Broker, this method throws a JMSEException.

Parameters:

- `topic`: the topic to access.
- `subscriptionName`: the name of the durable subscription.
- `messageSelector`: deliver only messages with properties that match the message selector expression.
- `sessionPool`: the server session pool to associate with this durable connection consumer.
- `maxMessages`: the maximum number of messages that can be assigned to a server session at one time.

Returns:

The durable connection consumer.

Throws:

- JMSEException if the JMS Connection fails to create a connection consumer because of an internal error, or because of incorrect arguments for `sessionPool` and `messageSelector`.
- InvalidSelectorException if the message selector is not valid.

See also:

ConnectionConsumer

createTopicSession

```
public TopicSession createTopicSession(boolean transacted,
     int acknowledgeMode)
    throws JMSEException
```

Create a TopicSession.

WebSphere MQ Event Broker note

For a direct connection to WebSphere MQ Event Broker, if `transacted` is true, this method throws a JMSEException.

Parameters:

- `transacted`: if true, the session is transacted.
- `acknowledgeMode`: one of:
 Session.AUTO_ACKNOWLEDGE
 Session.CLIENT_ACKNOWLEDGE

TopicConnection

Session.DUPS_OK_ACKNOWLEDGE

Indicates whether the consumer or the client acknowledge any messages that they receive. This parameter is ignored if the session is transacted.

Returns:

A newly-created topic session.

Throws:

JMSEException if JMS Connection fails to create a session because of an internal error, or a lack of support for the specific transaction and acknowledgement mode.

TopicConnectionFactory

```
public interface TopicConnectionFactory
extends ConnectionFactory
Subinterfaces: XATopicConnectionFactory
```

WebSphere MQ class: **MQTopicConnectionFactory**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQConnectionFactory
|
+----com.ibm.mq.jms.MQTopicConnectionFactory
```

A client uses a `TopicConnectionFactory` to create `TopicConnections` with a JMS publish/subscribe provider.

WebSphere MQ Event Broker note

For direct connections to WebSphere MQ Event Broker, properties accessed by methods marked with a § are ignored.

See also: `ConnectionFactory` and `XATopicConnectionFactory`

WebSphere MQ constructor

```
MQTopicConnectionFactory
public MQTopicConnectionFactory()
```

Methods

```
createTopicConnection
public TopicConnection createTopicConnection()
throws JMSException
```

Create a topic connection with default user identity. The connection is created in stopped mode. No messages are delivered until `Connection.start` method is explicitly called.

Returns:

A newly-created topic connection.

Throws:

- `JMSException` if JMS Provider fails to create a Topic Connection because of an internal error.
- `JMSSecurityException` if client authentication fails because of a non valid user name or password.

TopicConnectionFactory

createTopicConnection

```
public TopicConnection createTopicConnection
    (java.lang.String userName,
     java.lang.String password)
    throws JMSEException
```

Create a topic connection with specified user identity. The connection is created in stopped mode. No messages are delivered until `Connection.start` method is explicitly called.

Parameters:

- `userName`: the caller's user name.
- `password`: the caller's password.

Returns:

A newly-created topic connection.

Throws:

- `JMSEException` if JMS Provider fails to create a Topic Connection because of an internal error.
- `JMSSecurityException` if client authentication fails because of a non valid user name or password.

Note: This method is valid only for transport type `IBM_JMS_TP_CLIENT_MQ_TCPIP`. See `ConnectionFactory`.

getBrokerCCSubQueue * §

```
public String getBrokerCCSubQueue()
```

Get method for `brokerCCSubQueue` attribute.

Returns:

The name of the non-durable subscription queue to use for a `ConnectionConsumer`.

getBrokerControlQueue * §

```
public String getBrokerControlQueue()
```

Get method for `brokerControlQueue` attribute.

Returns:

The broker's control queue name

getBrokerPubQueue * §

```
public String getBrokerPubQueue()
```

Get method for `brokerPubQueue` attribute.

Returns:

The broker's publish queue name.

getBrokerQueueManager * §

```
public String getBrokerQueueManager()
```

Get method for brokerQueueManager attribute.

Returns:

The broker's queue manager name.

getBrokerSubQueue * §

```
public String getBrokerSubQueue()
```

Get method for brokerSubQueue attribute.

Returns:

The name of the non-durable subscription queue to use.

getBrokerVersion *

```
public int getBrokerVersion()
```

Get method for brokerVersion attribute.

Returns:

The broker's version number

getCleanupInterval * §

```
public long getCleanupInterval()
```

Get method for cleanupInterval attribute.

Returns:

How often the cleanup utility runs, in milliseconds

getCleanupLevel * §

```
public int getCleanupLevel()
```

Get method for cleanupLevel attribute.

Returns:

The value of cleanupLevel

getPubAckInterval * §

```
public int getPubAckInterval()
```

Get method for pubAckInterval attribute.

Returns:

The interval, in number of messages, between publish requests that require acknowledgement from the broker.

getReference *

```
public Reference getReference()
```

Return a reference for this topic connection factory.

Returns:

A reference for this topic connection factory.

Throws:

NamingException.

TopicConnectionFactory

getStatusRefreshInterval * §

```
public int getStatusRefreshInterval()
```

Get method for statusRefreshInterval attribute.

Returns:

The number of milliseconds between transactions to refresh publish/subscribe status.

getSubscriptionStore * §

```
public int getSubscriptionStore()
```

Get method for SUBSTORE property.

Returns:

An integer representing the current SUBSTORE property type.

setBrokerCCSubQueue * §

```
public void setBrokerCCSubQueue(String x) throws JMSEException
```

Set method for brokerCCSubQueue attribute.

Parameters:

brokerSubQueue: the name of the non-durable subscription queue to use for a ConnectionConsumer.

setBrokerControlQueue * §

```
public void setBrokerControlQueue(String x) throws JMSEException
```

Set method for brokerControlQueue attribute.

Parameters:

brokerControlQueue: the name of the broker control queue.

setBrokerPubQueue * §

```
public void setBrokerPubQueue(String x) throws JMSEException
```

Set method for brokerPubQueue attribute.

Parameters:

brokerPubQueue: the name of the broker publish queue.

setBrokerQueueManager * §

```
public void setBrokerQueueManager(String x) throws JMSEException
```

Set method for brokerQueueManager attribute.

Parameters:

brokerQueueManager: the name of the broker's queue manager.

setBrokerSubQueue * §

```
public void setBrokerSubQueue(String x) throws JMSEException
```

Set method for brokerSubQueue attribute.

Parameters:

brokerSubQueue: the name of the non-durable subscription queue to use.

setBrokerVersion *

```
public void setBrokerVersion(int x) throws JMSEException
```

Set method for brokerVersion attribute.

Parameters:

An integer representing one of the valid broker version number values. These are represented by the constants:

JMSC.MQJMS_BROKER_V1

JMSC.MQJMS_BROKER_V2

setCleanupInterval * §

```
public void setCleanupInterval(long x) throws JMSEException
```

Set method for cleanupInterval attribute.

Parameters:

How often the cleanup utility runs, in milliseconds

setCleanupLevel * §

```
public void setCleanupLevel(int x) throws JMSEException
```

Set method for cleanupLevel attribute.

Parameters:

An integer representing one of the valid cleanupLevel values.

These are represented by the constants:

JMSC.MQJMS_CLEANUP_NONE

JMSC.MQJMS_CLEANUP_SAFE

JMSC.MQJMS_CLEANUP_STRONG

JMSC.MQJMS_CLEANUP_AS_PROPERTY

setPubAckInterval * §

```
public void setPubAckInterval(int x)
```

Set method for pubAckInterval attribute. The number of messages to publish between requiring acknowledgement from the broker. The default is 20. Applications do not normally alter this value, and must not rely on this acknowledgement.

Parameters:

pubAckInterval: the number of messages to use as interval.

TopicConnectionFactory

setStatusRefreshInterval * §

```
public void setStatusRefreshInterval(int x)
```

Set method for statusRefreshInterval attribute.

Parameters:

statusRefreshInterval: the number of milliseconds between transactions to refresh publish/subscribe status.

setSubscriptionStore * §

```
public void setSubscriptionStore(int x) throws JMSEException
```

Set method for SUBSTORE property.

Parameters:

SubStoretype: an integer representing one of the valid subStore values. These are represented by the constants:

```
JMSC.MQJMS_SUBSTORE_QUEUE  
JMSC.MQJMS_SUBSTORE_BROKER  
JMSC.MQJMS_SUBSTORE_MIGRATE
```

TopicPublisher

public interface **TopicPublisher**
 extends **MessageProducer**

WebSphere MQ class: **MQTopicPublisher**

```

java.lang.Object
|
+----com.ibm.mq.jms.MQMessageProducer
      |
      +----com.ibm.mq.jms.MQTopicPublisher
  
```

A client uses a `TopicPublisher` for publishing messages on a topic. `TopicPublisher` is the publish/subscribe variant of a JMS message producer.

Methods

close *

public void **close**() throws `JMSException`

Because a provider can allocate some resources outside the JVM on behalf of a `TopicPublisher`, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Throws:

`JMSException` if JMS fails to close the producer because of an error.

Overrides:

`close` in class `MQMessageProducer`.

getTopic

public `Topic` **getTopic**() throws `JMSException`

Get the topic associated with this publisher.

Returns:

This publisher's topic

Throws:

`JMSException` if JMS fails to get the topic for this topic publisher because of an internal error.

publish

public void **publish**(`Message` message) throws `JMSException`

Publish a message to the topic. Use the topic's default delivery mode, time-to-live, and priority.

Parameters:

message: the message to publish

Throws:

- `JMSException` if JMS fails to publish the message because of an internal error.
- `MessageFormatException` if a non valid message is specified.
- `InvalidDestinationException` if a client uses this method with a `Topic` Publisher with a non valid topic.

TopicPublisher

publish

```
public void publish(Message message,  
                    int deliveryMode,  
                    int priority,  
                    long timeToLive) throws JMSEException
```

Publish a message to the topic specifying delivery mode, priority, and time-to-live to the topic.

WebSphere MQ Event Broker note

If deliveryMode is PERSISTENT or timeToLive is greater than 0, this method throws a JMSEException when you have a direct connection to WebSphere MQ Event Broker.

Parameters:

- message: the message to publish.
- deliveryMode: the delivery mode to use.
- priority: the priority for this message.
- timeToLive: the message's lifetime (in milliseconds).

Throws:

- JMSEException if JMS fails to publish the message because of an internal error.
- MessageFormatException if a non valid message is specified.
- InvalidDestinationException if a client uses this method with a Topic Publisher with a non valid topic.

publish

```
public void publish(Topic topic,  
                    Message message) throws JMSEException
```

Publish a message to a topic for an unidentified message producer. Use the topic's default delivery mode, time-to-live, and priority.

Parameters:

- topic: the topic to publish this message to.
- message: the message to send.

Throws:

- JMSEException if JMS fails to publish the message because of an internal error.
- MessageFormatException if a non valid message is specified.
- InvalidDestinationException if a client uses this method with a non valid topic.

publish

```
public void publish(Topic topic,  
                    Message message,  
                    int deliveryMode,  
                    int priority,  
                    long timeToLive) throws JMSEException
```

Publish a message to a topic for an unidentified message producer, specifying delivery mode, priority, and time-to-live.

WebSphere MQ Event Broker note

If `deliveryMode` is `PERSISTENT` or `timeToLive` is greater than 0, this method throws a `JMSEException` when you have a direct connection to WebSphere MQ Event Broker.

Parameters:

- `topic`: the topic to publish this message to.
- `message`: the message to send.
- `deliveryMode`: the delivery mode to use.
- `priority`: the priority for this message.
- `timeToLive`: the message's lifetime (in milliseconds).

Throws:

- `JMSEException` if JMS fails to publish the message because of an internal error.
- `MessageFormatException` if a non valid message is specified.
- `InvalidDestinationException` if a client uses this method with a non valid topic.

TopicRequestor

```
public class TopicRequestor  
extends java.lang.Object
```

```
java.lang.Object  
|  
+----javax.jms.TopicRequestor
```

JMS provides this `TopicRequestor` class to assist with making service requests.

The `TopicRequestor` constructor is given a non-transacted `TopicSession` and a destination `Topic`. It creates a `TemporaryTopic` for the responses, and provides a `request()` method that sends the request message and waits for its reply. Users are free to create more sophisticated versions.

Constructors

`TopicRequestor`

```
public TopicRequestor(TopicSession session,  
                      Topic topic) throws JMSEException
```

Constructor for the `TopicRequestor` class. This implementation assumes that the session parameter is non-transacted, and either `AUTO_ACKNOWLEDGE` or `DUPS_OK_ACKNOWLEDGE`.

Parameters:

- `session`: the topic session the topic belongs to.
- `topic`: the topic to perform the request/reply call on.

Throws:

`JMSEException` if a JMS error occurs.

Methods

`close`

```
public void close() throws JMSEException
```

Because a provider can allocate some resources outside the JVM on behalf of a `TopicRequestor`, clients must close them when they are not needed. You cannot rely on garbage collection to reclaim these resources eventually, because this might not occur soon enough.

Note: This method closes the session object passed to the `TopicRequestor` constructor.

Throws:

`JMSEException` if a JMS error occurs.

`request`

```
public Message request(Message message) throws JMSEException
```

Send a request and wait for a reply.

Parameters:

`message`: the message to send.

Returns:

The reply message.

Throws:

JMSEException if a JMS error occurs.

TopicSession

```
public interface TopicSession
extends Session
```

WebSphere MQ class: **MQTopicSession**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQSession
      |
      +----com.ibm.mq.jms.MQTopicSession
```

A **TopicSession** provides methods for creating **TopicPublishers**, **TopicSubscribers**, and **TemporaryTopics**.

See also: **Session**

WebSphere MQ constructor

MQTopicSession

```
public MQTopicSession(boolean transacted,
                      int acknowledgeMode) throws JMSEException
```

See **TopicConnection.createTopicSession**.

Methods

createDurableSubscriber

```
public TopicSubscriber createDurableSubscriber
(Topic topic,
 java.lang.String name) throws JMSEException
```

Create a durable subscriber to the specified topic.

WebSphere MQ Event Broker note

This method throws a **JMSEException** when you have a direct connection to WebSphere MQ Event Broker.

Parameters:

- **topic**: the topic to subscribe to.
- **name**: the name used to identify this subscription.

Throws:

- **JMSEException** if a session fails to create a subscriber because of a JMS error.
- **InvalidDestinationException** if the topic specified is not valid.

See **TopicSession.unsubscribe**

createDurableSubscriber

```
public TopicSubscriber createDurableSubscriber
    (Topic topic,
     java.lang.String name,
     java.lang.String messageSelector,
     boolean noLocal) throws JMSEException
```

Create a durable subscriber to the specified topic. A client can change an existing durable subscription by creating a durable subscriber with the same name and a new topic or message selector or both.

WebSphere MQ Event Broker note

This method throws a JMSEException when you have a direct connection to WebSphere MQ Event Broker.

Parameters:

- **topic**: the topic to subscribe to.
- **name**: the name used to identify this subscription.
- **messageSelector**: deliver only messages with properties that match the message selector expression. This value can be null.
- **noLocal**: if set, inhibits the delivery of messages published by its own connection.

Throws:

- JMSEException if a session fails to create a subscriber because of a JMS error or non valid selector.
- InvalidDestinationException if the topic specified is not valid.
- InvalidSelectorException if the message selector is not valid.

createPublisher

```
public TopicPublisher createPublisher(Topic topic)
    throws JMSEException
```

Create a publisher for the specified topic.

Parameters:

topic: the topic to publish to, or null if this is an unidentified producer.

Throws:

- JMSEException if a session fails to create a publisher because of a JMS error.
- InvalidDestinationException if the topic specified is not valid.

createSubscriber

```
public TopicSubscriber createSubscriber(Topic topic)
    throws JMSEException
```

Create a non-durable subscriber to the specified topic.

Parameters:

topic: the topic to subscribe to

Throws:

- JMSEException - if a session fails to create a subscriber because of a JMS error.

TopicSession

- `InvalidDestinationException` if the topic specified is not valid.

`createSubscriber`

```
public TopicSubscriber createSubscriber
    (Topic topic,
     java.lang.String messageSelector,
     boolean noLocal) throws JMSEException
```

Create a non-durable subscriber to the specified topic.

Parameters:

- `topic`: the topic to subscribe to.
- `messageSelector`: deliver only messages with properties that match the message selector expression. This value can be null.
- `noLocal`: if set, inhibits the delivery of messages published by its own connection.

Throws:

- `JMSEException` if a session fails to create a subscriber because of a JMS error or non valid selector.
- `InvalidDestinationException` if the topic specified is not valid.
- `InvalidSelectorException` if the message selector is not valid.

`createTemporaryTopic`

```
public TemporaryTopic createTemporaryTopic()
    throws JMSEException
```

Create a temporary topic. Its lifetime is that of the `TopicConnection` unless deleted earlier.

Returns:

A temporary topic.

Throws:

`JMSEException` if a session fails to create a temporary topic because of a JMS error.

`createTopic`

```
public Topic createTopic(java.lang.String topicName)
    throws JMSEException
```

Create a topic given a URI format topic name. (URI format is described in “Creating topics at runtime” on page 214.) This allows you to create a topic with a provider-specific name.

Note: Clients that depend on this ability are not portable.

Parameters:

`topicName`: the name of this topic.

Returns:

A topic with the given name.

Throws:

`JMSEException` if a session fails to create a topic because of a JMS error.

unsubscribe

```
public void unsubscribe(java.lang.String name)
                               throws JMSEException
```

Unsubscribe a durable subscription that has been created by a client.

WebSphere MQ Event Broker note

This method throws a JMSEException when you have a direct connection to WebSphere MQ Event Broker.

Note: Do not use this method while an active subscription exists. You must close() your subscriber first.

Parameters:

name: the name used to identify this subscription.

Throws:

- JMSEException if JMS fails to unsubscribe the durable subscription because of a JMS error.
- InvalidDestinationException if the subscription name specified is not valid.

|
|

TopicSubscriber

public interface **TopicSubscriber**
extends **MessageConsumer**

WebSphere MQ class: **MQTopicSubscriber**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQMessageConsumer
      |
      +----com.ibm.mq.jms.MQTopicSubscriber
```

A client uses a `TopicSubscriber` to receive messages that have been published to a topic. `TopicSubscriber` is the publish/subscribe variant of a JMS message consumer.

See also: `MessageConsumer` and `TopicSession.createSubscriber`

`MQTopicSubscriber` inherits the following methods from `MQMessageConsumer`:

- close
- getMessageListener
- receive
- receiveNoWait
- setMessageListener

Methods

`getNoLocal`

```
public boolean getNoLocal() throws JMSEException
```

Get the `NoLocal` attribute for this `TopicSubscriber`. The default value for this attribute is false.

Returns:

Set to true if locally-published messages are being inhibited.

Throws:

`JMSEException` if JMS fails to get `NoLocal` attribute for this topic subscriber because of an internal error.

`getTopic`

```
public Topic getTopic() throws JMSEException
```

Get the topic associated with this subscriber.

Returns:

This subscriber's topic.

Throws:

`JMSEException` if JMS fails to get topic for this topic subscriber because of an internal error.

XAConnection

public interface **XAConnection**

Subinterfaces: **XAQueueConnection** and **XATopicConnection**

WebSphere MQ class: **MQXAConnection**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQXAConnection
```

XAConnection extends the capability of connection by providing an XASession. Refer to Appendix E, “JMS JTA/XA interface with WebSphere Application Server V4” on page 417 for details about how WebSphere MQ JMS uses XA classes.

See also: **XAQueueConnection** and **XATopicConnection**

XAConnectionFactory

XAConnectionFactory

public interface **XAConnectionFactory**

Subinterfaces: **XAQueueConnectionFactory** and **XATopicConnectionFactory**

WebSphere MQ class: **MQXAConnectionFactory**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQXAConnectionFactory
```

Some application servers provide support to group JTS-capable resource use into a distributed transaction. To include JMS transactions in a JTS transaction, an application server requires a JTS-aware JMS provider. A JMS provider exposes its JTS support by using a JMS XAConnectionFactory, which an application server uses to create XASessions. XAConnectionFactory's are JMS-administered objects just like ConnectionFactories. It is expected that application servers use JNDI to find them.

Refer to Appendix E, "JMS JTA/XA interface with WebSphere Application Server V4" on page 417 for details about how WebSphere MQ JMS uses XA classes.

See also: **XAQueueConnectionFactory** and **XATopicConnectionFactory**

XAQueueConnection

public interface **XAQueueConnection**
 extends **QueueConnection** and **XAConnection**

WebSphere MQ class: **MQXAQueueConnection**

XAQueueConnection provides the same create options as QueueConnection. The only difference is that, by definition, an XAConnection is transacted. Refer to Appendix E, “JMS JTA/XA interface with WebSphere Application Server V4” on page 417 for details about how WebSphere MQ JMS uses XA classes.

See also: **XAConnection** and **QueueConnection**

Methods

createQueueSession

```

public QueueSession createQueueSession(boolean transacted,
                                           int acknowledgeMode)
                                           throws JMSEException
  
```

Create a QueueSession.

Parameters:

- **transacted**: if true, the session is transacted.
- **acknowledgeMode**: indicates whether the consumer or the client acknowledges any messages it receives. Possible values are:
 Session.AUTO_ACKNOWLEDGE
 Session.CLIENT_ACKNOWLEDGE
 Session.DUPS_OK_ACKNOWLEDGE

This parameter is ignored if the session is transacted.

Returns:

A newly-created queue session (this is not an XA queue session).

Throws:

JMSEException if JMS Connection fails to create a queue session because of an internal error.

createXAQueueSession

```

public XAQueueSession createXAQueueSession()
  
```

Create an XAQueueSession.

Throws:

JMSEException if JMS Connection fails to create an XA queue session because of an internal error.

XAQueueConnectionFactory

public interface **XAQueueConnectionFactory**
extends **QueueConnectionFactory** and **XAConnectionFactory**

WebSphere MQ class: **MQXAQueueConnectionFactory**

An **XAQueueConnectionFactory** provides the same create options as a **QueueConnectionFactory**. Refer to Appendix E, “JMS JTA/XA interface with WebSphere Application Server V4” on page 417 for details about how WebSphere MQ JMS uses XA classes.

See also: **QueueConnectionFactory** and **XAConnectionFactory**

Methods

createXAQueueConnection

```
public XAQueueConnection createXAQueueConnection()  
                                throws JMSException
```

Create an **XAQueueConnection** using the default user identity. The connection is created in stopped mode. No messages are delivered until the **Connection.start** method is called explicitly.

Returns:

A newly-created XA queue connection.

Throws:

- **JMSException** if the JMS provider fails to create an XA queue connection because of an internal error.
- **JMSSecurityException** if client authentication fails because of a non valid user name or password.

createXAQueueConnection

```
public XAQueueConnection createXAQueueConnection  
                                (java.lang.String userName,  
                                java.lang.String password)  
                                throws JMSException
```

Create an XA queue connection using a specific user identity. The connection is created in stopped mode. No messages are delivered until the **Connection.start** method is called explicitly.

Parameters:

- **userName**: the user name of the caller.
- **password**: the password for the caller.

Returns:

A newly-created XA queue connection.

XAQueueConnectionFactory

Throws:

- `JMSEException` if the JMS Provider fails to create an XA queue connection because of an internal error.
- `JMSSecurityException` if client authentication fails because of a non valid user name or password.

XAQueueSession

```
public interface XAQueueSession
extends XASession
```

WebSphere MQ class: **MQXAQueueSession**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQXASession
      |
      +----com.ibm.mq.jms.MQXAQueueSession
```

An XAQueueSession provides a regular QueueSession that can be used to create QueueReceivers, QueueSenders, and QueueBrowsers. Refer to Appendix E, “JMS JTA/XA interface with WebSphere Application Server V4” on page 417 for details about how WebSphere MQ JMS uses XA classes.

The XAResource that corresponds to the QueueSession can be obtained by calling the getXAResource method, which is inherited from XASession.

See also: **XASession**

Methods

getQueueSession

```
public QueueSession getQueueSession()
                        throws JMSEException
```

Get the queue session associated with this XAQueueSession.

Returns:

The queue session object.

Throws:

JMSEException if a JMS error occurs.

XASession

public interface **XASession**
 extends **Session**
 Subinterfaces: **XAQueueSession** and **XATopicSession**

WebSphere MQ class: **MQXASession**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQXASession
```

XASession extends the capability of Session by adding access to a JMS provider's support for JTA. This support takes the form of a javax.transaction.xa.XAResource object. The functionality of this object closely resembles that defined by the standard X/Open XAResource interface.

An application server controls the transactional assignment of an XASession by obtaining its XAResource. It uses the XAResource to assign the session to a transaction, prepare and commit work on the transaction, and so on.

An XAResource provides some fairly sophisticated facilities such as interleaving work on multiple transactions and recovering a list of transactions in progress.

A JTA-aware JMS provider must fully implement this functionality. To do this, a JMS provider can either use the services of a database that supports XA, or implement this functionality from scratch.

A client of the application server is given what appears to be a regular JMS Session. Behind the scenes, the application server controls the transaction management of the underlying XASession.

Refer to Appendix E, "JMS JTA/XA interface with WebSphere Application Server V4" on page 417 for details about how WebSphere MQ JMS uses XA classes.

See also: **XAQueueSession** and **XATopicSession**

Methods

commit

```
public void commit()
    throws JMSEException
```

Do not call this method for an XASession object. If it is called, it throws a TransactionInProgressException.

Specified by:

Commit in the Session interface.

Throws:

TransactionInProgressException if this method is called on an XASession.

getTransacted

```
public boolean getTransacted()
    throws JMSEException
```

Always returns true.

XASession

Specified by:

getTransacted in the Session interface.

Returns:

True if the session is in transacted mode.

Throws:

JMSEException if JMS fails to return the transaction mode because of an internal error in the JMS Provider.

getXAResource

```
public javax.transaction.xa.XAResource getXAResource()
```

Return an XA resource to the caller.

Returns:

an XA resource to the caller.

rollback

```
public void rollback()  
    throws JMSEException
```

Do not call this method for an XASession object. If it is called, it throws a TransactionInProgressException.

Specified by:

Rollback in the session interface.

Throws:

TransactionInProgressException if this method is called on an XASession.

XATopicConnection

public interface **XATopicConnection**
 extends **TopicConnection** and **XAConnection**

WebSphere MQ class: **MQXATopicConnection**

An XATopicConnection provides the same create options as TopicConnection. The only difference is that an XAConnection is transacted. Refer to Appendix E, “JMS JTA/XA interface with WebSphere Application Server V4” on page 417 for details about how WebSphere MQ JMS uses XA classes.

See also: **TopicConnection** and **XAConnection**

Methods

createTopicSession

```
public TopicSession createTopicSession(boolean transacted,
                                         int acknowledgeMode)
    throws JMSException
```

Create a TopicSession.

Specified by:

createTopicSession in interface TopicConnection.

Parameters:

- transacted: if true, the session is transacted.
- acknowledgeMode: one of:
 Session.AUTO_ACKNOWLEDGE
 Session.CLIENT_ACKNOWLEDGE
 Session.DUPS_OK_ACKNOWLEDGE

Indicates whether the consumer or the client acknowledges any messages it receives. This parameter is ignored if the session is transacted.

Returns:

A newly-created topic session (this is not an XA topic session).

Throws:

JMSException if JMS Connection fails to create a topic session because of an internal error.

createXATopicSession

```
public XATopicSession createXATopicSession()
    throws JMSException
```

Create an XATopicSession.

XATopicConnection

Throws:

JMSEException if the JMS Connection fails to create an XA topic session because of an internal error.

XATopicConnectionFactory

public interface **XATopicConnectionFactory**
 extends **TopicConnectionFactory** and **XAConnectionFactory**

WebSphere MQ class: **MQXATopicConnectionFactory**

An **XATopicConnectionFactory** provides the same create options as **TopicConnectionFactory**. Refer to Appendix E, “JMS JTA/XA interface with WebSphere Application Server V4” on page 417 for details about how WebSphere MQ JMS uses XA classes.

See also: **TopicConnectionFactory** and **XAConnectionFactory**

Methods

createXATopicConnection

```
public XATopicConnection createXATopicConnection()
                               throws JMSEException
```

Create an XA topic connection using the default user identity. The connection is created in stopped mode. No messages are delivered until the `Connection.start` method is called explicitly.

Returns:

A newly-created XA topic connection.

Throws:

- **JMSEException** if the JMS Provider fails to create an XA topic connection because of an internal error.
- **JMSSecurityException** if client authentication fails because of a non valid user name or password.

createXATopicConnection

```
public XATopicConnection createXATopicConnection(java.lang.String userName,
                                                    java.lang.String password)
                               throws JMSEException
```

Create an XA topic connection using the specified user identity. The connection is created in stopped mode. No messages are delivered until the `Connection.start` method is called explicitly.

Parameters:

- `userName`: the user name of the caller
- `password`: the password of the caller

Returns:

A newly-created XA topic connection.

Throws:

XATopicConnectionFactory

- `JMSEException` if the JMS Provider fails to create an XA topic connection because of an internal error.
- `JMSSecurityException` if client authentication fails because of a non valid user name or password.

XATopicSession

```
public interface XATopicSession
extends XASession
```

WebSphere MQ class: **MQXATopicSession**

```
java.lang.Object
|
+----com.ibm.mq.jms.MQXASession
|
+----com.ibm.mq.jms.MQXATopicSession
```

An XATopicSession provides a TopicSession, which you can use to create TopicSubscribers and TopicPublishers. Refer to Appendix E, “JMS JTA/XA interface with WebSphere Application Server V4” on page 417 for details about how WebSphere MQ JMS uses XA classes.

The XAResource that corresponds to the TopicSession can be obtained by calling the getXAResource method, which is inherited from XASession.

See also: **TopicSession** and **XASession**

Methods

getTopicSession

```
public TopicSession getTopicSession()
throws JMSEException
```

Get the topic session associated with this XATopicSession.

Returns:

The topic session object.

Throws:

- JMSEException if a JMS error occurs.

Part 4. Appendixes

Appendix A. Mapping between administration tool properties and programmable properties

WebSphere MQ classes for Java Message Service provides facilities to set and query the properties of administered objects either using the WebSphere MQ JMS administration tool, or in an application program. Table 37 shows the mapping between each property name used with the administration tool and the corresponding member variable it refers to. It also shows the mapping between symbolic property values used in the tool and their programmable equivalents.

Table 37. Comparison of representations of property values within the administration tool and within programs

Appendix B. Scripts provided with WebSphere MQ classes for Java Message Service

The following files are provided in the bin directory of your WebSphere MQ JMS installation. These scripts are provided to assist with common tasks that need to be performed while installing or using WebSphere MQ JMS. Table 38 lists the scripts and their uses.

Table 38. Utilities supplied with WebSphere MQ classes for Java Message Service

Utility	Use
Cleanup.bat	Runs the subscription cleanup utility, described in "Manual cleanup" on page 224.
DefaultConfiguration	Runs the default configuration application on non-Windows systems, as described in "JMS Postcard configuration" on page 22.
formatLog.bat	Converts binary log files to plain text, described in "Logging" on page 39.
IVTRun.bat IVTTidy.bat IVTSetup.bat	Runs the point-to-point installation verification test program, described in "Running the point-to-point IVT" on page 31.
JMSAdmin.bat	Runs the administration tool, described in Chapter 5, "Using the WebSphere MQ JMS administration tool" on page 41.
JMSAdmin.config	Configuration file for the administration tool, described in "Configuration" on page 42.
postcard.bat	Starts the JMS Postcard application, described in "JMS Postcard" on page 19.
PSIVTRun.bat	Runs the publish/subscribe installation verification test program described in "The publish/subscribe installation verification test" on page 35.
PSReportDump.class	Views broker report messages, described in "Handling broker reports" on page 225.
runjms.bat	Helps you to run JMS applications, described in "Running your own WebSphere MQ JMS programs" on page 38.
Note: On UNIX systems, the extension .bat is omitted from the filenames.	

Scripts

Appendix C. LDAP schema definition for storing Java objects

This appendix gives details of the schema definitions (objectClass and attribute definitions) needed in an LDAP directory for it to store Java objects. Read it if you want to use an LDAP server as your JNDI service provider in which to store WebSphere MQ JMS administered objects. Ensure that your LDAP server schema contains the following definitions; the exact procedure to achieve this varies from server to server. How to make the changes to some specific LDAP servers is covered later in this section.

Much of the data contained in this appendix has been taken from RFC 2713 *Schema for Representing Java Objects in an LDAP Directory*, which can be found at <http://www.faqs.org/rfcs/rfc2713.html>. LDAP server-specific information has been taken from Sun Microsystems' JNDI 1.2.1 LDAP service provider, available at <http://java.sun.com/products/jndi>.

Checking your LDAP server configuration

To check whether the LDAP server is already configured to accept Java objects, run the WebSphere MQ JMS administration tool JMSAdmin against your LDAP server (see "Invoking the administration tool" on page 41).

Try to create and display a test object using the following commands:

```
DEFINE QCF(1dapTest)
DISPLAY QCF(1dapTest)
```

If no errors occur, your server is properly configured to store Java objects and you can proceed to store JMS objects. However, if your LDAP server contains older schema definitions (for example, from an earlier draft of RFC 2713 such as the now-obsolete draft-ryan-java-schema-00 and draft-ryan-java-schema-01 specifications), update them with those described here.

If a SchemaViolationException occurs, or if the message Unable to bind to object is returned, your server is not properly configured. Either your server is not configured to store Java objects, permissions on the objects are not correct, or the provided suffix or context has not been set up. The following information helps you with the schema configuration part of your server setup.

Attribute definitions

Server-specific configuration details

This section describes special steps you need to take to use the following servers:

- “Netscape Directory (4.1 and earlier)”
- “Microsoft® Active Directory”
- “Sun Microsystems’ schema modification applications” on page 411
- “OS/400 V4R5 Schema Modification” on page 411

Netscape Directory (4.1 and earlier)

This level of Netscape Directory does not support the Octet String syntax; use Binary syntax (1.3.6.1.4.1.1466.115.121.1.5) instead. Netscape Directory 4.1 also has problems parsing an object class definition that contains a MUST clause without parentheses. The workaround is to add a superfluous value (objectClass) to each MUST clause.

Alternatively, you can use the Sun-supplied schema modification applications described in “Sun Microsystems’ schema modification applications” on page 411.

Microsoft® Active Directory

Within Active Directory, only the names of structural classes (not auxiliary classes) can appear in the object class attribute of an entry. You must redefine the abstract and auxiliary classes in the Java schema definition as structural. This has the following effects:

- The javaObject class now inherits from javaContainer

- The `javaNamingReference` and `javaSerializedObject` classes now inherit from `javaObject`

Instead of making these changes manually, you can use the Sun-supplied schema modification applications described in “Sun Microsystems’ schema modification applications”.

Sun Microsystems’ schema modification applications

You can use your LDAP server’s administration tool (for example, the Directory Management Tool for IBM’s SecureWay® Directory) to verify or add the definitions described above. Alternatively, Sun Microsystems’ JNDI 1.2.1 LDAP service provider (available at <http://java.sun.com/products/jndi>) contains Java applications (`CreateJavaSchema.java` and `UpdateJavaSchema.java`) that add or update the required schema definitions automatically. These applications contain workarounds for schema bugs and server-specific behavior in both Netscape Directory Server (pre-4.1 and 4.1) and Microsoft Windows 2000 Active Directory.

These applications are not packaged with WebSphere MQ classes for Java Message Service. Details on running them can be found in both the README and the application source contained in the Sun JNDI 1.2.1 LDAP service provider download.

OS/400 V4R5 Schema Modification

You can use your LDAP server’s administration tool (the Directory Management Tool for IBM’s SecureWay Directory) to verify or add the definitions described above.

OS/400 V4R5 LDAP Server is shipped with an out-of-date version of RFC 2713 schema for Java objects. Update this schema to the schema described above to operate correctly with JMSAdmin. When you modify the schema, delete any out-of-date definitions and uses of those definitions before adding the correct definitions.

OS/400 V5R1 is shipped with the current version of RFC 2713 and does not require these changes.

Appendix D. Connecting with other products

This section covers:

- How to set up a connection from WebSphere MQ JMS to a publish/subscribe broker in “Setting up a publish/subscribe broker”
- How to use WebSphere MQ Integrator V2 to route or transform messages sent to or from a JMS client in “Transformation and routing with WebSphere MQ Integrator V2” on page 414

Setting up a publish/subscribe broker

You can use WebSphere MQ Integrator V2 or WebSphere MQ Event Broker as the publish/subscribe broker for WebSphere MQ JMS. You can link to either across a connection to base WebSphere MQ, or you can directly connect to WebSphere MQ Event Broker across a TCP/IP connection. Each method requires some setup activities:

Linking across WebSphere MQ

- Base WebSphere MQ

First, create a broker publication queue. This is a WebSphere MQ queue on the broker queue manager; it is used to submit publications to the broker. You can choose your own name for this queue, but it must match the queue name in your TopicConnectionFactory’s BROKERPUBQ property. By default, a TopicConnectionFactory’s BROKERPUBQ property is set to the value SYSTEM.BROKER.DEFAULT.STREAM so, unless you want to configure a different name in the TopicConnectionFactory, name the queue SYSTEM.BROKER.DEFAULT.STREAM.

- WebSphere MQ Integrator V2

The next step is to set up a *message flow* within an execution group for the broker. The purpose of this message flow is to read messages from the broker publication queue. (If you want, you can set up multiple publication queues; each needs its own TopicConnectionFactory and message flow.)

The basic message flow consists of an MQInput node (configured to read from the SYSTEM.BROKER.DEFAULT.STREAM queue) whose output is connected to the input of a Publication (or MQOutput) node.

The message flow diagram therefore looks similar to the following:

Figure 7. WebSphere MQ Integrator message flow

When this message flow is deployed and the broker is started, from the JMS application’s perspective the WebSphere MQ Integrator V2 broker

Setting up a publish/subscribe broker

behaves like an MQSeries Publish/Subscribe broker. The current subscription state can be viewed using the WebSphere MQ Integrator Control Center.

Notes:

1. No modifications are required to WebSphere MQ classes for Java Message Service.
2. MQSeries Publish/Subscribe and WebSphere MQ Integrator V2 brokers cannot coexist on the same queue manager.
3. Details of the WebSphere MQ Integrator V2 installation and setup procedure are described in the *WebSphere MQ Integrator for Windows NT Version 2.0 Installation Guide*.

Direct connection to WebSphere MQ Event Broker across TCP/IP

For this, set up a *message flow* within an execution group on WebSphere MQ Event Broker. This message flow is to read messages from the TCP/IP socket on which the broker is listening.

The basic message flow consists of a JMSIPOptimised flow set to listen on the port configured for direct connections. By default, this port is 1506.

Note: WebSphere MQ Event Broker can be configured to listen for both direct connections across TCP/IP from WebSphere MQ JMS and connections made across TCP/IP through WebSphere MQ. In this case, the two listeners must be configured on different ports. The default port for a WebSphere MQ connection is 1414.

Transformation and routing with WebSphere MQ Integrator V2

You can use WebSphere MQ Integrator V2 to route or transform messages that are created by a JMS client application, and to send or publish messages to a JMS client.

The WebSphere MQ JMS implementation uses the mcd folder of the MQRFH2 to carry information about the message, as described in “The MQRFH2 header” on page 232. By default, the Message Domain (Msd) property is used to identify whether the message is a text, bytes, stream, map, or object message. This value is set depending on the type of the JMS message.

If the application calls `setJMSType`, it can set the mcd type field to a value of its choosing. This type field can be read by the WebSphere MQ Integrator message flow, and a receiving JMS application can use the `getJMSType` method to retrieve its value. This applies to all kinds of JMS message.

When a JMS application creates a text or bytes message, the application can set mcd folder fields explicitly by calling the `setJMSType` method and passing in a string argument in a special URI format as follows:

```
mcd://domain/[set]/[type][?format=fmt]
```

This URI form allows an application to set the mcd to a domain that is not one of the standard `jms_xxxx` values; for example, to domain `mrm`. It also allows the application to set any or all of the mcd `set`, `type`, and `format` fields.

The string argument to `setJMSType` is interpreted as follows:

1. If the string does not appear to be in the special URI format (it does not start with `mcd://`), the string is added to the mcd folder as the type field.

Transformation and routing

2. If the string starts with `mcd://`, conforms to the URI format, *and* the message is a Text or Bytes message, the URI string is split into its constituent parts. The domain part overrides the `jms_text` or `jms_bytes` value that would otherwise have been generated, and the remaining parts (if present) are used to set the set, type, and format fields in the `mcd`. Note that set, type, and format are all optional.
3. If the string starts with `mcd://` and the message is a Map, Stream, or Object message, the `setJMSType` call throws an exception. So you cannot override the domain, or provide a set or format for these classes of message, but you can provide a type.

When a WebSphere MQ message is received with an `Msd` domain other than one of the standard `jms_xxxx` values, it is instantiated as a JMS text or bytes message and a URI-style `JMSType` is assigned to it. If the format field of the `RFH2` is `MQFMT_STRING`, it becomes a `TextMessage`; otherwise it becomes a `BytesMessage`. The receiving application can read this using the `getJMSType` method.

Appendix E. JMS JTA/XA interface with WebSphere Application Server V4

WebSphere MQ classes for Java Message Service includes the JMS XA interfaces. These allow WebSphere MQ JMS to participate in a two-phase commit that is coordinated by a transaction manager that complies with the Java Transaction API (JTA).

This section describes how to use these features with the WebSphere Application Server, Advanced Edition, so that WebSphere Application Server can coordinate JMS send and receive operations, and database updates, in a global transaction.

Note: Before you use WebSphere MQ JMS and the XA classes with WebSphere Application Server, there might be additional installation or configuration steps. Refer to the `Readme.txt` file on the WebSphere MQ Using Java SupportPac Web page for the latest information (www.ibm.com/software/ts/mqseries/txppacs/ma88.html).

Using the JMS interface with WebSphere Application Server

This section provides guidance on using the JMS interface with the WebSphere Application Server Version 4, Advanced Edition.

You must already understand the basics of JMS programs, WebSphere MQ, and EJB beans. These details are in the JMS specification, the EJB V2 specification (both available from Sun), this manual, the samples provided with WebSphere MQ JMS, and other manuals for WebSphere MQ and WebSphere Application Server.

Administered objects

JMS uses administered objects to encapsulate vendor-specific information. This minimizes the impact of vendor-specific details on end-user applications. Administered objects are stored in a JNDI namespace, and can be retrieved and used in a portable manner without knowing the vendor-specific contents.

For standalone use, WebSphere MQ JMS provides the following classes:

- `MQQueueConnectionFactory`
- `MQQueue`
- `MQTopicConnectionFactory`
- `MQTopic`

WebSphere Application Server provides an additional pair of administered objects so that WebSphere MQ JMS can integrate with WebSphere Application Server:

- `JMSWrapXAQueueConnectionFactory`
- `JMSWrapXATopicConnectionFactory`

You use these objects in exactly the same way as the `MQQueueConnectionFactory` and `MQTopicConnectionFactory`. However, behind the scenes they use the XA versions of the JMS classes, and enlist the WebSphere MQ JMS `XAResource` in the WebSphere Application Server transaction.

Container-managed versus bean-managed transactions

Container-managed transactions are transactions in EJB beans that are demarcated automatically by the EJB container. Bean-managed transactions are transactions in EJB beans that are demarcated by the program (using the `UserTransaction` interface).

Two-phase commit versus one-phase optimization

The WebSphere Application Server coordinator invokes a true two-phase commit only if more than one `XAResource` is used in a particular transaction. Transactions that involve a single resource are committed using a one-phase optimization. This largely removes the need to use different `ConnectionFactory`s for distributed and non-distributed transactions.

Defining administered objects

You can use the WebSphere MQ JMS administration tool to define the WebSphere Application Server-specific connection factories and store them in a JNDI namespace. The `admin.config` file in `MQ_install_dir/bin` must contain the following lines:

```
INITIAL_CONTEXT_FACTORY=com.ibm.websphere.naming.WsnInitialContextFactory
PROVIDER_URL=iiop://hostname/
```

`MQ_install_dir` is the installation directory for WebSphere MQ JMS, and `hostname` is the name or IP address of the machine that is running WebSphere Application Server.

To access the `com.ibm.ejs.ns.jndi.CNInitialContextFactory`, you must add the file `ejs.jar` from the WebSphere Application Server lib directory to the `CLASSPATH`.

To create the new factories, use the `define` verb with the following two new types:

```
def WSQCF(name) [properties]
def WSTCF(name) [properties]
```

These new types use the same properties as the equivalent `QCF` or `TCF` types, except that only the `BIND` transport type is allowed (and therefore, client properties cannot be configured). For details, see “Administering JMS objects” on page 45.

Retrieving administration objects

In an EJB bean, you retrieve the JMS-administered objects using the `InitialContext.lookup()` method, for example:

```
InitialContext ic = new InitialContext();
TopicConnectionFactory tcf = (TopicConnectionFactory) ic.lookup("jms/Samples/TCF1");
```

The objects can be cast to, and used as, the generic JMS interfaces. Normally, there is no need to program to the WebSphere MQ specific classes in the application code.

Samples

There are three samples that illustrate the basics of using WebSphere MQ JMS with WebSphere Application Server Advanced Edition. These are in subdirectories of `MQ_samples_dir/ws`, where `MQ_samples_dir` is the samples directory for WebSphere MQ JMS. See Table 3 on page 10 to find where this is.

JTA/XA interface with WebSphere Application Server V4

- Sample1 demonstrates a simple put and get for a message in a queue by using container-managed transactions.
- Sample2 demonstrates a simple put and get for a message in a queue by using bean-managed transactions.
- Sample3 illustrates the use of the publish/subscribe API.

For details about how to build and deploy the EJB beans, refer to the WebSphere Application Server documentation.

The readme.txt files in each sample directory include example output from each EJB bean. The scripts provided assume that a default queue manager is available on the local machine. If your installation varies from the default, you can edit these scripts.

Sample1

Sample1EJB.java, in the sample1 directory, defines two methods that use JMS:

- putMessage() sends a TextMessage to a queue, and returns the MessageID of the sent message
- getMessage() reads the message with the specified MessageID back from the queue

Before you run the sample, you must store two administered objects in the WebSphere Application Server JNDI namespace:

QCF1 a WebSphere Application Server-specific queue connection factory
Q1 a queue

Both objects must be bound in the jms/Samples sub-context.

To set up the administered objects, you can either use the WebSphere MQ JMS administration tool and set them up manually, or you can use the script provided.

The WebSphere MQ JMS administration tool must be configured to access the WebSphere Application Server namespace. For details about how to configure the administration tool, refer to “Configuring for WebSphere Application Server V3.5” on page 44.

To set up the administered objects with typical default settings, you can enter the following command to run the script admin.scp:

```
JMSAdmin < admin.scp
```

The bean must be deployed with the getMessage and putMessage methods marked as TX_REQUIRED. This ensures that the container starts a transaction before entering each method, and commits the transaction when the method completes. Within the methods, you do not need any application code that relates to the transactional state. However, the message sent from putMessage occurs under syncpoint, and does not become available until the transaction is committed.

In the sample1 directory, there is a simple client program, Sample1Client.java, to call the EJB bean. There is also a script, runClient, to simplify running this program.

The client program (or script) takes a single parameter, which is used as the body of a TextMessage that is sent by the EJB bean putMessage method. The getMessage

JTA/XA interface with WebSphere Application Server V4

is called to read the message back off the queue and return the body to the client for display. The EJB bean sends progress messages to the standard output (stdout) of the application server, so you might want to monitor that output during the run.

If the application server is on a machine that is remote from the client, you might need to edit `Sample1Client.java`. If you do not use the defaults, you might need to edit the `runClient` script to match the local installation path and name of the deployed jar file.

Sample2

`Sample2EJB.java`, in the `sample2` directory, performs the same task as `sample1`, and requires the same administered objects. Unlike `sample1`, `sample2` uses bean-managed transactions to control the transactional boundaries.

If you have not already run `sample1`, ensure that you set up the administered objects `QCF1` and `Q1`, as described in “Sample1” on page 419.

The `putMessage` methods and `getMessage` methods start by obtaining an instance of `UserTransaction`. They use this instance to create a transaction using the `UserTransaction.begin()` method. After that, the main body of the code is the same as `sample1` until the end of each method. At the end of each method, the transaction is completed by the `UserTransaction.commit()` call.

In the `sample2` directory, there is a simple client program, `Sample2Client.java`, to call the EJB bean. There is also a script, `runClient`, to simplify running this program. You can use these in the same way as described for “Sample1” on page 419.

Sample3

`Sample3EJB.java`, in the `sample3` directory, demonstrates the use of the `publish/subscribe` API with WebSphere Application Server. Publishing a message is very similar to the point-to-point case. However, there are differences when receiving messages using a `TopicSubscriber`.

`Publish/subscribe` programs commonly use nondurable subscribers. These nondurable subscribers exist only for the lifetime of their owning sessions (or less if the subscriber is closed explicitly). Also, they can receive messages from the broker only during that lifetime.

To convert `sample1` to `publish/subscribe`, create a durable subscriber before the message is published. Durable subscribers persist as a deliverable end-point beyond the lifetime of the session. Therefore, the message is available for retrieval during the call to `getMessage()`.

The EJB bean includes two additional methods:

- `createSubscription` creates a durable subscription
- `destroySubscription` deletes a durable subscription

These methods (along with `putMessage` and `getMessage`) must be deployed with the `TX_REQUIRED` attribute.

JTA/XA interface with WebSphere Application Server V4

Before you run `sample3`, you must store two administered objects in the WebSphere Application Server JNDI namespace:

TCF1
T1

Both objects must be bound in the `jms/Samples` sub-context.

To set up the administered objects, you can either use the WebSphere MQ JMS administration tool and set them up manually, or you can use a script. The script `admin.scp` is provided in the `sample3` directory.

The WebSphere MQ JMS administration tool must be configured to access the WebSphere Application Server namespace. For details about how to configure the administration tool, refer to “Configuring for WebSphere Application Server V3.5” on page 44.

To set up the administered objects with typical default settings, you can enter the following command to run the script `admin.scp`:

```
JMSAdmin < admin.scp
```

If you have already run `admin.scp` to set up objects for `sample1` or `sample2`, there will be error messages when you run `admin.scp` for `sample3`. (These occur when you attempt to create the `jms` and `Samples` sub-contexts.) You can safely ignore these error messages.

Also, before you run `sample3`, ensure that the WebSphere MQ publish/subscribe broker (SupportPac MA0C) is installed and running.

In the `sample3` directory, there is a simple client program, `Sample3Client.java`, to call the EJB bean. There is also a script, `runClient`, to simplify running this program. You can use these in the same way as described for “Sample1” on page 419.

Appendix F. Using WebSphere MQ Java in applets with Java 1.2 or later

You might need to perform additional tasks to run an applet using WebSphere MQ Java classes in a Java virtual machine (JVM) at Java 1.2 level or greater. This is because the default security rules for applets with JVMs at these levels were changed to reduce the risk of damage by malevolent or misbehaving classes.

There are two different approaches that you can take:

1. Change the security settings on the browser and JVM to allow the use of WebSphere MQ Java packages.
2. Copy the WebSphere MQ Java classes to the same location as the applet you wish to run.

Changing browser security settings

Different errors can result from trying to run the same applet in different environments; for example, in IBM VisualAge for Java, in appletviewer (supplied with most Development Kits for Java) or in a Web browser such as Internet Explorer. The differences are to do with different security settings in each environment. You can change the behavior of the environments to allow an applet access to the classes it needs that are stored in package files.

In the following instructions, examples assume use of the Windows platforms. On other platforms, the instructions need slight modification.

For IBM VisualAge for Java:

Change the `java.policy` file found in `<vaj_install_dir>\ide\program\lib\security`, where `<vaj_install_dir>` is the directory in which you installed IBM VisualAge for Java.

Refer to "Running WebSphere MQ Java applications under the Java 2 Security Manager" on page 13 for general instructions about changes to this file. For applets, also check for the following changes to the permissions:

1. Comment out the line

```
permission java.net.SocketPermission "localhost:1024-", "listen";
```

and replace it with the following line:

```
permission java.net.SocketPermission "*", "accept, connect, listen, resolve";
```

2. Add the following lines:

```
permission java.util.PropertyPermission "MQJMS_LOG_DIR", "read";
permission java.util.PropertyPermission "MQJMS_TRACE_DIR", "read";
permission java.util.PropertyPermission "MQJMS_TRACE_LEVEL", "read";
permission java.util.PropertyPermission "MQ_JAVA_INSTALL_PATH", "read";
permission java.util.PropertyPermission "file.separator", "read";
permission java.util.PropertyPermission "user.name", "read";
permission java.util.PropertyPermission "com.ibm.mq.jms.cleanup", "read";
permission java.lang.RuntimePermission "loadLibrary.*";
```

Notes:

1. You might need to restart VisualAge for Java if you get the error message Unknown Java Error after repeated tests.

Changing browser security

2. Make sure that `<install_dir>\java\lib` is in the workspace classpath.

For appletviewer:

Find the policy file for your JDK and make the same changes as for IBM VisualAge for Java. For example, in the IBM Developer Kit for Windows, Java Technology Edition, Version 1.3, the `java.policy` file is found in the directory `<jdk_install_dir>\jre\lib\security`, where `<jdk_install_dir>` is the directory where the Developer Kit was installed.

For a Web browser:

To achieve consistent behavior for applets within different Web browsers, use the Sun Java plug-in.

1. Install the Sun Java plug-in 1.3.01 or later.
From this level, Netscape 6 is also supported.
2. Make the same changes to the `java.policy` file as listed above.
The policy file is found in `<java_plugin_install_dir>\lib\security`.
3. Make sure that your HTML applet tags are changed to run with the plug-in.
Download and run the Sun HTML Converter v1.3 to make the necessary changes.

Copying package class files

When a Java program is executed in the context of an applet (which is what is done when `appletviewer` is executed or a Web browser is used), by default the Java program has significant security restrictions applied to it. One of these restrictions is that all environment variables in effect when the applet is launched are ignored. This includes `CLASSPATH`.

As a result, unless you make the changes described in “Changing browser security settings” on page 423, when an applet is executed, each and every class that it needs must also be available for download from the same location as the applet code itself.

To achieve this on a Windows system, perform the following steps (non-Windows users need to perform similar tasks):

1. Download and install WINZIP (<http://www.winzip.com>) or equivalent file unzipping utility
2. Find the files containing the WebSphere MQ Java, or other package, classes that your applet needs.

For example, WebSphere MQ base Java classes are in a file called `com.ibm.mq.jar` usually found in the `C:\Program Files\IBM\WebSphere MQ\Java\lib` folder.

3. Using the unzipping utility you installed in step 1, extract *all* the files in the `.jar` file into the folder that contains your applet.

For the samples supplied with WebSphere MQ Java, the folder to use is `C:\Program Files\IBM\WebSphere MQ\Tools\Java\base`

This creates a sub-folder structure `com\ibm`.

4. Run your applet.

Appendix G. Information for SupportPac MA1G

This appendix contains information that is relevant to users of SupportPac MA1G “WebSphere MQ for MVS/ESA™ – WebSphere MQ classes for Java”. MA1G provides support for WebSphere MQ classes for Java from versions of OS/390 not supported by WebSphere MQ Java. It also provides support for CICS and High Performance Java (HPJ).

Users intending to use the WebSphere MQ base Java with CICS Transaction Server for OS/390 must be familiar with:

- Customer Information Control System (CICS) concepts
- Using the CICS Java Application Programming Interface (API)
- Running Java programs from within CICS

Users intending to use VisualAge for Java to develop OS/390 UNIX System Services High Performance Java (HPJ) applications must be familiar with the Enterprise Toolkit for OS/390 (supplied with VisualAge for Java Enterprise Edition for OS/390, Version 2).

Environments supported by SupportPac MA1G

SupportPac MA1G provides support for WebSphere MQ base Java from the following environments:

- OS/390 V2R6 or higher
- Java for OS/390, V1.1.8 or higher
- IBM MQSeries for MVS/ESA, Version 1.2 or higher
- High Performance Java (HPJ)

SupportPac MA1G also provides support for CICS TS1.3 or higher. Support for HPJ in this environment requires OS/390 V2R9 or higher.

SupportPac MA1G does *not* provide support for JMS.

Obtaining and installing SupportPac MA1G

Obtain SupportPac MA1G from the WebSphere MQ web site <http://www.ibm.com/software/ts/mqseries>. Follow links to Download and then SupportPacs to find the WebSphere MQ Java code.

The following procedure installs the WebSphere MQ classes for Java. The directory used for the installation needs at least 2MB of free storage. In the following, replace /u/joe/mqm with the path name of the directory you choose:

1. Remove any previous installation of this product using the following commands in the OpenEdition shell:

```
cd /u/joe
chmod -fR 700 mqm
rm -rf mqm
mkdir mqm
```

2. Using FTP binary mode, upload the file ma1g.tar.Z from your workstation to the HFS directory /u/joe/mqm.

Obtaining and installing

3. While in the OpenEdition shell, change to the installation directory `/u/joe/mqm`.
4. Uncompress and untar the file with the command

```
tar -xpozf ma1g.tar.Z
```
5. Set up your CLASSPATH and LIBPATH as described in “Environment variables” on page 10.

Verifying installation using the sample program

To verify installation of MA1G from UNIX System Services (USS), follow the instructions in “Verifying with the sample application” on page 16.

To verify installation of MA1G from CICS Transaction Server:

1. Define the sample application program (MQIVP) to CICS.
2. Define a transaction to run the sample application.
3. Put the queue manager name into the file used for standard input.
4. Run the transaction.

The program output is placed in the files used for standard and error output.

Refer to CICS documentation for more information on running Java programs and setting the input and output files.

Features not provided by SupportPac MA1G

SupportPac MA1G provides a subset of features available to other WebSphere MQ base Java applications. In particular, it does not support the ConnectionPooling feature described in Chapter 7, “Writing WebSphere MQ base Java programs” on page 63. The following classes and methods are not supported:

- Classes and interfaces
 - MQPoolServices
 - MQPoolServicesEvent
 - MQPoolToken
 - MQSimpleConnectionManager
 - MQPoolServicesEventListener
 - MQConnectionManager
 - ManagedConnection
 - ManagedConnectionFactory
 - ManagedConnectionMetaData
- Methods
 - MQEnvironment.getDefaultConnectionManager()
 - MQEnvironment.setDefaultConnectionManager()
 - MQEnvironment.addConnectionPoolToken()
 - MQEnvironment.removeConnectionPoolToken()
 - The six MQQueueManager constructors which allow a ConnectionManager or MQConnectionManager to be specified.

Attempting to use these classes, interfaces, or methods results in compile-time errors or runtime exceptions.

Running WebSphere MQ base Java applications under CICS Transaction Server for OS/390

To run a Java application as a transaction under CICS, you must:

1. Define the application and transaction to CICS by using the supplied CEDA transaction.
2. Ensure that the WebSphere MQ CICS adapter is installed in your CICS system. (See *WebSphere MQ for z/OS System Setup Guide* for details.)
3. Ensure that the JVM environment specified in the DHFJVM parameter of your CICS startup JCL (Job Control Language) includes appropriate CLASSPATH and LIBPATH entries.
4. Initiate the transaction by using any of your normal processes.

For more information on running CICS Java transactions, refer to your CICS system documentation.

Restrictions under CICS Transaction Server

In the CICS Transaction Server for OS/390 environment, only the main (first) thread is allowed to issue CICS or WebSphere MQ calls. It is therefore not possible to share MQQueueManager or MQQueue objects between threads in this environment, or to create a new MQQueueManager on a child thread.

Chapter 8, “Environment-dependent behavior” on page 91 identifies some restrictions and variations that apply to the WebSphere MQ classes for Java when running against a z/OS or OS/390 queue manager. Additionally, when running under CICS, the transaction control methods on MQQueueManager are not supported. Instead of issuing MQQueueManager.commit() or MQQueueManager.backout(), applications use the JCICS task synchronization methods, Task.commit() and Task.rollback(). The Task class is supplied by JCICS in the com.ibm.cics.server package.

Appendix H. SSL CipherSuites supported by WebSphere MQ

The following table lists the CipherSpecs supported by WebSphere MQ, and their associated CipherSuite names. Specify the CipherSpec name in the SSLCIPH property of the SVRCONN channel on the queue manager. Specify the CipherSuite name:

- In MQEnvironment.sslCipherSuite or MQC.SSL_CIPHER_SUITE_PROPERTY of WebSphere MQ base Java
- Using the setSSLCipherSuite() method of MQConnectionFactory in JMS
- Using the SSLCIPHERSUITE (SCPHS) property from JMSAdmin

The set of supported CipherSuites varies between JSSE providers; those CipherSuites not supported by the IBM implementation of JSSE are marked with an asterisk.

Table 49. CipherSpecs and matching CipherSuites

CipherSpec	CipherSuite
DES_SHA_EXPORT	SSL_RSA_WITH_DES_CBC_SHA
DES_SHA_EXPORT1024	SSL_RSA_EXPORT1024_WITH_DES_CBC_SHA *
NULL_MD5	SSL_RSA_WITH_NULL_MD5
NULL_SHA	SSL_RSA_WITH_NULL_SHA
RC2_MD5_EXPORT	SSL_RSA_EXPORT_WITH_RC2_CBC_40_MD5
RC4_56_SHA_EXPORT1024	SSL_RSA_EXPORT1024_WITH_RC4_56_SHA *
RC4_MD5_US	SSL_RSA_WITH_RC4_128_MD5
RC4_MD5_EXPORT	SSL_RSA_EXPORT_WITH_RC4_40_MD5
RC4_SHA_US	SSL_RSA_WITH_RC4_128_SHA
TRIPLE_DES_SHA_US	SSL_RSA_WITH_3DES_EDE_CBC_SHA

Appendix I. JMS exception messages

This section lists most common exceptions that can be generated by WebSphere MQ JMS. It does *not* include all messages that can be written to a trace file. If you receive an exception message not in this list (except in a trace file), or if the cause seems to be an error in WebSphere MQ JMS, contact your IBM service representative.

Reading variables in a message

Some messages display text or numbers that vary according to the circumstances giving rise to the message; these are known as *message variables*. Message variables are indicated in this book by the use of numbers in braces; for example, {0}, {1}, and so on.

MQJMS0000 Method {0} has been invoked at an illegal or inappropriate time or if the provider is not in an appropriate state for the requested operation.

Explanation: The normal reason for this exception is that the SSL certificate stores have not been defined. {0} identifies the method that has caused the problem.

User Response: See “Using Secure Sockets Layer (SSL)” on page 201 for more information.

MQJMS0002 JMS Client attempted to set invalid clientId on a connection.

Explanation: An application attempted to set the clientId property of a valid connection to null, or attempted to set the clientId property of an invalid connection.

User Response: The clientId property on a connection can only be set once, only to a non-null value, and only before the connection is used. Ensure that the connection is valid and that the clientId value is not null.

MQJMS0003 Destination not understood or no longer valid.

Explanation: The queue or topic may have become unavailable, the application may be using an incorrect connection for the queue or topic, or the supplied destination is not of the correct type for this method.

User Response: Check that WebSphere MQ is still running and the queue manager is available. Check that the right connection is being used for your queue or topic.

MQJMS0004 JMS Client has given JMS Provider a message selector with invalid syntax.

Explanation: The message selector string is empty or contains an invalid value or syntax.

User Response: Check the linked WebSphere MQ

exception reason and completion codes for more information.

MQJMS0005 Unexpected end of stream has been reached when a StreamMessage or BytesMessage is being read.

Explanation: The byte stream being read is shorter than the buffer supplied. This can also be caused by receiving a corrupt StreamMessage or BytesMessage.

User Response: Check the length of buffer supplied. Check system event logs for more information.

MQJMS0006 JMS Client attempts to use a data type not supported by a message or attempts to read data in the wrong type.

Explanation: Wrong data types used to read message property types.

User Response: Check that the message received and the properties to be read are of the type expected.

MQJMS0009 JMS Provider is unable to allocate the resources required for a method.

Explanation: Machine resources may be overloaded, the linked exception may give further information.

User Response: Check system resources and load.

MQJMS0010 Operation invalid because a transaction is in progress.

Explanation:

User Response: Wait for the current transaction to complete. See the linked WebSphere MQ exception for further information.

JMS exception messages

MQJMS0011 Call to Session.commit resulted in a rollback of the current transaction.

Explanation: The transaction failed resulting in a call to rollback to a safe state. See the linked exception for more information.

MQJMS1000 Failed to create JMS message.

Explanation: Invalid message type or properties were specified when creating a base message.

User Response: Check the linked WebSphere MQ exception Reason and Completion code for more information.

MQJMS1001 Unknown acknowledgement mode {0}.

Explanation: Invalid or no parameter {0} set for acknowledgement mode on the session.

User Response: See "Session" on page 349 for the possible values for acknowledgement mode.

MQJMS1004 Connection closed.

Explanation: An operation such as start() or stop() has been called on a connection that is already closed.

User Response: Ensure that the connection is open before performing any operation.

MQJMS1005 Unhandled state transition from {0} to {1}.

Explanation: The state transition is not valid, see log for more information.

User Response: Check the linked WebSphere MQ exception reason and completion code.

MQJMS1006 Invalid value for {0}: {1}

Explanation: Invalid value {1} for property {0}.

User Response: Check the linked WebSphere MQ exception reason and completion code. See Table 11 on page 48 for a list of valid values for this property.

MQJMS1008 Unknown value of transportType: {0}.

Explanation: The value given for transportType could not be used. {0} shows the invalid value.

User Response: See Table 11 on page 48 for a list of valid values for this property.

MQJMS1010 Not implemented.

Explanation: The function requested is not implemented. This can be thrown by message acknowledgement, if the session or acknowledgement parameters are invalid or incorrect.

MQJMS1011 Security credentials cannot be specified when using MQ bindings.

Explanation: The RRS queue does not support a client connection, and bindings connections do not support the specification of security credentials.

User Response: Ensure that you do not try to specify

security credentials when using a bindings connection.

MQJMS1012 No message listener.

Explanation: The message listener has stopped or was never started.

User Response: Restart the message listener and retry.

MQJMS1013 Operation invalid while session is using asynchronous delivery.

Explanation: You cannot perform the requested operation while the session is actively using asynchronous delivery mode.

User Response: See "Asynchronous delivery" on page 199 for further information.

MQJMS1014 Operation invalid for identified producer.

Explanation: The QueueSender.send method has been performed on an identified QueueSender, which contradicts the JMS specification

User Response: See "QueueSender" on page 343 and the JMS specification

(<http://java.sun.com/products/jms/docs.html>) for further information.

MQJMS1015 Unknown value of targetClient: {0}.

Explanation: The value for the targetClient property set by the application for this destination is not recognized by WebSphere MQ JMS.

User Response: See "Sending a message" on page 195 for valid values of the targetClient property.

MQJMS1017 Non-local MQ queue not valid for receiving or browsing.

Explanation: An attempt was made to perform an inappropriate operation on a non-local queue.

User Response: Check the queue properties.

MQJMS1018 No valid connection available.

Explanation: The queue is busy, there are network problems or a connection has not been defined for the object.

User Response: Create a valid connection for this operation.

MQJMS1019 Invalid operation for non-transacted session.

Explanation: Commit is not allowed on a session that is not transacted.

User Response: Check the linked IllegalStateException for more information. See "Session" on page 349 for further information.

MQJMS1020 Invalid operation for transacted session.

Explanation: Invalid acknowledgement mode for a transacted session. Acknowledge and Recover are not valid operations in transacted sessions.

User Response: See “Session” on page 349 for further information.

MQJMS1021 Recover failed: unacknowledged messages might not get redelivered.

Explanation: The system was unable to recover from a failure.

User Response: Consult the linked exception to determine why the call to recover failed.

MQJMS1022 Failed to redirect message.

Explanation: When performing asynchronous delivery, WebSphere MQ JMS attempted to redirect the message to the backout queue. No backout queue was defined.

User Response: Ensure that the backout queue is defined. Also, investigate why WebSphere MQ JMS was attempting to redirect the message. It might do so in response to a failing MessageListener implementation.

MQJMS1023 Rollback failed.

Explanation: The system was unable to rollback to a safe state.

User Response: Check the linked WebSphere MQ Exception reason and completion codes for further information.

MQJMS1024 Session closed.

Explanation: The session timed out or was closed; or either the connection or the queue manager was closed, implicitly closing the session.

User Response: Restart the session, and check all required resources are available.

MQJMS1025 Failed to browse message.

Explanation: No message was available for browsing. There may be no message on the Queue.

User Response: Check the linked WebSphere MQ Exception reason and completion codes. Check that a message is available for browsing.

MQJMS1026 ExceptionListener threw exception: {0}.

User Response: Check linked exceptions for further information.

MQJMS1027 Failed to reconstitute destination from {0}.

Explanation: A message has been received which contains invalid destination information in the RFH2 header.

User Response: Ensure that any messages being sent by non-JMS applications have correctly formatted destination information. In the case of RFH2 headers, pay special attention to the “Rto” (reply to) and “Dst”

(destination) elements of the XML portion of the header. Valid destination strings must start either “queue” or “topic”.

MQJMS1028 Element name is null.

Explanation: A null name string was passed to one of the “get value by name” methods of MapMessage.

User Response: Ensure that all name strings being used to retrieve values are non-null.

MQJMS1029 Property name is null.

Explanation: The itemExists method of MapMessage was invoked with a null item name; or a null name string was used as an argument to a method which retrieves property values by name from a JMS message.

User Response: Ensure that the name strings indicated do not have null values.

MQJMS1031 An internal error has occurred. Please contact your system administrator.

Explanation: Internal Error.

User Response: Contact your IBM representative.

MQJMS1032 close() failed because of {0}

Explanation: Internal Error. {0} indicates the reason for the error.

User Response: Contact your IBM representative.

MQJMS1033 start() failed because of {0}.

Explanation: {0} indicates why the session failed to start.

User Response: Contact your IBM representative.

MQJMS1034 MessageListener threw: {0}.

Explanation: When performing asynchronous delivery, the onMessage() method of the application’s MessageListener failed with a Throwable. WebSphere MQ JMS tries to redeliver or requeue the message.

User Response: Do not throw Throwables from the onMessage() method of a MessageListener.

MQJMS1035 Cannot transmit non-MQ JMS messages.

Explanation: Wrong message type used. This is a possible internal problem.

User Response: Check the message type. Contact your IBM representative if there appears to be an internal error.

MQJMS1036 Failed to locate resource bundle.

Explanation: The resource bundle is either not present or not in the application’s classpath.

User Response: Check that the classpath includes the location of property files.

JMS exception messages

MQJMS1038 Failed to log error.

Explanation: Log settings may be incorrect, see the linked LogException.

User Response: Check log settings are correct.

MQJMS1039 Trace file does not exist

Explanation: Trace settings may be incorrect.

User Response: Check trace settings and trace file existence. See “Tracing programs” on page 38 for more information on Trace.

MQJMS1040 Failed to connect to Trace stream.

Explanation: Trace settings may be incorrect.

User Response: See “Tracing programs” on page 38 for more information on Trace.

MQJMS1041 Failed to find system property {0}.

Explanation: The system property specified in {0} does not exist or was not found in the application’s classpath.

User Response: Check the classpath settings and the product installation.

MQJMS1042 Invalid delivery mode.

Explanation: Either an invalid value was specified for the delivery mode of a message producer, or an invalid delivery mode value was specified when publishing a message.

User Response: Check to ensure that the value specified is a valid enumeration for delivery mode.

MQJMS1043 JNDI failed due to {0}.

Explanation: {0} gives further information.

User Response: Check settings for LDAP, JNDI, and in the JMSAdmin.config file.

MQJMS1044 String is not a valid hexadecimal number - {0}.

Explanation: An attempt was made to specify a group ID or correlation ID which starts with the prefix “ID:” but is not followed by a well-formed hex value; or an attempt was made to receive a message which contains an RFH2 property of type bin.hex that does not have a well-formed hex value.

User Response: Ensure that a valid hex value always follows the “ID:” prefix when setting group ID or correlation ID values. Ensure that any RFH2 headers generated by non-JMS applications are well-formed.

MQJMS1045 Number outside of range for double precision S/390 Float {0}.

Explanation: This is a z/OS and OS/390 specific error.

MQJMS1046 The character set {0} is not supported.

Explanation: An attempt was made to send or receive a map message, stream message or text message whose body is encoded using a character set not supported by the JVM. In the case of text messages, this exception may be thrown when the body of the message is first queried, rather than at receive time.

User Response: Only set character encoding on a message to values known to be available to the receiving application.

MQJMS1047 The map message has an incorrect format.

Explanation: A map message was received, but its RFH2 header information is badly formatted.

User Response: Ensure any non-JMS applications are building well-formed RFH2 header information for inclusion in map messages.

MQJMS1048 The stream message has an incorrect format.

Explanation: A stream message was received, but its RFH2 header information is badly formatted.

User Response: Ensure any non-JMS applications are building well-formed RFH2 header information for inclusion in stream messages.

MQJMS1049 The JMS client attempted to convert a byte array to a String.

Explanation: Attempting to receive a byte array from a stream message using the readString method.

User Response: Either use the appropriate method to receive the data, or format the data placed into the stream message correctly.

MQJMS1050 The MQRFH2 header has an incorrect format.

Explanation: Receiving a message with a badly formed RFH2 header.

User Response: Ensure that any non-JMS applications building messages with RFH2 headers create well-formed RFH2 headers.

MQJMS1053 Invalid UTF-16 surrogate detected {0}.

Explanation: An invalid UTF-16 surrogate character has been encountered as part of a topic name or RFH2 property.

User Response: Ensure that, when specifying UTF-16, topic names or RFH2 properties are well-formed.

MQJMS1054 Invalid XML escape sequence detected {0}.

Explanation: An invalid XML escape sequence has been encountered in the RFH2 header of a received message.

User Response: Ensure that only valid XML escape

sequences are placed into any RFH2 headers built by non-JMS applications.

MQJMS1055 The property or element in the message has incompatible datatype {0}.

Explanation: Attempting to retrieve a property from a JMS message using an accessor method which specifies an incompatible type. For example, attempting to retrieve an integer property using the `getBooleanProperty` method.

User Response: Use an accessor method defined by the JMS specification as being able to retrieve property values of the required type.

MQJMS1056 Unsupported property or element datatype {0}.

Explanation: This error is caused by one of the following:

1. Attempting to set a property of a JMS message using an object which is not one of the supported types.
2. Attempting to set or receive a message whose RFH2 contains an element representing a property which does not have a valid type associated with it.

User Response: Ensure that when setting message properties, an object type described as being valid in the JMS specification is used. If this exception occurs when receiving a message containing an RFH2 header sent by a non-JMS application, ensure that the RFH2 header is well-formed.

MQJMS1057 Message has no session associated with it.

Explanation: An attempt was made to acknowledge a message on a session which is not in an open state.

User Response: Ensure that the session associated with the message has been correctly opened. Check that the session has not been closed.

MQJMS1058 Invalid message property name: {0}.

Explanation: Attempting to set a property that either does not have a valid property name, or is not a settable property.

User Response: Ensure that the property name used is a valid property name in accordance with the JMS specification. If the property name refers to a JMS or provider-specific extension property, ensure that this property is settable.

MQJMS1059 Fatal error - UTF8 not supported.

Explanation: The Java runtime environment you are using does not support the UTF-8 character encoding. JMS requires support for this encoding to perform some operations.

User Response: Consult the documentation and/or provider of your Java runtime environment to determine how to obtain support for the UTF-8 character encoding.

MQJMS1060 Unable to serialize object.

Explanation: An attempt has been made to serialize an `ObjectMessage` which contains a non-serializable object.

User Response: Ensure that `ObjectMessages` only contain serializable objects. If the object placed inside an `ObjectMessage` references other objects, these must also be serializable.

MQJMS1061 Unable to deserialize object.

Explanation: De-serialization of an `ObjectMessage` failed.

User Response: Ensure that the `ObjectMessage` being received contains valid data. Ensure that the class files representing object data contained within the `ObjectMessage` are present on the machine deserializing the `ObjectMessage`. If the object contained within the `ObjectMessage` references other objects, ensure that these class files are also present.

MQJMS1066 Invalid message element name: {0}.

Explanation: Attempting to set a message property using either an invalid property name, or the name of a property which cannot have its value set.

User Response: Ensure that the property name specified conforms to the JMS specification. If the property name supplied is that of a JMS property, or a vendor specific extension, ensure that this property name is settable.

MQJMS1067 Timeout invalid for MQ.

Explanation: An attempt was made to invoke the receive method on either a `QueueReceiver` or `TopicSubscriber` method, specifying a long timeout value which is not valid.

User Response: Ensure the timeout value specified is not negative and not greater than the value of `Integer.MAX_VALUE`.

MQJMS1068 Failed to obtain XAResource.

Explanation: JMS failed to create an XA Queue resource due to an error.

User Response: See the linked `XAException` for more information.

MQJMS1072 Could not inquire upon queue manager name.

Explanation: In `createConnectionConsumer()` or `createDurableConnectionConsumer()`, JMS could not determine the name of the queue manager.

User Response: Check your queue manager error logs for problems which may cause this. If there are no other error conditions, contact your IBM representative.

JMS exception messages

MQJMS1073 Specified MQ Queue is neither a QLOCAL nor a QALIAS.

Explanation: createConnectionConsumer() was called, but a queue of the wrong type was specified. Only QALIAS and QLOCALs can be used with the ConnectionConsumer feature.

User Response: Specify a queue of the correct type.

MQJMS1074 Unable to process null message.

Explanation: Internal error in WebSphere MQ JMS.

User Response: Contact your IBM representative.

MQJMS1075 Error writing dead letter header.

Explanation: JMS attempted to requeue a message to the dead letter queue, but could not construct a dead letter header.

User Response: Use the linked exception to determine the cause of this error.

MQJMS1076 Error reading dead letter header.

Explanation: JMS attempted to interpret a message with a dead letter header, but encountered a problem.

User Response: Use the linked exception to determine the cause of this error.

MQJMS1077 Connection and Destination mismatch.

Explanation: An operation was requested, but the Destination class is incompatible with the Connection class. Topics cannot be used with QueueConnections and Queues cannot be used with TopicConnections.

User Response: Supply a suitable Destination. This may represent an internal error condition in JMS; in this case contact your IBM representative.

MQJMS1078 Invalid Session object.

Explanation: The JMS ConnectionConsumer feature attempted to deliver a batch of messages to a Session. However, the Session contained in the ServerSession object returned by the ServerSessionPool was not a WebSphere MQ JMS Session.

User Response: This is an error in the ServerSessionPool. If you have supplied a ServerSessionPool, check its behavior. In a J2EE application server, this may represent an error in the application server; in which case, refer to your application server's documentation.

MQJMS1079 Unable to write message to dead letter queue.

Explanation: JMS attempted to requeue a message to the dead letter queue, but failed.

User Response: Use the linked exception to determine the cause of this error. If there is no linked exception, check that the queue manager has a defined dead letter queue. Once JMS has sent a message to the dead letter queue, the reason code stored in the message's DLH

can be used to determine why the message was dead-lettered.

MQJMS1080 No Backout-Requeue queue defined.

Explanation: JMS encountered a message which has been backed out more than the queue's Backout Threshold, however the queue doesn't have a Backout-Requeue queue defined.

User Response: Define a Backout-Requeue queue for the queue, or set the Backout Threshold to zero to disable poison message handling. Investigate the repeated backouts.

MQJMS1081 Message requeue failed.

Explanation: JMS found an error when requeuing a message which has been backed out more than the queue's Backout Threshold.

User Response: Use the linked exception to determine the cause of this error. Investigate the repeated backouts.

MQJMS1082 Failure while discarding message.

Explanation: JMS encountered an error while discarding a message, or while generating an exception report for a message to be discarded.

User Response: Use the linked exception to determine the cause of this error.

MQJMS1083 Invalid message batch size (must be >0).

Explanation: An invalid batch size parameter was passed to createConnectionConsumer() or createDurableConnectionConsumer().

User Response: Set a batch size greater than zero. In a J2EE application server, this may represent an error in the application server. Refer to your application server's documentation.

MQJMS1084 Null ServerSessionPool has been provided.

Explanation: The ServerSessionPool specified on createConnectionConsumer() or createDurableConnectionConsumer() was null.

User Response: Set an appropriate ServerSessionPool. In a J2EE application server, this may represent an error in the application server. Refer to your application server's documentation.

MQJMS1085 Error writing RFH.

Explanation: JMS attempted to construct an RFH message header, but encountered an error.

User Response: Use the linked exception to determine the cause of this error.

MQJMS1086 Error reading RFH.

Explanation: JMS encountered an error while parsing an RFH message header.

User Response: Use the linked exception to determine the cause of this error.

MQJMS1087 Unrecognized or invalid RFH content.

Explanation: JMS expected to find an RFH message header, but found it to be missing, malformed or lacking required data.

User Response: Investigate the source of the message. This may represent an internal error condition in JMS; in this case, contact your IBM representative.

MQJMS1088 Mixed-domain consumers acting on the same input is forbidden.

Explanation: A point-to-point ConnectionConsumer is using the subscriber queue of a publish/subscribe ConnectionConsumer.

User Response: Do not attempt to access subscriber queues using the point-to-point ConnectionConsumer facilities of JMS. Check your TopicConnectionFactory and Topic objects to make sure they are not using a QLOCAL intended for use by point-to-point applications as a subscriber queue.

MQJMS1089 Exception occurred reading message body: {0}.

Explanation: JMS encountered an exception while reading data from a message. The message being read is likely to be a response message from the publish/subscribe broker.

User Response: Use the linked exception to determine the cause of this error.

MQJMS2000 Failed to close MQ queue.

Explanation: JMS attempted to close a WebSphere MQ queue, but encountered an error. The queue may already be closed, or another thread may be performing an MQGET while close() is called.

User Response: Use the linked exception to determine the cause of this error. You may be able to perform the close() later.

MQJMS2001 MQQueue reference is null.

Explanation: JMS attempted to perform some operation on a null MQQueue object.

User Response: Check your system setup, and that all required queue names have been specified. This may represent an internal error condition in JMS; in this case, contact your IBM representative.

MQJMS2002 Failed to get message from MQ queue.

Explanation: JMS attempted to perform an MQGET; however WebSphere MQ reported an error.

User Response: Use the linked exception to determine the cause of this error.

MQJMS2003 Failed to disconnect queue manager.

Explanation: JMS encountered an error while attempting to disconnect.

User Response: Use the linked exception to determine the cause of this error.

MQJMS2004 MQQueueManager reference is null.

Explanation: JMS attempted to perform an operation on a null MQQueueManager object.

User Response: Check that the relevant object has not been closed. This may represent an internal error condition in JMS; in this case, contact your IBM representative.

MQJMS2005 Failed to create MQQueueManager for {0}.

Explanation: JMS could not connect to a queue manager. {0} gives the name of the queue manager.

User Response: Use the linked exception to determine the cause of this error. Check the queue manager is running and, if using client attach, that the listener is running and the channel, port and hostname are set correctly. If no queue manager name has been specified, check that the default queue manager has been defined.

MQJMS2006 MQ problem: {0}.

Explanation: JMS encountered some problem with WebSphere MQ. {0} describes the problem.

User Response: Use the included text and linked exception to determine the cause of this error.

MQJMS2007 Failed to send message to MQ queue.

Explanation: JMS attempted to perform an MQPUT; however WebSphere MQ reported an error.

User Response: Use the linked exception to determine the cause of this error.

MQJMS2008 Failed to open MQ queue.

Explanation: JMS attempted to perform an MQOPEN; however WebSphere MQ reported an error.

User Response: Use the linked exception to determine the cause of this error. Check that the specified queue and queue manager are defined correctly.

MQJMS2009 MQQueueManager.commit() failed.

Explanation: JMS attempted to perform an MQCMIT; however WebSphere MQ reported an error.

User Response: Use the linked exception to determine the cause of this error.

MQJMS2010 Unknown value for MQ queue definitionType: {0}.

Explanation: Unable to delete the temporary queue as the definitionType is not valid.

User Response: Check the setting of definitionType.

JMS exception messages

MQJMS2011 Failed to inquire MQ queue depth.

Explanation: WebSphere MQ JMS is unable to tell how many messages are on the queue.

User Response: Check that the queue and queue manager are available.

MQJMS2012 XACLOSE failed.

Explanation: See linked XAException for more details.

MQJMS2013 Invalid security authentication supplied for MQQueueManager.

Explanation: Bad username or password or both. In bindings mode, a supplied user ID does not match the logged in user ID.

User Response: Check that the user IDs used by WebSphere MQ are all assigned to the relevant groups and given appropriate user permissions.

MQJMS3000 Failed to create a temporary queue from {0}.

Explanation: Creation of temporary queue failed.

User Response: See linked exception for more information. Check that the TemporaryModel parameter against the QueueConnectionFactory is set to a valid model queue.

MQJMS3001 Temporary queue already closed or deleted.

Explanation: Temporary queue no longer exists or is equal to null.

User Response: Check to see that the queue has been created, and that the session is still available.

MQJMS3002 Temporary queue in use.

Explanation: Another program is using the queue.

User Response: Wait for the temporary queue to become free or create another.

MQJMS3003 Cannot delete a static queue.

Explanation: Attempted to delete a queue of type static, where a temporary queue was expected.

User Response: Check the expected queue type for deletion.

MQJMS3004 Failed to delete temporary queue.

Explanation: The temporary queue may be persistent or busy.

User Response: See the linked WebSphere MQ exception for more details. Wait if the queue is busy, or delete the queue manually if it is persistent.

MQJMS3005 Publish/Subscribe failed due to {0}.

Explanation: General error: {0} shows the reason.

User Response: Check the linked WebSphere MQ Exception reason and completion codes for more information. It is possible that the broker and queue

manager versions are incompatible.

MQJMS3006 Topic reference is null.

Explanation: Topic supplied to a publisher is null.

User Response: Use non-null values.

MQJMS3008 Failed to build command {0}.

Explanation: Broker message command parameters incorrect.

User Response: Check linked exception for cause.

MQJMS3009 Failed to publish command to MQ queue.

Explanation: Invalid command, queue unavailable or broker errors.

User Response: Check linked WebSphere MQ exception reason and completion codes for more information.

MQJMS3010 Failed to build publish message.

Explanation: Unable to build the base message for the broker.

User Response: See the linked WebSphere MQ Exception for further details. Check settings and parameters are all correct. See Chapter 11, "Programming publish/subscribe applications" on page 205 for more information.

MQJMS3011 Failed to publish message to MQ queue.

Explanation: See linked Exception for more information.

User Response: Check settings and parameters are all correct. See Chapter 11, "Programming publish/subscribe applications" on page 205 for more information.

MQJMS3013 Failed to store admin. entry.

Explanation: An add to the admin or status queue failed due to duplication or some other error. See any linked exception for more information.

User Response: Check for duplicates and retry.

MQJMS3014 Failed to open subscriber queue {0}.

User Response: See linked exception for more information.

MQJMS3017 Failed to delete subscriber queue {0}.

Explanation: {0} gives the queue name. See linked exception for more information.

User Response: See Chapter 11, "Programming publish/subscribe applications" on page 205 for more information on solving publish/subscribe problems.

MQJMS3018 Unknown durable subscription {0}.
Explanation: Could not locate the given subscription. For example, during an unsubscribe request.
User Response: See Chapter 11, “Programming publish/subscribe applications” on page 205 for more information.

MQJMS3020 TemporaryTopic out of scope.
Explanation: The current connection ID does not match the connection that created the temporary topic.

MQJMS3021 Invalid subscriber queue prefix: {0}.
Explanation: The name specified is not valid. It must begin with SYSTEM.JMS.D for durable subscriptions or SYSTEM.JMS.ND for non-durable subscriptions.
User Response: See Chapter 11, “Programming publish/subscribe applications” on page 205 for naming conventions.

MQJMS3022 Durable re-subscribe must use same subscriber queue; specified: {0}, original: {1}.
Explanation: {0} and {1} show the differing queue names. Unable to get a subscription due to wrong queue manager or queue.
User Response: Check settings.

MQJMS3023 Subscription has an active TopicSubscriber.
Explanation: Can be caused by a queue open problem or if a subscription already exists on the JVM. If running in WebSphere Application Server there can be other causes. See linked exception, if set, for more information.
User Response: Check settings.

MQJMS3024 Illegal use of uninitialized clientId.
Explanation: The clientId in the connection has not been set.
User Response: Set the clientId before attempting to perform any operation.

MQJMS3025 TemporaryTopic in use.
Explanation: Something else is currently using the topic.
User Response: Wait until the topic is free or create another topic. Ensure subscribers de-register when finished.

MQJMS3026 QueueSender is closed.
User Response: Open or re-open the queue sender if required.

MQJMS3027 Local transactions not allowed with XA sessions.

Explanation: A call pertaining to a local transaction was made on a Session involved with XA-coordinated transactions
User Response: This typically represents an error in an application server. Consult your application server’s documentation and any error logs.

MQJMS3028 TopicPublisher is closed.
User Response: Open or reopen the topic publisher if required.

MQJMS3029 Enlist failed (see linked Exception).
Explanation: JTSXA.enlist threw an exception that was caught by JMS.
User Response: Check the linked WebSphere MQ Exception reason and completion codes for more information. Contact your IBM representative.

MQJMS3031 clientId cannot be set after connection has been used.
Explanation: The clientId of a connection can be set only once and only before the connection is used.
User Response: Set the clientId before using the connection.

MQJMS3032 Resetting the clientId is not allowed.
Explanation: The clientId of a connection can be set only once and only before the connection is used.
User Response: Set the clientId before using the connection.

MQJMS3033 QueueReceiver is closed.
User Response: Open or reopen the receiver.

MQJMS3034 TopicSubscriber is closed.
User Response: Open or reopen the TopicSubscriber.

MQJMS3036 Broker side message selection valid only when using WebSphere MQ Integrator broker.
Explanation: Broker version and message selection are not consistent.
User Response: Ensure the broker version has been set in the ConnectionFactory. Use the method setBrokerVersion(JMSC.MQJMS_BROKER_V2) on the ConnectionFactory for WebSphere MQ Integrator or WebSphere MQ Event Broker.

MQJMS3037 Message Producer is closed.
Explanation: Either or both of the session and connection are closed.
User Response: Check to ensure that the session and connection are both available.

JMS exception messages

MQJMS3038 Message Consumer is closed.

Explanation: Either or both of the session and connection are closed.

User Response: Check to ensure that the session and connection are both available.

MQJMS3039 Illegal use of null name.

Explanation: Durable connection consumers must be named.

User Response: Check for null values.

MQJMS3040 Invalid broker control message content: {0}.

Explanation: {0} explains further.

User Response: Check the broker documentation for message content information.

MQJMS3042 Unrecognized message from Pub/Sub Broker.

Explanation: The message received from the broker was not of a recognized or supported format.

User Response: Check that the broker you are using is supported and refer to broker documentation for settings.

MQJMS3044 Cleanup level of NONE requested.

Explanation: Cleanup requested while cleanupLevel set to NONE.

User Response: Set cleanupLevel property to an appropriate value.

MQJMS3047 Subscription store type not supported by queue manager.

Explanation: Not an MQSPIQueue manager or deferred message not supported.

User Response: Possible incompatibility between queue manager version and broker. Specify a different type of subscription store or upgrade the queue manager. See "Subscription stores" on page 219 for more information.

MQJMS3048 Incorrect subscription store type.

Explanation: Subscription store changed within TopicConnection.

User Response: Contact your IBM representative.

MQJMS3049 Incorrect subscription type for this subscription store.

Explanation: TopicSubscriber was created with a different SUBSTORE setting than current TopicConnection.

User Response: Ensure TopicSubscribers are only used during the lifetime of their parent TopicConnection. See "Subscription stores" on page 219 for more information.

MQJMS4009 Context is not empty.

Explanation: Error deleting Context due to context not being empty.

User Response: Remove context contents before trying delete.

MQJMS4096 Binding non-administerable or not found.

Explanation: From JMSAdmin, an object was specified on the command line that either does not exist, or is not an object that JMSAdmin can administer.

User Response: Specify a valid object on the JMSAdmin command line.

MQJMS4097 Context not found.

Explanation: Could not find a context to match the name given.

User Response: Ensure the correct context name is specified.

MQJMS4104 Object is inactive, so cannot perform directory operations.

Explanation: The JNDI service is inactive.

User Response: See Chapter 5, "Using the WebSphere MQ JMS administration tool" on page 41 for JMSAdmin and JNDI information.

MQJMS4106 Object is not a WebSphere MQ JMS administered object.

User Response: See Chapter 5, "Using the WebSphere MQ JMS administration tool" on page 41.

MQJMS4111 Unable to create context.

Explanation: Administration service failed.

User Response: Check LDAP and JNDI settings.

MQJMS4112 Unable to create a valid object, please check the parameters supplied.

Explanation: Consistency check failed.

User Response: Contact your IBM representative.

MQJMS4113 Unable to bind object.

Explanation: Administration service bind or copy or move operation failed.

User Response: Check that you have correctly set up your JNDI provider.

MQJMS4115 An invalid name was supplied.

Explanation: JMSAdmin error. An invalid name was supplied when trying to delete a context.

User Response: Refer to Chapter 5, "Using the WebSphere MQ JMS administration tool" on page 41 for more about using JMSAdmin.

MQJMS4121 Cannot open configuration file.

Explanation: Configuration file may not exist.

User Response: Check MQ_JAVA_INSTALL_PATH environment variable exists and points to the installation directory of the base Java classes.

MQJMS4127 Invalid property in this context.

Explanation: JMSAdmin object value is invalid in the current context.

User Response: See Chapter 5, "Using the WebSphere MQ JMS administration tool" on page 41 for more about JMSAdmin.

MQJMS4130 Context not found or unremovable.

Explanation: The specified child context could not be deleted.

User Response: Ensure the correct context name was specified.

MQJMS4131 Expected and actual object types do not match.

Explanation: Requested and retrieved objects are of different types.

User Response: Check that you have specified the correct object type.

MQJMS4132 Client-bindings attribute clash.

Explanation: Client properties specified for a bindings connection.

User Response: Ensure the ConnectionFactory properties are correct.

MQJMS4133 ExitInit string supplied without Exit string.

Explanation: ExitInit string supplied but Exit is not set.

User Response: Set appropriate exit, or unset ExitInit string.

MQJMS4137 Unable to create a WebSphere MQ specific class. The WebSphere MQ classes may not have been installed or added to the classpath.

User Response: Check WebSphere Application Server installation and classpath variable.

MQJMS4139 Invalid authentication type supplied - using 'none'.

Explanation: AdminService JNDI initialization parameters contain an invalid authorization scheme, so "none" is used as the value instead.

User Response: See Chapter 5, "Using the WebSphere MQ JMS administration tool" on page 41 for more information.

MQJMS5053 * No broker response. Please ensure that the broker is running. *****

Explanation: Possible causes:

1. Broker is not running.
2. You are using BrokerVersion=V2 in your TopicConnectionFactory with the MQSeries Publish/Subscribe broker, which does not support this.
3. The Broker has rejected the Publication or Subscription and placed it on the SYSTEM.DEAD.LETTER.QUEUE

User Response: Ensure that your broker is running. Check the system event log for broker error messages. Check that the broker supports the BrokerVersion you are using. Check the SYSTEM.DEAD.LETTER.QUEUE for rejected messages.

MQJMS5054 The broker appears to be running, but the message did not arrive.

Explanation: Thrown by Installation Verification Test when the subscriber fails to receive the published message.

User Response: Check that you have set up the broker correctly. Check system event logs for broker error messages. Check the SYSTEM.DEAD.LETTER.QUEUE for messages rejected by the broker.

MQJMS5060 Unable to connect to queue manager.

Explanation: Thrown by Installation Verification Test.

User Response: Check that the queue manager is running and that its name is specified correctly in the IVTTest parameters.

MQJMS5061 Unable to access broker control queue on queue manager.

User Response: Check that the control queue exists. The default name is SYSTEM.BROKER.CONTROL.QUEUE.

MQJMS6040 Invalid socket family name: {0}.

Explanation: An invalid socket family name was given to an instance of IMBSocketFactory. {0} shows the bad name.

User Response: Contact your IBM representative.

MQJMS6041 An exception occurred while attempting to load socket factory class {0}, exception: <{1}>.

Explanation: Either a ClassNotFoundException, an InstantiationException or an IllegalAccessException occurred while trying to load a particular IMBSocketFactory. {0} gives the name of the class.

User Response: Contact your IBM representative.

JMS exception messages

MQJMS6059 An exception occurred while loading the minimal client security implementation.

User Response: Contact your IBM representative.

MQJMS6060 An unexpected exception in minimal client, exception = {0}.

Explanation: An unusual or unexpected exception occurred at the minimal client. {0} gives more details.

User Response: Contact your IBM representative.

MQJMS6061 A specified topic was malformed, topic = {0}.

Explanation: {0} gives the name of the malformed topic.

User Response: See "Using topics" on page 213 for more information.

MQJMS6062 EOF was encountered while receiving data in the minimal client.

User Response: Contact your IBM representative.

MQJMS6063 The broker indicated an error on the minimal client connection.

User Response: Refer to JMS or broker documentation. Contact your IBM representative.

MQJMS6064 Connector.send was called with an illegal message value.

Explanation: Connector.send was called with an illegal message value.

User Response: See Chapter 7, "Writing WebSphere MQ base Java programs" on page 63 for more information.

MQJMS6065 An illegal value was encountered for a field, value = {0}.

Explanation: {0} shows the illegal value.

User Response: See Table 37 on page 403 for a list of properties and their possible values.

MQJMS6066 An unexpected internal error occurred in the minimal client.

Explanation: Internal problem.

User Response: Contact your IBM representative.

MQJMS6067 A bytes message operation was requested on something that is not a bytes message.

Explanation: The wrong message type was found.

User Response: Check message type before performing type specific operations.

MQJMS6068 A text message operation was requested on something that is not a text message.

Explanation: The wrong message type was found.

User Response: Check message type before performing type specific operations.

MQJMS6069 A stream message operation was requested on something that is not a stream message.

Explanation: The wrong message type was found.

User Response: Check message type before performing type specific operations.

MQJMS6070 A map message operation was requested on something that is not a map message.

Explanation: The wrong message type was found.

User Response: Check message type before performing type specific operations.

MQJMS6071 The broker sent an invalid message during authentication.

User Response: See Chapter 11, "Programming publish/subscribe applications" on page 205 and the broker documentation for more information.

MQJMS6072 The broker requested an unavailable protocol during authentication.

User Response: See Chapter 11, "Programming publish/subscribe applications" on page 205 and the broker documentation for more information.

MQJMS6073 Minimal client connection rejected because of authentication failure.

User Response: See Chapter 11, "Programming publish/subscribe applications" on page 205 and the broker documentation for more information.

MQJMS6074 No QOP available in the minimal client.

Explanation: Indicates that QOP is not implemented in the current version of the minimal client.

User Response: Contact your IBM representative.

MQJMS6078 An attempt was made to write an invalid object type of class {0}.

Explanation: {0} identifies the invalid object's class.

User Response: See Chapter 11, "Programming publish/subscribe applications" on page 205 and the broker documentation for more information.

MQJMS6079 An exception occurred while attempting to load thread pooling support, exception = {0}.

Explanation: An exception was caught while attempting to load thread pooling support in the JMS client. Parameter {0} will give details of the exception.

User Response: Contact your IBM representative.

MQJMS6081 An attempt was made to read from a Stream message before a previous read has completed.

Explanation: Internal error.

User Response: Contact your IBM representative.

MQJMS6083 An exception occurred while initializing a thread pool instance, exception = {0}.

Explanation: A SocketThreadPoolException was caught while initializing a thread pool instance in the JMS client. {0} gives details of the exception.

User Response: Contact your IBM representative.

MQJMS6085 No ExceptionListener has been set.

User Response: Create an ExceptionListener.

MQJMS6088 The client-side connection monitor is terminating.

User Response: Restart the connection.

MQJMS6090 Attempted to synchronously receive on a MessageConsumer for which a listener is active.

Explanation: MessageConsumer.receive() was called but a message listener is already active on the connection.

User Response: See Chapter 7, "Writing WebSphere MQ base Java programs" on page 63 for more information.

MQJMS6091 An IOException occurred when starting or stopping delivery on the connection, exception = {0}.

Explanation: Parameter {0} gives details of the exception.

User Response: Restart the connection.

MQJMS6093 An exception occurred during synchronous receive, exception = {0}.

Explanation: Internal error, parameter {0} gives details of the exception.

User Response: Restart connection.

MQJMS6096 A JMSPriority level of {0} is outside the range specified in JMS.

Explanation: Parameter {0} gives the value that is in error.

User Response: See Table 37 on page 403 for valid values.

MQJMS6097 The specified JMSMessageID, {0}, is invalid.

Explanation: Incorrect syntax was used to specify a message ID in Message.setJMSMessageID. The correct syntax is ID:[0-9]+.

User Response: Check parameters. See Chapter 12,

"JMS messages" on page 227 for more information on message IDs.

MQJMS6105 No more client parameter changes allowed.

Explanation: An attempt was made to set a SessionConfig parameter when no more changes are allowed. Internal error.

User Response: Contact your IBM representative.

MQJMS6106 An exception occurred when initializing parameter {0}, exception {1}.

Explanation: {0} identifies the failing parameter and {1} the caught exception.

User Response: Contact your IBM representative.

MQJMS6115 An exception occurred while creating the TopicConnection, exception {0}.

Explanation: {0} gives details of the exception.

User Response: Contact your IBM representative.

MQJMS6116 This operation is not permitted on an entity that is closed.

Explanation: An operation was requested on a closed publisher, session, or connection.

User Response: Ensure that the publisher, session, or connection is open before trying this operation.

MQJMS6117 The {0} implementation of Topic is not supported.

Explanation: The Topic instance passed to a TopicPublisher or TopicSession method has an unsupported run-time implementation. {0} gives the class name of the unsupported implementation.

User Response: See "Using topics" on page 213 for more information on Topic implementations.

MQJMS6118 Topic {0} contains a wildcard, which is invalid for publishing.

Explanation: The Topic specified to a TopicPublisher method contained a wildcard. Wildcards are not allowed in Topics when publishing messages. The failing Topic is given by {0}.

User Response: See "Using topics" on page 213 for more information.

MQJMS6119 An IOException occurred while publishing, exception {0}.

Explanation: An IOException was caught while publishing a message. {0} gives details of the exception.

User Response: See Chapter 11, "Programming publish/subscribe applications" on page 205 for more information.

JMS exception messages

MQJMS6120 Attempted to use a temporary topic not created on the current connection.

Explanation: Invalid use of temporary topics and connections.

User Response: See Chapter 14, “JMS interfaces and classes” on page 265 for more information.

MQJMS6121 An IOException occurred while subscribing, exception {0}.

Explanation: An IOException was caught while subscribing. {0} gives details of the exception.

User Response: See Chapter 11, “Programming publish/subscribe applications” on page 205 for more information.

MQJMS6122 An exception occurred when creating subscription to {0}, {1}.

Explanation: An invalid subject or query syntax was used in the creation of a subscriber, resulting in an exception. The topic name, and caught exception are included as parameters of this event.

User Response: See Chapter 11, “Programming publish/subscribe applications” on page 205 and the broker documentation for more information.

MQJMS6232 While creating a TopicSubscriber, attempting to add the subscription to the matching engine resulted in exception: {0}.

Explanation: {0} gives details of the exception.

User Response: See Chapter 11, “Programming publish/subscribe applications” on page 205 and the broker documentation for more information.

MQJMS6234 An attempt was made to remove an object with Topic {0} from an empty matching engine: {1}.

Explanation: An attempt was made to remove from a null tree in match space. {0} gives the Topic and {1} gives the MatchTarget. Internal error.

User Response: Contact your IBM representative.

MQJMS6235 An attempt was made to remove an object with a Topic {0} from the matching engine, but it did not have a cache entry: {1}.

Explanation: Internal error.

User Response: Contact your IBM representative.

MQJMS6238 In attempting to access a field of a message, the following exception occurred: {0}.

Explanation: A corrupt message format was discovered. Internal error.

User Response: Contact your IBM representative.

MQJMS6240 An EvalCache get or put operation specified an invalid id.

Explanation: An operation expected the MinValue of an EvalCache to be increased, but it won't be. Internal Error.

User Response: Contact your IBM representative.

MQJMS6241 Too many content attributes were specified.

Explanation: Too many non-topic attributes were specified in Factor.createMatcherInternal. Internal error.

User Response: Contact your IBM representative.

MQJMS6246 An incorrect use of a the Topic wildcard character {0} was detected.

Explanation: The failing Topic is given by parameter {0}.

User Response: See “Using topics” on page 213 for more information.

MQJMS6247 The Topic segment separator {0} appears in an incorrect position.

Explanation: A subscription Topic separator was used incorrectly. {0} shows the bad separator.

User Response: See “Using topics” on page 213 for more information.

MQJMS6249 The following exception occurred while parsing a subscription selector: {0}.

Explanation: A TypeCheckException occurred while loading or invoking the match parser. This may indicate a syntax error in your Selector.

User Response: See “Message selectors” on page 199 for more information.

MQJMS6250 The escape character was used to terminate the following pattern: {0}.

Explanation: This may indicate a syntax error in your Selector.

User Response: See “Message selectors” on page 199 for more information.

MQJMS6251 The escape character {0} passed to the pattern tool is longer than one character.

Explanation: This may indicate a syntax error in your Selector.

User Response: See “Message selectors” on page 199 for more information.

MQJMS6252 A message field was expected to contain a value of type {0} but contained one of type {1}.

Explanation: This may indicate a syntax error in your Selector.

User Response: See “Message selectors” on page 199 for more information.

| **MQJMS6312 Non-authorized subscription to topic {0}.**
| **Explanation:** Attempting to create a subscription to a
| Topic that is not authorized for the client. {0} gives the
| Topic string.
| **User Response:** See Chapter 11, “Programming
| publish/subscribe applications” on page 205 and the
| broker documentation for more information.

JMS exception messages

Appendix J. Notices

This information was developed for products and services offered in the United States. IBM may not offer the products, services, or features discussed in this information in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this information. The furnishing of this information does not give you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

IBM World Trade Asia Corporation
Licensing
2-31 Roppongi 3-chome, Minato-ku
Tokyo 106, Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law:

INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY, OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the information. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this information at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Notices

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM United Kingdom Laboratories,
Mail Point 151,
Hursley Park,
Winchester,
Hampshire,
England
SO21 2JN.

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Programming License Agreement, or any equivalent agreement between us.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs. You may copy, modify, and distribute these sample programs in any form without payment to IBM for the purposes of developing, using, marketing, or distributing application programs conforming to IBM's application programming interfaces.

 - for WebSphere MQ Event Broker 54
 - mapping between admin. tool and
 - programs 403
 - message 227
 - of exit strings 54
 - of JMS objects 48
 - queue, setting 195
- properties and objects, valid
 - combinations 53
 - PROVIDER_PASSWORD property 43
 - PROVIDER_URL property 42
 - PROVIDER_USERDN property 43
 - providerutil.jar 9
 - PSIVT (Installation Verification Test
 - program) 35
 - PSIVTRun utility 35, 405
 - PSReportDump application 225
 - PUBACKINT object property 50
 - publications (publish/subscribe), local
 - suppressing 216
 - publish/subscribe
 - installation verification test program (PSIVT) 35
 - sample application with WebSphere Application Server V4 420
 - setup for 26
 - publish/subscribe broker, connecting
 - to 413
 - publishing messages 211

Q

- QMANAGER object property 50, 405
- Queue
 - interface 332
 - object 192
- queue manager
 - configuring for clients 15
 - connecting to 70
 - disconnecting from 70
 - operations on 69
- QUEUE object property 50, 405
- queue properties
 - setting 195
 - setting with set methods 197
- QueueBrowser interface 334
- QueueConnection interface 336

- QueueReceiver interface 340
- QueueRequestor class 341
- queues, accessing 70
- QueueSender interface 343
- QueueSession interface 346

R

- reading strings 72
- receiving
 - messages 198
 - messages in publish/subscribe mode 211
- RECEXIT object property 50, 405
- RECEXITINIT object property 50, 405
- report options, message 128, 251
- reports, broker 225
- resources, closing 200
- restrictions and variations
 - to core classes 427
- retrieving objects from JNDI 192
- runjms utility 38, 405
- running
 - applets 88
 - applications under CICS Transaction Server 427
 - in a Web browser 5
 - programs 38
 - standalone program 5
 - the IVT 31
 - the PSIVT 35
 - WebSphere MQ classes for Java programs 88
 - with appletviewer 5
 - your own programs 17
- runtime
 - creating factories 193
 - creating Topics 214
 - errors, handling 200

S

- sample applet
 - using to verify 29
- sample application
 - bean-managed transactions 420

- sslCipherSuite property 84
- SSLCRL object property 50, 55
- SSLPEERNAME object property 50, 55, 201
- sslPeerName property 85

- sslSocketFactory property 86
- standalone program, running 5
- starting a connection 193
- starting the administration tool 41
- STATREFRESHINT object property 50
- stream message 227
- StreamMessage
 - interface 354
 - type 198
- strings, reading and writing 72
- subcontexts, manipulating 45
- subscriber options 216
- subscriptions, receiving 211
- subset of messages, selecting 199, 227
- SUBSTORE object property 50
- Sun JMS interfaces and classes 265
- Sun Web site 3
- SupportPac MA1G
 - special considerations for 425
- suppressing local publications 216
- switch file for JTA/JDBC 81
- SYNCPOINTALLGETS object property 50

T

- TARGCLIENT object property 50, 405
- TCP/IP
 - client verifying 16
 - connection, programming 63
- TEMPMODEL object property 50, 405
- TemporaryQueue interface 362
- TemporaryTopic interface 363
- termination, unexpected 222
- testing WebSphere MQ classes for Java programs 88
- text message 227
- TextMessage
 - interface 364
 - type 198
- tokens, connection pooling 75
- Topic
 - interface 209, 365
 - names 213
 - names, wildcards 213
 - object 192
- TOPIC object property 50, 405
- TopicConnection 209
 - interface 368
- TopicConnectionFactory 209
 - interface 371
- TopicLoad.java 261
- TopicPublisher 211
 - interface 377
- TopicRequestor class 380
- TopicSession 209
 - interface 382
- TopicSubscriber 211
 - interface 386
- trace, default output location 38
- tracing
 - programs 88
 - the sample application 17
 - WebSphere MQ for Java Message Service 38
- transactions
 - bean-managed 418

- transactions (*continued*)
 - container-managed 418
 - sample application 419, 420
- TRANSPORT object property 50, 405
- transport, choosing 194
- two-phase commit
 - with WebSphere Application Server V4 418
- types of JMS message 197, 227

U

- unexpected application termination 222
- uniform resource identifier (URI) for queue properties 196
- URI for queue properties 196
- USE_INITIAL_DIR_CONTEXT property 43
- USECONPOOLING object property 50
- user exits
 - with SSL 74
 - writing 74
- user exits, writing 200
- uses for WebSphere MQ 3
- using
 - WebSphere MQ base Java 15
- utilities provided with WebSphere MQ classes for Java Message Service 405

V

- valid combinations of objects and properties 53
- verbs, WebSphere MQ supported 60
- verification
 - with JNDI (point-to-point) 32
 - with JNDI (publish/subscribe) 36
 - without JNDI (point-to-point) 31
 - without JNDI (publish/subscribe) 35
- verifying
 - client mode installation 29
 - TCP/IP clients 16
 - with the sample applet 29
 - with the sample application 16
 - your installation 19
- versions of software required 6
- VisiBroker
 - using 4

W

- Web browser
 - using 5
- Web server, configuring 12
- WebSphere Application Server 253
 - configuration 44
 - CosNaming namespace 42
 - CosNaming repository 42, 44
- WebSphere Application Server V4
 - JMS JTA/XA Interface 417
 - using with JMS 417
- WebSphere MQ
 - connection, losing 222
 - exceptions 200
 - interfaces 191
 - messages 231

- WebSphere MQ classes for Java classes 97
- WebSphere MQ Event Broker

- WebSphere MQ Event Broker properties 54
- WebSphere MQ Integrator V2
 - connecting as publish/subscribe broker 413
 - transforming and routing messages 414
- WebSphere MQ Message Descriptor (MQMD) 231
 - mapping with JMS 235
- WebSphere MQ Publish/Subscribe 26
- WebSphere MQ supported verbs 60
- wildcards in topic names 213
- writing
 - JMS programs 191
 - programs 63
 - publish/subscribe applications 207
 - strings 72
 - user exits 74, 200

X

- XAConnection interface 387
- XAConnectionFactory interface 388
- XAQueueConnection interface 336, 389
- XAQueueConnectionFactory
 - interface 338, 390
- XAQueueSession interface 392
- XAResource 393
- XASession interface 393
- XATopicConnection interface 395
- XATopicConnectionFactory interface 397
- XATopicSession interface 399

Z

- z/OS and OS/390
 - differences with 93

Sending your comments to IBM

If you especially like or dislike anything about this book, please use one of the methods listed below to send your comments to IBM.

Feel free to comment on what you regard as specific errors or omissions, and on the accuracy, organization, subject matter, or completeness of this book.

Please limit your comments to the information in this book and the way in which the information is presented.

To make comments about the functions of IBM products or systems, talk to your IBM representative or to your IBM authorized remarketer.

When you send comments to IBM, you grant IBM a nonexclusive right to use or distribute your comments in any way it believes appropriate, without incurring any obligation to you.

You can send your comments to IBM in any of the following ways:

- By mail, to this address:

User Technologies Department (MP095)
IBM United Kingdom Laboratories
Hursley Park
WINCHESTER,
Hampshire
SO21 2JN
United Kingdom

- By fax:
 - From outside the U.K., after your international access code use 44-1962-816151
 - From within the U.K., use 01962-816151
- Electronically, use the appropriate network ID:
 - IBM Mail Exchange: GBIBM2Q9 at IBMMAIL
 - IBMLink™: HURSLEY(IDRCF)
 - Internet: idrcf@hursley.ibm.com

Whichever method you use, ensure that you include:

- The publication title and order number
- The topic to which your comment applies
- Your name and address/telephone number/fax number/network ID.
