Foreword

1. Foreword

Typographical conventions in use

The **courier New** font is used for any character set to be entered, displayed or corresponding to generated code and for the name of files, directories, windows, menu or components.

Italics is used for titles of publications and chapters in cross-references.

The following icons are used:

note, remark, important point,

cross-reference to another location in the documentation or to another documentation,

Precaution to be taken (for risky or irreversible action...).

Terminological conventions in use

The terms "user" and "developer" are used in the Operator's Guide with the following meanings:

- □ the *user* is the person who uses the final Web application. He/she works on a personal computer on which a browser is installed.
- □ the *developer* is the person in charge of installing Pacbase Web Connection generating the revamping parameter files, and installing the final application on the users' computer.

The term *screens* is used for screens in an application developped with the Online System Development generator.

The term *page* is used for HTML pages generated with Pacbase Web Generator.

The term screen page is used for a page describing a screen.

General Presentation 9

2. General Presentation

2.1. Pacbase Web Connection

Pacbase Web Connection is designed to generate automatically Web applications from your existing VisualAge Pacbase applications at a low cost. It offers both an opening to Internet/Intranet and a greater use comfort (mouse-support, drop-down lists and interactive help).

With its numerous generation options, screens generated as HTML pages can be entirely customized both at the user interface level (addition of push buttons, etc.) and at the processing level (addition of field controls, etc.) by using Java language (Javascipt, Applets, etc.) or by using any HTML editor.

2.2. Required Configuration

The applications generated with Pacbase Web Connection are portable across multiple environments.

Pacbase Web Connection requires VisualAge Pacbase version 2.5, and runs on the following:

- □ Platforms: IBM, Windows NT, Windows 95, Windows 98, Bull, Digital, HP, Sun, Tandem, Unisys...
- ☐ TP monitors: CICS family, IMS, TDS, TP8, Tuxedo...
- □ Communication protocols: TCP/IP, CPI-C, ECI, Sockets, XATMI...
- □ Any navigators compatible with HTML 4.0 and Javascript 1.2 (Netscape 4.0, Internet Explorer 4.0).

The context server runs on Windows/NT and AIX.

The applications server runs on MVS/CICS, UNIX, Windows/NT, Tandem, GCOS7, GCOS8, and Unisys 2002.

2.3. Components

Pacbase Web Connection makes it possible to add a Web interface to traditional applications via the following components:

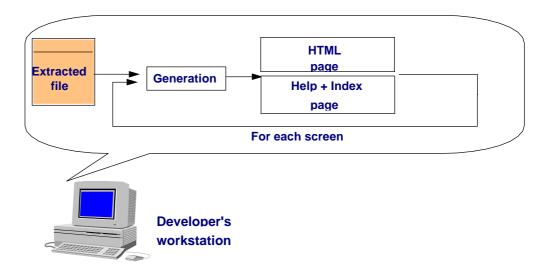

- □ The On-Line Systems Development generator by activating the option which enables the generation of a logical message.
- □ A sub-program which formats logical messages and transmits them to the communication layers, and inversely receives and decodes these messages.
- □ The communication layers.

- ☐ The context server which manages the user's context, merges the application messages with the HTML pages, and transmits the user's requests.
- ☐ The script to communicate with the context server: cgicgi.

2.4. Implementation Steps

The implementation consists in:

- extracting, from VisualAge Pacbase Repository, the files containing the description of your screens and transferring them on the developer's workstation,
- generating HTML pages, help and index pages,
- □ parameterizing the context server and the HTTP server to make them communicate.

3. Installing Pachase Web Connection

The installation procedure depends on the platform on which you install Pacbase Web Connection: Windows NT platform or AIX.

3.1. Installing Pacbase Web Connection to Windows NT

You can install the context server and the generator on two different workstations or on the same developer's workstation from which you want to revamp screens.

Pacbase Web Connection must be installed from the CD-Rom VisualAge Pacbase Workstation Components.

- □ Insert the CD Rom
- □ Start execution by clicking on the setup icon or the Setup.exe file located in the Windows directory. Select the language (English or French) to be used to display the application and to install the product. Then, in the list of products select Pacbase Web Connection.
- On the installation window which identifies the components, select the context server, Pacbase Web Generator component and the middleware.
 This component is required only on the workstation used by the context server.
- Select with the browser the directories under which must be installed the context server and the generator and specify the directory where PERL interpreter is installed.

The workstation on which the HTTP server runs must have a PERL interpreter. If it does not, the installation creates a directory under which this interpreter will be installed. The script (CGICGI.pl) which sets up the connection with the HTTP server and the context server will be copied in this directory.

- □ By default, the icons of the application are copied in Pacbase Web Connection folder (Program menu). However you can create another folder or choose an existing folder.
- ☐ If the Middleware component has been selected, a new directory is created in the directory chosen for the context server component. For each available platform, this directory contains an installation program which permits the recognition of a specific communication protocol used by the middleware component. The middleware is operational as soon as a specific protocol is installed.

If the HTTP server and the context server are installed on different machines, you must modify some parameters.

For more details, refer to Chapter *Implementation and communication*, Subchapter *Serveurs* 4.3.

3.2. Installing the Context Server as an NT Service

The context server can be installed under Windows/NT as an NT service. In this case, the context server starts automatically or can be started via the dialogue box which is used for all services.

To install the context server as a service, enter the following commands from the context server's set up directory:

```
pacweb -i [<No de socket>]
```

The socket number is optional. Its default value is 2345.

At installation, the context server is not automatically started. It must be started by pressing the « Start » button in the services dialogue box.

When the computer boots up, it is automatically started.

To uninstall the context server, enter the following command:

```
pacweb -d
```

These commands used for installation and uninstallation services can be executed correctly only if the user is authorized to "open a session as a service".

3.3. Installing Pacbase Web Connection to AIX system

You must start executing the script setup from PC250/Data/Aix directory on CD Rom.

When the script is executed, enter the name of the directory where you want to install Pacbase Web Connection components and specify the middleware type (debug mode or no debug mode).

All middleware features are installed by default to the default installation directory named **Pacweb**.

The setup is copying files, and at the end, you will find in the installation directory the following directories:

- ☐ The default directory named pacweb: contains the context server and all files relating to the middleware selected (ixo*.o),
- □ the default directory named pacwebgn: contains the HTML pages generator,
- ☐ The cgicgi directory: contains PERL files used to connect the HTTP server HTTP to the context server.

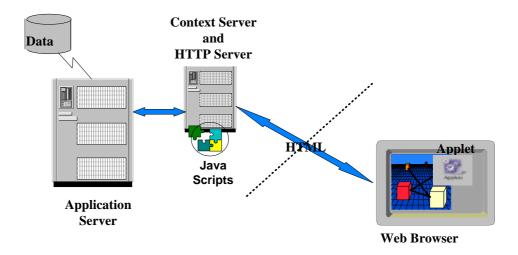

4. Implementation and Communication

4.1. Operation of an Application via a Web Browser

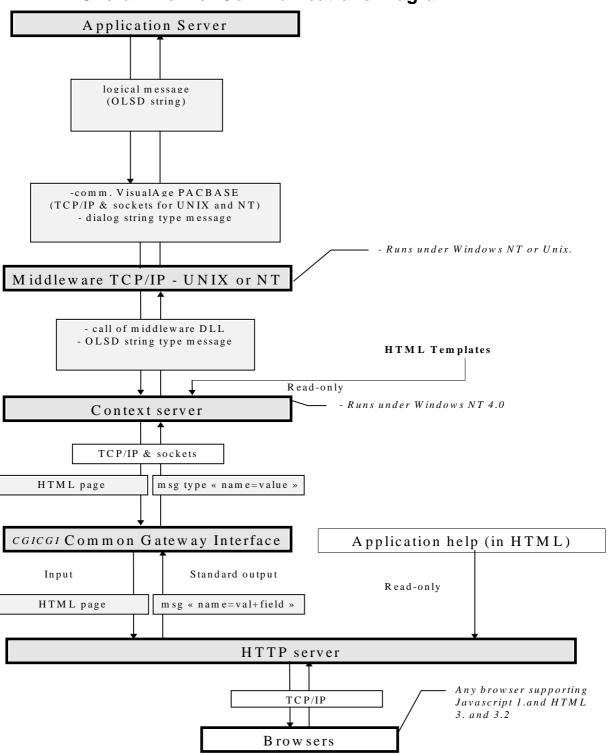

When it is used via a Web browser, the application has the following operating mode:

The user requests an access to the application by selecting a link in an HTML first page. This link activates the context server which:

- □ sets up a context for the management of the user's conversation and initializes a session if it is the first request, or retrieves an existing context if it is not the first request.
- □ transmits the request to the transactional application through the communication layers and transactional monitor.
- ☐ The application sends a logical message which corresponds to the requested screen.
- ☐ The logical message is decoded by the context server and then merged with the HTLM description of the screen.
- ☐ The HTLM page which results from the merge is transmitted to the user via the HTTP server.

4.2. Overall View of Communications Diagram

4.3. Servers

4.3.1. Parameters of the Context Server

The context server converses with an HTTP server and with the application server.

4.3.1.1. Parameters of HTTP Server / Context Server

The HTTP server and the context server communicate via a socket. By default, both servers are supposed to be on the same machine and to use the socket number 2345.

However you may install the servers on different machines and use another socket number.

In that case, you must modify the call of the CGI program which makes the link between the HTTP server and the context server. The name of the machine which supports the context server and the socket number must be added when CGI script is called in HTML pages. So you must modify the cgicgicall.tpl and cgicgifirstcall.tpl templates before generating the HTML pages of the On-Line Systems Development application.

If the machine on which the context server runs is symbolically named **srvpacweb** and if the socket number is 7801, you must overwrite the following line:

□ In the cgicgicall.tpl file:

```
#cgicgi%20+today.getTime()+'%20#monitor%20localhost'
par
'#cgicgi%20'+today.getTime()+'%20#monitor%20srvpacweb%20780
1'

In the cgicgifirstcall.tpl file:
'#cgicgi%20' + today.getTime() + '%20#monitor%20' + MyUser
+ '%20' + MyPasswd + '%20localhost'
par
'#cgicgi%20' + today.getTime() + '%20#monitor%20' + MyUser
+ '%20' + MyPasswd + '%20srvpacweb%207801'
```

You may also directly use the IP address of the context server machine. In that case, you will get the following line:

```
'#cgicgi%20'+ today.getTime()+
'%20#monitor%20192.7.12.57%207801' if 192.7.12.57 is the IP address of the machine.
```

You must also specify the socket number parameter at the context server activation via the -s option.

Example: pacweb -s 7801

4.3.1.2. Parameters of Context Server / Application Server

The communication protocol and the channel used between the context server and the application server are identified by the values of the [Middleware] block in the Application name >.ini file. These values are given by the developer in the Middleware tab of the generator window.

For more details, refer to Chapter Revamping an Application, Subchapter Pachase Web Generator Graphic Interface, Section Generation Options, Paragraph Middleware Options 6.1.1.1.

4.3.2. Parameters of the HTTP Server

The HTTP server must be configured so that the <code>cgicgi.pl</code> <code>Perl</code> script can run, and the help pages and icons of the pages generated by Pacbase Web Generator can be loaded. To do this, you must modify the correspondence rules of the URL/ file requests.

The correspondence rules of an HTTP server managing an OLSD application are the following:

□ Rule to run the Perl script

Exec /cgi/* <directory which contains the Perl
interpreter and the cgicgi.pl script>

Example: Exec /cgi/* c:\pacweb\Perl5*

☐ Rule to know the root directory of OLSD applications

The root directory is the directory where the first page of OLSD applications and the directories related to OLSD applications are located.

Example: Pass /pw/* c:\pacweb*

Rules to load the JavaScript files, icons and help pages of an OLSD application.

For a generated application where <ShortApplicationTitle> (corresponding to the short title of the application specified in the Short Application title option of the generation window, Application tab) is WE, you will obtain:

Pass /WE /* c :\pacweb\WE *

Examples are given for information only, take care of the different input rules depending on the server in use.

4.3.3. Context server operating mode

The context server manages the user context, merges the messages from the application with the HTML template pages. The result is sent to the HTTP server and transmitted to the user. In the other way, the user requests are edited by the context server to make them compatible with the application server.

4.3.4. Use of the HTML page templates by the context server

The context server always uses HTML pages templates. The templates are merged with the application's data, and the template labels are dynamically replaced.

The context server should be capable to access the HTML page templates used to design the screens.

In case the HTML page templates have been generated on a computer different from the one allocated to the context server execution, the templates should be copied on the computer used to execute the context server.

These template files are to be found in the <short_application_name>/app directory issued from generation.

In the context server, you must specify the path to the directory which contains the template files. This information is given through the following line: Instal_Dir in the « .ini » file relating to the application.

WARNING: The «.ini» file generated under windows/NT must be modified to take into account the AIX directory name in which the HTML pages are stored.

Example:

If the directory choosen at generation is c:\tmp and the « short application name » is WE, you obtain the following lines in the «.ini» file:

```
Instal_Dir= c:\tmp\WE\App
```

If the directory choosen under AIX to install the context server is /home/pacweb, and if si you have copied the HTML templates under the /home/pacweb/WEApp directory, you will have to replace this line by the following one:

```
Instal_Dir= /home/pacweb/WEApp
```

You must add to the HTML pages templates the «.ini» file modified as above, which describes the parameters used for the communication system.

This «.ini» file must be transferred under the same directory as pacweb.exe.

4.3.5. Use of the middleware by the context server

4.3.5.1. General remarks

The context server should be capable to access the middleware to communicate with the application server. On Windows/NT, the PATH environment variable specifies the complete path to the directory containing the dll relating to the type of middleware.

On the AIX system, the complete path to the directory containing the middleware (ixo*.o) must be specified in the environment variable LIBPATH. If the middleware and the context server are installed under the same directory, so the middleware can be started with the following commands:

```
LIBPATH=. pacweb.exe
```

If the middleware mode selected at installation is « debug », the middleware traces are activated when you set the environment variables as follows:

- ✓ IXOTRACE=1,
- ✓ IXOTRACE_FILE environment variables with the name of the file in which traces are recorded.

4.3.5.2. CPIC-XCP2 specific variables

The DACSID and DACCFG environment variables must be set so as to conform the instructions given in CPI-C/OSI Administrator's Guide.

4.3.5.3. VAPTCP variable used with a application server running on MVS or GCOS7

The VAPTCP environment variable must be initialized with the complete path to the file containing the transcodification tables when you use an application server running on MVS or GCOS7. However, by default, the context server uses the 819-297.nls file of the current working directory as a transcodification table file.

4.3.6. Activation of the context server

The context server must fetch the **pacweb.ini** files of the applications it manages. These files must be located under the current directory of the context server.

To start the context server, you can:

- □ click on its icon directly, if it is located in the same directory as the <name_appli>.ini files,
- or create a shortcut by indicating the directory containing the <name_appli>.ini file as being a current directory,
- or start it directly from a DOS session.

By default, the socket number used by the context server and the HTTP server is 2345.

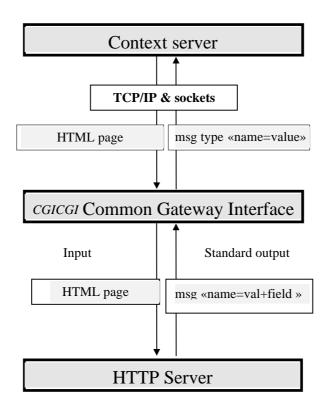

If another number is used, the context server must be activated with this socket number parameter via the -s option.

Example: pacweb -s 6789

4.4. Script cgicgi.pl

The cgicgi.pl script is used to transmit messages coming from the HTTP server to the context server.

The script is written in Perl language. It is translated from the HTTP server, for each HTML validation.

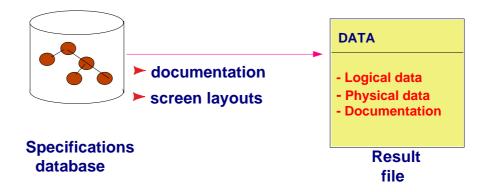

5. Extracting and transferring files

5.1. Extracting screens from the server

First you must extract the data required for local parameterizing from the referential.

- ☐ From the Dialog: application title, options, documentation
- ☐ From the Screen: definition, description, documentation
- ☐ From the Data Elements: name, code, length, autorized values, documentation
- Dialog help

The file which contains the descriptions of the screens to be revamped is output by the PACBASE GPRT (GEO option C4) procedure. The procedure output is a user file: PAC7GT (or GT for GCOS8 system) whose records are each 180-characters long (maximum).

For more information on the GPRT procedure, see the *User's Interface Guide* Reference Manual.

5.2. Transferring the extraction file to a computer

Downloading the PAC7GT or GT file on a computer is performed by the developer. The transfer utility must be parameterized so as to keep all special characters. The local resulting file of the transfer is what we will name here FILENAME.EXT.

The modification of the On-Line Systems Development programs for the implementation of Pacbase Web Connection is documented in the On-Line Systems Development Reference Manual.

Revamping an application 23

6. Revamping an application

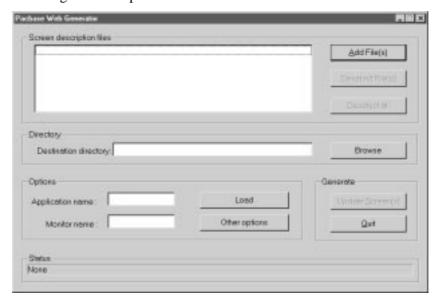

This stage consists on defining the options and parameters which will be used to revamp your VisualAge Pacbase application. To do that, you can use Pacbase Web Generator's graphic interface or a textual interface. The generator will change automatically the application's screens into HTML pages and the parameters selected are saved in files.

6.1. Pacbase Web Generator graphic interface

The parameter files which enable the application revamping are generated by Pacbase Web Generator, which handle data extracted from the database. This revamping step is automatic and only requests a very small participation from the developer.

To start the generator, you must execute Pacwebgen.exe, either directly from the file manager, or via a shortcut.

The following window opens.

Screen description files panel:

Select the extraction file(s) from which you will generate your HTML pages.

With the Add File(s) button, you can add one or more files in the list.

With the Deselect File(s) button, you can deselect one or more files.

With the Deselect all button, you can deselect all the files.

Directory panel:

Enter the directory in which the file structure tree will be generated. For example, if the destination directory is c:\pacweb2 and the application short title is WE, you will have:

- c:\pacweb2\WE_app: directory which contains the HTML templates of the application.
- c:\pacweb2\WE_help: directory which contains the HTML pages of the application help.
- c:\pacweb2\icon: directory which contains the icons displayed in HTML templates.
- c:\pacweb2\WE\js : directory containing JavaScripts function files.

The **browse** button enables you to select the destination directory. If the directory does not exist, a message appears.

Options panel:

Application name field:

Enter the name of the file **<Application** name>.ini in which the parameters of generation will be saved as for instance, the parameters of the Middleware used for the application.

Monitor name field:

Specify the name of the monitor activated by the application server.

Load button:

Click on this button to reload the <Application name>.ini file specified in the Application name field; all the options of generation defined previously will be kept.

The **Other options** button opens a notebook in which you can select generation options (see next section).

Generate panel:

Update Screen(s) button:

With this button, you can generate the extracted file.

Quit button:

With this button, you can quit Pacbase Web Generator.

The data displayed in the **Status** bar at the time of generation is stored in the **GEOC4report.txt** file.

If you generate your files directly, without any generation option, you will obtain a simple revamping.

6.1.1. Generation Options

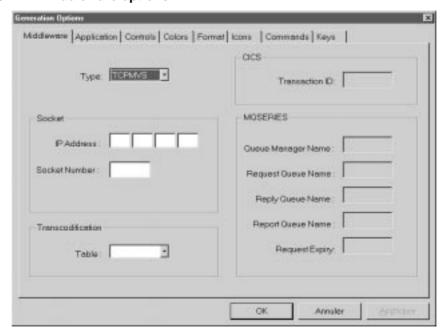

With these options, you can adapt the generation to your needs. You may modify:

- the suffix of the files which contain the HTML pages (htm or html).
- The type of Middleware and its parameters.
- general parameters: background color of the page (or background bitmap), color of links, visited links, and active links.
- the format of the labels associated with variable fields: use of the .libvar style or keep the initial attributes (color, intensity).
- the format of fixed labels: use of the .libfix style or keep the initial attributes (color, intensity).
- error management: via the display of an 'Alert' box (JavaScript) or via an error message field, or both as it is advised.
- the controls to be generated (via JavaScript functions): numeric or date, presence.
- the generation of fields containing values: maximum number of values for radio buttons (fields with a higher number of possible values are generated as listboxes).
- the name of icons in menu bars. These icons are to be found in the Pacwebgn/icon directory
- the labels associated with action and operation codes, associated display options.
- the location of function keys (on the bottom or the top of the page).
- the type of page branching: via a drop-down list, a radio button or an edit box.

All these generation options are saved in a file named <application name>.ini.

A click on the **Other options** button of the Pacbase Web Generator window will open a dialog box which contains generation options that you can use to personify your application windowing.

6.1.1.1. Middleware options

Type of middleware:

Select the type of middleware in use for the communication between the server of contexts and the application server (the server of contexts is designed to manage several applications using different communication protocols or different computers.

TCP/IP socket protocol

If the context server and the application server communicate via sockets, you must indicate the IP address of the application server and the Socket Number.

- CICS: CICS-ECI protocol
- CPIC : CICS-CPIC protocol

If the type of communication is CICS-ECI or CICS-CPIC, you must specify the transcodification table used to transfer messages between the two systems with the true page code. This table is supplied as a file named 819-297.nls. The complete access path to the file can be allocated to the VAPTCP environment variable. By default, the context server uses the 819-297.nls file which is located under the current working directory.

Example: SET VAPTCP=c:\pacweb\819-297.nls

Furthermore, with CICS-ECI you can enter via the Transaction ID field, the code of the CICS transaction which is activated for the communication.

CPICXCP2: CPICXCP2 protocol

This protocol is used for connections between a context server running under AIX and an application server on GCOS7 or GCOS8. You must specify the complete access path to the file containing the transcodification table on GCOS7.

TCPMVS: TCP/IP towards MVS protocol

This protocol is used for communication between a context server running on AIX or Windows/NT and an application server running under MVS and communicating via sockets. You must specify the complete access path to the file containing the transcodification table.

■ TCIS: TCP/IP protocol towards Unisys 2200

This protocol is used between a context server running on AIX or Windows/NT and an application server running on unisys 2200 which both communicate via sockets.

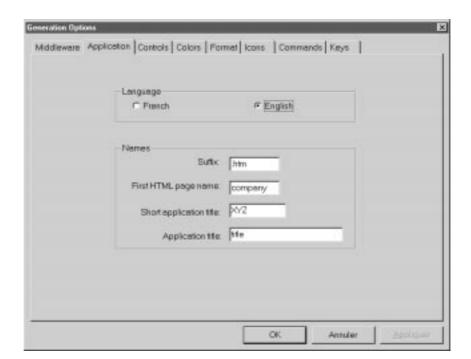

MQSERIES: MQSERIES protocol

If the communication is made through the use of MQSERIES protocol, you must specify the transcodification table as well as the parameters specific to this type of communication: name of the Queue Manager, name of the Queues (report, request et reply) and Request Expiry in seconds.

You will find in the following chart, the set of middlewares that may be used for connections between the context server and the application server:

Application server	Context server		
	AIX	NT	
MVS/CICS	TCPMVS	ECI	
		CPIC	
		TCPMVS	
MVS/IMS		MQSERIES	
UNIX*	SOCKET	SOCKET

6.1.1.2. Application Options

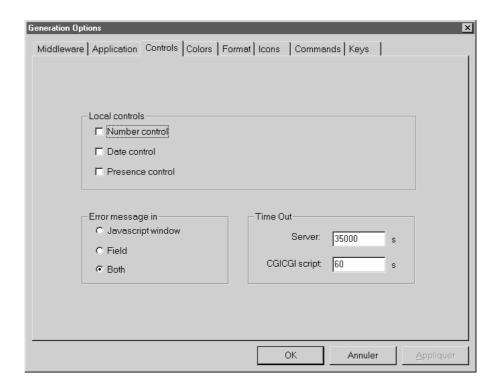

Language panel:

This option enables you to generate the first page and the standard messages of local controls in French or in English. The first page contains a title and the buttons which start the generated applications.

Names panel:

- Suffix field: suffix used in HTML file names (.htm ou .html)
- First HTML page name field: name of HTML first page
- Short application title field: character string which identifies the generated applications. It is used to create the directories which are specific to each application.
- Application title field: title which will appear in the start button of the application, in the first page.

6.1.1.3. Controls Options

Local controls panel:

With this option, you specify which local controls are to be performed: control on number, date, presence and cursor management.

In the screen description, you will find control options under the form:

- ChkNum for number control.
- Chkhere for presence control.
- ChkDate for date control.

These functions are described in the file public.js located in the js directory.

Error message in panel:

With this option, you can parameterize the display of errors.

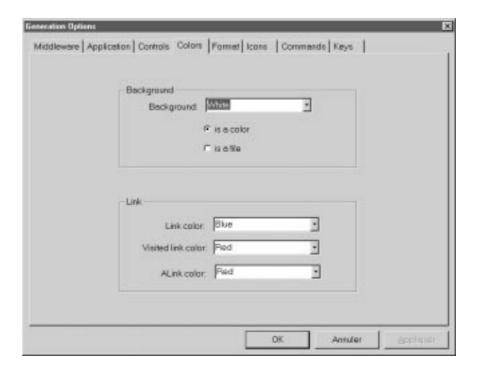

- Javascript window: the error message appears in a window directly in the browser.
- **Field:** The message appears at the bottom of the page as indicated in the layout.
- Both: Both displays simultaneously.

Time Out panel:

Server: indicates the response time of the server.

CGICGI script: indicates the response time of CGICGI program. This program enables the management of the connection between the HTTP server and the context server.

6.1.1.4. Colors Options

Colors:

With these options, you specify purely graphical parameters for the generation of pages.

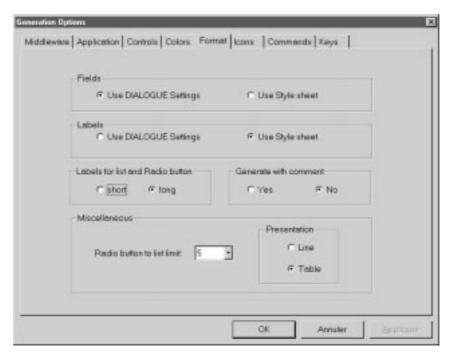

Background panel: Select the background color of the page.

- Is a color: select a color in the drop-down list.
- Is a file: select a bitmap in the directory:

<ShortApplicationTitle>\icon, <ShortApplicationTitle> is the
name entered in the Short Application title field of the Application
tab.

Link panel: select the color of non-visited links, of visited links and of activacted links. These colors are used only for help pages.

6.1.1.5. Format Options

Presentation of the fields making up a screen.

Fields panel: variable part of the screen

Use DIALOGUE settings:

Use of the display format as it is described in VisualAge Pacbase.

Use Style sheet:

Use of the .libvar style which is described in the style.css file.

Labels panel: fixed part of the screen.

Use DIALOGUE settings:

Use of the display format as it is defined in VisualAge Pacbase.

■ Use Style sheet:

Use of the .libfix style which is defined in the style.css file.

Labels for list and Radio button panel:

- **Short:** Use the short label as value displayed by a drop-down list or a radio-button.
- Long: Use the long label as value displayed by a drop-down list or a radio-button.

Generate with comment panel:

Add comments in your HTML pages so that a postprocessingor can modify the pages.

Miscellaneous panel:

Radio button to list limit: This value is the bound from which a choice list is displayed in a drop-down list rather than in radio-buttons.

Presentation panel: used to specify two modes of mapping:

- Line: this mapping mode takes into account a line to line layout.
- **Table:** this mapping mode takes into account vertical alignments defined in VisualAge Pacbase.

6.1.1.6. Icons Options

With these options:

- you name the files which contain the icons of the standard buttons. You can modify all displayed filenames.
- and you can enter the text of the default label associated with the icon in the Associated name field.

Help:

Enables the user to view help pages, the help on help and the help index.

For more details, see Chapter *Presentation of generated pages*, Sub-chapter *Structure of help pages* 7.3.

Exit:

Enables the user to quit the application or help pages.

Backward:

Enables the user to navigate in the help pages he/she has viewed already. By clicking on this button, he/she will view the previous page.

Forward:

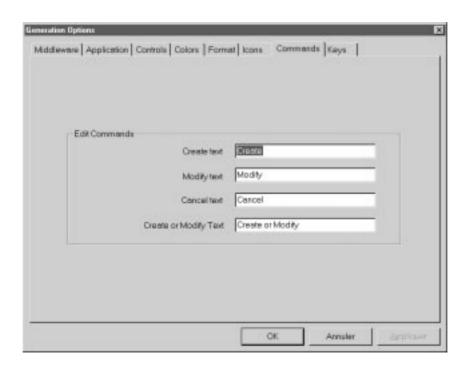

Enables the user to navigate in the help pages he/she has viewed already. By clicking on this button, he/she will view the next page.

Icon next to the title:

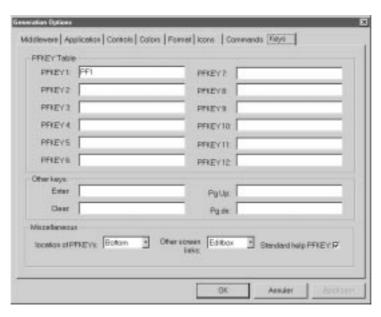

Insert icon next to each title: Enables you to insert a logo-type icon before the screen title.

Icon name: Name of the file which contains the icon to be inserted at the top of each page if the box Insert icon next to each title is checked.

6.1.1.7. Commands Options

On this screen, you generate a list of choices corresponding to action codes: Create, Modify, Cancel, Create or Modify.

6.1.1.8. Keys Options

This screen enables you to manage function keys.

PFKEY Table panel:

You may enter labels which will appear in the buttons associated with function keys on the top or bottom of the screen. You may insert up to 12 keys.

Other keys panel:

- **Enter:** Label of the button associated with the Enter key.
- Clear: Label of the button associated with the Clear key.
- Pg Up: Label of the button associated with the Page Up key.
- Pgdn: Label of the button associated with the Page down key.

Miscellaneaous panel:

- Location of PFKEYs: Enter the location of function keys in the screen: on the top or bottom of the screen or in the footer.
- Other screen links: Specify the type of link mapping between screens (drop-down list, radio button, edit box).
- Standard help PFKEY: When this option box is checked, the function keys used to activate the standard help and the standard contextual help, are mapped with the button format.

The standard help is directly generated by the application server unlike the HTML pages help which is generated from the extracted file.

6.2. Textual interface

6.2.1. Activating the generator

To start the generator on a textual interface, you need to enter the following commands:

PWCbatch.exe [-d destination_directory] [-i parameters_file] geofile

Destination_directory refers to the directory where the whole HTML pages are generated.

Parameters_file refers to the file containing the different generation parameters. The default file used is PacWebgen.ini.

Géofile refers to the file resulting from the extraction of the VisualAge Pacbase files containing the screen description (GEO C4).

6.2.2. Modifying the generation parameters

The file **Pacwebgen.ini** is used by default to generate an HTML application. You must fill some of the fields in the file before starting the generation.

If you want to start the generation with no parameter file, don't forget to enter the application name, the monitor name, the type of middleware and the different parameters relating to the selected middleware.

The generation parameters are:

Default value	Other value possible	Description
Suffix= .htm	.html	Suffix used to name HTML pages.
Error message= BOTH	WINDOW or FIELD	Parameterize the error messages display: error message displayed in a window or at the bottom of a page or both.
CGICGI timeout= 60		HTTP server timeout: indicates the response time of the server
Monitor=		Monitor name
Instal_Dir=		Name of the directory containing the pages which are accessed by the context server
App_CodePage=		Server page code
MWARE=	SOCKET/CICS/ CPICXCP2/TCPMVS/ MQSERIES	Type of middleware in use for the communication between the context server and the application server.

Default value	Other value possible	Description
MWTIMEOUT= 32200		Indicates the response time of the server
MWADDRESS=		IXO adress
MWCODEPAGE=	819	Client page code
MWQUEUEMANAGER=		If the communication is made through the use of MQSERIES protocol, you must specify the parameters specific to this type of communication, especially the name of the queue manager.
MWREQUESTQUEUE= MWREPLYQUEUE= MWREPORTQUEUE= MWREQUESTEXPIRY=		Name of the queues (report, request and reply) and request expiry in seconds. MQSeries Request Queue MQSeries Reply Queue MQSeries Report Queue
Language= ENGLISH	FRENCH	Generation language
First page name= company		First page name
Short application title= APPN		Character string used to create the different directories specific to each application.
Application title= title		Title displayed in the start button in the first page
Number control= NO	YES	Number control
Date control= NO	YES	Date control
Presence control= NO	YES	Presence control
Background= White		Background color of the page
Link color= Blue		Color of hypertext links
Visited link color= Red		Color of visited links

Default value	Other value possible	Description
A Link color= Red	-	Color of activated links
Field format= DIALOGUE	STYLE	DIALOGUE: Use of the display format as it is described in VisualAge Pacbase STYLE: use of a style sheet
Label format= STYLE	DIALOGUE	DIALOGUE: use of display as it is described in VisualAge Pacbase STYLE: use of a style sheet
Comment= NOCOMMENT	COMMENT	Generate with comments
Radio to list= 2		This value is the bound from which a choice list is displayed in a dropdown list rather than in radiobuttons
SLIabel= short	Long	Label type: short or long as value displayed in a drop-down list or a radio button.
presentation= table	Line	Présentation type: a line to line layout (Line) or vertical alignment defined in VisualAge Pacbase.
Icon next to the title=		Name of the icon to be inserted on the left of the title
Help icon=icon_help.gif		Name of the icon associated with the button used to display the help
Help text= Help		Text associated with the button used to display the help
Exit icon=icon_exit.gif		Name of the icon associated with the button used to quit the application.
Exit text= Exit		Label associated with the button used to quit the application.
<pre>Index icon= icon_index.gif</pre>		Name of the icon used for the Index button.
Index text= Index		Text associated with the index button
Backward icon=		Name of the icon used to access
icon_back.gif Backward text= Back		the previous page Text associate with the button backward page
Forward icon= icon_forward.gif		Name of the icon used for the forward page button.

Default value	Other possible values	Description
Forward text= Forward		Text associated to the
		forward page button.
C CMVT string= Create		Label of the create
		transaction code
M CMVT string= Modify		Label of the modify
_		transaction code
A CMVT string= Cancel		Label of the cancel
-		transaction code
X CMVT string= Create or		Label of the create/Modify
Modify		transaction code.
Function buttons= TOP	BOTTOM ou FOOTER	Location of the key
		functions: top of the screen,
		Bottom of the screen or in
		the footer.
Other screens= EDITBOX	BUTTONS ou	Used to specify the type of
	LISTBOX	link mapping between
		screens: editbox, radio
		bouton or listbox .
Common Enter Key=		Label associated with the
		Enter key
Common Clear Key=		Label associated with the
		Clear key
Common PageUp Key=		Label associated with the
		PageUp key
Common PageDown Key=		Label associated with the
Common DEKEY Toble		PageDown key Label associated with the
Common PFKEY Table=		
PF1,,,,,,,,		function keys.
Standard help PFKEY= NO	YES	Mapping of the standard
		help keys.

6.3. Generation Output

The generation of the interface outputs the following components:

- □ under the Destination Directory:
 - ✓ a ✓ a ApplicationName.ini file containing the application's parameters.

These files are then installed on the workstation where the context server is running.

ApplicationName corresponds to the name entered in the Application Name field in the generator.

✓ a first page, required for initializing the Dialog whose name is given by the field First HTML Page.

<FirstHTMLPage>.htm

- ☐ Under the app directory which is located in the Destination Directory/Short application title:
- ✓ a utility page which contains JavaScript utility functions or the HTML screen descriptions in *frames* (=fields), in a file whose name is given by the field Short application title.

<ShortApplicationTitle>app.htm

✓ a page for each screen, stored in a file named <screenCode> (on 6 characters) and suffixed htm or html (generation option):

<ScreenCode>.htm

✓ the following files:

editpl.htm, error.htm, fieldtpl.htm, hiddentpl.htm,
menubar.htm, notfoundtpl.htm, passwdtpl.htm

- ☐ Under the help directory which is located in the Destination Directory/Short application title:
 - √ a help page named <ShortApplicationTitle>help.htm
 - ✓ a help page for each screen, contained in a file named ShortApplicationTitle>_help_<ScreenCode> (on 6 characters) and suffixed htm. <ShortApplicationTitle> is the name entered in the Short Application Title option in the generation window, Application tab.
 - ✓ An index page for each screen, contained in a file named <ShortApplicationTitle>_index_<ScreenCode> (on 6 characters) and suffixed htm.
 - ✓ footer.htm: icons for help screens
 - ✓ helphelp: help on help

- ✓ <ShortApplicationTitle>_Index: general index
- ☐ Under the js directory which is located in the Destination Directory:
 - ✓ a public.js file for public functions used at General level
 - ✓ a private.js file for private functions used at General level
 - ✓ <ShortApplicationTitle>private.js: private functions used at Dialogue level
 - ✓ <ShortApplicationTitle>public.js: public functions used at Dialogue level
 - ✓ <ScreenCode>private.js: private functions used at Screen level
 - ✓ <ScreenCode>public.js: public functions used at Screen level
 - ✓ style.css: file used for the style
 - √ notfoundtplprivate.js and notfoundtplpublic.js
- For more information on the functions used at General, Dialogue and Screen levels, refer to Chapter *Customizing generated pages*, Sub-chapter *JavaScript functions 8.3*.
 - under the icon directory which is located in the Destination Directory/Short application title:
 - ✓ the bitmaps used in the different pages
 - under the generator's current directory:
 - ✓ A generation report in the **GEOC4report.txt** file.

When you re-generate a page, you lose all initial modifications entered in your HTML pages.

7. Presentation of generated pages

7.1. First Page

The First page contains User and Password fields used in an application whose server requires a user identification (CICS for example).

The label of the button used to start the application corresponds to the name you have entered in the **Application Title** field of the **Application** tab, in the generation options.

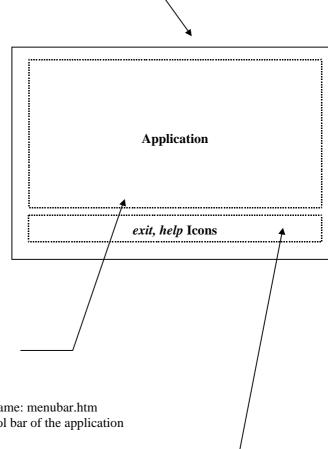

7.2. Structure of the general page

The HTML page is displayed in a general page which is made of two frames: the first one is used to display the application's screen and the other one to display the buttons which are controlling the application and the help windows.

File name: <ShortApplicationTitle>App.htm

Function: defines two frames app and menubar, loads basic

JavaScript functions

Frame name: app

Filename contained in the frame:

<ScreenName>.htm

Function: displays the requested screen

Frame name: menubar

Filename displayed in the frame: menubar.htm Function: displays the control bar of the application

7.2.1. Screen Description

The <ScreenName>.htm file which is generated contains the description of the screen. The screen is divided into two sections: the head and the body.

```
<HTML>
   Comments indicating that the screen results from a VisualAge Pacbase generation.
   META data which identify the screen (program code, generatio date, etc.)
   Screen title
   Call of the stylesheet
  JavaScript functions loading (at the screen level)
   </HEAD>
   <BODY>
      <FORM METHOD=POST>
     HIDDEN field used for the error message, the cursor positioning, the function
     key value
      Screen description:
      Literals
      INPUT and SELECT fields
      </FORM>
   </BODY>
   </HTML>
```

7.2.1.1. Head

This section contains the following data:

- □ identification of the program in use (META instructions),
- □ screen title,
- □ stylesheet name,
- □ loading of JavaScript functions.

Example:

```
<TITLE>screen title</TITLE>
<META NAME=" SESSI" CONTENT=" 5222 ">
<META NAME=" LIBRA " CONTENT=" xxx ">
<META NAME=" LIBRA " CONTENT=" 15012000 ">
<META NAME=" DATGN " CONTENT=" 15012000 ">
<META NAME=" TIMGN" CONTENT=" xxxxxxx">
<META NAME=" PROGE " CONTENT=" xxxxxxx">
<META NAME=" COBASE " CONTENT=" xxxxx ">
<LINK REL=STYLESHEET HREF="/zz/app/style.css" type="text/css">
<SCRIPT LANGUAGE="JavaScript" SRC="/zz/js/zzxxxxPrivate.js">
</SCRIPT>
<SCRIPT LANGUAGE="JavaScript" SRC="/zz/js/zzxxxxPublic.js">
</SCRIPT>
```

7.2.1.2. Body

This section contains the screen description. It contains a FORM instruction which specify the 'POST'action (parameter transfert option) and may include the list of controls to be performed (onSubmit).

The Body section has the following characteristics:

- □ Each new line creates a new line break (
 instruction) in a « Line » type generation.
- □ Each label or protected field is retrieved as a text, adapted to the generation parameters.
- □ Variable fields (protected or not):
 - ✓ F-type data element (displayed or protected on the screen but received by the program): a hidden field whose value is the label text must be added besides the label which is in a text form.
 - ✓ P-type data elements (displayed or protected on the screen but not received by the program): the data element is displayed as a simple text.
 - ✓ V-type data element (variable): each variable field is described with an <INPUT> or <SELECT> instruction, followed by the name of the corresponding data element (NAME attribute), the field length (MAXLENGTH attribute) and for input fields, the displayed length (equal to the maximum length at generation time, but it can be modified by the developer). This instruction does not contain the call to the appropriate control function; this is done in the submit (onSubmit-type Event Handler).

Example:

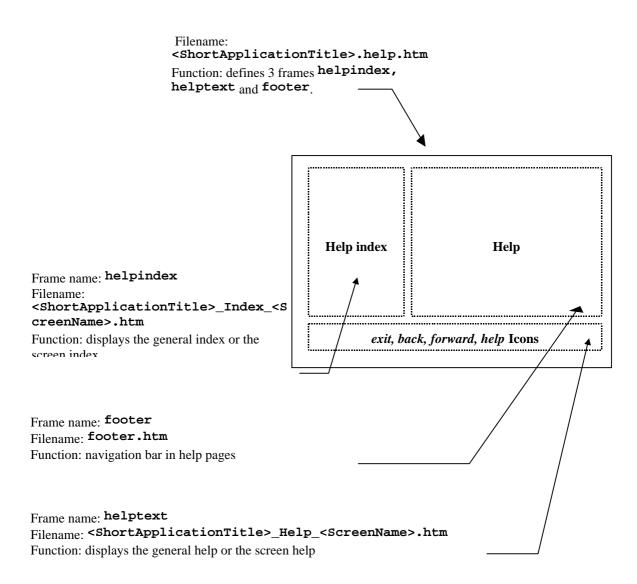

```
<INPUT TYPE='TEXT' NAME='COPOS'
CONTENT='#COPOS000101' MAXLENGTH=5 LENGTH=5>
```

- ☐ The fields whose values are unknown (such as **TEXT** or **PASSWORD**) include a CONTENT (or VALUE) attribute whose value is the name of the field prefixed by # (see example above).
- □ Each field which has a default value is initialized with this value (SELECTED attribute of BUTTON-type INPUT fields, SELECTED instruction of SELECT fields, etc.).

7.3. Structure of help pages

Help pages are generated from VisualAge Pacbase extracted file.

Help is generated directly in HTML and saved on the HTTP server. Help is structured as follow:

Structure of help in frames

The file <shortApplicationTitle>_Help.htm (<ShortApplicationTitle> was defined in the Short Application Title option) defines the size and location of the 3 frames. The 3 frames are described in 3 different files: (footer.htm, <ShortApplicationTitle>_Index_<NomEcran>.htm and <ShortApplicationTitle>_Help_<ScreenName>.htm)

7.3.1. Contextual Help

A help page is generated for each screen. This page contains:

□ the general help associated with the screen:

<ShortApplicationTitle>_Help_<ScreenName>.htm

It is displayed in the **helptext** frame.

□ the list of the screen's data elements with their long label, authorized values and associated documentation.

ShortApplicationTitle>_Index_<ScreenName>.htm.

It is displayed in the helpindex frame.

7.3.2. General Help (summary)

General help is designed to be displayed in the **helpindex** frame, i.e. the frame which can also contain the list of a screen's data elements.

General help contains the list of screens, each screen corresponding to a link on the help associated with this screen. The user then chooses the screen whose help he/she wants to view: the corresponding help page is displayed in the helptext frame and the screen index overwrites general help in the helpindex frame.

7.3.3. The Navigation Bar

The navigation bar is displayed in the **footer** frame, and described in the **footer.htm** file. It contains the following icons:

- □ Back and forward: to view help pages already viewed. These icons call the Javascript fuctions history.back() and history.forward() which are located in standard Javascript functions.
- □ Help: to display general help in the helpindex frame.
- □ Exit: to quit help.

8. Customizing generated pages

Generated HTLM pages can be entirely customized. You may modify the aspect of a page (add colors, icons, modify labels, layout or insert fields) by using an HTML page editor or by modifying the HTML page directly via a text editor.

However you must be careful not to delete the character strings which begin with #.

Example: Customizing the First Page

The first page is always generated. By default it contains a title field and a button to start the application. But this can be modified. For example, you may add buttons to start several applications from the same first page. To do this, you must copy the following HTML paragraph, located in the description of the generated first page, in the file whose name you have entered in the field **First HTML page name** of the **Application** tab.

```
<INPUT TYPE = « button » NAME = « WE » VALUE =
« Application title »

onClick = « openNewWin('/WE/app/','WE AppApp') »>
```

8.1. styles

The CSS1 (Cascading stylesheet) architecture is used for the presentation (size, font, colors...) of different fields in a page. These styles are described in the style.css file under the js directory.

- ☐ There is one style for each type of field:
 - ✓ .text for a text type field,
 - ✓ .passwd for secret type field,
 - ✓ .libfix for fixed labels,
 - ✓ .libvar for variable labels,
 - ✓ .radio for radio buttons,
 - ✓ .screentitle style used for the title of a screen,
 - ✓ .dropdown style used for drop-down lists.
- □ 3 styles when mapping repetitive fields:
 - ✓ .libtbl for the label of the table,
 - ✓ .rowodd for odd rows,
 - ✓ .roweven for even rows.
- and n styles are available to simulate the display of the Dialogues.

The names of these n styles are related to the names of the presentation attributes in VisualAge Pacbase. There are 56 different styles of .libXYC name, where X can take the N or B values (Normal, Bold), Y can take the N, B, U, R values (Normal, Bold, Underline, Reverse), and C can take W, R, P, Y, G, T B values (White, Red, Purple, Yellow, Green, Turquoise, Blue).

The styles can be modified, they are not overwritten once regenerated.

8.2. Automatic Modification of HTML Pages

Additional comment tags can be implemented at the generation (Generate with comment, Format options 6.1.1.5). These tags are added so as to enable automatic changes to be operated in the generated pages. They are used by the tool for a better reading of the generated page. In this way, it is possible to apply the same modification on a set of pages or to apply again the same changes after re-generation.

The generated tags are the following ones:

At the beginning of the screen line<!--!PWC!LINEx--> with x = Line number Each field is framed either by

```
<!--!PWC!field name-->
or
<!--!PWC!xCy--> (for the labels)
```

Example: Automatic deletion of a line and modification of the SIZE attribut in some of the fields.

This example is written in Perl.

```
# print current line until arg1
sub printuntil
  unless (/$_[0]/)
        print OUT;
        while (<IN>) {
               last if (/$_[0]/);
               print OUT;
        }
  }
# replace value of size if greater than 10
sub replacesize {
  &printuntil("SIZE=");
  s/SIZE=[0-9]{2,}/SIZE=15/;
# suppress a line
sub supline()
  local($wrk) = "<!--!PWC!LINE";</pre>
  local($search) = $wrk . $_[0] . "-->";
  if (/$search/)
        while (<IN>) \{
              last if (/$wrk/);
        }
  }
}
($filein) = @ARGV;
open (IN, $filein) | die "Cannot open file $filein
  :$filein \n";
open (OUT, ">result.htm");
while(<IN>) {
  &supline("19");
  if (/<!--!PWC!NOMRUE/)</pre>
        &replacesize();
        &printuntil("<!--!PWC!NOMRUE");</pre>
  }
  print OUT;
};
```

8.3. JavaScript Functions

8.3.1. Presentation of Javascript functions

You can cutomize your HTML pages, add controls by example or modify the aspect of each page through the writing of Javascript programs.

To manage HTML pages, the generated Javascript functions are divided into two categories: private and public functions.

Private functions are essential for the running of the whole application, they should not be modified by the user.

Public functions are empty generated functions so that the user can enter his own processing. Their name should not be modified.

Unlike public functions, private functions are systematically regenerated when generation is requested and all modifications are overwritten.

Furthermore, these functions are divided into 3 levels that we will name: General, Dialogue and Screen.

The General level functions are common to all dialogues, the Dialogue functions are related to a particular Dialogue and the Screen level functions are related to a particular screen.

If we take WX as short application name as an example, the name of the files in which will be stored the functions at generation is:

	General	Dialogue	Screen
Public	Public.js	WXPublic.js	xxxxxxPublic.js
Private	Private.js	WXPrivate.js	xxxxxxPrivate.js

8.3.1.1. Functions used at General Level

8.3.1.1.1. Private

□ openNewWin(strPath, strAppName)

This function opens a new navigator window. It is used to display the help.

□ Go(str)

Function activated when a page is validated either by activating a key function or a « Enter » key

□ ReadCook()

This function reads the name and the password the user entered in the FrontPage.

☐ UpdatePosCursor (aObjectText)

Store the field where the entry point is located.

□ SetPosCursor ()

This function sets the entry point.

□ DisplayError ()

Displays an error message in a JavaScript window if you asked this type of display at generation time.

□ PWCLoad()

Function activated when a page is loaded.

□ PWCUnload()

Function activated when a page is unloaded.

□ PWCChange(objet)

Function activated when a field is modified.

□ PWCKeyPressed(e)

This function is executed each time a keyboard is pressed. It is used to submit a page by pressing the Enter key.

□ PWCSubmit()

Function activated when a page is submitted.

□ Traces function

The TraceInit, Trace and TraceView functions are used to add a trace mechanism.

TraceInit initializes a variable in which additional messages are stored by use of the TraceView function. The display of the data contained in this variable and thus the display of traces, is triggered by the call of TraceView.

These functions can be used in all public or private functions.

8.3.1.1.2. Public

□ chkDate(type,field)

This function is used for date control of a field

□ chkNum(field)

This function is used for numeric control of a field

□ chkHere(field)

This function is used for presence control of a field

□ displayErr(str,field)

This function displays the errors detected by the control functions above.

□ initArray(),isEmpty(str), isANumber(str)

Functions used to implement control functions.

8.3.1.2. Functions used at Dialogue Level

8.3.1.2.1. Private

It does not include any functions but a file is available to receive possible improvements.

8.3.1.2.2. Public

All these functions are empty. They can be used as entry points to enter additional processing. They are called through the use of General level functions.

□ PWCLoadA()

Function called when a HTML page is loaded and **after** the specific processing defined at General level (Cf **PWCLoad())**.

□ PWCUnloadB()

Function called when a HTML page is unloaded and **before** the specific processing defined at General level (Cf. **PWCUnload()**).

□ PWCChangeA(object)

Function called when a field is modified in a HTML page and **after** the specific processing defined at General level (Cf. **PWCChange(objet)**).

□ PWCChangeB(object)

Function called when a field is modified in a HTML page and **before** the specific processing defined at General level (Cf. PWCChange).

□ PWCKeyPressedB()

Function called when a keyboard is pressed and **before** the specific processing defined at General level (Cf. PWCKeyPressed(e)).

□ PWCSubmitB()

Function called when a HTML page is submitted and **before** the specific processing defined at General level (Cf. **PWCSubmit()**).

8.3.1.3. Functions used at Screen Level

8.3.1.3.1. Private

□ check()

This function is launched before submitting a page. It performs numeric, presence and date controls which could have been requested at generation.

8.3.1.3.2. Public

□ PWCSCRLoadA()

Function called when the HTML page is loaded, **after** the specific processing defined at Général level (Cf. PWCUnload()) and **after** PWCLoadA().

□ PWCSCRUnloadB()

Function called when a HTML page is unloaded and **before** the specific processing defined at General level (Cf. PWCUnload()) and **before** the call of PWCUnloadB

□ PWCSCRChangeA(object)

Function called when a field is changed in a HTML page and **after** the specific processing defined at General level (Cf. **PWCChange(objet)**) and after PWCChangeA.

□ PWCSCRChangeB(object)

Function called when a field is changed in a HTML page and **before** the specific processing defined at General level (Cf. PWCChange(objet)) and before PWCChangeA.

□ PWCSCRKeyPressedB()

Function changed when a keyboard is pressed and **before** the specific processing defined at General level (Cf. **PWCKeyPressed(e)**) and before PWCKeyPressedB.

□ PWCSCRSubmitB()

Function called when a HTML page is submitted and **before** the specific processing defined at General level (Cf. **PWCSubmitB()**) and before PWCSubmitB.

8.3.2. Using JavaScript Functions as entry points

Public JavaScript functions described above can be used to insert JavaScript code. This code is aimed at modifying the standard behavior of pages.

Depending the level at which they are used (General, Dialogue or Screen), these modifications will impact one or several pages.

Example: Additional function changing lower cases into upper cases characters

If you want to change systematically lower cases values in the NOVOL1000101 field into upper cases for a given screen, you just need to change the code of PWCSCRChangeA function defined in the <screen_Name>Public.js file.

```
function PWCSCRChangeA(objet) {
  var wfrom = objet.name;

if (wfrom == "NOVOL1000101")
      objet.value = objet.value.toUpperCase()
}
```

8.4. Templates

8.4.1. Presentation of templates

The HTML template files generated by Pacbase Web Generator are built from generation template files.

The HTML template files used for the generation of pages contain labels which are dynamically replaced with the content of .tpl files.

8.4.1.1. Frontpage (First Page)

HTML page which contains the application starting button.

Template used	Template label	Replaced with the content of the following file

chknum.tpl	Numericity control function
drop-downbox.tpl	Drop-down list
editbox.tpl	Edit box
edittpl.tpl	Input field for a particular generation
endindex.tpl	End of index pages
errorcompat_fr.tpl	Error compatibility with the navigator in French
errorcompat_us.tpl	Error compatibility with the navigator in English
fieldtpl.tpl	Labelled field for a particular generation
firsthtmlpage.tpl	First page
firsthtmlpagetitle_fr.tpl	Title of first page in French
firsthtmlpagetitle_us.tpl	Title of first page in English
footer.tpl	help page footer
help.tpl	Partition of help pages in frames
helphelp_fr.tpl	French help on help
helphelp_us.tpl	English help on help
helpindex.tpl	Index page
helplabel_fr.tpl	French help title
helplabel_us.tpl	English help title
helplineindex.tpl	Link used by help indexes
helprub.tpl	Anchor for data element help
helpscreen.tpl	Page which contains all of a screen help
hiddenfield.tpl	Invisible field
hiddentpl.tpl	Template when generating particular hidden fields
indextitle fr.tpl	French Title for index

Templates	Description	
indextitle_us.tpl	English Title for index	
itemradio.tpl	Generation of a radio button item	
javacontrol.tpl	Check function	
label.tpl	Label of a data element on a screen	
lineindex.tpl	Link used by general index	
menubar.tpl	Screen footer	
Menubarpf.tpl	Screen footer with function keys.	
msgdate_fr.tpl	Message for date control in French	
msgdate_us.tpl	Message for date control in English	
msgday_fr.tpl	Message for date control (day) in French	
msgday_us.tpl	Message for date control (day) in English	
msgfield_fr.tpl	Champ	
msgfield_us.tpl	Field	
msglongdate_fr.tpl	Long message for date controls in French	
msglongdate_us.tpl	Long message for date controls in English	
msgmonth_fr.tpl	Message for date controls (month) in French	
msgmonth_us.tpl	Message for date controls (month) in English	
msgnoframes_fr.tpl	Message to signal the use of frames in French	
msgnoframes_us.tpl	Message to signal the use of frames in English	
msgnumber_fr.tpl	Message for numericity controls in French	
msgnumber_us.tpl	Message for numericity controls in English	
msgvalue_fr.tpl	Message for a value request in French	
msgvalue_us.tpl	Message for a value request in English	
notfound.tpl	inicocago for a value requeet in English	
Onclick.tpl	Contextual help for radio buttons	
Onfocus.tpl	Contextual help for texts lists etc	
option.tpl	Choice for a drop-down list	
outfield.tpl	Field	
pacwebgenini.tpl	Generation of the pacwebgen.ini file	
pacwebini.tpl	Generation of the pacweb.ini file	
passwdtpl.tpl	Secret field when generating a particular page	
password_fr.tpl	Password label for frontpage in French	
password_us.tpl	Password label for frontpage in English	
pfkey.tpl	Function key in menubarpf	
private.tpl	Private JavaScript functions	
privatedia.tpl	Private JavaScript functions at dialogue level	
privatescr.tpl	Private JavaScript functions at screen level	
public.tpl	Public JavaScript functions	
publicdia.tpl	Public JavaScript functions at dialogue level	
publicscr.tpl	Public JavaScript functions at screen level	
radio.tpl	Radio button	
row.tpl	Table row	
screen.tpl	General skeleton for a screen	
screenbutton.tpl	button	
screenbuttonbar.tpl	Button bar when branching on screens by pressing	
	buttons	
style.tpl	Stylesheet	
submit_fr.tpl	French label of submit button	
submit_us.tpl	English label of submit button	
table.tpl	Table	
titleicon.tpl	Addition of a title icon	
user_fr.tpl	User label for first screen in French	
user_us.tpl	User label for first screen in English	
1 4501_40.tp1	2001 ADDITION THOU DOLOGIT HT ETIGRIGHT	

8.4.4. Modifying the Templates

Pacbase Web Generator generates HTML pages from HTML template files.

The HTML template files used in the generation processing contain HTML syntax blocks which can be modified. These blocks enable you to build an elementary paragraph.

It is possible to modify these templates so as to apply these modifications to all generated pages.

To modify a template, we advise you to duplicate the files located in the template.htm directory in the template.usr directory rather than modify them directly.

Such is the case for the cgicgicall.tmp template which describes the code related to the starting of the cgicgi.pl script. You must modify this template if the context server and the HTTP server are not on the same machine. Replace the localhost string with the name (or IP address) of the machine on which the context server runs.
