## How to send your comments

Your feedback is important in helping to provide the most accurate and highest quality information.

- To send comments on articles in the WebSphere Application Server Information Center
  1. Display the article in your Web browser and scroll to the end of the article.
  2. Click on the **Feedback** link at the bottom of the article, and a separate window containing an e-mail form appears.
  3. Fill out the e-mail form as instructed, and click on **Submit feedback** .
- To send comments on PDF books, you can e-mail your comments to: **wasdoc@us.ibm.com** or fax them to 919-254-0206.

Be sure to include the document name and number, the WebSphere Application Server version you are using, and, if applicable, the specific page, table, or figure number on which you are commenting.

When you send information to IBM, you grant IBM a nonexclusive right to use or distribute the information in any way it believes appropriate without incurring any obligation to you.

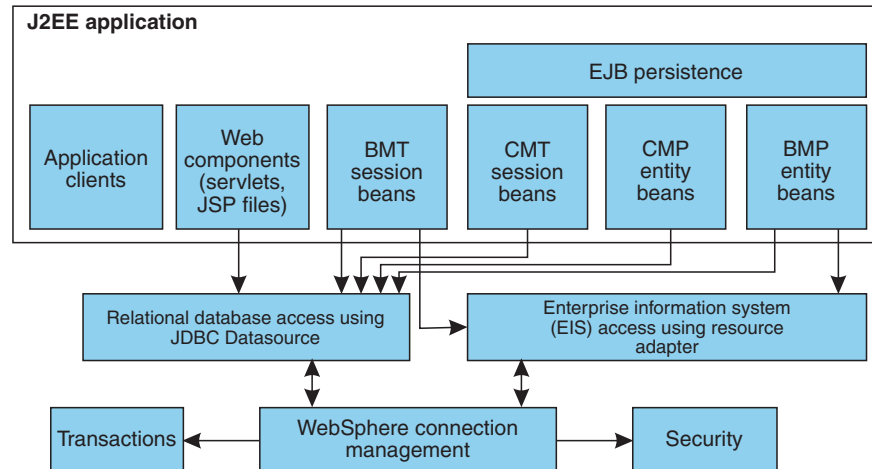

---

## Chapter 1. Welcome to Resources

The product supports all of the resources defined by the Java 2 Platform, Enterprise Edition (J2EE).

### Data access (JDBC and J2C)

The J2EE Connector architecture defines a standard architecture that enables the integration of various enterprise information systems (EIS) with application servers and enterprise applications. It defines a standard resource adapter used by a Java application to connect to an EIS. This resource adapter can plug into the application server and, through the Common Client Interface (CCI), provide connectivity between the EIS, the application server, and the enterprise application.

The Enterprise JavaBeans (EJB) 2.0 architecture for container-managed persistence (CMP) provides a separation between the client view of a bean (as presented by its home and remote interfaces) and the entity bean instance (which provides the implementation of the client view). This separation enables you to change an entity bean independently from its clients. It also means that you can redeploy an entity bean across different persistence managers and different persistent data stores, without requiring the redefinition or recompilation of the entity bean class.

The *Bean Provider* concentrates on the business logic of the object and defines the relationship through the abstract persistence schema; whereas the *Persistence Manager* is responsible for providing the implementation of the persistent fields and relationships, as well as all data access to the underlying persistent store. To achieve this portability, the EJB 2.0 data access model is based on the J2EE Connector Architecture (JCA) specification. This specification is different from the EJB 1.x data access model that used the JDBC Connection Manager (CM) model from Version 4.0.

The EJB 2.0 Persistence Resource Adapter model utilizes the JCA defined *Resource Adapter* to connect to various backend data stores without changing the persistence manager. JDBC applications that access relational databases using the JDBC API indirectly use a WebSphere Application Server Resource Adapter specifically designed to work with JDBC data sources. The product also enables any JCA compliant connector to plug in, enabling the application to access an EIS system.

Users of data sources do not see any differences in the programming model from previous releases because of the underlying use of the JCA architecture. JDBC users still configure and use data sources according to the JDBC programming model. Note that some applications migrating from previous versions of the product can experience behavioral differences because of J2EE Version 1.3 requirements.

WebSphere Application Server 5.0 provides support for the JDBC Connection Manager model from Version 4.0, enabling J2EE 1.2 applications to run unaltered. However, the EJB 2.0 module within a J2EE 1.3 application cannot use the 4.0 JDBC Connection Manager.

For more information, you can read the data access concept articles listed below:

- Resource adapter
- Connection factory
- JDBC providers
- Data sources
- Data access beans
- Connection management

## **Messaging**

The product supports **asynchronous messaging** as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables IBM WebSphere Application Server applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An application can explicitly poll for messages on a destination. The product also provides a message listener service that applications can use to automatically retrieve messages from JMS destinations for processing by message-driven beans, without the application having to explicitly poll JMS destinations.

The Enterprise edition provides *extended messaging*, which uses the EJB container to manage the messaging infrastructure, and provides more types of messaging beans. This enables application developers to concentrate on the business logic for enterprise beans and to leave the messaging usage to messaging objects and configuration of the EJB container.

Tools for working with messaging include the WebSphere Studio for developing and packaging J2EE applications that use JMS, message-driven beans, or extended messaging; the Application Assembly Tool, as described in *Assembling applications with the AAT*; and the product systems administration tools, as described in *Welcome to System Administration*.

For more information about implementing enterprise applications that use asynchronous messaging, see the following topics:

- Implementing WebSphere J2EE applications that use extended messaging, as described in .

## **Mail**

New terminology in Mail technology includes:

- Protocol Provider, a concept equivalent to Service Provider in the JavaMail specification
- Mail Provider, a holder of Protocol Providers

New features in Mail technology include:

- JavaMail specification level changed from 1.1 to 1.2, while JavaBeans Activation Framework (JAF) specification level remains at 1.0
- JavaMail implementation level changed from 1.1.3 to 1.2, and JAF implementation level moved up from 1.0.1 to 1.0.2.
- It is now easier to install and configure custom protocol providers
- You now can define your own custom mail providers, in addition to the built-in mail provider, to easily mix and match various custom and default protocol providers
- There is equal support for mail store protocols as for transport protocols, and equal support for POP3 as for IMAP
- Store-related APIs have been more thoroughly tested. You can define store-only mail sessions if you would like.

## URLs

Java 2 Platform, Enterprise Edition (J2EE) applications can use URLs as resources in the same way other J2EE resources, such as JDBC and JavaMail, are used. That is, they can look up references to logically named URL connection factories through the `java:comp/env/url` subcontext that have been declared in the application deployment descriptor and mapped to installation-specific URL resources.

## Resource environment entries

A resource environment reference maps a logical name used by the client application to the physical name of an object. For more information, see Resource environment entries.

---

## Chapter 2. Using asynchronous messaging

Use these topics to use asynchronous messaging with WebSphere Application Server, to enable enterprise applications to use JMS resources, message-driven beans, and extended messaging.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables WebSphere enterprise applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An enterprise application can explicitly poll for messages on a destination.

WebSphere Application Server also provides a message listener service that enterprise applications can use to automatically retrieve messages from JMS destinations for processing by message-driven beans, without the application having to explicitly poll JMS destinations.

With WebSphere Application Server enterprise services, enterprise applications can use another level of functionality for asynchronous messaging, called extended messaging. The application server manages the messaging infrastructure, and extra standard types of messaging beans are provided to add functionality to that provided by message-driven beans. This level of functionality enables application developers to concentrate on the business logic to be implemented by the enterprise beans and to leave the messaging usage to standard messaging objects and configuration of the extended messaging service.

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure JMS providers and their resources, and can control the activity of the JMS server and the messaging services.

For more information about implementing WebSphere enterprise applications that use asynchronous messaging, see the following topics:

- An overview of WebSphere asynchronous messaging
- Implementing WebSphere enterprise applications that use JMS
- Implementing WebSphere enterprise applications that use message-driven beans

For more information about JMS, see the JMS documentation at <http://java.sun.com/products/jms/docs.html>.

## Asynchronous messaging with WebSphere - an overview

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables WebSphere J2EE applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An J2EE application can explicitly poll for messages on a destination.

WebSphere Application Server also provides a message listener service that J2EE applications can use to automatically retrieve messages from JMS destinations for processing by message-driven beans, without the application having to explicitly poll JMS destinations.

With WebSphere Application Server enterprise services, J2EE applications can use another level of functionality for asynchronous messaging, called extended messaging. The application server manages the messaging infrastructure, and extra standard types of messaging beans are provided to add functionality to that provided by message-driven beans. This level of functionality enables application developers to concentrate on the business logic to be implemented by the Enterprise JavaBeans and to leave the messaging usage to standard messaging objects and configuration of the extended messaging service.

You can use the WebSphere administrative console to administer the WebSphere Application Server support for asynchronous messaging. For example, you can configure JMS providers and their resources, and can control the activity of the JMS server and the messaging services.

**Related concepts**

Security considerations for asynchronous messaging

An overview of messaging using message-driven beans

## Styles of messaging in applications

Applications can use the following styles of asynchronous messaging:

**Point-to-Point**

Point-to-point applications use queues to pass messages between each other. The applications are called point-to-point, because a client sends a message to a specific queue and the message is picked up and processed by a server listening to that queue. It is common for a client to have all its messages delivered to one queue. Like any generic mailbox, a queue can contain a mixture of messages of different types.

**Publish/subscribe**

Publish/subscribe systems provide named collection points for messages, called topics. To send messages, applications publish messages to topics. To receive messages, applications subscribe to topics; when a message is published to a topic, it is automatically sent to all the applications that are subscribers of that topic. By using a topic as an intermediary, message publishers are kept independent of subscribers.

Both styles of messaging can be used in the same application.

Applications can use asynchronous messaging in the following ways:

**One-way**

An application sends a message, and does not want a response. This pattern of use is often referred to as a datagram.

**Request / response**

An application sends a request to another application and expects to receive a response in return.

**One-way and forward**

An application sends a request to another application, which sends a message to yet another application.

These messaging techniques can be combined to produce a variety of asynchronous messaging scenarios.

For more information about how such messaging scenarios are used by WebSphere enterprise applications, see the following topics:

- An overview of asynchronous messaging with JMS
- An overview of asynchronous messaging with message-driven beans
- An overview of extended messaging

For more information about these messaging techniques and the Java Messaging Service (JMS), see Sun's Java Message Service (JMS) specification documentation.

## **WebSphere Application Server cloning and WebSphere MQ clustering**

This topic provides a summary of information about using WebSphere Application Server horizontal cloning with WebSphere MQ server clustering support. It describes a scenario that shows how the message listener service can be configured to take advantage of WebSphere MQ server clustering and provides some information about how to resolve potential runtime failures in the clustering scenario. The information in this topic is based on the scenario shown in the figure WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues.

**Note:** WebSphere MQ server clustering is only available with the full WebSphere MQ product installed as the JMS provider.

For a WebSphere application server configured to use the extended messaging service, each JMS listener is used to retrieve messages from destinations defined to the server. In the following information the listener configurations are the same for each WebSphere application server. Each application server host contains a WebSphere application server and an WebSphere MQ server. If a host is only used to distribute messages, it only contains an WebSphere MQ server. There can be many servers defined in the configuration, although for simplicity the information in this topic is based on a scenario containing only three servers as shown in "WebSphere Application Server cloning and WebSphere MQ clustering."

Figure 1. WebSphere Application Server horizontal cloning with WebSphere MQ clustered queues. This figure shows two WebSphere Application Server hosts, with horizontal clustering, and a messaging host used to distribute messages for WebSphere MQ server clustering. For more information, see the text that accompanies this figure.

The scenario shown in “WebSphere Application Server cloning and WebSphere MQ clustering” on page 7 comprises the following three hosts:

- Server host S1 contains the following servers:

**WebSphere MQ server.**

The server is defined to have a queue manager, QM1, and a local queue, Q1. The queue manager belongs to a cluster. The queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the WebSphere MQ cluster.

**WebSphere Application Server**

This contains a cloned application server, WAS1, which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Server host S2 contains the following servers:

**WebSphere MQ server.**

The server is defined to have a queue manager, QM2, and a local queue, Q1. The queue manager belongs to the same cluster as QM1 on host S1. As with QM1, the queue is populated by the WebSphere MQ server located on host M3. Applications can add messages directly to the queue, Q1, but would not be subjected to the control of the MQ cluster.

**WebSphere Application Server**

This contains a cloned application server, WAS2 (identical to WAS1 on host S1), which is configured with a JMS listener. The listener is configured to retrieve messages from JMS destination Q1.

- Messaging host M3 contains the following servers:

**WebSphere MQ server.**

The server is defined to have a queue manager, QM3, which also

belongs to the same cluster as QM1 and QM2. Applications add messages to the queue manager and queue Q1. The cluster to which this queue manager belongs causes messages to be distributed to all other queue managers in the cluster which have queue Q1 defined.

**Note:** Queue Q1 is not defined as a local queue on this host. If the queue was defined locally, then messages would remain on the server for local processing; messages would not be distributed by the queue manager cluster control to the other queue managers in the cluster that do have the queue defined.

This host does not have a WebSphere application server defined. All message retrieval processing is performed by the other two application servers on hosts S1 and S2.

### Recovery scenarios

There are several failure scenarios that could occur with the clustering configuration; for example:

- WAS server failures.

In this scenario the failure of any single WebSphere application server results in the messages for the specified destination remaining on the queue, until the server is restarted.

- WebSphere MQ Queue Manager failures.

There are two different failures to consider:

1. Failure of a queue manager on the same host as a WebSphere application server (for example, failure of QM2 on host S2). In this case messages are delivered to the other available application servers, until the WebSphere MQ server is back online, when messages are processed as expected.
2. Failure of the messaging host M3 and its queue manager, QM3. In this case, the result of an outage is more significant because no messages are delivered to the other queue managers in the cluster. In a fully-deployed and scaled production system, host M3 would not be designed to be a single point of failure, and additional messaging servers would be added to the cluster configuration.

---

## Using JMS and messaging in applications

Use these tasks to implement WebSphere J2EE applications that use JMS.

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

The base JMS support enables WebSphere enterprise applications to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An enterprise application can explicitly poll for messages on a destination.

Using the base support for JMS, you can build enterprise beans that use the JMS API directly to provide messaging services along with methods that implement business logic.

You can use the WebSphere administrative console to administer the JMS support of WebSphere Application Server. For example, you can configure JMS providers and their resources, and can control the activity of the JMS server.

For more information about implementing WebSphere enterprise applications that use JMS, see the following topics:

- An overview of WebSphere asynchronous messaging using JMS
- Administering WebSphere JMS support
- Developing a J2EE application to use JMS
- Developing a JMS client
- Deploying a J2EE application to use JMS
- Resolving problems with WebSphere JMS

For more information about JMS, see the JMS documentation at <http://java.sun.com/products/jms/docs.html>.

#### **Related tasks**

Implementing WebSphere enterprise applications that use message-driven beans

#### **Related information**

<http://java.sun.com/products/jms/docs.html>

## **WebSphere MQ and IBM WebSphere Application Server**

Applications written in the Java programming language running under IBM WebSphere Application Server can use the Java Messaging Service (JMS) specification to perform messaging. Point-to-point messaging in this environment is provided by a WebSphere MQ for z/OS queue manager. Two classes of configuration are available:

- A reduced function form of WebSphere MQ for z/OS, which is also known as the integral JMS provider, or IJP.

Here, the queue manager providing the point-to-point messaging runs the WebSphere MQ for z/OS base function code provided with IBM WebSphere Application Server. This environment is suited to simple messaging between JMS applications running in the IBM WebSphere Application Server environment.

- Full function WebSphere MQ for z/OS.

Here, the queue manager providing the point-to-point messaging runs WebSphere MQ for z/OS full function code installed as a separate product from IBM WebSphere Application Server for z/OS. In this environment, JMS applications running in the IBM WebSphere Application Server can participate fully in the functionality of a WebSphere MQ for z/OS network. For example, they can make use of the IMS Bridge, or exchange messages with WebSphere MQ for z/OS queue managers running on other platforms.

The information for WebSphere MQ for z/OS is supplied as a number of books, in PDF format. These books describe the full function form of WebSphere MQ for z/OS, but also identify the features, commands, API verbs, and so on, that are unavailable or restricted in the reduced function form. The WebSphere MQ for z/OS Library Web site describes the documentation available.

### **Connection between IBM WebSphere Application Server and a queue manager**

If the queue manager providing point-to-point messaging is a reduced function queue manager, connection must be through either TCP client/server channel. In JMS terms, this means choosing client transport for the queue connection factory object. The integral JMS provier (IJP) supports direct IP transport or MQ transport.

If the queue manager providing point-to-point messaging is a full function queue manager, you can choose either client transport or bindings transport for the queue connection factory object. If you choose bindings transport, the WebSphere

Application Server and the queue manager must both exist on the same z/OS image. If you choose client transport, you must install the Client Attachment feature of WebSphere MQ for z/OS.

Both types of connection support transactional applications: the client transport by using XA protocols; the bindings transport by using a WebSphere Application Server stub, CSQBWSTB, which uses RRS services.

#### **Related concepts**

Resource Recovery Services (RRS)

WebSphere Application Server for z/OS supports resource adapters that use Resource Recovery Services (RRS) to support global transaction processing. RRS is an z/OS extension to the JCA resource adapter specifications.

“Integral JMS provider (IJP)”

#### **Integral JMS provider (IJP)**

The WebSphere MQ for z/OS information tells you what reduced function means by identifying those functions not available in the reduced function form of WebSphere MQ for z/OS supplied with WebSphere Application Server, both in general terms, and at the command level. The list below summarizes the restrictions in the reduced function form of WebSphere MQ for z/OS:

##### **Queue sharing groups**

Queue sharing groups are not available:

- If you set the QSGDATA system parameter to anything other than blank, the queue manager does not start.
- CSQ5PQSG does not run.

##### **Clusters**

Clusters are not available. You cannot:

- Define SYSTEM.CLUSTER queues
- Define, alter, or delete CLUSSDR or CLUSRCVR channels
- Set queue CLUSTER or CLUSNL attributes to anything other than blank
- Set queue manager REPOS or REPOSNL attributes to anything other than blank

The following commands have no effect:

- RESET or REFRESH CLUSTER
- SUSPEND or RESUME QMGR CLUSTER or CLUSNL
- DISPLAY CLUSQMGR

The following functions do not run:

- Mover repository manager
- CLUSSDR or CLUSRCVR channels

##### **Distributed queuing**

The reduced function form of WebSphere MQ for z/OS supplied with WebSphere Application Server does not support channels other than server-connection channels. This means that:

- MCA channels are not available:
  - You cannot define, alter, or delete SDR, SVR, RCVR, or RQSTR channels
  - SDR, SVR, RCVR, or RQSTR channels do not run
- Only SVRCONN channels are available; you cannot define or alter CLNTCONN channels

##### **TCP types other than OESOCKET**

If you set the TCPTYPE system parameter to anything other than OESOCKET, the mover does not start.

**LU62 communications**

You cannot use LU6.2 channels and listeners. Specifically, you must not set the LU62CHL system parameter to anything other than 0 or the mover does not start.

**Events**

Events are not available; you cannot:

- Define SYSTEM.ADMIN queues
- Enable queue manager event attributes

**CICS connection**

There is no support for the WebSphere MQ for z/OS CICS connection. As a result, an MQCONN or MQCONNX from a CICS transaction fails with an MQRC\_CONNECTION ERROR.

**IMS connection**

There is no support for the WebSphere MQ for z/OS IMS connection. As a result, an MQCONN or MQCONNX from an IMS application fails with an MQRC\_CONNECTION ERROR.

**RRS connection**

There is no support for the WebSphere MQ for z/OS RRS connection. As a result, an MQCONN or MQCONNX from an RRS application fails with an MQRC\_CONNECTION ERROR.

**IMS Bridge**

There is no support for the WebSphere MQ for z/OS IMS Bridge; the resource manager does not start.

**Measured usage license charge (MULC)**

This function is bypassed.

## **An overview of WebSphere asynchronous messaging using JMS**

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface. JMS provides a common way for Java programs (clients and J2EE applications) to create, send, receive, and read asynchronous requests, as JMS messages.

This topic provides an overview of asynchronous messaging using JMS support provided by WebSphere Application Server. For more details about JMS, see Sun's Java Message Service (JMS) specification documentation.

The base support for asynchronous messaging using JMS, shown in the figure .dita, provides the common set of JMS interfaces and associated semantics that define how a JMS client can access the facilities of a JMS provider. This enables WebSphere J2EE applications, as JMS clients, to exchange messages asynchronously with other JMS clients by using JMS destinations (queues or topics). An J2EE application can use JMS queue destinations for point-to-point messaging and JMS topic destinations for publish/subscribe messaging. An J2EE application can explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

*Figure 2. Asynchronous messaging using JMS.* This figure shows an enterprise application polling a JMS destination to retrieve an incoming message, which it processes with a business logic bean. The business logic bean uses standard JMS calls to process the message; for example, to extract data or to send the message on to another JMS destination. For more information, see the text that accompanies this figure.

With the base JMS/XA support, the J2EE application uses standard JMS calls to process messages, including any responses or outbound messaging. Responses can be handled by an enterprise bean acting as a sender bean, or handled in the enterprise bean that receives the incoming messages. Optionally, this process can use two-phase commit within the scope of a transaction. This level of functionality for asynchronous messaging is called bean-managed messaging, and gives an enterprise bean complete control over the messaging infrastructure; for example, for connection and session pool management. The application server has no role in bean-managed messaging.

WebSphere Application Server also supports automatic asynchronous messaging using message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) and JMS listeners (part of the JMS application server facilities). Messages are automatically retrieved from JMS destinations, optionally within a transaction, then sent to the message-driven bean in an J2EE application, without the application having to explicitly poll JMS destinations. For more information about asynchronous messaging with message-driven beans, see *An overview of asynchronous messaging with message-driven beans*

With WAS Enterprise, J2EE applications can use another level of functionality for asynchronous messaging called extended messaging. The application server manages the messaging infrastructure, and extra standard types of messaging beans are provided to add functionality to that provided by message-driven beans. This level of functionality enables application developers to concentrate on the business logic to be implemented by the enterprise beans and to leave the messaging usage to standard messaging objects and configuration of the extended messaging service.

An overview of messaging using message-driven beans

## WebSphere JMS support - components

The main components of WebSphere JMS support are shown in the following figure and described after the figure:

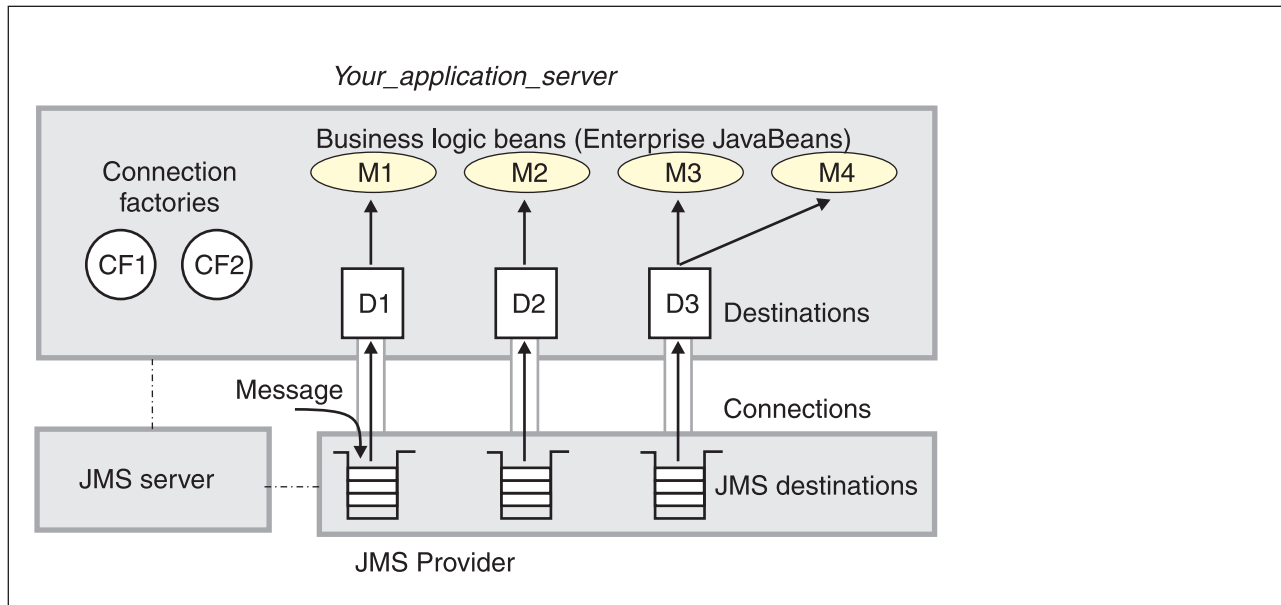

Figure 3. The main components of WebSphere JMS support. This figure shows the main components of WebSphere JMS support, from JMS provider through a connection to a destination, then to a WebSphere enterprise application (acting as a JMS client) that processes the message retrieved from the destination. For more information, see the text that accompanies this figure.

WebSphere Application Server supports asynchronous messaging based on the Java Messaging Service (JMS) of a JMS provider that conforms to the JMS specification version 1.0.2 and supports the Application Server Facility (ASF) function defined within that specification. WebSphere Application Server provides an embedded JMS provider and administration objects for WebSphere MQ as the JMS provider. You can use the embedded JMS provider, install WebSphere MQ JMS on top of the embedded WebSphere JMS, or install and configure another JMS provider.

JMS functions (of JMS providers) within the WebSphere Application Server administration domain are served by one or more JMS servers. There can be at most one JMS server on each node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

A connection factory is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

A WebSphere J2EE application can explicitly poll for messages on a destination then retrieve messages for processing by business logic beans (enterprise beans).

The WebSphere Application Server support for message-driven beans and extended messaging builds on this base JMS support. For more information, see the related topics.

### Related concepts

Message-driven beans - components

## WebSphere MQ JMS connection pooling

To improve the overall performance of JMS within the system, the message listener service enables the connection pooling facility provided by the WebSphere MQ JMS implementation. This support does not affect the performance of a message listener, because it retains its connections while listening on a destination, but does affect the overall JMS system performance. When a connection is no longer required, WebSphere MQ can pool the connection then reuse it later instead of destroying it.

**Note:** This support is only available if WebSphere MQ is configured as the JMS provider.

To enable WebSphere MQ connection pooling and configure the characteristics of the WebSphere MQ connection pool, see *Enabling WebSphere MQ JMS connection pooling*.

## Administering WebSphere JMS support

Use these tasks with the WebSphere administrative console to manage JMS providers and their resources, and other runtime components of WebSphere JMS support.

You can use the WebSphere administrative console to configure the embedded WebSphere JMS provider or an WebSphere MQ JMS provider. If you install another JMS provider, you need to configure that JMS provider by using the tools and information provided with the JMS provider. For each JMS provider, you can configure the properties of JMS resources.

You can also use the WebSphere administrative console to configure and control other runtime components of WebSphere JMS support, including the following:

- The WebSphere JMS server
- The message listener service, listener ports, and the listener for each message-driven bean
- Input and output ports for extended messaging.

You can update the configuration data at any time, but if it is updated, the updates only take effect when the appropriate server is next started.

For information about the specific tasks used to administer WebSphere JMS support, see the following topics:

- Installing and configuring a JMS provider
- Moving from the internal JMS provider to WebSphere MQ
- Enabling security for the embedded WebSphere JMS provider
- Displaying administrative lists of JMS resources
- Managing WebSphere internal JMS servers
- Configuring JMS provider resources

For more information about JMS resources, see the JMS documentation at <http://java.sun.com/products/jms/docs.html>.

Administering message listeners for message-driven beans

## Installing and configuring a JMS provider

This topic describes the different ways that you can implement a JMS provider for use with WebSphere Application Server.

For IBM WebSphere Application Server to support bean-managed messaging, you need to install and configure one or more JMS providers that conform to the JMS specification version 1.0.2. To use message-driven beans the JMS provider must support the Application Server Facility (ASF) function defined within that specification.

You can install and use the Embedded Messaging Server option of WebSphere Application Server, install WebSphere MQ as the JMS provider, or install another “generic” JMS provider. If you install both embedded messaging and WebSphere MQ as JMS providers, for example, WebSphere applications can use JMS resources provided by both the embedded WebSphere JMS provider and the WebSphere MQ JMS provider.

- Installing WebSphere embedded messaging as the JMS provider

**Note:**

- WebSphere embedded messaging as the JMS provider supports both queues (for point-to-point messaging) and topics (for publish/subscribe messaging).
  - You can install IBM WebSphere Application Server with embedded messaging on the same host as an existing WebSphere MQ installation, which must be at a supported level of MQ features.
  - You can install IBM WebSphere Application Server with embedded messaging then later install WebSphere MQ for use as a JMS provider.
- Installing WebSphere MQ as the JMS provider.

**Note:**

- You can install WebSphere MQ before IBM WebSphere Application Server. If you then want to install embedded messaging, you must ensure that the WebSphere MQ installation is at a supported level of MQ features.
  - If you do not want to use the embedded WebSphere JMS provider, you can install IBM WebSphere Application Server without the **Embedded Messaging Server** option. You are recommended to install and use the WebSphere Application Server **Embedded Messaging Client**.
  - You can install WebSphere MQ for use as a JMS provider on top of WebSphere Application Server embedded messaging; this results in a single JMS installation.
    - For point-to-point messaging WebSphere applications can continue to use WebSphere queue resources (through the embedded messaging JMS provider) or WebSphere MQ queue resources that you define to IBM WebSphere Application Server.
    - For publish/subscribe messaging, WebSphere applications can continue to use WebSphere topic resources (through the embedded messaging JMS provider) or WebSphere MQ topic resources that you define to IBM WebSphere Application Server, and which are provided by a Publish/Subscribe broker installed in addition to the base WebSphere MQ.
  - If you install WebSphere MQ as the JMS provider, you can use the WebSphere administrative console to administer the WebSphere MQ JMS provider resources, such as queue connection factories. However, you cannot administer MQ security, which is administered through WebSphere MQ.
- Installing another JMS provider, which must conform to the JMS specification and, to use message-driven beans, support the ASF function. If you want to use a JMS provider other than the embedded WebSphere JMS provider or a WebSphere MQ JMS provider, you should complete the following steps:

1. Installing and configuring the JMS provider and its resources by using the tools and information provided with the JMS provider.
2. Defining the JMS provider to WebSphere Application Server as a generic JMS provider.

**Note:** You cannot use the WebSphere administrative console to administer the JMS provider or its resources.

For more information about scenarios and considerations for using WebSphere MQ with IBM WebSphere Application Server, see the White Papers and Red books provided by WebSphere MQ; for example, through the WebSphere MQ library Web page at <http://www-3.ibm.com/software/ts/mqseries/library/>

To install a JMS provider for IBM WebSphere Application Server, consider the following scenarios:

**A new IBM WebSphere Application Server server machine, hostA.**

This scenario starts with adding embedded messaging as the JMS provider, then optionally adding WebSphere MQ as an alternative JMS provider. Each stage summarizes the messaging functions that can be added.

1. Installing embedded messaging as the only JMS provider.

You want to be able to run WebSphere applications that use the WebSphere JMS resources for both point-to-point and publish/subscribe messaging.

- a. Install IBM WebSphere Application Server with the **Embedded Messaging Server** and **Embedded Messaging Client** options.
- b. Use the administrative console to configure WebSphere JMS resources; for example, WebSphere Queue Connection Factories and WebSphere Topic Connection Factories.
- c. On any client machines that are to use the WebSphere JMS resources, install IBM WebSphere Application Server with the **Embedded Messaging Client** option.

2. Adding WebSphere MQ as an alternative JMS provider for point-to-point messaging.

Besides the point-to-point and publish/subscribe messaging that uses the embedded WebSphere JMS resources (from the preceding step), you want to be use WebSphere MQ Queue resources for point-to-point messaging.

- a. Install WebSphere MQ 5.3 with the required features. For more information about installing WebSphere MQ, see the WebSphere MQ Quick Beginnings book for your machine's platform.
- b. Use the administrative console to configure WebSphere MQ Queue Connection Factories and WebSphere MQ Queue Destinations.

3. Adding WebSphere MQ Event Broker for alternative publish/subscribe messaging.

For publish/subscribe messaging, you want to be able to run WebSphere applications that use the WebSphere MQ Topic resources or the embedded WebSphere Topic resources (such as those configured in preceding steps).

- a. Install WebSphere MQ Event Broker. For more information about installing WebSphere MQ Event Broker, see the WebSphere MQ Event Broker Installation Guide for your machine's platform.
- b. Use the administrative console to configure WebSphere MQ Topic Connection Factories and WebSphere MQ Topic Destinations.

**An existing WebSphere MQ 5.2 server and broker machine, hostA, where you want to install embedded messaging as the JMS provider.**

1. Upgrade to WebSphere MQ 5.3 with the required features. For more information about upgrading to WebSphere MQ 5.3, see “Migrating from an earlier version” in the WebSphere MQ Quick Beginnings book for your machine’s platform.
2. To continue using publish/subscribe messaging, upgrade to a supported broker such as WebSphere MQ Event Broker.
3. Install IBM WebSphere Application Server with the **Embedded Messaging Server** and **Embedded Messaging Client** options.
4. Use the administrative console to configure WebSphere JMS resources; for example, WebSphere Queue Connection Factories and WebSphere Topic Connection Factories.
5. If you want WebSphere applications to use the WebSphere MQ resources, use the administrative console to configure WebSphere MQ JMS resources; for example, WebSphere MQ Queue Connection Factories and WebSphere MQ Destinations.
6. On any client machines that are to use the WebSphere JMS resources, install IBM WebSphere Application Server with the **Embedded Messaging Client** option.

You can run WebSphere applications that use both the WebSphere JMS resources and WebSphere MQ JMS resources for messaging.

**An existing WebSphere MQ server machine, hostA, where you want to use WebSphere MQ as the only JMS provider.**

1. For point-to-point messaging, ensure that you have installed WebSphere MQ 5.3 with required features. For publish/subscribe messaging, ensure that you have also installed a supported broker such as WebSphere MQ Event Broker. For more information about installing WebSphere MQ 5.3 and Event Broker, see the WebSphere MQ Quick Beginnings book and WebSphere MQ Event Broker Installation Guide for your machine’s platform.
2. Install IBM WebSphere Application Server without any of the **Embedded Messaging Server** and **Embedded Messaging Client** options.
3. Use the administrative console to configure WebSphere MQ JMS resources; for example, WebSphere MQ Queue Connection Factories and WebSphere MQ Topic Connection Factories.
4. On any client machines that are to use the WebSphere JMS resources, install IBM WebSphere Application Server with the **Embedded Messaging Client** option.

You can run WebSphere applications that use the WebSphere MQ JMS resources for point-to-point or (with a supported broker installed) publish/subscribe messaging.

**Related tasks**

Moving from the embedded WebSphere JMS provider to WebSphere MQ

**Related information**

WebSphere MQ messaging platform-specific books

WebSphere MQ Event Broker Installation Guide for your machine’s platform

<http://java.sun.com/products/jms/docs.html>

**Installing WebSphere MQ as the JMS provider:**

Use this task to install and configure WebSphere MQ with support for the Java Message Service (JMS) for use with the WebSphere Application Server.

To install and configure WebSphere MQ (MQSeries) for use as a JMS provider to IBM WebSphere Application Server, complete the following steps:

1. Install WebSphere MQ 5.3, with the required MQ features, as described in the installation instructions provided with WebSphere MQ.

These notes apply both if you want to use an existing WebSphere MQ 5.3 installation or if you want to install, or upgrade to, a new WebSphere MQ 5.3 installation.

**Note:** The WebSphere Application Server Enterprise package includes copies of the WebSphere MQ 5.3 and Event Broker installation packages, with restricted licensing for use with WebSphere Application Server Enterprise. (WebSphere MQ Event Broker is not available for Linux.) For more information about the usage restrictions for the WebSphere MQ 5.3 and Event Broker installation packages, see the WebSphere Application Server Enterprise licensing information.

If you want to use the original WebSphere MQ 5.3 release, ensure that you install the CSD03 update.

If you want to use WebSphere MQ 5.3 on the same machine as WebSphere Application Server embedded messaging, ensure that you install the following MQ features:

- For a WebSphere Application Server **Embedded Messaging Server** installation, the required MQ features are “Server” and “Java Messaging”.
- For a WebSphere Application Server **Embedded Messaging Client** installation, the only required MQ feature is “Java Messaging”.

You can use the WebSphere MQ 5.3 installation package provided with WebSphere Application Server Enterprise to install the required MQ features into an existing WebSphere MQ 5.3 or to install a new WebSphere MQ 5.3 with the required MQ features for use with WebSphere Application Server Enterprise subject to the licensing conditions.

For information about installing WebSphere MQ 5.3, or migrating to WebSphere MQ 5.3 from an earlier release, see the appropriate WebSphere MQ *Quick Beginnings* book, as listed above.

2. If you want to use WebSphere MQ - Publish/Subscribe support, you need to provide a Publish/Subscribe broker.

For example, you can do this by using either WebSphere MQ Event Broker or WebSphere MQ Integrator (formerly MQSeries Integrator). For more information about these products, see the following Web sites:

- WebSphere MQ Event Broker Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#eventb>
- WebSphere MQ Integrator Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#integrator>

3. Follow the WebSphere MQ 5.3 instructions for verifying your installation setup.
4. For AIX, see the WebSphere MQ 5.3 readme.txt for additional steps.
5. If you want to install IBM WebSphere Application Server on the same host as WebSphere MQ, and have not yet done so, install IBM WebSphere Application Server. If you do not want to use the embedded WebSphere JMS provider, you can install WebSphere MQ then install WebSphere Application Server without the **Embedded Messaging Server** option. You are recommended to install and use the WebSphere Application Server **Embedded Messaging Client**.

6. Set the MQJMS\_LIB\_ROOT environment variable to the directory where WebSphereMQ\Java\lib is installed. IBM WebSphere Application Server uses the MQJMS\_LIB\_ROOT to locate the WebSphere MQ libraries for the WebSphere MQ JMS Provider.

This task has installed WebSphere MQ for use as the JMS provider with WebSphere Application Server.

You can configure JMS resources to be provided by WebSphere MQ, by using the WebSphere administrative console to define WebSphere MQ resources.

#### **Related tasks**

Moving from the embedded WebSphere JMS provider to WebSphere MQ  
Configuring resources for the WebSphere MQ JMS provider

#### **Defining a generic JMS provider:**

Use this task to define a new JMS provider to WebSphere Application Server, for use instead of the embedded WebSphere JMS provider or a WebSphere MQ JMS provider.

Before starting this task, you should have installed and configured the JMS provider and its resources by using the tools and information provided with the JMS provider.

To define a new generic JMS provider to WebSphere Application Server, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> Generic JMS Providers** This displays the existing generic JMS providers in the content pane.
2. To define a new generic JMS provider, click **New** in the content pane. Otherwise, to change the definition of an existing JMS provider, click the JMS provider. This displays the properties used to define the JMS provider in the content pane.
3. Specify appropriate properties for the JMS provider.
4. Click **OK**.
5. To save your configuration, click **Save** on the task bar of the Administrative console window.
6. To have the changed configuration take effect, stop then restart the application server.

#### **Related information**

Properties of a generic JMS provider

#### **Installing WebSphere embedded messaging as the JMS provider:**

Use this task to install the Embedded Messaging options of IBM WebSphere Application Server for use as the JMS provider.

Installing the WebSphere embedded messaging feature for WebSphere Application Server for z/OS V5 is done in two parts:

- The first part consists of the SMP/E install process and as such is documented in detail in the IBM WebSphere Application Server for z/OS V5 Program Directory.

- The second part consists of the customization process which is completed using the Customization Dialog. This process is documented in detail in the IBM WebSphere Application Server for z/OS V5 Installation and Customization Guide.

Both of these publications are readily available on the WebSphere Application Server for z/OS library page.

If you have installed the Embedded Messaging Server option on top of WebSphere MQ, the MQ command `setmqcap` is set to use parameter 0 instead of -1, which results in:

- Issuing a license-unit message to the MQ console window whenever a queue manager starts
- Writing a message to the MQ error log

To prevent this, after you have completed the installation of IBM WebSphere Application Server, issue the `setmqcap -1` command from a command line.

### **Moving from the embedded WebSphere JMS provider to WebSphere MQ**

Use this task to move from the embedded WebSphere JMS provider to WebSphere MQ as the provider of messaging services and resources for WebSphere enterprise applications.

To move from the embedded WebSphere JMS provider to WebSphere MQ as the provider of messaging services and resources for WebSphere enterprise applications, you need to install and configure a supported level of WebSphere MQ with the required MQ features.

Existing JMS resource definitions for the embedded WebSphere JMS provider continue to work with WebSphere MQ as the JMS provider, so you do not need to redefine those JMS resources. However, to take advantage of the extra configuration options for WebSphere MQ, you can use the administrative console to define new JMS resources as WebSphere MQ resources; for example, to define MQ Queue Connection Factories.

1. For WebSphere MQ point-to-point messaging, install the base WebSphere MQ product.
2. Configure WebSphere MQ queue resources to IBM WebSphere Application Server.
  - For point-to-point messaging WebSphere applications can continue to use WebSphere queue resources (through the embedded messaging JMS provider) or WebSphere MQ queue resources.
  - For publish/subscribe messaging, WebSphere applications can continue to use WebSphere topic resources (through the embedded messaging JMS provider).
3. For WebSphere MQ publish/subscribe messaging, install a Publish/Subscribe broker, such as WebSphere MQ Event Broker.

For more information about installing WebSphere MQ Event Broker or WebSphere MQ Integrator (formerly MQSeries Integrator), see the following Web sites:

- WebSphere MQ Event Broker Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#eventb>
- WebSphere MQ Integrator Web site at <http://www-4.ibm.com/software/ts/mqseries/platforms/#integrator>

4. Configure WebSphere MQ topic resources to IBM WebSphere Application Server. For publish/subscribe messaging, WebSphere applications can continue to use WebSphere topic resources (through the embedded messaging JMS provider) or WebSphere MQ topics.

## **Managing WebSphere internal JMS servers**

Use this task to manage WebSphere internal JMS servers on WebSphere Application Server Network Deployment and WebSphere Application Server Enterprise.

Each JMS server provides the functions of the JMS provider for a node in your administrative domain. There can be at most one JMS server on each node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

You can use the WebSphere administrative console to display a list of all JMS servers, to show and control their runtime status. You can also configure a general set of JMS server properties, which add to the default values of WebSphere MQ properties configured automatically for the embedded WebSphere JMS provider.

**Note:** In general, the default values of WebSphere MQ properties are adequate for WebSphere internal JMS servers. However, if you are running high messaging loads, you may need to change some WebSphere MQ properties; for example, WebSphere MQ properties for log file locations, file pages, and buffer pages. For more information about configuring WebSphere MQ properties, see the *WebSphere MQ System Administration* book, SC33-1873, which is available from the IBM Publications Center or from the WebSphere MQ collection kit, SK2T-0730.

To manage a WebSphere internal JMS server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> JMS Servers**. This displays a table of the JMS servers, showing their runtime status.
2. If you want to change the runtime status of a JMS server, complete the following steps:
  - a. In the table of JMS servers, select the JMS servers that you want to act on.
    - To act on one or more specific JMS servers, select the checkbox next to the JMS server name.
    - To act on all JMS servers, select the checkbox next to the JMS servers title of the table.

- b. Click one of the actions displayed to change the status of the JMS servers; for example, click **Stop** to stop a JMS server.

The status of the JMS servers that you have acted on is updated to show the result of your actions.

3. If you want to change the properties of a JMS server, click the name of the JMS server. This displays the properties of the JMS server in the content pane.
4. Specify appropriate properties for the JMS server.  
If you want the JMS server to be started automatically, set the **Initial state** property to started.  
If you want to add a new queue to be hosted by the JMS server, add the administrative name of the queue to the Queue Names field. (The name must match the name of a WebSphere Queue administrative object, including the use of upper- and lowercase.) Similarly, if you want to remove a queue from the JMS server, remove its name from that field.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the JMS Server.

## **Configuring JMS provider resources**

Use the following tasks to configure JMS provider resources needed to support enterprise beans that exploit JMS services.

- Configuring resources for the embedded WebSphere JMS provider
  - Configuring a queue connection factory
  - Configuring a topic connection factory
  - Configuring a queue destination
  - Configuring a topic destination
- Configuring resources for the WebSphere MQ JMS provider
  - Configuring a queue connection factory
  - Configuring a topic connection factory
  - Configuring a queue destination
  - Configuring a topic destination
- Configuring resources for a generic JMS provider
  - Configuring a JMS connection factory
  - Configuring a JMS destination

### **Configuring resources for the embedded WebSphere JMS provider:**

Use the following tasks to configure the connection factories and destinations for the embedded WebSphere JMS provider.

You only need to complete these tasks if your WebSphere Application Server environment uses the embedded WebSphere JMS provider to support enterprise applications that use JMS.

- Configuring a queue connection factory
- Configuring a topic connection factory
- Configuring a queue destination
- Configuring a topic destination

*Configuring a queue connection factory, embedded WebSphere JMS provider:*

Use this task to configure the properties of a queue connection factory for use with the embedded WebSphere JMS provider. This task contains an optional step for you to create a new queue connection factory.

To configure the properties of a queue connection factory for use with the embedded WebSphere JMS provider, use the administrative console to complete the following steps:

1. Display the embedded WebSphere JMS provider.
  - a. In the navigation pane, click **Resources-> WebSphere JMS Provider**
  - b. In the content pane, click the name of the WebSphere JMS provider that you want to work with.

This displays in the content pane a table of properties for the WebSphere JMS provider, including links to the types of JMS resources supported by the JMS provider.

2. In the content pane, under Additional Properties, click **WebSphere Queue Connection Factories** This displays any existing queue connection factories for the WebSphere JMS provider in the content pane.
3. To create a new queue connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing queue connection factory, click one of the connection factories displayed. This displays the properties for the queue connection factory in the content pane.
4. Specify appropriate properties for the queue connection factory.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

**Related tasks**

*Configuring a topic connection factory, embedded WebSphere JMS provider:*

Use this task to configure the properties of a topic connection factory for use with the embedded WebSphere JMS provider. This task contains an optional step for you to create a new topic connection factory.

To configure the properties of a topic connection factory for use with the embedded WebSphere JMS provider, use the administrative console to complete the following steps:

1. Display the embedded WebSphere JMS provider.
  - a. In the navigation pane, click **Resources-> WebSphere JMS Provider**
  - b. In the content pane, click the name of the WebSphere JMS provider that you want to work with.

This displays in the content pane a table of properties for the WebSphere JMS provider, including links to the types of JMS resources supported by the JMS provider.

2. In the content pane, under Additional Properties, click **WebSphere Topic Connection Factories** This displays any existing topic connection factories for the WebSphere JMS provider in the content pane.
3. To create a new topic connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing topic connection factory, click one of the connection factories displayed. This displays the properties for the topic connection factory in the content pane.
4. Specify appropriate properties for the topic connection factory.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

**Related reference**

*Configuring a queue destination, embedded WebSphere JMS provider:*

Use this task to configure the properties of a queue destination for use with the embedded WebSphere JMS provider. This task contains an optional step for you to create a new queue destination.

To configure the properties of a queue destination for use with the embedded WebSphere JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider** This displays in the content pane a table of properties for the WebSphere JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the content pane, under Additional Properties, click **WebSphere Queue Destinations** This displays any existing queue destinations for the WebSphere JMS provider in the content pane.
3. To create a new queue destination, click **New** in the content pane. Otherwise, to change the properties of an existing queue destination, click one of the destinations displayed. This displays the properties for the queue destination in the content pane.
4. Specify appropriate properties for the queue destination.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To make a queue destination available to applications, you need to host the queue on a JMS server. To add a new queue to a JMS server or to change an existing queue on a JMS server, you define the administrative name of the queue to the JMS server, as described in Managing WebSphere internal JMS servers.
8. To have the changed configuration take effect, stop then restart the application server.

**Related reference**

## Properties of topic connection factories, WebSphere MQ JMS provider

### *Configuring a queue destination, WebSphere MQ JMS provider:*

Use this task to configure the properties of a queue destination for use with the WebSphere MQ JMS provider. This task contains an optional step for you to create a new queue destination factory.

To configure the properties of a queue destination factory for use with the WebSphere MQ JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources-> WebSphere MQ JMS Provider** This displays in the content pane a table of properties for the WebSphere MQ JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the contents pane, under Additional Properties, click **WebSphere MQ Queue Destinations** This displays a table listing any existing queue destinations, with a summary of their properties.
3. To define a new queue destination, click **New** in the content pane. Otherwise, to change the properties of an existing queue destination, click one of the destinations displayed. This displays the properties for the queue destination in the content pane.
4. Specify appropriate properties for the queue destination.
5. If you have already defined the properties for the queue manager that is to host the queue, the queue connection properties defined to WebSphere MQ are automatically retrieved and displayed. Otherwise, define the queue connection properties.

**Note:** To be able to view or change these properties, the WebSphere MQ Queue Manager on which the queue resides must be configured for remote administration and be running.

More details about these properties are provided in WebSphere MQ config properties for the queue destination.

6. If needed, change the WebSphere MQ config properties for the queue destination.
7. Click **Apply**.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.
9. To have the changed configuration take effect, stop then restart the application server.

#### **Related reference**

### *Configuring a topic destination, WebSphere MQ JMS provider:*

Use this task to configure the properties of a topic destination for use with the WebSphere MQ JMS provider. This task contains an optional step for you to create a new topic destination factory.

To configure the properties of a topic destination factory for use with the WebSphere MQ JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources-> WebSphere MQ JMS Provider** This displays in the content pane a table of properties for the WebSphere MQ JMS provider, including links to the types of JMS resources supported by the JMS provider.
2. In the content pane, under Additional Properties, click **WebSphere MQ Topic Destinations** This displays a table listing any existing topic destinations, with a summary of their properties.
3. To create a new topic destination, click **New** in the content pane. Otherwise, to change the properties of an existing topic destination, click one of the destinations displayed. This displays the properties for the topic destination in the content pane.
4. Specify appropriate properties for the topic destination.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

#### **Related reference**

Properties of topic destinations, WebSphere MQ JMS provider

*Configuring WebSphere MQ JMS connection pooling:*

Use this task to configure properties of WebSphere MQ JMS connection pooling.

To enable WebSphere MQ JMS connection pooling, complete the following steps:

1. Start the WebSphere Administrative console.
2. In the navigation pane, select **Servers-> Application Servers-> your\_app\_server** This displays the properties of the application server, *your\_app\_server*, in the content pane.
3. In the Additional Properties table, select **Message Listener Service properties** This displays the Message Listener Service properties in the content pane.
4. Select Custom Properties, then add the following properties:
  - mqjms.pooling.threshold**  
The maximum number of unused connections in the pool.
  - mqjms.pooling.timeout**  
The timeout in milliseconds for unused connections in the pool.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

#### **Related concepts**

WebSphere MQ connection pooling

#### **Configuring resources for a generic JMS provider:**

Use the following tasks to configure the connection factories and destinations for a generic JMS provider (not the embedded WebSphere JMS provider or the WebSphere MQ JMS provider).

You only need to complete these tasks if your WebSphere Application Server environment uses another JMS provider to support enterprise applications that use JMS. To enable use of another JMS provider, you must have installed and configured the JMS provider, as described in *Defining a new JMS provider to WebSphere Application Server*.

- Configuring a JMS connection factory
- Configuring a JMS destination

*Configuring a JMS connection factory, generic JMS provider:*

Use this task to configure the properties of a JMS connection factory for use with a generic JMS provider other than the embedded WebSphere JMS provider or WebSphere MQ.

To configure the properties of a JMS connection factory for use with a generic JMS provider, use the administrative console to complete the following steps:

1. Display the JMS provider.
  - a. In the navigation pane, click **Resources-> Generic JMS Providers**
  - b. In the content pane, click the name of the JMS provider that you want to work with.

This displays in the content pane a table of properties for the JMS provider, including links to the types of JMS resources supported by the JMS provider.

2. In the Additional Properties list in the contents pane, select **JMS Connection Factories** This displays a table listing any existing JMS connection factories, with a summary of their properties.
3. To create a new JMS connection factory, click **New** in the content pane. Otherwise, to change the properties of an existing JMS connection factory, click one of the connection factories displayed. This displays the properties for the JMS connection factory in the content pane.
4. Specify appropriate properties for the JMS connection factory.
5. Click **OK**.
6. To save your configuration, click **Save** on the task bar of the Administrative console window.
7. To have the changed configuration take effect, stop then restart the application server.

#### **Related reference**

Properties of queue connection factories, generic JMS provider

*Configuring a JMS destination, a generic JMS provider:*

Use this task to configure the properties of a JMS destination for use with a generic JMS provider (other than the embedded WebSphere JMS provider or the WebSphere MQ JMS provider).

To configure the properties of a JMS destination for use with a generic JMS provider, use the administrative console to complete the following steps:

1. In the navigation pane, click **Resources-> Generic JMS Providers** This displays in the content pane a list of any existing generic JMS providers.
2. In the content pane, click the JMS provider that you want to support the JMS destination. This displays in the content pane a table of properties for the JMS provider, including links to the types of JMS resources supported by the JMS provider.

3. In the Additional Properties list in the contents pane, select **JMS Destinations**. This displays a table listing any existing JMS destinations, with a summary of their properties.
4. To create a new JMS destination, click **New** in the content pane. Otherwise, to change the properties of an existing queue destination, click one of the destinations displayed. This displays the properties for the JMS destination in the content pane.
5. Specify appropriate properties for the JMS destination.
6. Click **OK**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

Properties of queue destinations, generic JMS provider

## Configuring authorization security for the embedded WebSphere JMS provider

Use this task to configure authorization security for the embedded WebSphere JMS provider.

To configure authorization security for the embedded WebSphere JMS provider complete the following steps.

**Note:** Security for the embedded WebSphere JMS provider is enabled when you enable global security for WebSphere Application Server. For more information about enabling global security, see *Managing secured applications*.

1. Configure authorization settings to access JMS resources owned by the embedded WebSphere JMS provider. Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by settings in the *wemspath/wempsname/config/integral-jms-authorizations.xml* file.

The settings grant or deny authenticated userids access to internal JMS provider resources (queues or topics). As supplied, the *integral-jms-authorisations.xml* file grants the following permissions:

- Read and write permissions to all queues.
- Pub, sub, and persist to all topics.

To configure authorization settings, edit the *integral-jms-authorisations.xml* file according to the information in this topic and in that file.

2. Edit the *queue-admin-userids* element to create a list of userids with administrative access to all queues. Administrative access is needed to create queues and perform other administrative activities on queues. For example, consider the following *queue-admin-userids* section:

```
<queue-admin-userids>
  <userid>adminid1</userid>
  <userid>adminid2</userid>
</queue-admin-userids>
```

In this example the userids *adminid1* and *adminid2* are defined to have administrative access to all queues.

3. Edit the *queue-default-permissions* element to define the default queue access permissions. These permissions are used for queues for which you do not

define specific permissions (in queue sections). If this section is not specified, then access permissions exist only for those queues for which you have specifically created queue elements.

For example, consider the following queue-default-permissions element:

```
<queue-default-permissions>
  <permission>write</permission>
</queue-default-permissions>
```

In this example the default access permission for all queues is **write**. This can be overridden for a specific queue by creating a queue element that sets its access permission to **read**.

4. If you want to define specific access permissions for a queue, create a queue element, then define the following elements:

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
  </public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

In this example for the queue q1, the userid `useridr` has read permission, the userid `useridw` has write permission, the userid `useridrw` has both read and write permissions, and all other userids have no access permissions (`<public></public>`).

5. Edit topic elements to define the access permissions for publish/subscribe topic destinations.

For topics, you can grant and deny access permissions. Full permission inheritance is supported on topics. If you do not define specific access permissions for a userid on a specific topic then permissions are inherited first from the public permissions on that topic then from the parent topic. The inheritance of access permissions continues until the root topic from which the root permissions are assumed.

- a. If you want to define default access permissions for the root topic, edit a topic element with an empty name element. If you omit such a topic section, topics have no default topic permissions other than those defined by specific topic elements. For example, consider the following topic element for the root topic:

```
<topic>
  <name></name>
  <public>
    <permission>+pub</permission>
  </public>
</topic>
```

In this example, the default access permission for all topics is set to publish. This can be overridden by other topic elements for specific topic names.

- b. If you want to define access permissions for a specific topic, create a topic element with the name for the topic then define the access permissions in the public and authorize elements of the topic element. For example, consider the following topic section:

```
<topic>
  <name>a/b/c</name>
  <public>
    <permission>+sub</permission>
  </public>
  <authorize>
    <userid>useridpub</userid>
    <permission>+pub</permission>
  </authorize>
</topic>
```

In this example, the subscribe permission is granted to anyone accessing any topic whose name starts with a/b/c. Also, the userid `useridpub` is granted publish permission for any topic whose name starts with a/b/c.

6. Save the `integral-jms-authorizations.xml` file.

If the dynamic update setting is selected, changes to the `integral-jms-authorizations.xml` file become active when the changed file is saved, so there is no need to stop and restart the JMS server. If the dynamic update setting is not selected, you need to stop and restart the JMS server to make changes active.

Dynamic updating is available, by ensuring proper tagging in the `integral-jms-authorizations.xml` file `<dynamic-update>true</dynamic-update>`.

#### **Related concepts**

Security considerations for asynchronous messaging

#### **Related tasks**

Managing WebSphere internal JMS servers

Configuring JMS provider resources

#### **Authorization settings for embedded WebSphere JMS provider resources:**

Use the `integral-jms-authorizations.xml` file to view or change the authorization settings for JMS resources owned by the embedded WebSphere JMS provider.

Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by the following settings in the `wemppath/wempsname/config/integral-jms-authorizations.xml` file.

This structure of the settings in `integral-jms-authorizations.xml` is shown in the following example. Descriptions of these settings are provided after the example. To configure authorization settings, follow the instructions provided in [Configuring authorization security for the embedded WebSphere JMS provider](#)

```
<integral-jms-authorizations>

  <dynamic-update>true</dynamic-update>

  <queue-admin-userids>
    <userid>adminid1</userid>
    <userid>adminid2</userid>
  </queue-admin-userids>
```

```

<queue-default-permissions>
  <permission>write</permission>
</queue-default-permissions>

<queue>
  <name>q1</name>
  <public>
  </public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
</queue>

<queue>
  <name>q2</name>
  <public>
    <permission>write</permission>
  </public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
</queue>

<topic>
  <name></name>
  <public>
    <permission>+pub</permission>
  </public>
</topic>

<topic>
  <name>a/b/c</name>
  <public>
    <permission>+sub</permission>
  </public>
  <authorize>
    <userid>useridpub</userid>
    <permission>+pub</permission>
  </authorize>
</topic>

</integral-jms-authorizations>

```

*dynamic-update*: Controls whether or not the JMS Server checks dynamically for updates to this file.

**true** (Default) Enables dynamic update support.

**false** Disables dynamic update checking and improves authorization performance.

*queue-admin-userids*: This element lists those userids with administrative access to all WebSphere queue destinations. Administrative access is needed to create queues and perform other administrative activities on queues. You define each userid within a separate userid sub element:

**<userid>adminid</userid>**

Where *adminid* is a user ID that can be authenticated by IBM WebSphere Application Server.

*queue-default-permissions*: This element defines the default queue access permissions that are assumed if no permissions are specified for a specific queue name. These permissions are used for queues for which you do not define specific permissions (in queue elements). If this element is not specified, then no access permissions exist unless explicitly authorized for individual queues.

You define the default permission within a separate permission sub element:

**<permission>read-write</permission>**

Where *read-write* is one of the following keywords:

**read** By default, userids have read access to WebSphere queue destinations.

**write** By default, userids have write access to WebSphere queue destinations.

*queue*: This element contains the following authorization settings for a single queue destination:

**name** The name of the queue.

**public** The default public access permissions for the queue. This is used only for those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the queue.

You define each default permission within a separate permission element.

**authorize**

The access permissions for a specific userid. Within each authorize element, you define the following elements:

**userid** The userid that you want to assign a specific access permission.

**permission**

An access permission for the associated userid.

You define each permission within a separate permission element.

Each permission element can contain the keyword read or write to define the access permission.

For example, consider the following queue element:

```
<queue>
  <name>q1</name>
  <public>
</public>
  <authorize>
    <userid>useridr</userid>
    <permission>read</permission>
  </authorize>
  <authorize>
    <userid>useridw</userid>
    <permission>write</permission>
  </authorize>
  <authorize>
    <userid>useridrw</userid>
    <permission>read</permission>
    <permission>write</permission>
  </authorize>
</queue>
```

*topic*: This element contains the following authorization settings for a single topic destination:

Each topic element has the following sub elements:

**name** The name of the topic, without wildcards or other substitution characters.

**public** The default public access permissions for the topic. This is used only for

those userids that have no specific authorize element. If you leave this element empty, or do not define it at all, only those userids with authorize elements can access the topic.

You define each default permission within a separate permission element.

**authorize**

The access permissions for a specific userid. Within each authorize element, you define the following elements:

**userid** The userid that you want to assign a specific access permission.

**permission**

An access permission for the associated userid.

You define each permission within a separate permission element. Each permission element can contain one of the following keywords to define the access permission:

- +pub** Grant publish permission
- +sub** Grant subscribe permission
- +persist**  
Grant persist permission
- pub** Deny publish permission
- sub** Deny subscribe permission
- persist**  
Deny persist permission

**Displaying administrative lists of JMS resources**

Use this task with the WebSphere administrative console to display administrative lists of JMS resources.

You can use the WebSphere administrative console to display lists of the following types of JMS resources. You can use the panels displayed to select JMS resources to administer, or to create or delete JMS resources (where appropriate).

To display administrative lists of JMS resources, complete the following general steps:

1. Start the WebSphere administrative console.
2. In the navigation pane, expand the appropriate path to select the type of JMS provider (as shown in the following table).
3. If appropriate, in the content pane, select a specific JMS provider. This displays the properties for the JMS provider, and an Additional Properties list of links to the types of JMS resources provided.
4. In the content pane, under Additional Resources, select the link for the type of JMS resource. This displays a list of the selected JMS resource type in the content pane.

*Table 1. Network Deployment and Enterprise - Administrative panels for JMS resources*

### JMS server collection:

Each JMS server provides the functions of the JMS provider for a node in your administrative domain. Use this panel to list the JMS servers within the administration domain, or to select a JMS server to view or change its configuration properties.

There can be at most one JMS server on each node in the administration domain, and any application server within the domain can access JMS resources served by any JMS server on any node in the domain.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> JMS Servers**.

To view or change the properties of a JMS server, select its name in the list displayed.

To act on one or more of the JMS servers listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

**Related tasks**

Managing WebSphere internal JMS servers

**Related reference****Buttons**

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

**Scope**

Use Scope settings to filter the contents of an administrative console collection table to a particular cell, node, or server, for example. Changing the value for Scope allows you to see other variables that apply to an object and might change the contents of the collection table.

**Filter**

Use the Filter settings to specify how to filter entries shown in a collection view.

**Preferences**

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

**Related information**

An overview of WebSphere asynchronous messaging using JMS

*WebSphere internal JMS server settings:*

The JMS functions on a node within the WebSphere Application Server administration domain are served by the JMS server on that node. Use this panel to view or change the configuration properties of the selected JMS server.

You can use this panel to configure a general set of JMS server properties, which add to the default values of properties configured automatically for the embedded WebSphere JMS provider.

Before you set any of the values on this panel, configure the JMS Server for each node by using the WebSphere Application Server ISPF Customization Dialog.

**Related tasks**

Managing WebSphere internal JMS servers

**Related information**

An overview of WebSphere asynchronous messaging using JMS

*Name:*

The name by which the JMS server is known for administrative purposes within IBM WebSphere Application Server.

This name should not be changed.

<b>Data type</b>	String
<b>Units</b>	Not applicable
<b>Default</b>	WebSphere Internal JMS Server
<b>Range</b>	Not applicable

*Description:*

A description of the JMS server, for administrative purposes within IBM WebSphere Application Server.

This string should not be changed.

<b>Data type</b>	String
<b>Default</b>	WebSphere Internal JMS Server

*Number of threads:*

The number of concurrent threads to be used by the publish/subscribe matching engine

The number of concurrent threads should only be set to a small number.

<b>Data type</b>	Integer
<b>Units</b>	Threads
<b>Default</b>	1
<b>Range</b>	Greater than or equal to 1.

*Queue Names:*

The names of the queues hosted by this JMS server. Each queue name must be added on a separate line.

Each queue listed in this field must have a separate queue administrative object with the same administrative name. To make a queue available to applications, define a WebSphere queue and add its name to this field on the JMS Server panel for the host on which you want the queue to be hosted.

<b>Data type</b>	ASCII
<b>Units</b>	Queue name
<b>Default</b>	Not applicable
<b>Range</b>	Each entry in this field is a queue name of up to 45 characters, which must match exactly (including use of upper- and lowercase characters) the WebSphere queue administrative object defined for the queue.

*Initial state:*

The state that you want the JMS server to have when it is next restarted.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Started

**Range**

**Started** The JMS server is started automatically.

**Stopped**

The JMS server is not started automatically. If any deployed enterprise applications are to use JMS server functions provided by the JMS server, the system administrator must start the JMS server manually or select the Started value of this property then restart the JMS server.

To restart the JMS server, stop then restart that JMS server.

**JMS provider collection:**

Use this panel to list JMS providers, or to select a JMS provider to view or change its configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand one of the following paths:
  - **Resources-> WebSphere JMS Provider**
  - **Resources-> WebSphere MQ JMS Provider**
  - **Resources-> Generic JMS Providers**

To view or change the properties of a JMS provider or its resources, select its name in the list displayed.

To define a new generic JMS provider, on the **Resources-> Generic JMS Providers** page click **New**.

To act on one or more of the JMS providers listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

**Name** The name by which this JMS provider is known for administrative purposes.

**Description**

A description of this JMS provider for administrative purposes.

**Related reference****Buttons**

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

**Scope**

Use Scope settings to filter the contents of an administrative console collection table to a particular cell, node, or server, for example. Changing the value for Scope allows you to see other variables that apply to an object and might change the contents of the collection table.

**Preferences**

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

**Related information**

An overview of WebSphere asynchronous messaging using JMS

*WebSphere JMS provider settings:*

Use this panel to view the configuration properties of the embedded WebSphere JMS provider that is installed with WebSphere Application Server. *You cannot change these properties.*

To view this administrative console page, click **Resources-> WebSphere JMS Provider**

*Name:*

The name by which the JMS provider is known for administrative purposes.

<b>Data type</b>	String
<b>Default</b>	WebSphereJMSProvider

*Description:*

A description of the JMS provider, for administrative purposes within IBM WebSphere Application Server.

<b>Data type</b>	String
<b>Default</b>	Built-in WebSphere JMS Provider

*WebSphere MQ JMS provider settings:*

Use this panel to view the configuration properties of the WebSphere MQ JMS provider. These properties apply only if you have installed WebSphere MQ as the JMS provider over the internal JMS provider installed with WebSphere Application Server. *You cannot change these properties.*

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider**

*Name:*

The name by which the WebSphere MQ JMS provider is known for administrative purposes.

<b>Data type</b>	String
<b>Default</b>	WebSphereMQJMSProvider

*Description:*

A description of the JMS provider, for administrative purposes within IBM WebSphere Application Server.

<b>Data type</b>	String
<b>Default</b>	WebSphere MQ JMS provider

*Classpath:*

The Java classpath for the JMS provider. The list of paths or JAR file names that together form the location for the JMS provider classes.

<b>Data type</b>	String
<b>Default</b>	\$MQJMS_LIB_ROOT

*Native Library Path:*

The native library path for the JMS provider. An optional path to any native libraries needed by the JMS provider.

<b>Data type</b>	String
<b>Default</b>	\$MQJMS_LIB_ROOT

The Native Library Path property is set to the directory where the WebSphere MQ Java feature is installed.

*JMS provider settings:*

If you want to use a JMS provider other than the embedded WebSphere JMS provider or the WebSphere MQ JMS provider, use this panel to configure properties of the JMS provider.

To view this administrative console page, click **Resources-> Generic JMS Providers-> *provider\_name***

*Name:*

The name by which the JMS provider is known for administrative purposes.

<b>Data type</b>	String
<b>Default</b>	Null

*Description:*

A description of the JMS provider, for administrative purposes

<b>Data type</b>	String
<b>Default</b>	Null

*Classpath:*

The Java classpath for the JMS provider. The list of paths or JAR file names that together form the location for the JMS provider classes.

<b>Data type</b>	String
<b>Default</b>	Null

*Native Library Path:*

The native library path for the JMS provider. An optional path to any native libraries needed by the JMS provider.

<b>Data type</b>	String
<b>Default</b>	Null

*External initial context factory:*

The Java classname of the initial context factory for the JMS provider.

For example, for an LDAP service provider the value has the form:  
com.sun.jndi.ldap.LdapCtxFactory.

<b>Data type</b>	String
<b>Default</b>	Null

*External provider URL:*

The JMS provider URL for external JNDI lookups.

For example, an LDAP URL for a JMS provider has the form:  
ldap://hostname.company.com/contextName.

<b>Data type</b>	String
<b>Default</b>	Null

### **WebSphere Queue connection factory collection:**

The queue connection factories configured in the embedded WebSphere JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere queue connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere Queue Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

#### **Related reference**

Buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Scope

Use Scope settings to filter the contents of an administrative console collection table to a particular cell, node, or server, for example. Changing the value for Scope allows you to see other variables that apply to an object and might change the contents of the collection table.

Connection pool settings

Use this page to configure connection pool settings.

J2C authentication data settings

Use this page as a central place for administrators to define authentication data, which includes user identities and passwords. These can reference authentication data entries by resource adapters, data sources and other configurations that require authentication data using an alias.

#### **Related information**

An overview of WebSphere asynchronous messaging using JMS

*Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible

from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

*Name:*

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

**Data type** String  
**Default** Null

*JNDI name:*

The JNDI name that is used to bind the connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Description:*

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String  
**Default** Null

*Category:*

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Component-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

**Data type** Pick-list

*Container-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

**Data type** Pick-list

*Mapping-Configuration Alias:*

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

**Data type** Pick-list

*Node:*

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

**Data type** String  
**Units** Enum  
**Default** Null  
**Range** Pull-down list of nodes in the WebSphere administrative domain.

*XA Enabled:*

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server. In WebSphere Application Server Enterprise the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

**Data type** Checkbox  
**Default** Selected (enabled for XA coordination)  
**Range** **Selected**  
The connection factory is enabled for XA-coordination of messages  
**Cleared**  
The connection factory is not enabled for XA coordination of messages  
**Recommended** Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

*Connection pool:*

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

*Session pool:*

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

*Session pool settings:*

Use this page to configure session pool settings.

This administrative console page is common to a range of resource types; for example, JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Session Pool**. For example: click **Resources > WebSphere JMS Providers > WebSphere Queue Connection Factories > connection\_factory > Session Pool**.

#### **Related concepts**

Connection pooling

When accessing any database, the initial database connection is an expensive operation. Connection pooling enables administrators to establish a pool of database connections that applications can share on an application server. When connection pooling capabilities are used, performance improvements up to 20 times the normal results are realized.

#### **Related reference**

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

*Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

#### *Connection Timeout:*

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

The wait is necessary when the maximum value of connections (**Max Connections**) to a particular connection pool is reached. For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a `ConnectionWaitTimeoutException`. It usually does not make sense to retry the `getConnection()` method, because if a longer wait time is required, you should set the **Connection Timeout** setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If *Connection Timeout* is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of **Max Connections**).

If **Max Connections** is set to 0, which enables an infinite number of physical connections, then the *Connection Timeout* value is ignored.

**Data type** Integer

<b>Units</b>	Seconds
<b>Default</b>	180
<b>Range</b>	0 to max int

*Max Connections:*

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the `Max Connections` value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in `Connection Timeout` for a physical connection to become free.

If `Max Connections` is set to 0, the `Connection Timeout` value is ignored.

For better performance, set the value for the connection pool lower than the value for the `Max Connections` option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

*Min Connections:*

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for `Aged Timeout`, the minimum is not maintained. All connections with an expired age are discarded.

For example if the **Min Connections** value is set to 3, and one physical connection is created, the `Unused Timeout` thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the **Min Connections** setting.

<b>Data type</b>	Integer
<b>Default</b>	1
<b>Range</b>	0 to max int

*Reap Time:*

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if **Reap Time** is set to 60, the pool maintenance thread runs every 60 seconds. The `Reap Time` interval affects the accuracy of the **Unused Timeout** and **Aged Timeout** settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the `Reap Time` value less than the values of `Unused Timeout` and `Aged Timeout`. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value

specified in **Unused Timeout**, until it reaches the number of connections specified in **Min Connections**. The pool maintenance thread also discards any connections that remain active longer than the time value specified in **Aged Timeout**.

The **Reap Time** interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set **Reap Time** to 0, or set both **Unused Timeout** and **Aged Timeout** to 0. The recommended way to disable the pool maintenance thread is to set **Reap Time** to 0, in which case **Unused Timeout** and **Aged Timeout** are ignored. However, if **Unused Timeout** and **Aged Timeout** are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	180
<b>Range</b>	0 to max int

*Unused Timeout:*

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the **Unused Timeout** value higher than the **Reap Timeout** value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the **Min Connections** setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (**Reap Time** is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the **Reap Time** value. For more information, see **Reap Time**.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	1800
<b>Range</b>	0 to max int

*Aged Timeout:*

Specifies the interval in seconds before a physical connection is discarded.

Setting **Aged Timeout** to 0 supports active physical connections remaining in the pool indefinitely. Set the **Aged Timeout** value higher than the **Reap Timeout** value for optimal performance. For example, if the **Aged Timeout** value is set to 1200, and the **Reap Time** value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the **Reap Time** value. For more information, see **Reap Time**.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	0
<b>Range</b>	0 to max int

### *Purge Policy:*

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. JCA data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

**Data type**  
**Default**  
**Range**

String  
FailingConnectionOnly

#### **EntirePool**

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

#### **FailingConnectionOnly**

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

### **WebSphere topic connection factory collection:**

The topic connection factories configured in the embedded WebSphere JMS provider for publish/subscribe messaging with JMS topics.

This panel shows a list of the WebSphere topic connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere Topic Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

#### Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

<b>Data type</b>	String
------------------	--------

#### Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

<b>Data type</b>	String
<b>Default</b>	Null

#### JNDI name:

The JNDI name that is used to bind the topic connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Description:*

A description of this topic connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String

**Default** Null

*Category:*

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Node:*

The WebSphere node name of the administrative node where the JMS server runs for this connection factory. Connections created by this factory connect to that JMS server.

**Data type** Enum

**Default** Null

**Range** Pull-down list of nodes in the WebSphere administrative domain.

*Port:*

Which of the two ports that connections use to connect to the JMS Server. The QUEUED port is for full-function JMS publish/subscribe support, the DIRECT port is for non-persistent, non-transactional, non-durable subscriptions only.

**Note:** Message-driven beans cannot use the direct listener port for publish/subscribe support. Therefore, any topic connection factory configured with **Port** set to `Direct` cannot be used with message-driven beans.

**Data type** Enum

**Units** Not applicable

**Default** QUEUED

## Range

### QUEUED

The listener port used for full-function JMS-compliant, publish/subscribe support.

### DIRECT

The listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for publish/subscribe support.

The TCP/IP port numbers for these ports are defined on the WebSphere Internal JMS Server.

### *Component-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

### *Container-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere

messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

*Mapping-Configuration Alias:*

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

**Data type** Pick-list

*Clone Support:*

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

<b>Data type</b>	Enum
<b>Default</b>	Cleared
<b>Range</b>	<b>Selected</b> Clone support is enabled. <b>Cleared</b> Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

*Client ID:*

The JMS client identifier used for connections to the queue manager.

<b>Data type</b>	String
<b>Range</b>	A valid JMS client ID

*XA Enabled:*

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you clear this checkbox property (for non-XA coordination), the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (session.commit and session.rollback) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server. In WebSphere Application Server Enterprise the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to DIRECT this property does not apply, and always adopts non-XA coordination.

<b>Data type</b>	Checkbox
<b>Default</b>	Selected (enabled for XA coordination)
<b>Range</b>	<p><b>Selected</b> The connection factory is enabled for XA-coordination of messages</p> <p><b>Cleared</b> The connection factory is not enabled for XA coordination of messages</p>
<b>Recommended</b>	Do not enable XA coordination when the message queue or topic received is the only resource in the transaction. Enable XA coordination when other resources, including other queues or topics, are involved.

*Connection pool:*

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

*Session pool:*

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

**WebSphere Queue destination collection:**

The queue destinations configured in the embedded WebSphere JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere queue destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the queue destination.

3. In the Additional Properties list in the contents pane, select **WebSphere Queue Destination**.

To view or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

##### Scope

Use Scope settings to filter the contents of an administrative console collection table to a particular cell, node, or server, for example. Changing the value for Scope allows you to see other variables that apply to an object and might change the contents of the collection table.

*Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

*Name:*

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*JNDI name:*

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Description:*

A description of the queue, for administrative purposes

**Data type** String

**Default** Null

*Category:*

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Persistence:*

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

**Data type** Enum  
**Default** APPLICATION DEFINED  
**Range** **APPLICATION DEFINED**  
Messages on the destination have their persistence defined by the application that put them onto the queue.  
**NON-PERSISTENT**  
Messages on the destination are not persistent.  
**PERSISTENT**  
Messages on the destination are persistent.  
**QUEUE DEFINED**  
[WebSphere MQ destination only]  
Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property

**Data type** Enum  
**Units** Not applicable  
**Default** APPLICATION DEFINED  
**Range** **APPLICATION DEFINED**  
The priority of messages on this destination is defined by the application that put them onto the destination.  
**QUEUE DEFINED**  
[WebSphere MQ destination only]  
Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.  
**SPECIFIED**  
The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

*Specified priority:*

If the **Priority** property is set to *Specified*, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to *Specified*, messages sent to this queue have the priority value specified by this property.

<b>Data type</b>	Integer
<b>Units</b>	Message priority level
<b>Default</b>	0
<b>Range</b>	0 (lowest priority) through 9 (highest priority)

*Expiry:*

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION DEFINED
<b>Range</b>	<b>APPLICATION DEFINED</b> The expiry timeout for messages on this queue is defined by the application that put them onto the queue. <b>UNLIMITED</b> Messages on this queue have no expiry timeout, so those messages never expire. <b>SPECIFIED</b> The expiry timeout for messages on this queue is defined by the <b>Specified expiry</b> property. <i>If you select this option, you must define a timeout on the <b>Specified expiry</b> property.</i>

*Specified expiry:*

If the **Expiry timeout** property is set to *Specified*, type here the number of milliseconds (greater than 0) after which messages on this queue expire

<b>Data type</b>	Integer
<b>Units</b>	Milliseconds
<b>Default</b>	0
<b>Range</b>	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

**WebSphere topic destination collection:**

The topic destinations configured in the embedded WebSphere JMS provider for publish/subscribe messaging with JMS topics. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

This panel shows a list of the WebSphere topic destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the topic destination.
3. In the Additional Properties list in the contents pane, select **WebSphere Topic Destination**.

To view or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

#### **Related concepts**

Buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Filter

Use the Filter settings to specify how to filter entries shown in a collection view.

Preferences

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

*WebSphere topic settings:*

Use this panel to view or change the configuration properties of the selected topic destination for use with the embedded WebSphere JMS provider.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. Connections to the topic are created by the associated topic connection factory. A topic for use with the embedded WebSphere JMS provider has the following properties.

To view this administrative console page, click **Resources-> WebSphere JMS Provider-> (In content pane, under Additional Properties) WebSphere Topic destinations-> *destination\_name***

#### **Related reference**

Buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Scope

Use Scope settings to filter the contents of an administrative console collection table to a particular cell, node, or server, for example. Changing the value for

Scope allows you to see other variables that apply to an object and might change the contents of the collection table.

*Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

- Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.
- Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.
- Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

*Name:*

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*JNDI name:*

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Description:*

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

**Data type** String

**Default** Null

*Category:*

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Topic:*

The name of the topic as defined to the JMS provider.

**Data type** String

**Default** Null

**Range** The topic value can be dot notation and include wildcard characters.

*Persistence:*

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

**Data type** Enum

**Default** APPLICATION DEFINED

**Range** APPLICATION DEFINED

Messages on the destination have their persistence defined by the application that put them onto the queue.

**NON-PERSISTENT**

Messages on the destination are not persistent.

**PERSISTENT**

Messages on the destination are persistent.

**QUEUE DEFINED**

[WebSphere MQ destination only]  
Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION DEFINED
<b>Range</b>	<b>APPLICATION DEFINED</b> The priority of messages on this destination is defined by the application that put them onto the destination. <b>QUEUE DEFINED</b> [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. <b>SPECIFIED</b> The priority of messages on this destination is defined by the <b>Specified priority</b> property. <i>If you select this option, you must define a priority on the <b>Specified priority</b> property.</i>

*Specified priority:*

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

<b>Data type</b>	Integer
<b>Units</b>	Message priority level
<b>Default</b>	0
<b>Range</b>	0 (lowest priority) through 9 (highest priority)

*Expiry:*

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION DEFINED

## Range

### APPLICATION DEFINED

The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

### UNLIMITED

Messages on this queue have no expiry timeout, so those messages never expire.

### SPECIFIED

The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

*Specified expiry:*

If the **Expiry timeout** property is set to Specified, type here the number of milliseconds (greater than 0) after which messages on this queue expire

**Data type**

Integer

**Units**

Milliseconds

**Default**

0

**Range**

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

## WebSphere MQ queue connection factory collection:

The queue connection factories configured in the WebSphere MQ JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere MQ queue connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Queue Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

### Related information

An overview of WebSphere asynchronous messaging using JMS

*WebSphere MQ queue connection factory settings:*

Use this panel to view or change the configuration properties of the selected queue connection factory for use with the WebSphere MQ JMS provider. These configuration properties control how connections are created to the associated JMS queue destination.

A queue connection factory is used to create JMS connections to queue destinations. The queue connection factory is created by the WebSphere MQ JMS provider. A queue connection factory for the WebSphere MQ JMS provider has the following properties.

#### Note:

- The property values that you specify must match the values that you specified when configuring WebSphere MQ for JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book, and the *WebSphere MQ System Administration* book, SC33-1873, which are available from the WebSphere MQ messaging platform-specific books Web page at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Queue Connection Factories-> *connection\_factory***

WebSphere MQ library Web page at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>

#### Name:

The name by which this queue connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the JMS connection factories across the WebSphere administrative domain.

#### Data type

String

#### JNDI name:

The JNDI name that is used to bind the connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form `jms/Name`, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Description:*

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String  
**Default** Null

*Category:*

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Component-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (`res-auth`) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Restriction:**

1. User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.
2. If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type=BINDINGS** on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
  - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server

process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws a “MQJMS2013 invalid security authentication supplied for MQQueueManager” error.

- Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

#### *Container-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

#### **Restriction:**

1. User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.
2. If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type=BINDINGS** on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
  - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws a “MQJMS2013 invalid security authentication supplied for MQQueueManager” error.
  - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

#### *Queue manager:*

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	A valid WebSphere MQ queue manager name, as 1 through 48 ASCII characters

*Host:*

The name of the host on which the WebSphere MQ queue manager runs, for client connection only.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	A valid TCP/IP hostname

*Port:*

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

<b>Data type</b>	Integer
<b>Default</b>	Null
<b>Range</b>	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

*Channel:*

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	1 through 20 ASCII characters

*Transport type:*

Specifies whether the WebSphere MQ client connection or JNI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	BINDINGS

## Range

## BINDINGS

JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and comes at some security risks that should be addressed through the use of EJB roles.

If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type=BINDINGS** on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:

- To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws a “MQJMS2013 invalid security authentication supplied for MQQueueManager” error.
- Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

## CLIENT

WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

## DIRECT

For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in non-transactional, nondurable and non-persistent Publish/Subscribe messaging. DIRECT is only works for clients and message-driven beans using the non-ASF protocol.

## QUEUED

QUEUED is a standard TCP protocol.

## Recommended

### Queue connection factory transport type

BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

### Topic connection factory transport type

DIRECT is the fastest and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is fallback for all other cases. Note, WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This also happens with client-side based applications unless the broker's maxClientQueueSize is set to 0. You can set this to 0 with the command `#wempschangeproperties WAS_nodeName_server1 -e default -o DynamicSubscriptionEngine -n maxClientQueueSize -v 0 -x executionGroupUUID`, where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

### *Model queue definition:*

The name of the model queue definition that can be used by the queue manager to create temporary queues if a queue requested does not already exist.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

### *Client ID:*

The JMS client identifier used for connections to the WebSphere MQ queue manager.

<b>Data type</b>	String
<b>Default</b>	Null

### *CCSID:*

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

<b>Data type</b>	String
<b>Units</b>	Integer
<b>Default</b>	Null
<b>Range</b>	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

*Message retention:*

Select this check box to specify that unwanted messages are to be left on the queue. Otherwise, unwanted messages are dealt with according to their disposition options.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Cleared
<b>Range</b>	<p><b>Selected</b> Unwanted messages are left on the queue.</p> <p><b>Cleared</b> Unwanted messages are dealt with according to their disposition options.</p>

*XA Enabled:*

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you set this property to `NON_XA`, the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server. In WebSphere Application Server Enterprise the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always takes the value `NON_XA`.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	XA enabled
<b>Range</b>	<p><b>XA</b> The connection factory is for XA-coordination of messages</p> <p><b>NON_XA</b> The connection factory is for non-XA coordination of messages</p>

**Recommended**

Do not enable XA when the message queue or topic received is the only resource in the transaction. Enable XA when other resources, including other queues or topics, are involved.

*Connection pool:*

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

*Session pool:*

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

**WebSphere MQ topic connection factory collection:**

The topic connection factories configured in the WebSphere MQ JMS provider for publish/subscribe messaging with JMS topics.

This panel shows a list of the WebSphere MQ topic connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS Provider**.
2. In the content pane, select the JMS provider that you want to support the connection factory.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Topic Connection Factory**.

To view or change the properties of a connection factory, select its name in the list displayed.

To act on one or more of the connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

**Default** Null

*Category:*

A category used to classify or group this topic connection factory, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Component-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (`res-auth`) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

*Container-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

*Queue manager:*

The name of the WebSphere MQ queue manager for this connection factory. Connections created by this factory connect to that queue manager.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	A valid WebSphere MQ queue manager name, as 1 through 48 ASCII characters

*Host:*

The name of the host on which the WebSphere MQ queue manager runs, for client connection only.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	A valid TCP/IP hostname

*Port:*

The TCP/IP port number used for connection to the WebSphere MQ queue manager, for client connection only.

This port must be configured on the WebSphere MQ queue manager.

<b>Data type</b>	Integer
<b>Default</b>	Null
<b>Range</b>	A valid TCP/IP port number, configured on the WebSphere MQ queue manager.

*Channel:*

The name of the channel used for connection to the WebSphere MQ queue manager, for client connection only.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	1 through 20 ASCII characters

*Transport type:*

Specifies whether the WebSphere MQ client connection or JNI bindings are used for connection to the WebSphere MQ queue manager. The external JMS provider controls the communication protocols between JMS clients and JMS servers. Tune the transport type when you are using non-ASF nonpersistent, nondurable, nontransactional messaging or when you want to satisfy security issues and the client is local to the queue manager node.

**Data type**

Enum

**Units**

Not applicable

**Default**

BINDINGS

**Range**

**BINDINGS**

JNI bindings are used to connect to the queue manager. BINDINGS is a shared memory protocol and can only be used when the queue manager is on the same node as the JMS client and comes at some security risks that should be addressed through the use of EJB roles.

**CLIENT**

WebSphere MQ client connection is used to connect to the queue manager. CLIENT is a typical TCP-based protocol.

**DIRECT**

For WebSphere MQ Event Broker using DIRECT mode. DIRECT is a lightweight sockets protocol used in nontransactional, nondurable and nonpersistent Publish/Subscribe messaging. DIRECT is only works for clients and message-driven beans using the non-ASF protocol.

**QUEUED**

QUEUED is a standard TCP protocol.

## Recommended

### Queue connection factory transport type

BINDINGS is faster by 30% or more, but it lacks security. When you have security concerns, BINDINGS is more desirable than CLIENT.

### Topic connection factory transport type

DIRECT is the fastest and should be used where possible. Use BINDINGS when you want to satisfy additional security tasks and the queue manager is local to the JMS client. QUEUED is fallback for all other cases. Note, WebSphere MQ 5.3 before CSD2 with the DIRECT setting can lose messages when used with message-driven beans and under load. This also happens with client-side based applications unless the broker's maxClientQueueSize is set to 0. You can set this to 0 with the command `#wempschangeproperties WAS_nodeName_server1 -e default -o DynamicSubscriptionEngine -n maxClientQueueSize -v 0 -x executionGroupUUID`, where executionGroupUUID can be found by starting the broker and looking in the Event Log/Applications for event 2201. This value is usually ffffffff-0000-0000-000000000000.

### *Broker control queue:*

The name of the broker's control queue, to which all command messages (except publications and requests to delete publications) are sent

The name of the broker's control queue. Publisher and subscriber applications, and other brokers, send all command messages (except publications and requests to delete publications) to this queue.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

### *Broker queue manager:*

The name of the WebSphere MQ queue manager that provides the publish/subscribe message broker.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

*Broker publication queue:*

The name of the broker's input queue that receives all publication messages for the default stream

The name of the broker's input queue (stream queue) that receives all publication messages for the default stream. Applications can also send requests to delete publications on the default stream to this queue.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

*Broker subscription queue:*

The name of the broker's queue from which non-durable subscription messages are retrieved

The name of the broker's queue from which non-durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

*Broker CC subscription queue:*

The name of the broker's queue from which non-durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

The name of the broker's queue from which non-durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

*Broker version:*

Whether the message broker is provided by the WebSphere MQ MA0C Supportpac or newer versions of WebSphere message broker products

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Advanced

**Range****Advanced**

The message broker is provided by newer versions of WebSphere message broker products, such as WebSphere MQ Integrator and EventBroker.

**Basic**

The message broker is provided by the WebSphere MQ MA0C SupportPac (MQSeries - Publish/Subscribe) or MQSI working in MA0C compatibility mode.

*Model queue definition:*

The name of the model queue definition that the broker can use to create dynamic queues for non-default streams if the stream queue does not already exist

The name of the model queue definition that the broker can use to create dynamic queues to receive publications for streams other than the default stream. This is only used if the stream queue does not already exist. If this model queue definition does not exist, all stream queues must be defined by the administrator.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

*CCSID:*

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

<b>Data type</b>	String
<b>Units</b>	Integer
<b>Default</b>	Null
<b>Range</b>	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

*Clone Support:*

Select this checkbox to enable clone support to allow the same durable subscription across topic clones.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable

<b>Default</b>	Cleared
<b>Range</b>	<b>Selected</b> Clone support is enabled.
	<b>Cleared</b> Clone support is disabled.

If you select this property, you must also specify a value for the **Client ID** property.

*Client ID:*

The JMS client identifier used for connections to the queue manager.

<b>Data type</b>	String
<b>Range</b>	A valid JMS client ID, as ASCII characters

*XA Enabled:*

Specifies whether the connection factory is for XA or non-XA coordination of messages and controls if the application server uses XA QCF/TCF. Enable XA if multiple resources are not used in the same transaction.

If you set this property to `NON_XA`, the JMS session is still enlisted in a transaction, but uses the resource manager local transaction calls (`session.commit` and `session.rollback`) instead of XA calls. This can lead to an improvement in performance. However, this means that only a single resource can be enlisted in a transaction in WebSphere Application Server. In WebSphere Application Server Enterprise the last participant support enables you to enlist one non-XA resource with other XA-capable resources.

For a WebSphere Topic Connection Factory with the **Port** property set to `DIRECT` this property does not apply, and always takes the value `NON_XA`.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	XA enabled
<b>Range</b>	<b>XA</b> The connection factory is for XA-coordination of messages <b>NON_XA</b> The connection factory is for non-XA coordination of messages
<b>Recommended</b>	Do not enable XA when the message queue or topic received is the only resource in the transaction. Enable XA when other resources, including other queues or topics, are involved.

*Connection pool:*

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection

pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

*Session pool:*

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

### **WebSphere MQ queue destination collection:**

The queue destinations configured in the WebSphere MQ JMS provider for point-to-point messaging with JMS queues.

This panel shows a list of the WebSphere MQ queue destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS provider**.
2. In the content pane, select the JMS provider that you want to support the queue destination.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Queue Destination**.

To view or change the properties of a queue destination, select its name in the list displayed.

To act on one or more of the queue destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

#### **Related reference**

##### Buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

##### Preferences

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

#### **Related information**

An overview of WebSphere asynchronous messaging using JMS

*WebSphere MQ queue settings:*

Use this panel to view or change the configuration properties of the selected queue destination for use with the WebSphere MQ JMS provider.

A queue destination is used to configure the properties of a JMS queue. Connections to the queue are created by the associated queue connection factory for the WebSphere MQ JMS provider. A queue for use with the WebSphere MQ JMS provider has the following properties.

**Note:**

- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Queue Destinations-> *destination\_name***

*Name:*

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

**Data type** String

*JNDI name:*

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Description:*

A description of the queue, for administrative purposes

**Data type** String

**Default** Null

*Category:*

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Persistence:*

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION_DEFINED
<b>Range</b>	<b>Application defined</b> Messages on the destination have their persistence defined by the application that put them onto the queue. <b>Queue defined</b> [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. <b>Persistent</b> Messages on the destination are persistent. <b>Non persistent</b> Messages on the destination are not persistent.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION_DEFINED
<b>Range</b>	<b>Application defined</b> The priority of messages on this destination is defined by the application that put them onto the destination. <b>Queue defined</b> [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. <b>Specified</b> The priority of messages on this destination is defined by the <b>Specified priority</b> property. <i>If you select this option, you must define a priority on the <b>Specified priority</b> property.</i>

*Specified priority:*

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to **Specified**, messages sent to this queue have the priority value specified by this property.

<b>Data type</b>	Integer
<b>Units</b>	Message priority level
<b>Default</b>	Null
<b>Range</b>	0 (lowest priority) through 9 (highest priority)

*Expiry:*

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION_DEFINED
<b>Range</b>	<b>Application defined</b> The expiry timeout for messages on this queue is defined by the application that put them onto the queue. <b>Specified</b> The expiry timeout for messages on this queue is defined by the <b>Specified expiry</b> property. <i>If you select this option, you must define a timeout on the <b>Specified expiry</b> property.</i> <b>Unlimited</b> Messages on this queue have no expiry timeout, so those messages never expire.

*Specified expiry:*

If the **Expiry timeout** property is set to **Specified**, type here the number of milliseconds (greater than 0) after which messages on this queue expire

<b>Data type</b>	Integer
<b>Units</b>	Milliseconds
<b>Default</b>	Null
<b>Range</b>	Greater than or equal to 0 • 0 indicates that messages never timeout • Other values are an integer number of milliseconds

*Base queue name:*

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

*Base queue manager name:*

The name of the WebSphere MQ queue manager to which messages are sent

This queue manager provides the queue specified by the **Base queue name** property.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	A valid WebSphere MQ Queue Manager name, as 1 through 48 ASCII characters

*CCSID:*

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

<b>Data type</b>	String
<b>Units</b>	Integer
<b>Default</b>	Null
<b>Range</b>	1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

*Use native encoding:*

Select this checkbox to indicate that the queue destination should use native encoding (appropriate encoding values for the Java platform).

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Cleared
<b>Range</b>	<b>Cleared</b> Native encoding is not used, so specify the properties below for integer, decimal, and floating point encoding. <b>Selected</b> Native encoding is used (to provide appropriate encoding values for the Java platform).

For more information about encoding properties, see the *WebSphere MQ Using Java* document.

*Integer encoding:*

If native encoding is not enabled, select whether integer encoding is normal or reversed.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	NORMAL
<b>Range</b>	<b>NORMAL</b> Normal integer encoding is used. <b>REVERSED</b> Reversed integer encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

*Decimal encoding:*

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	NORMAL
<b>Range</b>	<b>NORMAL</b> Normal decimal encoding is used. <b>REVERSED</b> Reversed decimal encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

*Floating point encoding:*

If native encoding is not enabled, select the type of floating point encoding.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	IEEE NORMAL
<b>Range</b>	<b>IEEE NORMAL</b> IEEE normal floating point encoding is used. <b>IEEE REVERSED</b> IEEE reversed floating point encoding is used. <b>S390</b> S390 floating point encoding is used.

For more information about encoding properties, see the WebSphere MQ *Using Java* document.

*Target client:*

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	MQSeries
<b>Range</b>	<b>MQSeries</b> The target is a non-JMS, traditional WebSphere MQ application.
	<b>JMS</b> The target is a JMS-compliant application.

*Queue manager host:*

The name of host for the queue manager on which the queue destination is created.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	A valid TCP/IP hostname

*Queue manager port:*

The number of the port used by the queue manager on which this queue is defined.

<b>Data type</b>	String
<b>Units</b>	A valid TCP/IP port number.
<b>Default</b>	Null
<b>Range</b>	A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.

*Server connection channel name:*

The name of the channel used for connection to the WebSphere MQ queue manager.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	1 through 20 ASCII characters

*User name:*

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

<b>Data type</b>	String
<b>Default</b>	Null

*Password:*

The password, used with the **User name** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

<b>Data type</b>	String
<b>Default</b>	Null

*WebSphere MQ queue settings (MQ Config):*

Use this panel to view or change the configuration properties defined to WebSphere MQ for the selected queue destination.

A queue destination is used to configure the properties of a JMS queue. A queue for use with the WebSphere MQ JMS provider has the following extra properties defined to WebSphere MQ.

### Notes

#### Note:

- Some properties displayed are read-only and cannot be changed.
- To be able to view or change properties, the WebSphere MQ Queue Manager on which the queue resides must be configured for remote administration and be running.
- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the WebSphere MQ *Using Java* book; for example from the WebSphere MQ multiplatform library Web page at <http://www.ibm.com/software/ts/mqseries/library/manualsa/manuals/crosslatest.html>.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Queue Destinations-> destination\_name-> (In content pane, under Additional Properties) MQ Config**

*Base queue name:*

The name of the queue to which messages are sent, on the queue manager specified by the **Base queue manager name** property.

<b>Data type</b>	String
------------------	--------

*Base queue manager name:*

The name of the WebSphere MQ queue manager to which messages are sent.

This queue manager provides the queue specified by the **Base queue name** property.

<b>Data type</b>	String
------------------	--------

*Queue manager host:*

The name of host for the queue manager on which the queue destination is created.

**Data type** String

*Queue manager port:*

The number of the port used by the queue manager on which this queue is defined.

**Data type** Integer  
**Range** A valid TCP/IP port number. This port must be configured on the WebSphere MQ queue manager.

*Server connection channel name:*

The name of the channel used for connection to the WebSphere MQ queue manager.

**Data type** String  
**Range** 1 through 20 ASCII characters

*User ID:*

The user ID used, with the **Password** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

**Data type** String

*Password:*

The password, used with the **User name** property, for authentication when connecting to the queue manager to define the queue destination.

If you specify a value for the **User name** property, you must also specify a value for the **Password** property.

**Data type** String

*Name:*

The name of the queue defined to the WebSphere MQ queue manager.

**Data type** String  
**Range** 1 through 48 ASCII characters.

*Description:*

The WebSphere MQ queue description, for administrative purposes within WebSphere MQ.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	1 through 64 ASCII characters.

*Inhibit Put:*

Whether or not put operations are allowed for this queue.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Cleared
<b>Range</b>	<b>Allowed</b> Put operations are allowed for this queue. <b>Not allowed</b> Put operations are not allowed for this queue.

*Persistence:*

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION_DEFINED
<b>Range</b>	<b>Application defined</b> Messages on the destination have their persistence defined by the application that put them onto the queue. <b>Queue defined</b> [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. <b>Persistent</b> Messages on the destination are persistent. <b>Non persistent</b> Messages on the destination are not persistent.

*Cluster name:*

The name of the cluster to which the WebSphere MQ queue manager belongs.

If you specify a value for **Cluster name**, you cannot specify a value for **Cluster name list**. Cluster names must conform to the rules described in the *WebSphere MQ MQSC Command Reference* book.

<b>Data type</b>	String
------------------	--------

<b>Default</b>	Null
<b>Range</b>	A valid WebSphere MQ name for a queue manager cluster, as 1 through 48 ASCII characters

*Cluster name list:*

The name of the cluster namelist to which the WebSphere MQ queue manager belongs.

If you specify a value for **Cluster name**, you cannot specify a value for **Cluster name list**.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	A valid WebSphere MQ name for a list of queue manager clusters, as 1 through 48 ASCII characters

*Default Binding:*

The default binding to be used when the queue is defined as a cluster queue.

<b>Data type</b>	Enum
<b>Default</b>	Null
<b>Range</b>	A
	<b>On open</b>
	The queue handle is bound to a specific instance of the cluster queue when the queue is opened.
	<b>Not fixed</b>
	The queue handle is not bound to any particular instance of the cluster queue. This allows the queue manager to select a specific queue instance when the message is put, and to change that selection subsequently should the need arise.

*Inhibit Get:*

Whether or not get operations are allowed for this queue.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Cleared
<b>Range</b>	<b>Allowed</b>
	Get operations are allowed for this queue.
	<b>Not allowed</b>
	Get operations are not allowed for this queue.

*Maximum queue depth:*

The maximum number of messages allowed on the queue.

<b>Data type</b>	Integer
<b>Units</b>	Messages
<b>Default</b>	
<b>Range</b>	A value greater than or equal to zero, and less than or equal to: <ul style="list-style-type: none"><li>• 999 999 999 if the queue is on OS/390</li><li>• 640 000 if the queue is on any other WebSphere MQ platform</li></ul> <p>For more information about the maximum value allowed, see the <i>WebSphere MQ MQSC Command Reference</i>.</p> <p>If this value is reduced, any message that is already on the queue are not affected, even if the number of messages exceeds the new maximum.</p>

*Maximum Message Length:*

The maximum length, in bytes, of messages on this queue.

<b>Data type</b>	Integer
<b>Units</b>	Bytes
<b>Default</b>	
<b>Range</b>	A value greater than or equal to zero, and less than or equal to the maximum message length for the queue manager and WebSphere MQ platform. For more information about the maximum value allowed, see the <i>WebSphere MQ MQSC Command Reference</i> .
	If this value is reduced, any message that is already on the queue are not affected, even if the message length exceeds the new maximum.

*Shareability:*

Whether multiple applications can get messages from this queue.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Not shareable
<b>Range</b>	<b>Not shareable</b> Only one application instance can get messages from the queue. <b>Shareable</b> More than one application instance can get messages from the queue.

*Input Open Option:*

The default share option for applications opening this queue for input

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Cleared
<b>Range</b>	<b>Exclusive</b> The open request is for exclusive input from the queue. <b>Shared</b> The open request is for shared input from the queue.

*Message Delivery Sequence:*

The order in which messages are delivered from the queue in response to get requests.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Priority
<b>Range</b>	<b>Priority</b> Messages are delivered in first-in-first-out (FIFO) order within priority. This is the default supplied with WebSphere MQ, but your installation might have changed it. <b>FIFO</b> Messages are delivered in FIFO order. Priority is ignored for messages on this queue.

*Backout threshold:*

The maximum number of times that a message can be backed out. If this threshold is reached, the message is requeued on the backout queue specified by the **Backout Requeue name** property.

The WebSphere MQ queue manager keeps a record of the number of times that each message has been backed out. When this number reaches a configurable threshold, the connection consumer requeues the message on a named backout queue. If this requeue fails for any reason, the message is removed from the queue and either requeued to the dead-letter queue, or discarded.

<b>Data type</b>	Integer
<b>Default</b>	0
<b>Range</b>	<b>0</b> Never requeue messages <b>1 or more</b> The number of times that a message has been backed, at which the message is requeued on a named backout queue.

*Backout Requeue name:*

The name of the backout queue to which messages are requeued if they have been backed out more than the backout threshold.

The WebSphere MQ queue manager keeps a record of the number of times that each message has been backed out. When this number reaches a configurable threshold, the connection consumer requeues the message on a named backout queue. If this requeue fails for any reason, the message is removed from the queue and either requeued to the dead-letter queue, or discarded.

<b>Data type</b>	String
<b>Default</b>	Null
<b>Range</b>	1 through 48 characters.

*Harden Get Backout:*

Whether hardening should be used to ensure that the count of the number of times that a message has been backed out is accurate.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Cleared
<b>Range</b>	<p><b>Not hardened</b> The count is not hardened. This is the default supplied with WebSphere MQ, but your installation might have changed it.</p> <p><b>Hardened</b> The count is hardened.</p>

**WebSphere MQ topic destination collection:**

The topic destinations configured in the WebSphere MQ JMS provider for publish/subscribe messaging with JMS topics. Use this panel to create or delete topic destinations, or to select a topic destination to view or change its configuration properties.

This panel shows a list of the WebSphere MQ topic destinations with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> WebSphere MQ JMS provider**.
2. In the content pane, select the JMS provider that you want to support the topic destination.
3. In the Additional Properties list in the contents pane, select **WebSphere MQ Topic Destination**.

To view or change the properties of a topic destination, select its name in the list displayed.

To act on one or more of the topic destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

**Related reference**

Buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

## Preferences

An overview of WebSphere asynchronous messaging using JMS

#### *WebSphere MQ topic settings:*

Use this panel to view or change the configuration properties of the selected topic destination for use with the WebSphere MQ JMS provider.

A topic destination is used to configure the properties of a JMS topic for the associated JMS provider. Connections to the topic are created by the associated topic connection factory. A topic for use with the WebSphere MQ JMS provider has the following properties.

#### **Note:**

- The property values that you specify must match the values that you specified when configuring WebSphere MQ JMS resources. For more information about configuring WebSphere MQ JMS resources, see the *WebSphere MQ Using Java* book.
- In WebSphere MQ, names can have a maximum of 48 characters, with the exception of channels which have a maximum of 20 characters.

To view this administrative console page, click **Resources-> WebSphere MQ JMS Provider-> (In content pane, under Additional Properties) WebSphere MQ Topic Destinations-> *destination\_name***

#### *Name:*

The name by which the topic is known for administrative purposes within IBM WebSphere Application Server.

**Data type** String

#### *JNDI name:*

The JNDI name that is used to bind the topic into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

#### *Description:*

A description of the topic, for administrative purposes within IBM WebSphere Application Server.

**Data type** String

**Default** Null

*Category:*

A category used to classify or group this topic, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Persistence:*

Whether all messages sent to the destination are persistent, non-persistent, or have their persistence defined by the application

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION_DEFINED
<b>Range</b>	<b>Application defined</b> Messages on the destination have their persistence defined by the application that put them onto the queue. <b>Queue defined</b> [WebSphere MQ destination only] Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties. <b>Persistent</b> Messages on the destination are persistent. <b>Non persistent</b> Messages on the destination are not persistent.

*Priority:*

Whether the message priority for this destination is defined by the application or the **Specified priority** property

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	APPLICATION_DEFINED

**Range****Application defined**

The priority of messages on this destination is defined by the application that put them onto the destination.

**Queue defined**

[WebSphere MQ destination only]  
Messages on the destination have their persistence defined by the WebSphere MQ queue definition properties.

**Specified**

The priority of messages on this destination is defined by the **Specified priority** property. *If you select this option, you must define a priority on the **Specified priority** property.*

*Specified priority:*

If the **Priority** property is set to Specified, type here the message priority for this queue, in the range 0 (lowest) through 9 (highest)

If the **Priority** property is set to Specified, messages sent to this queue have the priority value specified by this property.

**Data type**

Integer

**Units**

Message priority level

**Default**

Null

**Range**

0 (lowest priority) through 9 (highest priority)

*Expiry:*

Whether the expiry timeout for this queue is defined by the application or the **Specified expiry** property, or messages on the queue never expire (have an unlimited expiry timeout)

**Data type**

Enum

**Units**

Not applicable

**Default**

APPLICATION\_DEFINED

**Range****Application defined**

The expiry timeout for messages on this queue is defined by the application that put them onto the queue.

**Specified**

The expiry timeout for messages on this queue is defined by the **Specified expiry** property. *If you select this option, you must define a timeout on the **Specified expiry** property.*

**Unlimited**

Messages on this queue have no expiry timeout, so those messages never expire.

*Specified expiry:*

If the **Expiry timeout** property is set to **Specified**, type here the number of milliseconds (greater than 0) after which messages on this queue expire

**Data type**

Integer

**Units**

Milliseconds

**Default**

Null

**Range**

Greater than or equal to 0

- 0 indicates that messages never timeout
- Other values are an integer number of milliseconds

*Base topic name:*

The name of the topic to which messages are sent

**Data type**

String

**Range**

Depends on the broker used. For details, see the documentation for your broker; for example the *WebSphere MQ Event Broker* library at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/v>

*CCSID:*

The coded character set identifier for use with the WebSphere MQ queue manager.

This coded character set identifier (CCSID) must be one of the CCSIDs supported by WebSphere MQ.

**Data type**

String

**Units**

Integer

**Default**

Null

**Range**

1 through 65535

For more information about supported CCSIDs, and about converting between message data from one coded character set to another, see the *WebSphere MQ System Administration* and the *WebSphere MQ Application Programming Reference* books. These are available from the WebSphere MQ messaging multiplatform and platform-specific books Web pages; for example, at <http://www-3.ibm.com/software/ts/mqseries/library/manualsa/manuals/platspecific.html>, the IBM Publications Center, or from the WebSphere MQ collection kit, SK2T-0730.

*Use native encoding:*

Select this checkbox to indicate that the queue destination should use native encoding (appropriate encoding values for the Java platform).

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Cleared
<b>Range</b>	<p><b>Cleared</b></p> <p>Native encoding is not used, so specify the properties below for integer, decimal, and floating point encoding.</p> <p><b>Selected</b></p> <p>Native encoding is used (to provide appropriate encoding values for the Java platform).</p> <p>For more information about encoding properties, see the WebSphere MQ <i>Using Java</i> document.</p>

*Integer encoding:*

If native encoding is not enabled, select whether integer encoding is normal or reversed.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	NORMAL
<b>Range</b>	<p><b>NORMAL</b></p> <p>Normal integer encoding is used.</p> <p><b>REVERSED</b></p> <p>Reversed integer encoding is used.</p> <p>For more information about encoding properties, see the WebSphere MQ <i>Using Java</i> document.</p>

*Decimal encoding:*

If native encoding is not enabled, select whether decimal encoding is normal or reversed.

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	NORMAL

**Range****NORMAL**

Normal decimal encoding is used.

**REVERSED**

Reversed decimal encoding is used.

For more information about encoding properties, see the *WebSphere MQ Using Java* document.

*Floating point encoding:*

If native encoding is not enabled, select the type of floating point encoding.

**Data type**

Enum

**Units**

Not applicable

**Default**

IEEENORMAL

**Range****IEEENORMAL**

IEEE normal floating point encoding is used.

**IEEEREVERSED**

IEEE reversed floating point encoding is used.

**S390**

S390 floating point encoding is used.

For more information about encoding properties, see the *WebSphere MQ Using Java* document.

*Target client type:*

Whether the receiving application is JMS-compliant or is a traditional WebSphere MQ application

**Data type**

Enum

**Units**

Not applicable

**Default**

MQ

**Range****MQ**

The target is a non-JMS, traditional WebSphere MQ application.

**JMS**

The target is a JMS-compliant application.

*Broker Dur Sub Queue:*

The name of the broker's queue from which durable subscription messages are retrieved

The name of the broker's queue from which durable subscription messages are retrieved. The subscriber specifies the name of the queue when it registers a subscription.

**Data type**

String

**Units**

En\_US ASCII characters

**Default**

Null

**Range**

1 through 48 ASCII characters

### *Broker CC Dur Sub Queue:*

The name of the broker's queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

The name of the broker's queue from which durable subscription messages are retrieved for a ConnectionConsumer. This property applies only for use of the Web container.

<b>Data type</b>	String
<b>Units</b>	En_US ASCII characters
<b>Default</b>	Null
<b>Range</b>	1 through 48 ASCII characters

### **JMS connection factory collection:**

The JMS connection factories configured in the associated JMS provider for both point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS connection factories, or to select a connection factory to view or change its configuration properties.

This panel shows a list of the generic JMS connection factories with a summary of their configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> Generic JMS Providers**.
2. In the content pane, select the JMS provider that you want to support the JMS connection factory.
3. In the Additional Properties list in the contents pane, select **Generic JMS Connection Factory**.

To view or change the properties of a JMS connection factory, select its name in the list displayed.

To act on one or more of the JMS connection factories listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

*Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JMS Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you set **Max Connections** to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

*Name:*

The name by which this JMS connection factory is known for administrative purposes within IBM WebSphere Application Server. The name must be unique within the associated JMS provider.

**Data type** String

*Type:*

Whether this connection factory is for creating JMS queue destinations or JMS topic destinations.

Select one of the following options:

**Queue**

A JMS queue connection factory for point-to-point messaging.

**Topic** A JMS topic connection factory for publish/subscribe messaging.

*JNDI name:*

The JNDI name that is used to bind the connection factory into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

*Description:*

A description of this connection factory for administrative purposes within IBM WebSphere Application Server.

**Data type** String

**Default** Null

*Category:*

A category used to classify or group this connection factory, for your IBM WebSphere Application Server administrative records.

**Data type** String

*Component-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for application-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

*Container-managed Authentication Alias:*

This alias specifies a user ID and password to be used to authenticate connection to a JMS provider for container-managed authentication.

This property provides a list of the J2C authentication data entry aliases that have been defined to WebSphere Application Server. You can select a data entry alias to be used to authenticate the creation of a new connection to the JMS provider.

If you have enabled global security for WebSphere Application Server, select the alias that specifies the user ID and password used to authenticate the creation of a new connection to the JMS provider. The use of this alias depends on the resource authentication (res-auth) setting declared in the connection factory resource reference of an application component's deployment descriptors.

**Note:** User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

*Mapping-Configuration Alias:*

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations. For more information about the mapping configurations, see Java Authentication and Authorization service configuration entry settings.

**Data type**

Pick-list

*Connection pool:*

Specifies an optional set of connection pool settings.

Connection pool properties are common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

Change the size of the connection pool if concurrent server-side access to the JMS resource exceeds the default value. The size of the connection pool is set on a per queue or topic basis. See the following table for details.

*Session pool:*

An optional set of session pool settings.

This link provides a panel of optional connection pool properties, common to all J2C connectors.

The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.

### **Generic JMS destination collection:**

The JMS destinations configured in the associated JMS provider for point-to-point and publish/subscribe messaging. Use this panel to create or delete JMS destinations, or to select a JMS destination to view or change its configuration properties.

To view this administrative console page, use the administrative console to complete the following steps:

1. In the navigation pane, expand **Resources-> Generic JMS Providers**.
2. In the content pane, select the JMS provider that you want to support the JMS destination.
3. In the Additional Properties list in the contents pane, select **Generic JMS Destination**.

To view or change the properties of a JMS destination, select its name in the list displayed.

To act on one or more of the JMS destinations listed, click the check boxes next to the names of the objects that you want to act on, then use the buttons provided.

### *Generic JMS destination settings:*

Use this panel to view or change the configuration properties of the selected JMS destination for use with the associated JMS provider.

A JMS destination is used to configure the properties of a JMS destination for the associated generic JMS provider. Connections to the JMS destination are created by the associated JMS connection factory. A JMS destination for use with a generic JMS provider (not the embedded WebSphere JMS provider or WebSphere MQ JMS provider) has the following properties.

To view this administrative console page, click **Resources-> Generic JMS Providers-> *provider\_name*-> JMS Destinations-> *destination***

### *Name:*

The name by which the queue is known for administrative purposes within IBM WebSphere Application Server.

**Data type** String

### *Type:*

Whether this JMS destination is a queue (for point-to-point) or topic (for publish/subscribe).

Select one of the following options:

#### **Queue**

A JMS queue destination for point-to-point messaging.

**Topic** A JMS topic destination for publish/subscribe messaging.

### *JNDI name:*

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

### *Description:*

A description of the queue, for administrative purposes

### *Category:*

A category used to classify or group this queue, for your IBM WebSphere Application Server administrative records.

**Data type** String

*External JNDI name:*

The JNDI name that is used to bind the queue into the application server's name space.

As a convention, use the fully qualified JNDI name; for example, in the form *jms/Name*, where *Name* is the logical name of the resource.

This name is used to link the platform binding information. The binding associates the resources defined by the deployment descriptor of the module to the actual (physical) resources bound into JNDI by the platform.

**Data type** String

### **Asynchronous messaging - security considerations**

This topic describes considerations that you should be aware of if you want to use security for asynchronous messaging with WebSphere Application Server. Security for messaging operates as a part of the WebSphere Application Server global security, and is enabled only when global security is enabled.

When global security is enabled, JMS connections made to the JMS provider are authenticated, and access to JMS resources owned by the JMS provider are controlled by access authorizations. Also, all requests to create new connections to the JMS provider must provide a user ID and password for authentication. The user ID and password do not need to be provided by the application. If authentication is successful, then the JMS connection is created; if the authentication fails then the connection request is ended.

Standard J2C authentication is used for a request to create a new connection to the JMS provider. You can specify a Component-managed Authentication Alias and a Container-managed Authentication Alias for each JMS connection factory. The use of the associated J2C authentication data entries depends on the resource authentication (*res-auth*) setting, as follows:

- If your resource authentication (*res-auth*) is set to *Application*, set the alias in the Component-managed Authentication Alias. If the application that tries to create a connection to the JMS provider specifies a user ID and password, those values are used to authenticate the creation request. If the application does not specify a user ID and password, the values defined by the Component-managed Authentication Alias are used. If the connection factory is not configured with a Component-managed Authentication Alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.
- If your *res-auth* is set to *Container*, set the Container-managed Authentication Alias. The values defined by the Container-managed Authentication Alias are used to authenticate the creation request. If you do not specify an alias, then you receive a runtime JMS exception when an attempt is made to connect to the JMS provider.

#### **Restriction:**

1. User IDs longer than 12 characters cannot be used for authentication with the embedded WebSphere JMS provider. For example, the default Windows NT user ID, **Administrator**, is not valid for use with embedded WebSphere messaging, because it

contains 13 characters. Therefore, an authentication alias for a WebSphere JMS provider connection factory must specify a user ID no longer than 12 characters.

2. If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type=BINDINGS** on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:
  - To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process. If the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws a “MQJMS2013 invalid security authentication supplied for MQQueueManager” error.
  - Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

Authorization to access JMS resources owned by the embedded WebSphere JMS provider is controlled by authorization data in the config\integral-jms-authorisations.xml file. For information about editing this file, see Configuring security for the embedded WebSphere JMS provider.

#### **Related concepts**

An overview of asynchronous messaging with WebSphere

## **Using WebSphere MQ functions from JMS applications**

By default, JMS messages held on WebSphere MQ queues use an MQRFH2 header to hold some of the JMS message header information. Many legacy WebSphere MQ applications cannot process messages with these headers, and require their own characteristic headers, for example the MQCIH for CICS Bridge, or MQWIH for WebSphere MQ Workflow applications. The section “Mapping JMS to a native WebSphere MQ application” in the chapter “JMS Messages” of covers these special considerations.

## **Designing an enterprise application to use JMS**

This topic describes things to consider when designing an enterprise application to use the JMS API directly for asynchronous messaging.

This topic describes things to consider when designing an enterprise application to use the JMS API directly for asynchronous messaging.

1. The application refers to JMS resources that are predefined, as administered objects, to WebSphere Application Server.

Details of JMS resources that are used by enterprise applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support. An enterprise application can retrieve these objects from the JNDI namespace and use them without needing to know anything about their implementation. This enables the underlying messaging architecture defined by the JMS resources to be changed without requiring changes to the enterprise application. When designing an enterprise application, you need to identify the details of the following types of JMS resources:

Point-to-Point	Publish/Subscribe
QueueConnectionFactory Queue	TopicConnectionFactory Topic

A connection factory is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

For more information about the properties of these JMS resources, see *Configuring JMS provider resources*.

- The application server pools connections and sessions with the JMS provider to improve performance. This is independent from any WebSphere MQ connection pooling. You need to configure the connection and session pool properties appropriately for your applications, otherwise you may not get the connection and session behavior that you want.
- Applications can cache JMS connections, sessions, and producers or consumers. Due to the pooling mentioned above this may not give as much of a performance improvement as you might expect.

You *must not* cache session handles in stateless session beans that operate in transactions started by a client of the bean. Caching handles in this way causes the bean to be returned to the pool while the session is still involved in the transaction. Also, you should not cache non-durable subscribers due to the restriction mentioned above.

- A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see *The effect of transaction context on non-durable subscribers*.
- If you want to use authentication with embedded WebSphere messaging, you cannot have user IDs longer than 12 characters. For example, the default Windows NT user ID, **administrator**, is not valid for use with WebSphere internal messaging, because it contains 13 characters.
- For messaging operations, you should write application programs that use only references to the interfaces defined in Sun's `javax.jms` package.

JMS defines a generic view of a messaging that maps onto the underlying transport. An enterprise application that uses JMS, makes use of the following interfaces that are defined in Sun's `javax.jms` package:

**Connection**

Provides access to the underlying transport, and is used to create Sessions.

**Session**

Provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`.

**MessageProducer**

Used to send messages.

**MessageConsumer**

Used to receive messages.

The generic JMS interfaces are subclassed into the following more specific versions for Point-to-Point and Publish/Subscribe behavior:

Point-to-Point	Publish/Subscribe
QueueConnection	TopicConnection
QueueSession,	TopicSession,
QueueSender	TopicSender
QueueReceiver	TopicReceiver

For more information about using these JMS interfaces, see the Java Message Service Documentation and the WebSphere MQ *Using Java* book, SC34-5456.

The section “J2EE.6.7 Java Message Service (JMS) 1.0 Requirements” of the J2EE specification gives a list of methods that must not be called in Web and EJB containers. This is enforced in IBM WebSphere Application Server by throwing a `javax.jms.IllegalStateException`.

7. The following points, as defined in the EJB specification, apply to the use of flags on `createxxxSession` calls:
  - The `transacted` flag passed on `createxxxSession` is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the `transacted` flag is not used and, if set to true, the application should use `session.commit()` and `session.rollback()` to control the completion of the work. In an EJB2.0 module, if the `transacted` flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the `unresolvedAction` attribute of the method applies to the JMS work.
  - Clients cannot use `Message.acknowledge()` to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the `createxxxSession` call, then messages are automatically acknowledged by the application server and `Message.acknowledge()` is not used.
8. Decide what message selectors are needed.

You can use the JMS message selector mechanism to select a subset of the messages on a queue so that this subset is returned by a `receive` call. The selector can refer to fields in the JMS message header and fields in the message properties.

9. Acting on messages received.

When a message is received, you can act on it as needed by the business logic of the application. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, you need to cast from the generic `Message` class (which is the declared return type of the `receive` methods) to the more specific subclass, such as `TextMessage`. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the `instanceof` operator is used to check that the message received is of the `TextMessage` type. The message content is then extracted by casting to the `TextMessage` subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...
```

```
String replyString = ((TextMessage) inMessage).getText();
```

10. Using a listener to receive messages asynchronously.

An alternative to making calls to `QueueReceiver.receive()` is to register a method that is called automatically when a suitable message is available; for example:

```

...
MyClass listener =new MyClass();
queueReceiver.setMessageListener(listener);
//application continues with other application-specific behavior.
...

```

When a message is available, it is retrieved by the `onMessage()` method on the listener object.

```

import javax.jms.*;
public class MyClass implements MessageListener
{
public void onMessage(Message message)
{
System.out.println("message is "+message);
//application specific processing here
...
}
}

```

**Note:** A `MessageListener` can only be used in the client container. (The J2EE specification forbids the use of the JMS `MessageListener` mechanism for the asynchronous receipt of messages in the EJB and Web containers.)

For asynchronous message delivery, the application code cannot catch exceptions raised by failures to receive messages. This is because the application code does not make explicit calls to `receive()` methods. To cope with this situation, you can register an `ExceptionListener`, which is an instance of a class that implements the `onException()` method. When an error occurs, this method is called with the `JMSException` passed as its only parameter.

For more details about using listeners to receive messages asynchronously, see the [Java Message Service Documentation](#).

**Note:** An alternative to developing your own JMS listener class, you can use a message-driven bean, as described in [Implementing WebSphere enterprise applications that use message-driven beans](#).

#### 11. Warning when receiving messages within a server-side application component.

Take care when performing a `JMS receive()` from a server-side application component if that `receive()` invocation is waiting on a message produced by another application component that is deployed in the same server. Such a `JMS receive()` is synchronous, so blocks until the response message is received.

This type of application design can lead to the consumer/producer problem where the entire set of work threads can be exhausted by the receiving component, which has been blocked waiting for responses, leaving no available worker thread for which to dispatch the application component that would generate the response JMS message.

To illustrate this problem, picture a servlet and a message-driven bean deployed in the same server. When this servlet dispatches a request it sends a message to a queue which is serviced by the message-driven bean (that is, messages produced by the servlet are consumed by the message-driven bean's `onMessage()` method). The servlet subsequently issues a `receive()`, waiting for a reply on a temporary `ReplyTo` queue. The message-driven bean's `onMessage()` method performs a database query and sends back a reply to the servlet on the temporary queue. If a large number of servlet requests occur at once (relative to the number of server worker threads), then it is likely that all available server worker threads will be used to dispatch a servlet request,

send a message, and wait for a reply. The application server enters a deadly-embrace condition whereby no threads remain to process any of the message-driven beans that are now pending. Since the servlets are waiting in blocking receives, the server hangs, likely leading to application failure.

Possible solutions are:

- a. Ensure that the number of worker threads (# of threads per server region \* # of server regions per server) exceeds the number of concurrent dispatches of the application component doing the receive() so that there is always a worker thread available to dispatch the message producing component.
- b. Use an application topology that places the receiver application component in a separate server than the producer application component. While worker thread usage can still need to be carefully considered under such a deployment scenario, this separation ensures that there are always be threads that cannot be blocked by the message receiving component. There can be other interactions to consider, such as an application server that has multiple applications installed.
- c. Refactor your application to do the message receives from a client component, which will not compete with the producer component for worker threads. Furthermore, the client component can do asynchronous (non-blocking) receives, which are prohibited from J2EE servers. So, for example, the example application above could be refactored to have a client sending messages to a queue and then waiting for a response from the MDB.

### **The effect of transaction context on non-durable subscribers**

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. A non-durable subscriber is invalidated whenever a sharing boundary (in general, a local or global transaction boundary) is crossed, resulting in a `javax.jms.IllegalStateException` with message text "Non-durable subscriber invalidated on transaction boundary".

For example, in the following scenario the non-durable subscriber is invalidated at the begin user transaction. This is because the local transaction context in which the subscriber was created ends when the user transaction begins:

```
...
create subscriber
...
begin user transaction -
...
complete user transaction -
...
use subscriber
...
```

If you want to cache a subscriber (to wait to receive messages that arrived since it was created), then use a durable subscriber (for which this restriction does not apply). Do not cache non-durable subscribers.

## **Developing a J2EE application to use JMS**

Use this task to develop a J2EE application to use the JMS API directly for asynchronous messaging.

This topic gives an overview of the steps needed to develop a J2EE application (servlet or enterprise bean) to use the JMS API directly for asynchronous messaging.

This topic only describes the JMS-related considerations; it does not describe general J2EE application programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing a J2EE application to use JMS, see the Java Message Service Documentation and the WebSphere MQ *Using Java* book, SC34-5456.

Details of JMS resources that are used by J2EE applications are defined to WebSphere Application Server and bound into the JNDI namespace by the WebSphere administrative support.

To use JMS, any method of a J2EE application completes the following general steps:

1. Import JMS packages. A J2EE application that uses JMS starts with a number of import statements for JMS, which should include at least the following:

```
import javax.jms.*;           //JMS interfaces
import javax.naming.*;       //Used for JNDI lookup of administered objects
```

2. Get an initial context.

```
try {
    ctx = new InitialContext(env);
    ...
}
```

3. Retrieve administered objects from the JNDI namespace. The `InitialContext.lookup()` method is used to retrieve administered objects (a queue connection factory and the queue destinations); for example, to receive a message from a queue

```
qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
inQueue = (Queue)ctx.lookup( qnameIn );
...
```

4. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The `createQueueConnection()` method on the factory object is used to create the connection.

```
connection = qcf.createQueueConnection();
```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, `MessageConsumers` that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```
connection.start();
```

5. Create a session, for sending or receiving messages. The session provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`. The `createQueueSession` method is used on the connection to obtain a session. The method takes two parameters:

- A boolean that determines whether or not the session is transacted.
- A parameter that determines the acknowledge mode.

```
boolean transacted = false;
session = connection.createQueueSession( transacted,
                                         Session.AUTO_ACKNOWLEDGE);
```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the application terminates unexpectedly.

The following points, as defined in the EJB specification, apply to these flags:

- The transacted flag passed on createQueueSession is ignored inside a global transaction and all work is performed as part of the transaction. Outside of a transaction the transacted flag is not used and, if set to true, the application should use session.commit() and session.rollback() to control the completion of the work. In an EJB2.0 module, if the transacted flag is set to true and outside of an XA transaction, then the session is involved in the WebSphere local transaction and the unresolved action attribute of the method applies to the JMS work.
- Clients cannot use using Message.acknowledge() to acknowledge messages. If a value of CLIENT\_ACKNOWLEDGE is passed on the createxxxSession call, then messages are automatically acknowledged by the application server and Message.acknowledge() is not used.

6. Send a message.

- a. Create MessageProducers to create messages. For point-to-point messaging the MessageProducer is a QueueSender that is created by passing an output queue object (retrieved earlier) into the createSender method on the session. A QueueSender is normally created for a specific queue, so that all messages sent using that sender are sent to the same destination.

```
QueueSender queueSender = session.createSender(inQueue);
```

- b. Create the message. Use the session to create an empty message and add the data passed.

JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

In this example, a text message is created from the outString property:

```
TextMessage outMessage = session.createTextMessage(outString);
```

- c. Send the message.

To send the message, the message is passed to the send method on the QueueSender:

```
queueSender.send(outMessage);
```

7. Receive replies.

- a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a JMSCorrelationID.

```
messageID = outMessage.getJMSMessageID();
```

The correlation ID is then used in a message selector, to select only messages that have that ID:

```
String selector = "JMSCorrelationID = '"+messageID+"'";
```

- b. Create a MessageReceiver to receive messages. For point-to-point the MessageReceiver is a QueueReceiver that is created by passing an input queue object (retrieved earlier) and the message selector into the createReceiver method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

- c. Retrieve the reply message. To retrieve a reply message, the receive method on the QueueReceiver is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the receive call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message

available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the `receiveNoWait()` method. In this example, the receive call returns when the message arrives, or after 2000ms, whichever is sooner.

- d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, it is necessary to cast from the generic `Message` class (which is the declared return type of the receive methods) to the more specific subclass, such as `TextMessage`. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the `instanceof` operator is used to check that the message received is of the `TextMessage` type. The message content is then extracted by casting to the `TextMessage` subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...
```

```
String replyString = ((TextMessage) inMessage).getText();
```

8. Closing down. If the application needs to create many short-lived JMS objects at the `Session` level or lower, it is important to close all the JMS resources used. To do this, you call the `close()` method on the various classes (`QueueConnection`, `QueueSession`, `QueueSender`, and `QueueReceiver`) when the resources are no longer required.

```
queueReceiver.close();
```

```
...
```

```
queueSender.close();
```

```
...
```

```
session.close();  
session = null;
```

```
...
```

```
connection.close();  
connection = null;
```

9. Publishing and subscribing messages. To use JMS Publish/Subscribe support instead of point-to-point messaging, the general actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as `TopicPublisher` instead of `QueueSender`), as shown in the following example to publish a message:

```
// Creating a TopicPublisher  
TopicPublisher pub = session.createPublisher(topic);  
...  
pub.publish(outMessage);  
...  
// Closing TopicPublisher  
pub.close();
```

10. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw `JMSEExceptions` to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

Unlike normal Java exceptions, a `JMSEException` can contain another exception embedded in it. The implementation of `JMSEException` does not include the embedded exception in the output of its `toString()` method. Therefore, you need to check explicitly for an embedded exception and print it out, as shown in the following example:

```
catch (JMSEException je)  
{  
    System.out.println("JMS failed with "+je);
```

```

        Exception le = je.getLinkedException();
        if (le != null)
        {
            System.out.println("linked exception "+le);
        }
    }
}

```

After you have packaged your application, you can next deploy the application into WebSphere Application Server, as described in [Deploying a J2EE application to use JMS](#).

[Developing an enterprise application to use message-driven beans](#)

## Developing a JMS client

Use this task to develop a JMS client application to use messages to communicate with enterprise applications.

This topic gives an overview of the steps needed to develop a JMS client application, based on a sample client provided with WebSphere Application Server. This topic only describes the JMS-related considerations; it does not describe general client programming, which you should already be familiar with. For detailed information about these steps, and for examples of developing JMS clients, see the [Java Message Service Documentation](#) and the [WebSphere MQ \*Using Java\* book](#), SC34-5456.

A JMS client assumes that the JMS resources (such as a queue connection factory and queue destination) already exist. A client application can use JMS resources administered by the application server or administered by the client container regardless of whether the client application is running on the same machine as the server or remotely.

- If you want your client application to use server-administered JMS objects, configure the client application to use those resources as Resource Environment References in the Application Assembly Tool.
- If you want your client application to use client container-administered JMS resources, then configure those resources as Resource References.

For more information about developing client applications and configuring JMS resources for them, see [Developing J2EE application client code and related tasks](#).

To use JMS, a typical JMS client program completes the following general steps:

1. Import JMS packages. An enterprise application that uses JMS starts with a number of import statements for JMS; for example:

```

import javax.naming.Context;
import javax.naming.InitialContext;
import javax.rmi.PortableRemoteObject;
import javax.jms.*;

```

2. Get an initial context.

```

    try
    {
        ctx = new InitialContext(env);
    }
    ...

```

3. Define the parameters that the client wants to use; for example, to identify the queue connection factory and to assemble a message to be sent.

```

public class JMSppSampleClient
{
    public static void main(String[] args)
        throws JMSEException, Exception
    {
    }
}

```

```

{
    String messageID          = null;
    String outString         = null;
    String qcfName           = "java:comp/env/jms/ConnectionFactory";
    String qnameIn           = "java:comp/env/jms/Q1";
    String qnameOut          = "java:comp/env/jms/Q2";
    boolean verbose          = false;

    QueueSession             session = null;
    QueueConnection          connection = null;
    Context                  ctx      = null;

    QueueConnectionFactory qcf      = null;
    Queue                   inQueue  = null;
    Queue                   outQueue = null;

```

...

4. Retrieve administered objects from the JNDI namespace. The `InitialContext.lookup()` method is used to retrieve administered objects (a queue connection factory and the queue destinations):

```

        qcf = (QueueConnectionFactory)ctx.lookup( qcfName );
...
        inQueue = (Queue)ctx.lookup( qnameIn );
        outQueue = (Queue)ctx.lookup( qnameOut );
...

```

5. Create a connection to the messaging service provider. The connection provides access to the underlying transport, and is used to create sessions. The `createQueueConnection()` method on the factory object is used to create the connection.

```

        connection = qcf.createQueueConnection();

```

The JMS specification defines that connections should be created in the stopped state. Until the connection starts, `MessageConsumers` that are associated with the connection cannot receive any messages. To start the connection, issue the following command:

```

        connection.start();

```

6. Create a session, for sending and receiving messages. The session provides a context for producing and consuming messages, including the methods used to create `MessageProducers` and `MessageConsumers`. The `createQueueSession` method is used on the connection to obtain a session. The method takes two parameters:

- A boolean that determines whether or not the session is transacted.
- A parameter that determines the acknowledge mode.

```

        boolean transacted = false;
        session = connection.createQueueSession( transacted,
                                                Session.AUTO_ACKNOWLEDGE);

```

In this example, the session is not transacted, and it should automatically acknowledge received messages. With these settings, a message is backed out only after a system error or if the client application terminates unexpectedly.

7. Send the message.
  - a. Create `MessageProducers` to create messages. For point-to-point the `MessageProducer` is a `QueueSender` that is created by passing an output queue object (retrieved earlier) into the `createSender` method on the session. A `QueueSender` is normally created for a specific queue, so that all messages sent using that sender are sent to the same destination.

```

        QueueSender queueSender = session.createSender(inQueue);

```

- b. Create the message. Use the session to create an empty message and add the data passed.

JMS provides several message types, each of which embodies some knowledge of its content. To avoid referencing the vendor-specific class names for the message types, methods are provided on the Session object for message creation.

In this example, a text message is created from the `outString` property, which could be provided as an input parameter on invocation of the client program or constructed in some other way:

```
TextMessage outMessage = session.createTextMessage(outString);
```

- c. Send the message.

To send the message, the message is passed to the `send` method on the `QueueSender`:

```
queueSender.send(outMessage);
```

## 8. Receive replies.

- a. Create a correlation ID to link the message sent with any replies. In this example, the client receives reply messages that are related to the message that it has sent, by using a provider-specific message ID in a `JMSCorrelationID`.

```
messageID = outMessage.getJMSMessageID();
```

The correlation ID is then used in a message selector, to select only messages that have that ID:

```
String selector = "JMSCorrelationID = '"+messageID+"'";
```

- b. Create a `MessageReceiver` to receive messages. For point-to-point the `MessageReceiver` is a `QueueReceiver` that is created by passing an input queue object (retrieved earlier) and the message selector into the `createReceiver` method on the session.

```
QueueReceiver queueReceiver = session.createReceiver(outQueue, selector);
```

- c. Retrieve the reply message. To retrieve a reply message, the `receive` method on the `QueueReceiver` is used:

```
Message inMessage = queueReceiver.receive(2000);
```

The parameter in the `receive` call is a timeout in milliseconds. This parameter defines how long the method should wait if there is no message available immediately. If you omit this parameter, the call blocks indefinitely. If you do not want any delay, use the `receiveNoWait()` method. In this example, the `receive` call returns when the message arrives, or after 2000ms, whichever is sooner.

- d. Act on the message received. When a message is received, you can act on it as needed by the business logic of the client. Some general JMS actions are to check that the message is of the correct type and extract the content of the message. To extract the content from the body of the message, you need to cast from the generic `Message` class (which is the declared return type of the `receive` methods) to the more specific subclass, such as `TextMessage`. It is good practice always to test the message class before casting, so that unexpected errors can be handled gracefully.

In this example, the `instanceof` operator is used to check that the message received is of the `TextMessage` type. The message content is then extracted by casting to the `TextMessage` subclass.

```
if ( inMessage instanceof TextMessage )
```

```
...  
    String replyString = ((TextMessage) inMessage).getText();
```

9. Closing down. If the application needs to create many short-lived JMS objects at the Session level or lower, it is important to close all the JMS resources used. To do this, you call the `close()` method on the various classes (`QueueConnection`, `QueueSession`, `QueueSender`, and `QueueReceiver`) when the resources are no longer required.

```
    queueReceiver.close();  
...  
    queueSender.close();  
...  
    session.close();  
    session = null;  
...  
    connection.close();  
    connection = null;
```

10. Publishing and subscribing messages. To use publish/subscribe support instead of point-to-point messaging, the general client actions are the same; for example, to create a session and connection. The exceptions are that topic resources are used instead of queue resources (such as `TopicPublisher` instead of `QueueSender`), as shown in the following example to publish a message:

```
// Creating a TopicPublisher  
    TopicPublisher pub = session.createPublisher(topic);  
...  
    pub.publish(outMessage);  
...  
    // Closing TopicPublisher  
    pub.close();
```

11. Handling errors Any JMS runtime errors are reported by exceptions. The majority of methods in JMS throw `JMSEExceptions` to indicate errors. It is good programming practice to catch these exceptions and display them on a suitable output.

Unlike normal Java exceptions, a `JMSEException` can contain another exception embedded in it. The implementation of `JMSEException` does not include the embedded exception in the output of its `toString()` method. Therefore, you need to check explicitly for an embedded exception and print it out, as shown in the following example:

```
    catch (JMSEException je)  
    {  
        System.out.println("JMS failed with "+je);  
        Exception le = je.getLinkedException();  
        if (le != null)  
        {  
            System.out.println("linked exception "+le);  
        }  
    }
```

## **Deploying a J2EE application to use JMS**

This topic describes how to deploy a J2EE application to use JMS.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for JMS, that can be deployed in WebSphere Application Server.

To deploy a J2EE application to use JMS, complete the following steps:

1. Configuring the application for deployment.  
Use the the application assembly tool to configure the deployment attributes for the application, as described in *Assembling applications*.
2. Use the WebSphere administrative console to install the application.  
This stage is a standard WebSphere Application Server task, as described in *Installing applications*.

#### **Related tasks**

Deploying and managing applications

## **Troubleshooting WebSphere Messaging**

Use this overview task to help resolve a problem that you think is related to the WebSphere Messaging.

To identify and resolve problems that you think are related to WebSphere Messaging, you can use the standard WebSphere Application Server troubleshooting facilities. If you encounter a problem that you think might be related to WebSphere Messaging, complete the following stages. Some problems and their troubleshooting are specific to whether you are using the embedded WebSphere Messaging or WebSphere MQ as the JMS provider.

1. Check for common problems related to WebSphere Messaging. For example, check that the JMS server has been started, that you have added queue names to the list on the JMS server page of the Administrative Console, and that you have successfully installed the WebSphere Messaging function.  
For tips about solving problems related to the WebSphere Messaging, see *Tips for troubleshooting WebSphere Messaging*. If those tips do not help you fix the problem, complete the following general stages.
2. Check the Release Notes for specific problems and workarounds The section *Possible Problems and Suggested Fixes* of the Release Notes, available from the WebSphere Application Server library web site, is updated regularly to contain information about known defects and their workarounds. Check the latest version of the Release Notes for any information about your problem. If the Release Notes do not contain any information about your problem, you can also search the Technotes database on the WebSphere Application Server web site.
3. Check for WebSphere Messaging messages in the application server's output log. Check the SystemOut log for error messages for messages related to WebSphere Messaging; look for the prefixes MSGS and WMSG. The associated message reference information provides an explanation and any user actions to resolve the problem.
4. Check your JMS resource configurations If the WebSphere Messaging functions seem to be running properly (the JMS server is running without problems), check that the JMS resources have been configured correctly. For example, check that queue destinations and their connection factories have corresponding JNDI names, that the JNDI names match those configured for the messaging applications, and that the connection factories are configured onto nodes that can provide the JMS resources.

5. Get a detailed exception dump for WebSphere Messaging. If the information obtained in the preceding steps is still inconclusive, you can enable the application server debug trace for the “Messaging” group to provide a detailed exception dump.

#### **Related tasks**

Troubleshooting problems with message-driven beans  
Administering WebSphere JMS support

### **Tips for troubleshooting WebSphere Messaging**

This topic provides a set of tips to help you troubleshoot problems with WebSphere Messaging.

- The JMS server may not be started by default when WebSphere Messaging is installed
- The JMS server tries to start, but fails
- An MDB listener fails to start
- Failure to create a queue connection
- Embedded WebSphere Messaging failed to install on top of an existing WebSphere MQ product
- Problems running JMS applications with security enabled
- Queue manager fails to stop on Redhat Linux

#### **The JMS server does not start when starting the WebSphere administrative server**

During installation, the system PATH setting is updated to include the WebSphere Messaging directories. If you try to start the WebSphere administrative server from a session that does not use the updated system PATH, the JMS Server fails to start properly. To resolve this after installing WebSphere Application Server stop then restart your host or open a new session that uses the updated system PATH.

Also, when installing WebSphere Application Server, the JMS server is not configured to start automatically by default, except on Windows if the messaging samples are installed. So, generally, if you want to use JMS resources on that host, use the administrative console to configure the JMS server to start automatically. For more information about managing JMS servers, see Administering WebSphere JMS support.

Finally, check that the JMS server has started before trying to use WebSphere Messaging. For SystemOut.log messages that indicate the JMS server has started successfully, see the following tip The JMS server tries to start, but fails.

#### **The JMS server tries to start, but fails**

To see if the JMS Server has started, check the *was\_home*\logs\server\SystemOut log. If the JMS server started successfully, you should see the following lines:

```
...
[date time] 58217585 JMSProvider    A MSGS0050I: Starting the Queue Manager
[date time] 58217585 JMSProvider    A MSGS0051I: Queue Manager open for business
[date time] 58217585 JMSProvider    A MSGS0052I: Starting the Broker
[date time] 58217585 JMSProvider    A MSGS0053I: Broker open for business
```

If the JMS server tries to start, but fails, you should see messages indicating that the queue manager could not start, like the following:

```
...
[date time] 58228abf QueueManagerM E MSGS0153E: The Queue Manager process could not be started - e
002: No such file or directory
```

## An MDB listener fails to start

If an MDB listener fails to start, you should see the following message:

```
WMSG0019E: Unable to start MDB Listener {0}, JMSDestination {1} : {2}
```

To troubleshoot the cause of an MDB listener not starting, check the following factors:

- Check that the administrative resources have been configured correctly; for example, use the administrative console to check the listener port properties: Destination JNDI name and Connection factory JNDI name. Check that other properties of the listener port, destination, and connection factory are correct.
- Check that the queue exists and has been added to the JMS server.
- Check that the queue manager and JMS server have started.
- Check that the Remote Queue Manager Listener has started.
- If security is enabled, check that a component-managed authentication alias has been specified on the queue connection factory or topic connection factory used by the message-driven bean. This is not required if security is not enabled.
- Check that the user ID used to start the MDB listener has 12 characters or less.

## Failure to create a queue connection

If WebSphere Application Server fails to create a queue connection, the SystemOut.log contains messages like the following:

```
[date time] 577cb554 PoolManager E J2CA0046E: Method addNewConnection caught javax.resource.spi.Re
```

Check that the JMS server is running (including that the Internal WebSphere Messaging or WebSphere MQ JMS provider was installed correctly) as described in preceding tips.

**Note:** In a Network Deployment or Enterprise multi-node cell, the JMS server used by a messaging application can be on a different node to the application. Either check that all JMS servers in the cell have started, or use the Administrative console to determine which JMS server the application is trying to connect to (look at the Node property of the appropriate connection factory), then check that the JMS server has started.

## Embedded WebSphere Messaging failed to install on top of an existing WebSphere MQ product

When preparing to install WebSphere Application Server on a host that already has WebSphere MQ installed, you should ensure that WebSphere MQ is at a prerequisite level, as described in the Release Notes and Supported hardware, software, and APIs page of the WebSphere Application Server library web site. You can also check the WebSphere MQ Support service summary Web page at <http://www-3.ibm.com/software/ts/mqseries/support/summary/>.

If you have a problem installing the embedded WebSphere Messaging function, first check the mq\_install.log. Failures during the WebSphere Messaging prereq stage usually indicate a shortage of space. Failures after this stage are usually due to a conflict between messaging components already installed on the machine and the levels required to support the J2EE 1.3 specification.

If the embedded WebSphere Messaging function installed successfully, you should see messages like the following in mq\_install.log:

```

...
date time MsiInstallProduct() returning ERROR_SUCCESS (0)
date time ===== Exiting Publish And Subscribe Install =====
date time <<Function Successful>> return code WASM_ERROR_SUCCESS (0)
date time ===== End of WebSphere Messaging Install Log =====

```

You can also check the createMQ.log for any messages that indicate a configuration problem with the installation of WebSphere Messaging.

### Problems running JMS applications with security enabled

When trying to run a JMS application with security enabled, you can encounter problems indicated by one of the error messages:

**MSGS0508E: The JMS Server security service was unable to authenticate userid:**

This indicates that the JMS connection has not provided the WebSphere JMS server with any security credentials.

**WMSG0019E: Unable to start MDB Listener PSSampleMDB, JMSDestination Sample/JMS/listen : javax.jms.JMSSecurityException:**

This indicates that the security credentials supplied are not valid.

In both cases the problem can be removed by doing one of the following:

- If the authentication mechanism is set to *Application*, then the application needs to supply valid credentials.
- If the authentication mechanism is set to *Container*, then you need to configure the JMS ConnectionFactory with a container-managed *Authentication Alias* and ensure that the associated username and password are valid.

**MQJMS2013 invalid security authentication supplied for MQQueueManager**

If using a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, and the user specified is not the current logged on user for the WebSphere Application Server process, then the WebSphere MQ JMS Bindings authentication throws a “MQJMS2013 invalid security authentication supplied for MQQueueManager” error.

If you want to use a WebSphere MQ JMS Provider JMS connection when using Bindings transport mode, you set the property **Transport type=BINDINGS** on the WebSphere MQ Queue Connection Factory. You must also choose one of the following options:

- To use security credentials, ensure that the user specified is the currently logged on user for the WebSphere Application Server process.
- Do not specify security credentials. On the WebSphere MQ Connection Factory, ensure that both the **Component-managed Authentication Alias** and the **Container-managed Authentication Alias** properties are not set.

For more information about messaging security, see Asynchronous messaging - security considerations.

### Queue manager fails to stop on Redhat Linux

When trying to stop an application server on Redhat Linux, the queue manager can hang with a Java core dump, and the last message in the SystemOut.log file is “Stopping Queue manager...”.

This is caused by a known RedHat problem ([https://bugzilla.linux.ibm.com/show\\_bug.cgi?id=2336](https://bugzilla.linux.ibm.com/show_bug.cgi?id=2336)), that was introduced in libstdc++-2.96-116.7.2 and beyond.

The workaround is to go back to the libstdc++-2.96-108.1 level.

## Messaging: Resources for learning

The WebSphere MQ for z/OS library includes books specific to the z/OS platform, and family books that apply to all WebSphere MQ products, including WebSphere MQ for z/OS .

### WebSphere MQ for z/OS publications

Publications specific to the z/OS platform are as follows:

- WebSphere MQ for z/OS Concepts and Planning Guide  
GC34-6051, describes the concepts of WebSphere MQ for z/OS and tells you how to plan your WebSphere MQ for z/OS systems.
- WebSphere MQ for z/OS System Setup Guide  
SC34-6052, tells you how to customize WebSphere MQ for z/OS after you have installed it. It also tells you how to monitor system use and performance, and how to set up security.
- WebSphere MQ for z/OS System Administration Guide  
SC34-6053, tells you how to operate WebSphere MQ for z/OS using commands, panels, and utilities, and how to write applications to administer WebSphere MQ for z/OS . The latter part of the book deals with termination, recovery, and restart.
- WebSphere MQ for z/OS Problem Determination Guide  
GC34-6054, will help you to determine the causes of WebSphere MQ for z/OS problems, resolve those problems, deal with the IBM support center, and handle APARs.
- WebSphere MQ for z/OS Messages and Codes  
GC34-6056, lists all the user messages and abend reason codes returned by WebSphere MQ for z/OS , with explanations and suggested responses. It is designed for use as a quick reference, and is linked with the WebSphere MQ for z/OS Problem Determination Guide, which you should also consult if a message indicates that there is a WebSphere MQ for z/OS problem.

### WebSphere MQ family publications

WebSphere MQ family books that include information for WebSphere MQ for z/OS:

- WebSphere MQ Script (MQSC) Command Reference  
SC34-6055, describes the MQSC commands, used by system operators and administrators to manage queue managers. It introduces the commands and tells you how to use them, before describing the commands in detail, in alphabetic order.
- WebSphere MQ Intercommunication  
SC34-6059, describes intercommunication between WebSphere MQ products. It introduces the concepts of intercommunication (transmission queues, message channel agent programs, and communication links) that are brought together to form message channels. It describes how geographically-separated queue managers are linked together by message channels to form a network of queue

managers. It discusses the distributed-queuing management (DQM) facility of WebSphere MQ, which provides the services that enable applications to communicate using queue managers.

- WebSphere MQ Application Programming Reference  
SC34-6062, introduces the concepts of messages and queues, and gives a full description of the WebSphere MQ programming interface, including data types, function calls, attributes, return codes, and constants.
- WebSphere MQ Application Programming Guide  
SC34-6064, introduces the concepts of messages and queues, and shows you how to design, write, and build applications that use the services that WebSphere MQ provides.
- WebSphere MQ Using Java  
SC34-6066, tells you how to install, and write programs with, the WebSphere MQ classes for Java to access WebSphere MQ systems, and the WebSphere MQ classes for Java Message Service to access both Java Message Service (JMS) and WebSphere MQ applications.
- WebSphere MQ Using C++  
SC34-6067, describes the C++ programming-language binding to the WebSphere MQ Message Queue Interface (MQI). It introduces the binding, describes considerations associated with using C++ with WebSphere MQ, and describes the WebSphere MQ C++ classes.

---

## Using message-driven beans in applications

WebSphere Application Server supports asynchronous messaging as a method of communication based on the Java Message Service (JMS) programming interface.

Message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification) extend the base JMS support and the Enterprise JavaBean component model to provide automatic asynchronous messaging. When a message arrives on a destination, a listener passes the message to a new instance of a user-developed message-driven bean for processing.

You can use WebSphere Studio Application Developer to develop applications that use message-driven beans. You can use the WebSphere Application Server runtime tools, like the administrative console, to deploy and administer applications that use message-driven beans.

For more information about implementing WebSphere enterprise applications that use message-drive beans, see the following topics:

- An overview of message-driven beans
- Designing an enterprise application to use a message-driven bean
- Developing an enterprise application to use a message-driven bean
- Deploying an enterprise application to use a message-driven bean
- Configuring message listener resources for message-driven beans
- Troubleshooting problems with message-driven beans

### Related tasks

Implementing WebSphere enterprise applications that use JMS

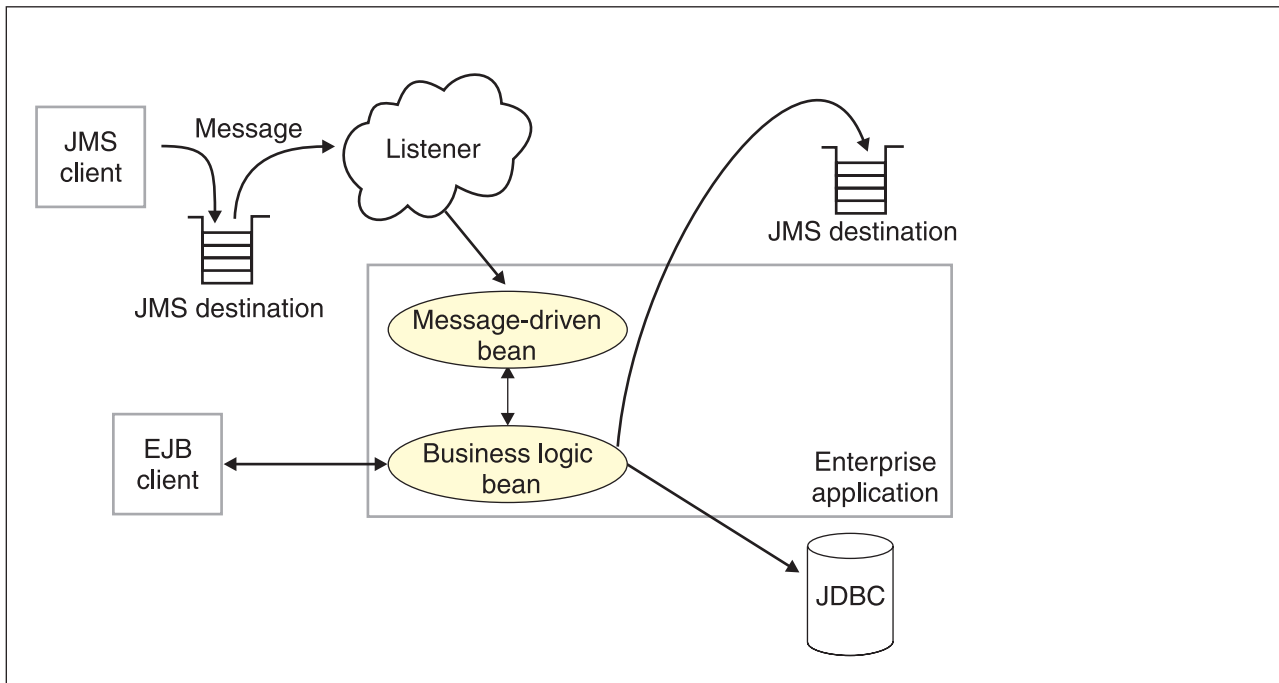

## Message-driven beans - an overview

WebSphere Application Server supports automatic asynchronous messaging with message-driven beans (a type of enterprise bean defined in the EJB 2.0 specification). Messaging with message-driven beans is shown in the figure "Message-driven beans - an overview."

The support for message-driven beans is based on the message listener service, which comprises a listener manager that controls and monitors one or more listeners. Each listener monitors a JMS destination for incoming messages. When a message arrives on the destination, the listener passes the message to a new instance of a user-developed message-driven bean (an enterprise bean) for processing. The listener then looks for the next message without waiting for the bean to return.

Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.

You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.

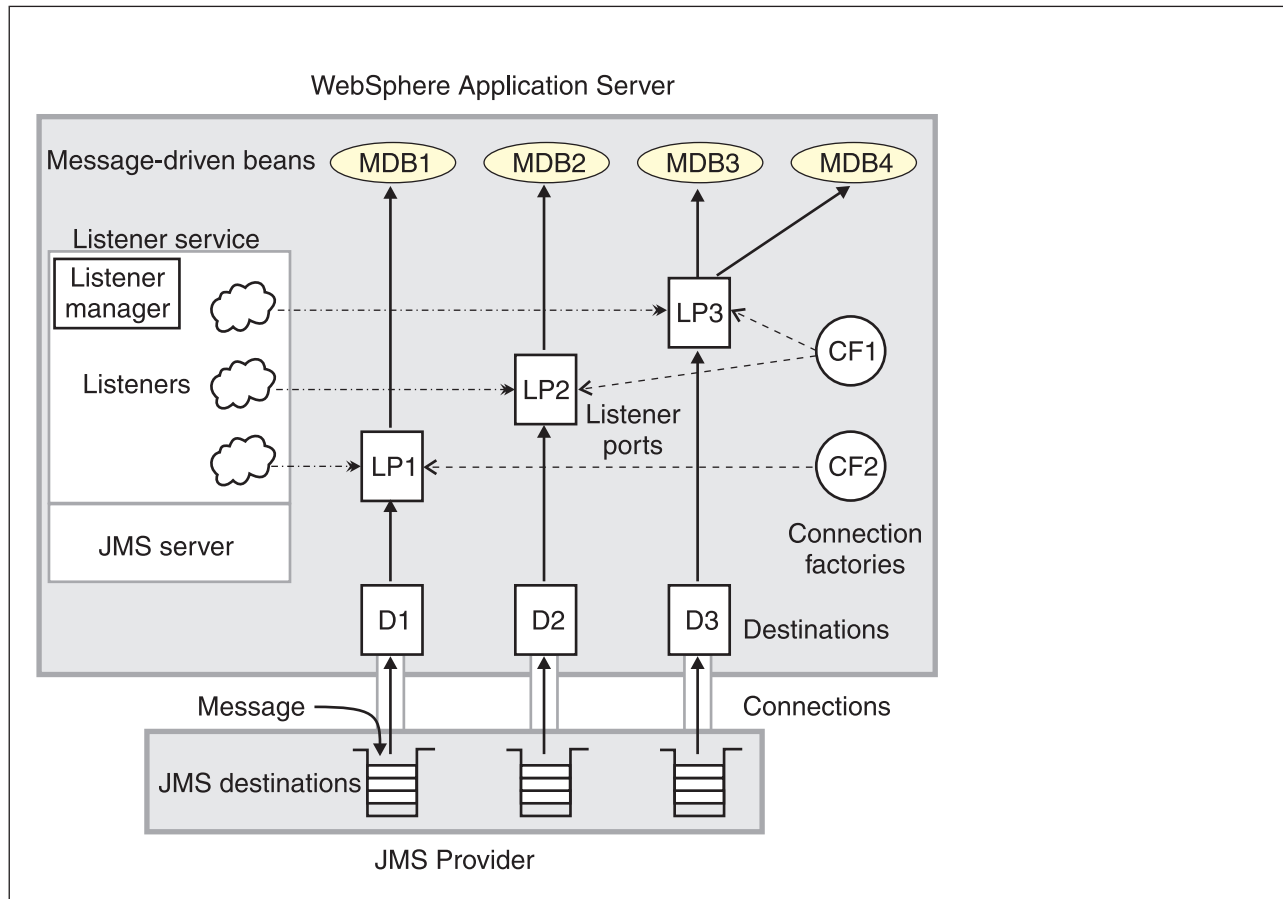

*Figure 4. Message-driven beans and the message listener service.* This figure shows an incoming message being passed by a JMS listener to a message-driven bean, which passes the message on to a business logic bean for business processing. This messaging is controlled by the listener manager. For more information, see the text that accompanies this figure.

## Message-driven beans - components

The WebSphere Application Server support for message-driven beans is based on JMS message listeners and the message listener service, and builds on the base support for JMS. The main components of WebSphere Application Server support

for message-driven beans are shown in the following figure and described after the figure:

*Figure 5. The main components for message-driven beans.* This figure shows the main components of WebSphere support for message-driven beans, from JMS provider through a connection to a destination, listener port, then deployed message-driven bean that processes the message retrieved from the destination. Each listener port defines the association between a connection factory, destination, and a deployed message-driven bean. The other main components are the message listener service, which comprises a listener for each listener port, all controlled by the same listener manager. For more information, see the text that accompanies this figure.

The message listener service is an extension to the JMS functions of the JMS provider and provides a listener manager, which controls and monitors one or more JMS listeners.

Each listener monitors either a JMS queue destination (for point-to-point messaging) or a JMS topic destination (for publish/subscribe messaging).

A connection factory is used to create connections with the JMS provider for a specific JMS queue or topic destination. Each connection factory encapsulates the configuration parameters needed to create a connection to a JMS destination.

A listener port defines the association between a connection factory, a destination, and a deployed message-driven bean. Listener ports are used to simplify the administration of the associations between these resources.

When a deployed message-driven bean is installed, it is associated with a listener port and the listener for a destination. When a message arrives on the destination, the listener passes the message to a new instance of a message-driven bean for processing.

When an application server is started, it initializes the listener manager based on the configuration data. The listener manager creates a dynamic session thread pool for use by listeners, creates and starts listeners, and during server termination controls the cleanup of listener message service resources. Each listener completes several steps for the JMS destination that it is to monitor, including:

- Creating a JMS server session pool, and allocating JMS server sessions and session threads for incoming messages.
- Interfacing with JMS ASF to create JMS connection consumers to listen for incoming messages.
- If specified, starting a transaction and requesting that it is committed (or rolled back) when the EJB method has completed.
- Processing incoming messages by invoking the `onMessage()` method of the specified enterprise bean.

#### **Related concepts**

Components of WebSphere JMS support

### **Message-driven beans - transaction support**

Message-driven beans can handle messages read from JMS destinations within the scope of a transaction. If transaction handling is specified for a JMS destination, the JMS listener starts a global transaction *before* it reads any incoming message from that destination. When the message-driven bean processing has finished, the JMS listener commits or rolls back the transaction (using JTA transaction control).

#### **Note:**

- All messages retrieved from a specific destination have the same transactional behavior.

If messages are queued to be sent within a global transaction they are sent when the transaction is committed. If the processing of a message causes the transaction to be rolled back, then the message that caused the bean instance to be invoked is left on the JMS destination.

You can configure the **Maximum retries** property of the listener port to define the maximum number of times the listener attempts to read a message from a destination. When the Max retries limit is reached, the listener for that destination is stopped. When you have resolved the problem, you must then restart the listener.

Listener port properties

## **Designing an enterprise application to use message-driven beans**

This topic describes things to consider when designing an enterprise application to use message-driven beans.

The considerations in this topic are based on a generic enterprise application that uses one message-driven bean to retrieve messages from a JMS queue destination and passes the messages on to another enterprise bean that implements the business logic.

To design an enterprise application to use message-driven beans, complete the following steps:

1. Identify the JMS resources that the application is to use. This helps to identify the properties of resources that need to be used within the application and

configured as application deployment descriptors or within WebSphere Application Server.

JMS resource type	Properties
Queue connection factory	<b>Name:</b> SamplePtoPQueueConnectionFactory <b>JNDI Name:</b> Sample/JMS/QCF
Queue destination	<b>Name:</b> Q1 <b>JNDI Name:</b> Sample/JMS/Q1
Listener port (for the destination)	<b>Name:</b> SamplePtoPListenerPort <b>Connection Factory JNDI Name:</b> Sample/JMS/QCF <b>Destination JNDI Name:</b> Sample/JMS/Q1 <b>Maximum Sessions:</b> 5 <b>Maximum Retries:</b> 10 <b>Maximum Messages:</b> 1
Message-driven bean (deployment properties)	<b>Name:</b> JMSppSampleMDBBean <b>Transaction type:</b> Container <b>Destination type:</b> Queue <b>Listener port name:</b> SamplePtoPListenerPort
Business logic bean	<b>Name:</b> MyLogicBean

Ensure that you use consistent values where needed; for example, the JNDI names for the connection factory and destination must be the same for both those resources and the equivalent properties of the listener port.

2. Separation of business logic. You are recommended to develop a message-driven bean to delegate the business processing of incoming messages to another enterprise bean. This provides clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client.
3. Security considerations.  
Messages arriving at a destination being processed by a listener have no client credentials associated with them; the messages are anonymous. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component. For more information about EJB security, see EJB component security.
4. General JMS considerations For Publish/Subscribe messaging, choose the JMS server port to be used depending on your needs for transactions or performance:

**Queued port**

The TCP/IP port number of the listener port used for all point-to-point and Publish/Subscribe support.

**Direct port**

The TCP/IP port number of the listener port used for direct TCP/IP connection (non-transactional, non-persistent, and non-durable subscriptions only) for Publish/Subscribe support.

**Note:** Message-driven beans cannot use the direct listener port for Publish/Subscribe support. Therefore, any topic connection factory configured with **Portset** to **Direct** cannot be used with message-driven beans.

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that

existed when the subscriber was created. For more information about this context restriction, see *The effect of transaction context on non-durable subscribers*.

## Developing an enterprise application to use message-driven beans

Use this task to develop an enterprise application to use a message-driven bean. The message-driven bean is invoked by a JMS listener when a message arrives on the input queue that the listener is monitoring.

You are recommended to develop the message-driven bean to delegate the business processing of incoming messages to another enterprise bean, to provide clear separation of message handling and business processing. This also enables the business processing to be invoked by either the arrival of incoming messages or, for example, from a WebSphere J2EE client. Responses can be handled by another enterprise bean acting as a sender bean, or handled in the message-driven bean.

You develop an enterprise application to use a message-driven bean like any other enterprise bean, except that a message-driven bean does not have a home interface or a remote interface.

This topic describes how to develop a completely new message-driven bean class. If you have a WAS 4.0 enterprise application that uses the JMS listener, you can migrate that application to use message-driven beans.

For more information about writing the message-driven bean class, see *Creating a message-driven bean* in the WebSphere Studio help bookshelf.

To develop an enterprise application to use a message-driven bean, complete the following steps:

1. Creating the Enterprise Application project, as described in the WebSphere Studio article *Creating an Enterprise Application project*.
2. Creating the message-driven bean class.

You can use the New Enterprise Bean wizard of WebSphere Studio Application Developer to create an enterprise bean with a bean type of Message-driven bean. The wizard creates appropriate methods for the type of bean.

By convention, the message bean class is named *nameBean*, where *name* is the name you assign to the message bean; for example:

```
public class MyJMSppMDBBean implements MessageDrivenBean, MessageListener
```

The message-driven bean class must define and implement the following methods:

- `onMessage(message)`, which must meet the following requirements:
  - The method must have a single argument of type `javax.jms.Message`.
  - The throws clause must *not* define any application exceptions.
  - If the message-driven bean is configured to use bean-managed transactions, it must call the `javax.transaction.UserTransaction` interface to scope the transactions. Because these calls occur inside the `onMessage()` method, the transaction scope does not include the initial message receipt. This means the application server is given one attempt to process the message.

To handle the message within the `onMessage()` method (for example, to pass the message on to another enterprise bean), you use standard JMS. (This is known as bean-managed messaging.)

- `ejbCreate()`

You must define and implement an `ejbCreate` method for each way in which you want a new instance of an enterprise bean to be created.

- `ejbRemove()`.

This method is invoked by the container when a client invokes the `remove` method inherited by the enterprise bean's home interface from the `javax.ejb.EJBHome` interface. This method must contain any code that you want to execute before an enterprise bean instance is removed from the container (and the associated data is removed from the data source).

For example, the following code extract shows how to access the text and the JMS MessageID, from a JMS message of type `TextMessage`:

The result of this step is a message-driven bean that can be assembled into an

```
public void onMessage(javax.jms.Message msg)
{
    String text      = null;
    String messageID = null;

    try
    {
        text = ((TextMessage)msg).getText();

        System.out.println("senderBean.onMessage(), msg text2: "+text);

        //
        // store the message id to use as the Correlator value
        //
        messageID = msg.getJMSMessageID();

        // Call a private method to put the message onto another queue
        putMessage(messageID, text);
    }
    catch (Exception err)
    {
        err.printStackTrace();
    }
    return;
}
```

*Figure 6. Code example: The `onMessage()` method of a message bean.* This figure shows a code extract for a basic `onMessage()` method of a sample message-driven bean. The method unpacks the incoming text message to extract the text and message identifier and calls a private `putMessage` method (defined within the same message bean class) to put the message onto another queue.

.EAR file for deployment.

3. Assembling and packaging the application for deployment.

You can use WebSphere Studio to assemble and package the application for deployment.

The result of this task is an .EAR file, containing an application message-driven bean, that can be deployed in WebSphere Application Server.

After you have developed an enterprise application to use message-driven beans, configure and deploy the application; for example, define the listener ports for the message-driven beans and, optionally, change the deployment descriptor attributes

for the application. For more information about configuring and deploying an application that uses message-driven beans, see [Deploying an enterprise application to use message-driven beans](#)

## Deploying an enterprise application to use message-driven beans

Use this task to deploy an enterprise application to use message-driven beans.

This task description assumes that you have an .EAR file, which contains an application enterprise bean with code for message-driven beans, that can be deployed in WebSphere Application Server.

To deploy an enterprise application to use message-driven beans, complete the following steps:

1. Use the WebSphere administrative console to define the listener ports for the application, as described in [Adding a new listener port](#).
2. For each message-driven bean in the application, use the application assembly tool to configure the deployment attributes to match the listener port definitions, as described in [Configuring deployment attributes for a message-driven bean](#).
3. Use the WebSphere administrative console to install the application

This stage is a standard WebSphere Application Server task, as described in [Installing a new application](#).

When you install the application, you are prompted to specify the name of the listener port that the application is to use for late responses. Select the listener port, then click **OK**.

[Assembly properties for message beans](#)

[Use this page to configure the assembly properties of message-driven beans](#)

### Configuring deployment attributes for a message-driven bean

Use this task to configure the message-driven beans deployment attributes for an enterprise bean, to override the deployment attributes defined within the application EAR file.

This task description assumes that you have an EAR file, which contains an application enterprise bean developed as a message-driven bean, that can be deployed in WebSphere Application Server.

**Note:** After deployment code has been generated for an application, the deployable archive is renamed with the prefix `Deployed_`. Any subsequent changes to the archive from within the Application Assembly Tool are applied to the version of the archive that existed prior to code generation. To see changes reflected in your application, you must regenerate deployment code and re-install the deployable archive.

To configure the message-driven beans deployment attributes for an enterprise bean, use the application assembly tool to configure the deployment attributes of the application to match the listener port definitions:

1. Launch the Application Assembly Tool.
2. Create or edit the application EAR file. For example, to change attributes of an existing application, click **File-> Open** then select the the EAR file.
3. In the navigation pane, select the message-driven bean instance; for example, expand *ejb\_module\_instance*-> **Message-driven beans** then select the bean instance. A property dialog notebook for the message-driven bean is displayed in the property pane.
4. Specify general deployment properties.
  - a. In the property pane, select the General tab.
  - b. Specify the following properties:

**Transaction type**

Whether the message bean manages its own transactions or the container manages transactions on behalf of the bean. All messages retrieved from a specific destination have the same transactional behavior. To enable the transactional behavior that you want, you must configure the JMS destination with the same transactional behavior as you configure for the message bean.

**Bean** The message bean manages its own transactions

**Container**

The container manages transactions on behalf of the bean

5. Specify advanced deployment properties.
  - a. In the property pane, select the Advanced tab.
  - b. Specify the following properties:

**Message selector**

The JMS message selector to be used to determine which messages the message bean receives; for example:

```
JMSType='car' AND color='blue' AND weight>2500
```

The selector string can refer to fields in the JMS message header and fields in the message properties. Message selectors cannot reference message body values.

**Acknowledge mode**

How the session acknowledges any messages it receives.

This property applies only to message-driven beans that uses bean-managed transaction demarcation (**Transaction type** is set to Bean).

**Auto Acknowledge**

The session automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.

**Dups OK Acknowledge**

The session lazily acknowledges the delivery of messages. This is likely to result in the delivery of some duplicate messages if JMS fails, so it should be used only by consumers that are tolerant of duplicate messages.

As defined in the EJB specification, clients cannot use using `Message.acknowledge()` to acknowledge messages. If a value of `CLIENT_ACKNOWLEDGE` is passed on the `createxxxSession` call,

then messages are automatically acknowledged by the application server and `Message.acknowledge()` is not used.

**Destination type**

Whether the message bean uses a queue or topic destination.

**Queue**

The message bean uses a queue destination.

**Topic** The message bean uses a topic destination.

**Subscription durability**

Whether a JMS topic subscription is durable or non-durable.

**Durable**

A subscriber registers a durable subscription with a unique identity that is retained by JMS. Subsequent subscriber objects with the same identity resume the subscription in the state it was left in by the earlier subscriber. If there is no active subscriber for a durable subscription, JMS retains the subscription's messages until they are received by the subscription or until they expire.

**Nondurable**

Non-durable subscriptions last for the lifetime of their subscriber object. This means that a client sees the messages published on a topic only while its subscriber is active. If the subscriber is not active, the client is missing messages published on its topic.

A non-durable subscriber can only be used in the same transactional context (for example, a global transaction or an unspecified transaction context) that existed when the subscriber was created. For more information about this context restriction, see *The effect of transaction context on non-durable subscribers*.

6. Specify bindings deployment properties.
  - a. In the property pane, select the Bindings tab.
  - b. Specify the following property:

**Listener port name**

The name of the listener port for this message-driven bean.

7. To apply the changes and close the Application Assembly Tool, click **OK**. Otherwise, to apply the values but keep the property dialog open for additional edits, click **Apply**.
8. To see changes reflected in your application, regenerate deployment code and reinstall the deployable archive.

**Related reference**

The effect of transaction context on non-durable subscribers

**Related information**

Assembly properties for message beans

Use this page to configure the assembly properties of message-driven beans

## Configuring message listener resources for message-driven beans

Use the following tasks to configure resources needed by the message listener service to support message-driven beans.

- Configuring the message listener service
- Adding a new listener port
- Configuring a listener port

- Configuring security for message-driven beans

**Related reference**

Important files for message-driven beans and extended messaging

**Configuring the message listener service**

Use this task to configure the properties of the message listener service for an application server.

To configure the properties of the message listener service for an application server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. Specify appropriate properties of the message listener service.
5. Optional: Specify any of the following optional properties that you need, as **Custom properties** of the message listener service:  
NON.ASF.RECEIVE.TIMEOUT, MQJMS.POOLING.TIMEOUT, MQJMS.POOLING.THRESHOLD, MAX.RECOVERY.RETRIES, and RECOVERY.RETRY.INTERVAL.

For more information about these custom properties, see Custom Properties.

6. Click **OK**.
7. Save your configuration.
8. To have the changed configuration take effect, stop then restart the Application Server.

**Message listener service:**

The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.

This panel displays links to the Additional Properties pages for Listener Ports and Custom Properties for the message listener service.

To view this administrative console page, click **Servers-> application\_server->**

**Message Listener Service**

**Related reference**

Tuning parameter index

*Name:*

The name by which the message listener service is known for administrative purposes.

<b>Data type</b>	String
<b>Default</b>	MsgLService

*Description:*

A description of the message listener service, for administrative purposes

<b>Data type</b>	String
<b>Default</b>	Null

*Thread pool:*

Controls the maximum number of threads the Message Listener Service is allowed to run. Select this link to display the service thread pool properties.

Adjust this parameter when multiple message-driven beans are deployed in the same application server and the sum of their maximum session values exceeds the default value of 10.

<b>Data type</b>	Integer
<b>Units</b>	Not applicable
<b>Default</b>	Minimum: 10, maximum 50
<b>Range</b>	Not applicable
<b>Recommended</b>	Set the minimum to the sum of all message-driven beans maximum session values. Set the maximum to anything equal or greater than the minimum.

*Custom Properties:*

An optional set of name and value pairs for custom properties of the message listener service.

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL

*Message listener service custom properties:*

Use this panel to view or change an optional set of name and value pairs for custom properties of the message listener service.

To view this administrative console page, click **Servers-> application\_server-> Message Listener Service-> (In content pane, under Additional Properties) Custom Properties**

You can use the Custom properties page to define the following properties for use by the message listener service.

- NON.ASF.RECEIVE.TIMEOUT
- MQJMS.POOLING.TIMEOUT
- MQJMS.POOLING.THRESHOLD
- MAX.RECOVERY.RETRIES
- RECOVERY.RETRY.INTERVAL

**Related reference**

## Message listener service properties

### *NON.ASF.RECEIVE.TIMEOUT:*

The JMS server has two modes of operation, Application Server Facilities (ASF) and non-Application Server Facilities. ASF is meant to provide concurrency and transactional support for applications. Non-ASF mode is still transactional, but the path length is streamlined to improve performance.

Use Non-ASF if:

- Message order is a strict requirement
- Concurrent PTP messages are desired
- The property `NON.ASF.RECEIVE.TIMEOUT` exists and has a value greater than 0

Do not use Non-ASF if concurrent publications and subscriptions messages are desired because ASF provides better throughput.

<b>Data type</b>	Integer
<b>Units</b>	Milliseconds
<b>Default</b>	ASF mode (custom property not created)
<b>Range</b>	
<b>Recommended</b>	The value is the number of milliseconds it takes for a message to be delivered. If a timeout occurs, it must recycle causing extra work. This should be set to lower than the transaction timeout, but close to it with several (10 or more) seconds to spare. The seconds to spare should be more if under extreme loads in which threads are waiting long periods of time to get CPU cycles.

### *MQJMS.POOLING.TIMEOUT:*

The number of milliseconds after which a connection in the pool is destroyed if it has not been used.

An `MQSimpleConnectionManager` allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if it has not been used for five minutes.

<b>Data type</b>	Integer
<b>Units</b>	Milliseconds
<b>Default</b>	5 minutes
<b>Range</b>	

### *MQJMS.POOLING.THRESHOLD:*

The maximum number of unused connections in the pool.

An `MQSimpleConnectionManager` allocates connections on a most-recently-used basis, and destroys connections on a least-recently-used basis. By default, a connection is destroyed if there are more than ten unused connections in the pool.

<b>Data type</b>	Integer
<b>Units</b>	Number of connections
<b>Default</b>	10

## Range

### *MAX.RECOVERY.RETRIES:*

The maximum number of times that the listener service tries to get a message from a listener port before the associated listener is stopped, in the range 0 through 2147483647.

<b>Data type</b>	Integer
<b>Units</b>	Retry attempts
<b>Default</b>	0 (no retries)
<b>Range</b>	0 (no retries) through 2147483647

### *RECOVERY.RETRY.INTERVAL:*

The time in seconds between retry attempts by the listener service to get a message from a listener port.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	10
<b>Range</b>	1 through 2147483647

### *Message listener port collection:*

The message listener ports configured in the administrative domain

This panel displays a list of the message listener ports configured in the administrative domain. Each listener port is used with a message-driven bean to automatically receive messages from an associated JMS destination. You can use this panel to add new listener ports or to change the properties of existing listener ports. For more information about the property fields for listener ports, see [Listener port properties](#).

To view this administrative console page, click **Servers-> application\_server-> Message Listener Service-> Listener Ports**

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

[Preferences](#)

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

#### **Related information**

[An overview of WebSphere asynchronous messaging using JMS](#)

### *Listener port settings:*

A listener port is used to simplify administration of the association between a connection factory, destination, and deployed message-driven bean.

Use this panel to view or change the configuration properties of the selected listener port.

To view this administrative console page, click **Servers-> application\_server-> Message Listener Service-> Listener Ports-> listener\_port**

#### Related reference

Tuning parameter index

#### *Name:*

The name by which the listener port is known for administrative purposes.

<b>Data type</b>	String
<b>Default</b>	Null

#### *Initial state:*

The state that you want the listener port to have when the application server is next restarted

<b>Data type</b>	Enum
<b>Units</b>	Not applicable
<b>Default</b>	Started
<b>Range</b>	<b>Started</b> When the application server is next started, the listener port is started automatically. <b>Stopped</b> When the application server is next started, the listener port is not started automatically. If message-driven beans are to use this listener port on the application server, the system administrator must start the port manually or select the Started value of this property then restart the application server.

#### *Description:*

A description of the listener port, for administrative purposes within IBM WebSphere Application Server.

<b>Data type</b>	String
<b>Default</b>	Null

#### *Connection factory JNDI name:*

The JNDI name for the JMS connection factory to be used by the listener port; for example, jms/connFactory1.

<b>Data type</b>	String
------------------	--------

**Default** Null

*Destination JNDI name:*

The JNDI name for the destination to be used by the listener port; for example, `jms/destn1`.

If the extended messaging service is to use this listener port to handle late responses, the value of this property must match the JMS response destination on the output port used by the sender bean. Also cannot use a temporary destination for late responses.

**Data type** String  
**Default** Null

*Maximum sessions:*

Specifies the maximum number of concurrent JMS server sessions used by a listener to process messages.

Each session corresponds to a single listener thread, but does not control the number of concurrently processed messages. Adjust this parameter when the machine running the process application does not realize the available capacity and produces less throughput by running long processes.

This parameter helps to add some level of concurrency so that messages are received concurrently before the synchronized part of receiving the message occurs. A 40% increase in throughput is observed in a process application with long running processes on a NetFinity 5500 500 MHz, 4-way, 4GB RAM system.

An alternative to making this change in the administrative console is to change the maximum sessions value in the `server.xml` file under the listener ports stanza as follows:

```
<listenerPorts xmi:id="ListenerPort_1" name="bpeIntListenerPort"
description="Internal Listener Port for Process Choreographer"
connectionFactoryJNDIName="jms/bpeCF" destinationJNDIName="jms/bpeIntQueue"
maxSessions="5" maxRetries="10" maxMessages="1">
<stateManagement xmi:id="StateManageable_5" initialState="START" />
</listenerPorts>
```

**Data type** Integer  
**Units** Sessions  
**Default** 1  
**Range** 1 through 2147483647  
**Recommended** If message concurrency, that is multiple messages processed simultaneously, is desired, set the value to 2-4 sessions per system processor. Keep the value as low as possible to eliminate client thrashing. If a strict message order is desired, set the value to 4 so there is always a thread waiting in a hot state, blocked on receiving the message.

*Maximum retries:*

The maximum number of times that the listener tries to deliver a message before the listener is stopped, in the range 0 through 2147483647.

The maximum number of times that the listener tries to deliver a message to a message-driven bean instance before the listener is stopped.

<b>Data type</b>	Integer
<b>Units</b>	Retry attempts
<b>Default</b>	0 (no retries)
<b>Range</b>	0 (no retries) through 2147483647

*Maximum messages:*

The maximum number of messages that the listener can process in one JMS server session.

Adjust this parameter when message order is not a strict requirement. This parameter controls the concurrency level in the listener service.

<b>Data type</b>	Integer
<b>Units</b>	Number of messages
<b>Default</b>	1
<b>Range</b>	1 through 2147483647
<b>Recommended</b>	If message concurrency, that is multiple messages processed simultaneously, is desired, set the value to 2-4 sessions per system processor. Keep the value as low as possible to eliminate client thrashing. If a strict message order is desired, set the value to 1.

## Adding a new listener port

Use this task to add a new listener port to the message listener service, so that message-driven beans can be associated with the port to retrieve messages.

To add a new listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, select **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, click **New**.
6. Specify appropriate properties for the listener port.
7. Click **OK**.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.
9. To have the changed configuration take effect, stop then restart the application server.

If enabled, the listener port is started automatically when a message-driven bean associated with that port is installed.

**Related reference**

Listener port properties

### **Configuring a listener port**

Use this task to change the properties of an existing listener port, used by message-driven beans associated with the port to retrieve messages.

To configure the properties of a listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, click **Listener Ports**. This displays a list of the listener ports.
5. Click the listener port that you want to modify. This displays the properties of the listener port in the content pane.
6. Specify appropriate properties for the listener port.
7. Click **OK**.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.
9. To have the changed configuration take effect, stop then restart the application server.

**Related reference**

Listener port properties

### **Deleting a listener port**

Use this task to delete a listener port from the message listener service, to prevent message-driven beans associated with the port from retrieving messages.

To delete a listener port, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, select **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, select the checkbox for the listener port that you want to delete.
6. Click **Delete**. This action stops the port (needed to allow the port to be deleted) then deletes the port.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.

8. To have the changed configuration take effect, stop then restart the application server.

### Configuring security for message-driven beans

Use this task to configure resource security and security permissions for message-driven beans.

Messages arriving at a listener port have no client credentials associated with them. The messages are anonymous.

To call secure enterprise beans from a message-driven bean, the message-driven bean needs to be configured with a RunAs Identity deployment descriptor. Security depends on the role specified by the RunAs Identity for the message-driven bean as an EJB component.

For more information about EJB security, see EJB component security. For more information about configuring security for your application, see Assembling secured applications.

JMS connections used by message-driven beans can benefit from the added security of using J2C container-managed authentication. To enable the use of J2C container authentication aliases and mapping, define a J2C container-managed alias on the JMS connection factory definition that the MDB is using to listen upon (defined by the **Connection factory JNDI name** property of the listener port). If defined, the listener uses the container-managed authentication alias for its JMSConnection security credentials instead of any application-managed alias. To set the container-managed alias, use the administrative console to complete the following steps:

1. To display the listener port settings, click **Servers-> application\_server-> Message Listener Service-> Listener Ports-> listener\_port**
2. To get the name of the JMS connection factory, look at the **Connection factory JNDI name** property.
3. Display the JMS connection factory properties. For example, to display the properties of a queue connection factory provided by the embedded WebSphere JMS provider, click **Resources-> WebSphere JMS Provider-> (In content pane, under Additional Properties) WebSphere Queue Connection Factories-> connection\_factory**
- 4.
5. Set the **Container-managed Authentication Alias** property.

### Administering listener ports

Use the following tasks to administer listener ports, which each define the association between a connection factory, a destination, and a message-driven bean.

You can use the WebSphere administrative console to administer listener ports, as described in the following tasks.

- Adding a new listener port  
Use this task to create a new listener port, to specify a new association between a connection factory, a destination, and a message-driven bean. This enables deployed message-driven beans associated with the port to retrieve messages from the destination.
- Configuring a listener port  
Use this task to view or change the configuration properties of a listener port.
- Starting a listener port

Use this task to start a listener port manually.

- Stopping a listener port

Use this task to stop a listener port manually.

**Note:** If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. You do not normally need to start or stop a listener port manually.

#### **Related tasks**

Adding a new listener port

Configuring a listener port

Deleting a listener port

#### **Starting a listener port:**

Use this task to start a listener port on an application server, to enable the listeners for message-driven beans associated with the port to retrieve messages.

A listener is active, that is able to receive messages from a destination, if the deployed message-driven bean, listener port, and message listener service are all started. Although you can start these components in any order, they must all be in a started state before the listener can retrieve messages.

If configured as enabled, a listener port is started automatically when a message-driven bean associated with that port is installed. However, you can start a listener port manually, as described in this topic.

When a listener port is started, the listener manager tries to start the listeners for each message-driven bean associated with the port. If a message-driven bean is stopped, the port is started but the listener is not started, and remains stopped. If you start a message-driven bean, the related listener is started.

To start a listener port on an application server, use the administrative console to complete the following steps:

1. If you want the listener for a deployed message-driven bean to be able to receive messages at the port, check that the message-driven bean has been started.
2. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
3. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
4. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
5. In the content pane, select **Listener Ports**. This displays a list of the listener ports.
6. Select the checkbox for the listener port that you want to start.
7. Click **Start**.
8. To save your configuration, click **Save** on the task bar of the Administrative console window.

#### **Stopping a listener port:**

Use this task to stop a listener port on an application server, to prevent the listeners for message-driven beans associated with the port from retrieving messages.

When you stop a listener port as described in this topic, the listener manager stops the listeners for all message-driven beans associated with the port.

To stop a listener port on an application server, use the administrative console to complete the following steps:

1. In the navigation pane, select **Servers-> Application Servers** This displays a table of the application servers in the administrative domain.
2. In the content pane, click the name of the application server. This displays the properties of the application server in the content pane.
3. In the Additional Properties table, select **Message Listener Service** This displays the Message Listener Service properties in the content pane.
4. In the content pane, select **Listener Ports**. This displays a list of the listener ports.
5. In the content pane, select the listener port that you want to stop.
6. Click **Stop**.
7. To save your configuration, click **Save** on the task bar of the Administrative console window.
8. To have the changed configuration take effect, stop then restart the application server.

## Important files for message-driven beans and extended messaging

The following files in the WAS\_HOME/temp directory are important for the operation of the WebSphere Application Server messaging service, so should not be deleted. If you do need to delete the WAS\_HOME/temp directory or other files in it, ensure that you preserve the following files.

### *server\_name*-durableSubscriptions.ser

You should not delete this file, because the messaging service uses it to keep track of durable subscriptions for message-driven beans. If you uninstall an application that contains a message-driven bean, this file is used to unsubscribe the durable subscription.

### *server\_name*-AsyncMessageRequestLog.ser

You should not delete this file, because the messaging service uses it to keep track of late responses that need to be delivered to the late response message handler for the extended messaging provider.

## Troubleshooting message-driven beans

Use this overview task to help resolve a problem that you think is related to message-driven beans.

Message-driven beans support uses the standard WebSphere Application Server troubleshooting facilities. If you encounter a problem that you think might be related to the message-driven beans, complete the following stages:

1. Check for messages about message-driven beans in the application server's SystemOut log at *was\_home*\logs\server\SystemOut. Look in the SystemOut log for messages that indicate a problem with JMS resources for message-driven beans, such as listener ports.

2. Check for more messages in the application server's SystemOut log. If the JMS server is running, but you have problems accessing JMS resources, check the SystemOut log file, which should contain more error messages and extra details about the problem.
3. Check the Release Notes for specific problems and workarounds The section *Possible Problems and Suggested Fixes* of the Release Notes, available from the WebSphere Application Server library web site, is updated regularly to contain information about known defects and their workarounds. Check the latest version of the Release Notes for any information about your problem. If the Release Notes does not contain any information about your problem, you can also search the Technotes database on the WebSphere Application Server web site.
4. Check that message listener service has started. The message listener service is an extension to the JMS functions of the JMS provider. It provides a listener manager that controls and monitors one or more JMS listeners, which each monitor a JMS destination on behalf of a deployed message-driven bean.
5. Check your JMS resource configurations If the WebSphere Messaging functions seem to be running properly (the JMS server is running without problems), check that the JMS resources have been configured correctly. For example, check that the listener ports have been configured correctly and have been started.
6. Check for problems with the WebSphere Messaging functions For more information about troubleshooting WebSphere Messaging, see the related topics.
7. Get a detailed exception dump for messaging. If the information obtained in the preceding steps is still inconclusive, you can enable the application server debug trace for the "Messaging" group to provide a detailed exception dump.

## Message-driven beans samples

The following examples are provided, as part of the WebSphere Samples Gallery, to illustrate use of the message-driven beans support. When the Samples are installed on your local machine, they are available to try out. Locate them at <http://localhost:9080/WSsamples/>. (The default port is 9080.) For more information about where to find the Samples Gallery, see Samples Gallery.

- Point-to-point samples:
  - "Tutorial: Creating JMS message sample"
 

This tutorial is designed to help you develop and deploy a JMS message sample application that tests the WebSphere Application Server message-driven beans support in a point-to-point scenario. This sample illustrates how to develop and deploy an application that comprises the following components:

    - A Java/JMS program that writes a message to a queue.
    - A message-driven bean that is invoked by a JMS listener when a message arrives on a defined queue.

For more information about this sample, see the samples article "Tutorial: Creating JMS message sample" that is installed with the Samples option.

- "Sample: Message Listener (point-to-point)"
 

This sample is designed to demonstrate the use and behavior of message-driven beans for a simple point-to-point scenario. This sample uses the JMS message sample deployed in the sample above.

For more information about this sample, see the samples article "Sample: Message Listener (Point-to-Point)" that is installed with the Samples option.

- Publish/subscribe samples

- "Tutorial: Creating JMS message publish/subscribe sample"

This tutorial is designed to help you develop and deploy a JMS message sample application that tests the WebSphere Application Server message-driven beans support in a publish/subscribe scenario. This sample illustrates how to develop and deploy an application that comprises the following components:

- A client program that starts the message sequence by publishing a message to a selected topic.
    - A message-driven bean that is invoked by a JMS listener when the broker passes a message to the listener from a topic to which it has subscribed.

For more information about this sample, see the samples article "Tutorial: Creating JMS message publish/subscribe sample" that is installed with the Samples option.

- "Sample: Message Listener (publish/subscribe)"

This sample is designed to demonstrate the use and behavior of message-driven beans for a simple publish/subscribe scenario. This sample uses the JMS message sample deployed in the publish/subscribe sample above.

For more information about this sample, see the samples article "Sample: Message Listener (publish/subscribe)" that is installed with the Samples option.

## Chapter 3. Accessing data from applications

Various enterprise information systems (EIS) use different methods for storing data. These *backend* data stores might be relational databases, procedural transaction programs, or object-oriented databases. IBM WebSphere Application Server provides several options for accessing an information system's backend data store:

- Programming directly to the database through the JDBC 2.0 Optional Package API.
  - Programming to the procedural backend transaction through various J2EE Connector Architecture (JCA) 1.0 compliant connectors.
  - Programming in the bean-managed persistence (BMP) bean or servlets indirectly accessing the backend store through either the JDBC API or JCA compliant connectors. The prerequisite Web site details which databases and drivers are currently supported.
  - Using container-managed persistence (CMP) beans.
  - **5.0.1 +** Using embedded Structured Query Language in Java (SQLJ) support with applications that use DB2 as a backend database.
  - Using the IBM data access beans, which also use the JDBC API, but give you additional ability to manipulate result sets.
1. Develop data access applications Develop your application to access data using the various ways available through the WebSphere Application Server. You can access data through APIs, container-managed persistence beans, bean-managed persistence beans, session beans, or Web components.
  2. Assemble data access applications Assemble your application by creating and mapping resource references.
  3. Deploy data access applications Ensure that the appropriate database objects are available. Create or configure any databases or tables required, set necessary configuration parameters to handle expected load, and configure any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.

---

### Resource adapter

A resource adapter is a system-level software driver that a Java application uses to connect to an enterprise information system (EIS).

A resource adapter plugs into an application server and provides connectivity between the EIS, the application server, and the enterprise application.

An application server vendor extends its system once to support the connector architecture and is then assured of seamless connectivity to multiple EISs. Likewise, an EIS vendor provides one standard resource adapter with the capability to plug into any application server that supports the connector architecture.

WebSphere Application Server provides the relational resource adapter (RRA) implementation in this release. This resource adapter provides data access through JDBC calls to access the database dynamically. The connection management is based on the J2EE Connector Architecture (JCA) connection management architecture. It provides connection pooling, local transaction, and security support.

Container-managed persistence (CMP) beans data access is managed by the WebSphere Persistence Manager indirectly. The JCA Specification supports Persistence Manager delegation of the data access to the JCA resource adapter without knowing the specific backend store. For the relational database access, Persistence Manager utilizes the relational resource adapter to access the data from the database. You can find the supported database platforms for the JDBC API at the WebSphere Application Server prerequisite Web site.

## J2EE Connector Architecture resource adapters

A J2EE Connector Architecture (JCA) resource adapter is any resource adapter conforming to the JCA Specification.

The product supports any resource adapter that implements version 1.0 of this specification. Although not part of WebSphere Application Server, IBM supplies resource adapters for enterprise systems such as: the Customer Information Control System (CICS), Host On-Demand (HOD), Information Management System (IMS), Systems, Applications, and Products (SAP) R/3, and Crossworlds, as separate products.

The general approach to writing an application that uses a JCA resource adapter is to develop enterprise bean session beans or services with tools such as WebSphere Studio Application Developer Integration Edition (WSADIE) or VisualAge for Java Enterprise Access Builder. The session bean uses the *javax.resource.cci* interfaces to communicate with an enterprise information system through the resource adapter.

## Resource Recovery Services (RRS)

WebSphere Application Server for z/OS supports resource adapters that use Resource Recovery Services (RRS) to support global transaction processing. RRS is an z/OS extension to the JCA resource adapter specifications.

WebSphere Application Server for z/OS supports the J2EE Connector Architecture (JCA) 1.0., and because of this, any resource adapter that is designed to use the 1.0 level of the J2EE Connector Architecture (JCA) is supported.

In addition to the 3 types of transaction support defined by JCA, WebSphere Application Server for z/OS supports a fourth type, **RRSTransactional** support, which is a z/OS only extension to the architecture. Resource adapters that are capable of using RRS and that properly indicate to WAS z/OS they are RRSTransactional will be supported as RRS compliant resource adapters.

z/OS resource adapters that are capable of using RRS are:

- IMS Connector for Java
- CICS CTG ECI J2EE Connector
- IMS JDBC Connector
- DB2 for z/OS Local JDBC connector when used as a JDBC Provider under the WebSphere Relational Resource Adapter (RRA)

All RRS Compliant resource adapters are required to support the property **RRSTransactional** in their ManagedConnectionFactory and must support a getter method for the property.

```
java.lang.Boolean.RRSTransactional=true;
```

```
java.lang.Boolean getRRSTransactional(){  
    // Determine if the adapter can run RRSTransactional based  
    // on it's configuration, and set the RRSTransactional property  
    // appropriately to true or false.  
    return RRSTransactional;  
}
```

RRS support is only applicable in a local environment, where the backend must reside on the system. CICS and IMS resources adapters may use **RRSTransactional** support only when these adapters are configured to use local interfaces to their backend resource manager, which as stated above must reside on the same system as the IBM WebSphere Application Server for z/OS. These adapters are also capable of being configured to a remote instance of their backend resource manager. In this case, the adapters will respond "false" when the `getRRSTransactional()` method is invoked and instead of running as RRSTransactional will use whichever one of the three types of J2EE Transaction support they have chosen to support.

### Related concepts

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

## Scope

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource’s properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type**

String

**Name**

Specifies the name of the resource provider.

Data type String

**Description**

Specifies a description of the relational resource adapter.

Data type String

**Archive path**

Specifies the path to the Resource Adapter Archive (RAR) file containing the module for this resource adapter.

Data type String

**Classpath**

Specifies a list of paths or Java Archive (JAR) file names, which together form the location for the resource provider classes.

Data type String

**Native path**

Specifies a list of paths that forms the location for the resource provider native libraries.

Data type String

## Data access portability features

The WebSphere Application Server relational resource adapter (RRA) provides a portability feature that enables applications to access data from different databases without changing the application. In addition, WebSphere Application Server enables you to plug in a data source that is not supported by WebSphere persistence. However, the data source *must* be implemented as either the *XADataSource* or the *ConnectionPoolDataSource*, and it must be in compliance with the JDBC 2.x specification.

You can achieve application portability through the following:

**DataStoreHelper interface**

With this interface, each data store platform can plug in its own private data store specific functions that the relational resource adapter run time uses. WebSphere Application Server provides an implementation for each supported JDBC provider.

In addition, the interface also provides a *GenericDataStoreHelper* class for unsupported data sources to use. You can subclass the *GenericDataStoreHelper* or other WebSphere provided helpers to support any new data source.

For more information, see the Javadoc **DataStoreHelper** in the Javadoc index.

The following code segment shows how a new data store helper is created to add two new error mappings for an unsupported data source.

```

public class NewDSHelper extends GenericDataStoreHelper
{
    public NewDSHelper()
    {
        super(null);
        java.util.Hashtable myErrorMap = null;
        myErrorMap = new java.util.Hashtable(2);
        myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
        myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
        myErrorMap.put("S1000", MyTableNotFoundException.class);
        setUserDefinedMap(myErrorMap);
        ...
    }
}

```

### WSCallHelper class

With this class, applications can invoke any JDBC object proprietary methods that are not defined through the administrative console or standard APIs. This helper also enables applications to invoke many non-JDBC object methods.

All methods are static: see Javadoc **WSCallHelper** in the Javadoc index.

The following code segment illustrates using this helper class (with a DB2 data source):

```

Connection conn = ds.getConnection();
// get connection attribute
String connectionAttribute =(String) WSCallHelper.jdbcCall(DataSource.class, ds,
    "getConnectionAttribute", null, null);
// setAutoClose to false
WSCallHelper.jdbcCall(java.sql.Connection.class,
    conn, "setAutoClose",
    new Object[] { new Boolean(false)},
    new Class[] { boolean.class });
// get data store helper
DataStoreHelper dsHelper = WSCallHelper.getDataStoreHelper(ds);

```

## Connection factory

An application component uses a *connection factory* to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS).

Examples of connections include database connections, Java Message Service connections, and SAP R/3 connections.

## CMP Connection Factories collection

Use this page to view existing CMP connection factories settings.

These are the connection factories used by a container-managed persistence (CMP) bean to access any backend data store. A CMP Connection Factory is used by EJB model 2.0 Entities with CMP version 2.x. Connection factories listed on this page are created automatically under the WebSphere Relational Resource Adapter when you check the box *Use this DataSource in container managed persistence (CMP)* in the General Properties area on the Data Source page. You cannot modify or delete automatically created connection factories.

To view this administrative console page, click **Resources >Resource Adapters >WebSphere Relational Resource Adapter > CMP Connection Factories**.

## Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

**Name:**

Specifies the display name for the resource.

**Data type** String

**JNDI name:**

Specifies the JNDI name of the resource.

**Data type** String

**Description:**

Specifies a description for the resource.

**Data type** String

**Category:**

Specifies a category string which can be used to classify or group the resource.

**Data type** String

**Authentication Preference:**

Specifies which of the authentication mechanisms that are defined for the corresponding resource adapter applies to this connection factory.

For example, if two authentication mechanism entries are defined for a resource adapter (*KerbV5* and *Basic Password*), this specifies one of those two types. If the authentication mechanism preference specified is not an authentication mechanism available on the corresponding resource adapter, it is ignored.

**Data type** String

**Component-managed authentication alias:**

References authentication data for component-managed signon to the resource.

**Data type** Drop-down list

**Container-managed authentication alias:**

References authentication data for container-managed signon to the resource.

Data type

## JDBC providers

Installed applications use JDBC providers to access data from databases.

The JDBC provider and data source together are functionally equivalent to the J2EE Connector Architecture (JCA) Connection Factory. The WebSphere Application Server prerequisite Web site has a current list of supported providers.

## Data sources

An application uses a *data source* to access the data from the database.

A data source is associated with a JDBC provider that supplies the specific JDBC driver implementation class. The data source represents the J2EE Connector Architecture (JCA) connection factory for the relational resource adapter.

You can create multiple data sources associated with the same JDBC provider. Each JDBC provider supports the interfaces defined by Sun Microsystems listed below. These interfaces enable the application to run in a single-phase or two-phase transaction protocol.

- *ConnectionPoolDataSource* - a data source that supports application participation in all transactions, including two-phase commit transactions. When this kind of data source is involved in a global transaction, transaction recovery is not provided by the transaction manager. The application is responsible for providing the backup recovery process if multiple resource managers are involved.
- *XADataSource* - a data source that supports application participation in a single-phase or a global (two-phase) transaction environment. When this data source is involved in a global transaction, the transaction manager provides transaction recovery.

Previously, the function of data access was provided by a single connection manager (CM) architecture. This connection manager architecture remains available

to support J2EE 1.2 applications, but a new connection manager architecture is provided, based on the JCA architecture supporting the new J2EE 1.3 application style.

These two separate CM architectures are represented by two types of data sources. To choose the right data source, administrators must understand the nature of their applications, EJB modules, and enterprise beans.

- Data source (Version 4.0) - this data source runs under the CM architecture. Applications using this data source behave as if they were running in Version 4.0.
- Data source - this data source uses the JCA standard architecture to provide J2EE 1.3 support. It runs under the JCA connection manager and the relational resource adapter. Applications using this type of data source might behave differently because of the J2EE 1.3 architecture.

#### **Choice of data source**

- J2EE 1.2 application - all enterprise beans, JDBC applications, or Servlets 2.2 components must use the **4.0** data source.
- J2EE 1.3 application -
  - EJB 1.1 Module - all EJB 1.x beans must use the **4.0** data source.
  - EJB 2.0 Module - enterprise beans that include container-managed persistence (CMP) Version 2.0 and 1.x must use the **new** data source.
  - JDBC applications and Servlet 2.3 - must use the **new** data source.

## **Data access beans**

Data access beans provide a rich set of features and function, while hiding much of the complexity associated with accessing relational databases.

They are Java classes written to the JavaBeans Specification.

You can use the data access beans in JavaBeans-compliant tools, such as the IBM *WebSphere Studio Application Developer (WSAD)*. Because the data access beans are also Java classes, you can use them like ordinary classes.

The data access beans (in the package *com.ibm.db*) offer the following capabilities:

### Feature

#### Details

#### Caching query results

You can retrieve SQL query results all at once and place them in a cache. Programs using the result set can move forward and backward through the cache or jump directly to any result row in the cache.

For large result sets, the data access beans provide ways to retrieve and manage *packets*, subsets of the complete result set.

#### Updating through result cache

Programs can use standard Java statements (rather than SQL statements) to change, add, or delete rows in the result cache. You can propagate changes to the cache in the underlying relational table.

#### Querying parameter support

The base SQL query is defined as a Java String, with parameters replacing some of the actual values. When the query runs, the data access beans provide a way to replace the parameters with values made available at run time. Default mappings for common data types are provided, but you can specify whatever your Java program and database require.

#### Supporting metadata

A *StatementMetaData* object contains the base SQL query. Information about the query (*metadata*) enables the object to pass parameters into the query as Java data types.

Metadata in the object maps Java data types to SQL data types (as well as the reverse). When the query runs, the Java-datatyped parameters are automatically converted to SQL data types as specified in the metadata mapping.

When results return, the metadata object automatically converts SQL data types back into the Java data types specified in the metadata mapping.

## Connection management architecture

The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the J2EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and DataSources defined by the JDBC 2.0 Extensions Specification.

To make DataSource connections manageable by this CM that works only with RAs, WebSphere Application Server Version 5.0 provides its own resource adapter. From the CM point of view, JDBC DataSources and JCA connection factories look the same. Users of DataSources do not experience any programmatic or behavioral differences in their applications because of the underlying JCA architecture. JDBC users still configure and use DataSources according to the JDBC programming model.

Applications migrating from previous versions of WebSphere Application Server might experience some behavioral differences because of the change from J2EE 1.2 requirements to J2EE 1.3 requirements. These differences are not related to the adoption of the JCA architecture.

If you have J2EE 1.2 applications using the JDBC API that you wish to run in WebSphere Application Server 5.0, the JDBC CM from Version 4.0 is still provided as a configuration option. Using this configuration option enables J2EE 1.2 applications to run unaltered. If you migrate a Version 4.0 application to Version 5.0, using the Version 5.0 migration tools, the application automatically uses the Version 4.0 connection manager after migration. However, EJB 2.0 modules in J2EE 1.3 applications cannot use the JDBC CM from Version 4.0.

## Connection pooling

When accessing any database, the initial database connection is an expensive operation. *Connection pooling* enables administrators to establish a pool of database connections that applications can share on an application server. When connection pooling capabilities are used, performance improvements up to 20 times the normal results are realized.

Each time a resource attempts to access a backend store (such as a database), the resource must connect to that data store. A connection requires resources to create, maintain, and then release the connection when it is no longer required.

The total data store overhead for an application is particularly high for Web-based applications because Web users connect and disconnect more frequently. In addition, user interactions are typically shorter. Often, more effort is spent connecting and disconnecting than is spent during the interactions. Also, because Internet requests can arrive from virtually anywhere, you can find usage volumes large and difficult to predict.

To help lessen these overhead problems, the WebSphere Application Server enables administrators to establish a pool of backend connections that applications can share on an application server. Connection pooling spreads the connection overhead across several user requests, thereby conserving resources for future requests.

WebSphere Application Server supports JDBC 2.0 Standard Extension APIs to provide support for connection pooling and connection reuse. The connection pool is used to direct JDBC calls within the application, as well as for enterprise beans using the database.

Each entity EJB transaction requires an additional connection to the database specifically to handle the transaction. Take this into account when calculating the number of data source connections.

On UNIX platforms, a separate DB2 process is created for each connection and these processes quickly affect performance on systems with low memory and cause errors.

If clones are used, one data pool exists for each clone. This is important when configuring the database maximum connections.

Tuning parameter index

### **Benefits of connection pooling**

Connection pooling can improve the response time of any application that requires connections, especially Web-based applications. When a user makes a request over the Web to a resource, the resource accesses a data source. With connection pooling, most user requests do not incur the overhead of creating a new connection because the data source can locate and use an existing connection from the pool of connections. When the request is satisfied and the response is returned to the user, the resource returns the connection to the connection pool for reuse. The overhead of a disconnect is avoided. Each user request incurs a fraction of the cost for connecting or disconnecting. After the initial resources are used to produce the connections in the pool, additional overhead is insignificant because the existing connections are reused.

### **When to use connection pooling**

Use WebSphere connection pooling in an application that meets any of the following criteria:

- It cannot tolerate the overhead of obtaining and releasing connections whenever a connection is used.
- It requires Java Transaction API (JTA) transactions within WebSphere Application Server.
- It needs to share connections among multiple users within the same transaction.
- It needs to take advantage of product features for managing local transactions within the application server.
- It does not manage the pooling of its own connections.
- It does not manage the specifics of creating a connection, such as the database name, user name, or password

### **How connections are pooled together**

Whenever you configure a unique data source or connection factory you are required to give it a unique Java Naming and Directory Interface (JNDI) name. Use this name, along with its configuration information, to create a *connection pool*. A separate connection pool exists for each configured data source or connection factory.

A separate instance of a given configured connection pool is created on each application server that uses that data source or connection factory. For example, if you run a three server cluster in which all of the servers use *myDataSource*, and *myDataSource* has a *maximum connections* setting of 10, then you can generate up

to 30 connections (three servers times 10 connections). Be sure to consider this fact when determining how many connections to your backend resource you can support.

It is also important to note that when using *connection sharing*, it is only possible to share connections obtained from the same connection pool.

**Avoiding a deadlock:** Deadlock can occur if the application requires more than one concurrent connection per thread, and the database connection pool is not large enough for the number of threads. Suppose each of the application threads requires two concurrent database connections and the number of threads is equal to the maximum connection pool size. Deadlock can occur when both of the following are true:

- Each thread has its first database connection, and all are in use.
- Each thread is waiting for a second database connection, and none would become available since all threads are blocked.

To prevent the deadlock in this case, the value set for the database connection pool must be at least one higher, one of the waiting threads to complete its second database connection and free up to allow database connections.

To avoid deadlock, code the application to use, at most, one connection per thread. If the application is coded to require C concurrent database connections per thread, the connection pool must support at least the following number of connections, where T is the maximum number of threads.

$$T * (C - 1) + 1$$

The connection pool settings are directly related to the number of connections that the database server is configured to support. If the maximum number of connections in the pool is raised, and the corresponding settings in the database are not raised, the application fails and SQL exception errors are displayed in the `stderr.log` file.

## Connection life cycle

A `ManagedConnection` object is always in one of three states: *DoesNotExist*, *InFreePool*, or *InUse*.

Before a connection is created, it must be in the *DoesNotExist* state. After a connection is created, it can be in either the *InUse* or the *InFreePool* state, depending on whether it is allocated to an application.

Between these three states are *transitions*. These transitions are controlled by *guarding conditions*. A guarding condition is one in which *true* indicates when you can take the transition into another legal state. For example, you can make the transition from the *InFreePool* to *InUse* state only if:

- the application has called the data source or connection factory `.getConnection` method (`getConnection`)
- a free connection is available in the pool with matching properties (`freeConnectionAvailable`)
- and one of the two following conditions are true:
  - the `getConnection` request is on behalf of a resource reference that is marked `unsharable`
  - the `getConnection` request is on behalf of a resource reference that is marked `shareable` but no `shareable` connection in use has the same properties.

This transition description follows:

InFreePool > InUse:  
 getConnection AND  
 freeConnectionAvailable AND  
 NOT(shareableConnectionAvailable)

Here is a list of guarding conditions and descriptions.

Condition	Description
ageTimeoutExpired	Connection is older than its ageTimeout value.
close	Application calls close method on the Connection object.
fatalErrorNotification	A connection has just experienced a fatal error.
freeConnectionAvailable	A connection with matching properties is available in the free pool.
getConnection	Application calls getConnection method on DataSource or ConnectionFactory object.
markedStale	Connection is marked as stale, typically in response to a FatalErrorNotification.
noOtherReferences	There is only one connection handle to the ManagedConnection, and the Transaction Service is not holding a reference to the ManagedConnection.
noTx	No transaction is in force.
poolSizeGTMin	Connection pool size is greater than the minimum pool size (minimum number of connections)
poolSizeLTMax	Pool size is less than the maximum pool size (maximum number of connections)
shareableConnectionAvailable	The getConnection request was for a shareable connection and one with matching properties is in use and available to share.
TxEnds	The transaction has ended.
unshareableConnectionRequest	The getConnection request is for an unshareable connection.
unusedTimeoutExpired	Connection is in the free pool and not in use past its unused timeout value.

#### Getting connections

The first set of transitions covered are those in which the application requests a connection from either a data source or a connection factory. In some of these

scenarios, a new connection to the database results. In others, the connection might be retrieved from the connection pool or shared with another request for a connection.

### DoesNotExist

Every connection begins its life cycle in the DoesNotExist state. When an application server starts, the connection pool does not exist. Therefore, there are no connections. The first connection is not created until an application requests its first connection. Additional connections are created as needed, according to the guarding condition.

```
getConnection AND
NOT(freeConnectionAvailable) AND
poolSizeLTMax AND
(NOT(shareableConnectionAvailable) OR
(unshareableConnectionRequest))
```

This transition specifies that a Connection object is not created unless the following conditions occur:

- The application calls the *getConnection()* method on the data source or connection factory
- No connections are available in the free pool (NOT(freeConnectionAvailable))
- The pool size is less than the maximum pool size (poolSizeLTMax)
- If the request is for a sharable connection and there is no sharable connection already in use with the same sharing properties (NOT(shareableConnectionAvailable)) OR the request is for an unsharable connection (unshareableConnectionRequest)

All connections begin in the DoesNotExist state and are only created when the application requests a connection. The pool grows from 0 to the maximum number of connections as applications request new connections. The pool is **not** created with the minimum number of connections when the server starts.

If the request is for a sharable connection and a connection with the same sharing properties is already in use by the application, the connection is shared by two or more requests for a connection. In this case, a new connection is not created. For users of the JDBC API these sharing properties are most often *userid/password* and *transaction context*; for users of the Resource Adapter Common Client Interface (CCI) they are typically *ConnectionSpec*, *Subject*, and *transaction context*.

### InFreePool

The transition from the InFreePool state to the InUse state is the most common transition when the application requests a connection from the pool.

```
InFreePool>InUse:
getConnection AND
freeConnectionAvailable AND
(unshareableConnectionRequest OR
NOT(shareableConnectionAvailable))
```

This transition states that a connection is placed in use from the free pool if:

- the application has issued a *getConnection()* call
- a connection is available for use in the connection pool (*freeConnectionAvailable*),
- and one of the following is true:
  - the request is for an unsharable connection (*unshareableConnectionRequest*)

- no connection with the same sharing properties is already in use in the transaction. (NOT(shareableConnectionAvailable)).

Any connection request that a connection from the free pool can fulfill does not result in a new connection to the database. Therefore, if there is never more than one connection used at a time from the pool by any number of applications, the pool never grows beyond a size of one. This number can be less than the minimum number of connections specified for the pool. One way that a pool grows to the minimum number of connections is if the application has multiple concurrent requests for connections that must result in a newly created connection.

## InUse

The idea of connection sharing is seen in the transition on the InUse state.

```
InUse>InUse:
getConnection AND
ShareableConnectionAvailable
```

This transition states that if an application requests a shareable connection (getConnection) with the **same** sharing properties as a connection that is already in use (ShareableConnectionAvailable), the existing connection is shared.

The same user (*user name* and *password*, or *subject*, depending on authentication choice) can share connections but only within the same transaction and only when all of the sharing properties match. For JDBC connections, these properties include the *isolationLevel* which is configurable on the resource-reference (IBM WebSphere extension) to data source default. For a resource adapter factory connection, these properties include those specified on the *ConnectionSpec*. Because a transaction is normally associated with a single thread, you should **never** share connections across threads.

**Note:** It is possible to see the same connection on multiple threads at the same time, but this situation is an error state usually caused by an application programming error.

## Returning connections

All of the transitions so far have covered getting a connection for application use. From this point, the transitions result in a connection closing and either returning to the free pool or being destroyed. Applications should explicitly close connections (note: the connection that the user gets back is really a connection handle) by calling **close()** on the Connection object. In most cases, this action results in the following transition:

```
InUse>InFreePool:
(close AND
noOtherReferences AND
NoTx AND
UnshareableConnection)
OR
(ShareableConnection AND
TxEnds)
```

Conditions that cause the transition from the InUse state are:

- If the application (or the container) calls **close()** (close) and there are no references (noOtherReferences) either by the application (application sharing) or by the transaction manager (NoTx - who holds a reference when the connection is enlisted in a transaction), the Connection object returns to the free pool.

- If the connection was enlisted in a transaction but the transaction manager ends the transaction (txEnds), and the connection was a shareable connection (ShareableConnection), the connection closes and returns to the pool.

When the application calls close() on a connection, it is returning the connection to the pool of free connections; it is **not** closing the connection to the data store. When the application calls close() on a currently shared connection, the connection is *not returned* to the free pool. Only after the application drops the last reference to the connection, and the transaction is over, is the connection returned to the pool. Applications using unsharable connections must take care to close connections in a timely manner. Failure to do so can starve out the connection pool making it impossible for any application running on the server to get a connection.

When the application calls close() on a connection enlisted in a transaction, the connection is not returned to the free pool. Because the transaction manager must also hold a reference to the connection object, the connection cannot return to the free pool until the transaction ends. Once a connection is enlisted in a transaction, you cannot use it in any other transaction by any other application until after the transaction is complete.

There is a case where an application calling close() can result in the connection to the data store closing and bypassing the connection return to the pool. This situation happens if one of the connections in the pool is considered stale. A connection is considered stale if you can no longer use it to contact the data store. For example, a connection is marked stale if the data store server is shut down. When a connection is marked as stale, the entire pool is cleaned out by default because it is very likely that all of the connections are stale for the same reason (or you can set your configuration to clean just the failing connection). This cleansing includes marking all of the currently InUse connections as stale so they are destroyed upon closing. The following transition states the behavior on a call to close() when the connection is marked as stale:

```
InUse>DoesNotExist:
close AND
markedStale AND
NoTx AND
noOtherReferences
```

This transition states that if the application calls close() on the connection and the connection is marked as stale during the pool cleansing step (markedStale), the connection object closes to the data store and is not returned to the pool.

Finally, you can close connections to the data store and remove them from the pool.

This transition states that there are three cases in which a connection is removed from the free pool and destroyed.

1. If a fatal error notification is received from the resource adaptor (or data source). A fatal error notification (FatalErrorNotification) is received from the resource adaptor when something happens to the connection to make it unusable. All connections currently in the free pool are destroyed.
2. If the connection is in the free pool for longer than the unused timeout period (UnusedTimeoutExpired) and the pool size is greater than the minimum number of connections (poolSizeGTMin), the connection is removed from the free pool and destroyed. This mechanism enables the pool to shrink back to its minimum size when the demand for connections decreases.

3. If an age timeout is configured and a given connection is older than the timeout. This mechanism provides a way to recycle connections based on age.

## Unshareable and shareable connections

The product supports both *unshareable* and *shareable* connections. An unshareable connection is not shared with other components in the application. The component using this connection has full control of this connection.

You can share a shareable connection with other components within the same transaction as long as each *getConnection* request has the same connection properties. To enable connection sharing for data sources, the following connection properties must be the same:

- Java Naming and Directory Interface (JNDI) name. While not actually a *connection* property, this requirement simply means that you can only share connections from the same *dataSource* in the same server.
- Resource authentication
- In relational databases:
  - Isolation level
  - Readonly
  - Catalog
  - TypeMap

To enable connection sharing for resource adapters within the same transaction, the following connection properties must be the same:

- JNDI name. While not actually a *connection* property, this requirement simply means that you can only share connections from the same resource adapter in the same server.
- Resource authentication

In addition, the *ConnectionSpec* used to get the connection must also be the same.

Access to a resource marked as **Unshareable** means that there is a 1-to-1 relationship between the connection handle a component is using and the physical connection the handle is associated with. This access implies that every call to *getConnection* returns a connection handle solely for the requesting user. Typically, you must choose unshareable if you might do things to the connection that could result in unexpected behavior occurring to another application that is sharing the connection (for example, changing the isolation level).

Marking a resource as **Shareable** allows for greater scalability. Instead of creating new physical connections on every *getConnection* invocation, the physical connection (that is, managed connection) is shared through multiple connection handles, as long as each *getConnection* request has the same connection properties. But, sharing a connection means that each user must not do anything to the connection that could change its behavior and disrupt a sharing partner (for example, changing the isolation level). The user also cannot code an application *expecting* sharing to take place because it is up to the run time to decide whether or not to share a particular connection.

For WebSphere Application Server, all sharing of connections is relative to the current Unit of Work (UOW) boundary. Anyone within a specific transaction, when getting a connection from a specific connection pool, gets a handle to the same physical connection (if the sharing properties are the same).

### **Factors that determine sharing**

The listing here is not an exhaustive one. The product might or might not share connections under different circumstances.

- Only connections acquired with the same resource reference (resource-ref), which specifies the res-sharing-scope as *Shareable*, are candidates for sharing. The resource-ref properties of *res-sharing-scope*, *res-auth*, and *res-isolation-level* help determine if it is possible to share a connection. The *res-isolation-level* is a WebSphere extension.
- You can only share connections that are requested with the same properties.
- Connection Sharing only occurs between different component instances if they are within a transaction (container- or user-initiated transaction).
- Connection Sharing only occurs within a sharing boundary. Current sharing boundaries include *Transactions* and *LocalTransactionContainment (LTC)* boundaries.
- Connection Sharing rules within an LTC Scope:
  - For shareable connections, only *Connection Reuse* is allowed within a single component instance. Connection reuse occurs when the following actions are taken with a connection: get, use, commit/rollback, close; get, use, commit/rollback, close. Note that if you use the LTC resolution-control of *ContainerAtBoundary* then no start/commit is needed because that action is handled by the container.

The connection returned on the second *get* is the same connection as that returned on the first *get* (if the same properties are used). Because the connection use is serial, only one connection handle to the underlying physical connection is used at a time, so true *connection sharing* does not take place. The term “*reuse*” is more accurate.

- Shareable connections between transactions (either container-managed transactions (CMT), bean-managed transactions (BMT), or LTC transactions) follow these caching rules:
  - In general, setting properties on shareable connections is not allowed because a user of one connection handle might not anticipate a change made by another connection handle. This limitation is part of the J2EE 1.3 standard.
  - General users of resource adapters can set the connection properties on the connection factory *getConnection* call by passing them in a *ConnectionSpec*.

However, the properties set on the connection during one transaction are not guaranteed to be the same when used in the next transaction. Because it is not valid to share connections outside of a sharing scope, connection handles are moved off of the physical connection with which they are currently associated when a transaction ends. That physical connection is returned to

the free connection pool. Connections are cleaned before going in the free pool. The next time the handle is used, it is automatically associated with an appropriate connection. The appropriateness is based on the security login information, connection properties, and (for the JDBC API) the *isolation level* specified in the extended resource reference, passed in on the original request that returned the current handle. Any properties set on the connection after it was retrieved are lost.

- For JDBC users, WebSphere Application Server provides an extension to enable you to pass the connection properties through the ConnectionSpec. Use caution when setting properties and sharing connections in a local transaction scope. Ensure that other components with which the connection is shared are expecting the behavior resulting from your settings.
- You cannot set the *IsolationLevel* when using a shareable connection for the JDBC API using a relational resource adapter in a global transaction. The product provides an extension to the resource reference to enable you to specify the isolation level. If your application requires the use of multiple isolation levels, create multiple resource references and map them to the same data source or connection factory.

## Connection handles

A connection handle is a representation of a physical connection.

To use a backend resource (such as a relational database) in the WebSphere Application Server you must get a connection to that resource. When you call the *getConnection()* method, you get a *connection handle* returned. The handle is not the physical connection. The physical connection is managed by the connection manager.

There are two significant configurations or usage patterns that affect how connection handles are used and how they behave. The first is the *res-sharing-scope*, which is defined by the resource-reference used to look up the DataSource or Connection Factory. This property tells the connection manager whether or not you can share this connection.

The second factor that affects connection handle behavior is the *usage pattern*. There are essentially two usage patterns. The first is called the *get/use/close* pattern. This usage pattern is where an application, within a single method and without calling another method that might get a connection from the same data source or connection factory:

1. gets a connection
2. does its work
3. commits (if appropriate)
4. closes the connection.

The second usage pattern is called the *cached handle* pattern. This is where an application:

1. gets a connection
2. begins a global transaction
3. does work on the connection
4. commits a global transaction
5. does work on the connection again

A cached handle is a connection handle that is held across transaction and method boundaries by an application. Cached handle support requires some additional connection handle management across these boundaries, which can impact

performance. For example, in a JDBC application, *Statements*, *PreparedStatement*s, and *ResultSet*s are closed implicitly after a transaction ends, but the connection remains valid.

You are encouraged **not** to cache the connection across the transaction boundary for shareable connections, the get/use/close pattern is preferred. The following code segment shows the cached connection pattern.

```
Connection conn = ds.getConnection();
    ut.begin();
    conn.prepareStatement("....."); --> Connection runs in global transaction mode
    ...
    ut.commit();
    conn.prepareStatement("....."); ---> Connection still valid but runs in autoCommit(True);
    ...
```

### **Unshareable connections**

Some characteristics of connection handles retrieved with a *res-sharing-scope* of **unshareable** are described in the following sections.

#### **The possible benefits of unshared connections**

- Your application always maintains a direct link with a physical connection (managed connection).
- The connection always has a one-to-one relationship between the connection handle and the managed connection.
- In most cases, the connection does not close until the application closes it.
- You can use a cached unshared connection handle across multiple transactions.
- The connection can have a performance advantage in some cached handle situations. Because unshared connections do not have the overhead of moving connection handles off managed connections at the end of the transaction, there is less overhead in using a cached unshared connection.

#### **The possible drawbacks of unshared connections**

- Inefficient use of your connection resources. For example, if within a single transaction you get more than one connection (with the same properties) using the same data source or connection factory (same resource-ref) then you use multiple physical connections when you use unshareable connections.
- Wasted connections. It is important not to keep the connection handle open (that is, you have not called the *close()* method) any longer than it is needed. As long as you keep an unshareable connection open you tie up the physical connection, even if you currently are not using it.
- Deadlock considerations. Depending on how your components interact with the database within a transaction, using unshared connections can lead to deadlocks in the database. For example, within a transaction, component A gets a connection to data source X and updates table 1, and then calls component B. Component B gets another connection to data source X, and updates/reads table 1 (or even worse the same row as component A). In some circumstances, depending on the particular database, its locking scheme, and the transaction isolation level, a deadlock can occur.

In the same scenario, but with a *shared* connection, a deadlock does not occur because all the work was done on the same connection. It is worth noting that when writing code which uses shared connections, it is important that the code be written in such a way that it expects other work to be done on the same connection, possibly within the same transaction. If you decide to use an unshareable connection, you must set the *maximum connections* property on the connection factory or data source correctly. An exception occurs if you try to exceed the maximum connections value.

## Shareable connections

Some characteristics of connection handles retrieved with a *res-sharing-scope* of **shareable** are described in the following sections.

### The possible benefits of shared connections

- They can share a managed connection with one or more connection handles within a sharing, boundary depending upon how the handle is retrieved and which connection properties are used.
- They can more efficiently use resources. Shareable connections are not valid outside of their sharing boundary. For this reason, at the end of a sharing boundary (such as transaction) the connection handle is no longer associated with the managed connection it was using within the sharing boundary (this applies only when using the cached handle pattern). The managed connection is returned to the free connection pool for reuse. Connection resources are not held longer than the end of the current sharing scope.

If the cached handle pattern is used, then the next time the handle is used within a new sharing scope, the application server run time assures that the handle is reassociated with a managed connection appropriate for the current sharing scope and with the same properties with which the handle was originally retrieved. Remember that it is not appropriate to change properties on a shareable connection. If properties are changed, other components that share the same connection might experience unexpected behavior. Furthermore, when using cached handles, the value of the changed property might not be remembered across sharing scopes.

### The possible drawbacks of shared connections

- Sharing within a single component (such as an enterprise bean and its related Java objects) is not always supported. The current specification allows resource adapters the choice of only allowing one active connection handle at a time.

If a resource adapter chooses to implement this option then the following scenario results in an *invalid handle exception*: A component using shareable connections gets a connection and uses it. Without closing the connection, the component calls a utility class (Java object) which gets a connection (handle) to the same managed connection and uses it. Because the resource adapter only supports one active handle, the first connection handle is no longer valid. If the utility object returns without closing its handle, the first handle remains invalid and use of it causes an exception.

**Note:** This exception occurs only when calling a utility object (a Java object).

Not all resource adapters have this limitation, it depends on their implementation. The WebSphere Relational Resource Adapter (RRA) does not have this limitation. Any *DataSource* used through the RRA does not have this limitation. If you encounter a resource adapter with this limitation you can work around it by serializing your access to the managed connection. If you always close your connection handle before getting another, or close your handle before calling code which gets another handle, and you always close your handle

before you return from the method, you can allow two pieces of code to share the same managed connection. You just cannot use the connection for both events at the same time.

- Trying to change the *isolation level* on a shareable JDBC based connection in a global transaction (those supported by the RRA) causes an exception. The correct way to get connections with different transaction isolation levels is by configuring the IBM extended resource-reference.
- Closing connection handles for shareable connections by an application is NOT supported and causes errors. However, you can avoid this limitation by using the Relational Resource Adapter.

## Connections and transactions

All connection usage occurs within the scope of either a global transaction or a local transaction containment (LTC).

Connection behavior depends on your current operating scope. This article discusses some of the common characteristics you see when using connections in one of the transaction scopes of the product.

You can only share connections within a global transaction scope (assuming other sharing rules are met). However, you can *serially reuse* connections within an LTC scope. A get/use/close connection pattern followed by another get/use/close (to the same data source or connection factory) enables you to reuse the same connection. See Unshareable and shareable connections for more details.

### JDBC AutoCommit behavior

All JDBC connections, when first obtained through a *getConnection* call, have `AutoCommit = TRUE` by default.

- If you operate within an LTC and have its resolution-control set to *Application*, then `AutoCommit` remains *TRUE* unless changed by the application.
- If you operate within an LTC and have its resolution-control set to *ContainerAtBoundary*, then the application should **not** touch the `AutoCommit` setting. The WebSphere Application Server run time sets the `AutoCommit` value to *FALSE* before work begins, then commits or rolls back the work as appropriate at the end of the LTC scope.
- If you use a connection within a global transaction, then regardless of the user changing the `AutoCommit` setting, upon first use of the connection to do work the database ignores the `AutoCommit` setting so that the transaction service that controls the commit and rollback processing can manage the transaction. After the transaction completes, the `AutoCommit` value returns to the value it had before the first use of the connection. So even if the `AutoCommit` value is set to *TRUE* before the connection is used in a global transaction, you need not set the value to *FALSE* since the value is ignored by the database. In this example, after the transaction completes, the `AutoCommit` value of the connection returns to *TRUE*.
- If you use multiple distinct connections within a global transaction, all work is guaranteed to commit or roll back together. This is not the case for a local transaction containment (LTC scope). Within an LTC, work done on one connection commits or rolls back independently from work done on any other connection within the LTC.

Using the transaction service

These topics provide information about using transactions with WebSphere applications

## One phase commit and two phase commit resources

One phase commit resources are such that work being done on a one phase connection cannot mix with other connections and ensure that the work done on all of the connections completes or fails atomically. The product does not allow more than one one-phase commit connection in a global transaction. Furthermore, it does not allow a one phase commit connection in a global transaction with one or more two phase commit connections. You can coordinate only multiple two phase commit connections within a global transaction.

Note that any time you do multiple *getConnection* calls using a resource reference that specifies *res-sharing-scope=Unshareable*, then you get multiple physical connections. This situation also occurs when *res-sharing-scope=Shareable* but the sharing rules are broken. In either case, if you run in a global transaction, ensure the resources involved are enabled for two phase commit (also sometimes referred to as *JTA Enabled*). Failure to do so results in an *XAException* that logs the following message: *WTRN0063E: An illegal attempt to enlist a one phase capable resource with existing two phase capable resources has occurred.*

---

## Developing data access applications

You can access data in various ways:

- using standard or extended APIs
- using container-managed persistence beans
- using bean-managed persistence beans, session beans, or Web components.

### 1. Decide how to implement data access.

The Enterprise JavaBeans (EJB) programming model provides several distinct server-side component types: entity, session, and message-driven beans, and servlets. Of these types, entity beans are typically used to model business components in an application. Entity beans have both *state* and *behavior*.

The state of entity beans is persistent and is stored in a database. As changes are made to an entity bean, its state is kept in synchronization with the database record representing the bean. There are two types of entity beans provided by the EJB model and these two types differ in the mechanism used to provide persistence. These two types of entity beans are *container-managed persistence* (CMP) beans and *bean-managed persistence* (BMP) beans.

With BMP beans, the developer manually produces code to manage the persistent state of the bean.

With CMP beans, the EJB container manages the beans persistent state. Persistent state management is a complex and difficult task and using CMP beans allows the developer to concentrate on business logic by delegating persistence behavior to the container. Typical examples of CMP beans are *Customer*, *Account*, and so on. Because CMP beans are objects, their data (state) is accessed using field accessors. For example, a *Customer* entity bean is likely to have fields such as *name* and *phoneNumber*. These pieces of data are accessed using the accessor methods *getName()/setName()* and *getPhoneNumber()/setPhoneNumber()*. As a developer, you are not concerned with

how this data is eventually stored and retrieved from the backend database and can assume that the integrity of the data is maintained by the container.

**5.0.1 +** Starting with WebSphere Application Server Version 5.0.1, you can use Structured Query Language in Java (SQLJ) support with both BMP and CMP beans when DB2 is your backend database.

2. Create a JDBC provider and data source (Creating and configuring a JDBC provider and data source ), or create a J2EE Connector Architecture (JCA) connection factory (Configuring Java 2 Connector connection factories in the administrative console). An application component uses a connection factory to access a connection instance, which the component then uses to connect to the underlying enterprise information system (EIS). A data source is associated with a JDBC provider that supplies the specific JDBC driver implementation class. The data source represents the JCA connection factory for the relational resource adapter.
3. Look up a data source or connection factory using a resource reference (Looking up data sources with resource references for relational access). Using a resource reference to access your data source or connection factory is required when running in WebSphere Application Server.
4. Get a connection to a data source (Connection management architecture). The connection management architecture for both relational and procedural access to enterprise information systems (EIS) is based on the J2EE Connector Architecture (JCA) specification. The Connection Manager (CM), which pools and manages connections within an application server, is capable of managing connections obtained through both resource adapters (RAs) defined by the JCA specification, and DataSources defined by the JDBC 2.0 Extensions Specification.
5. Use thread identity to assign an owner to the connection.

## Data access application programming interface support

Applications can access the backend data through the standard J2EE 1.3 defined application programming interfaces (APIs).

The standard APIs do not always provide a complete solution for an application that runs in an application server. For example, the JDBC programming model sometimes does not completely work with the J2EE Connector Architecture (JCA) Specification (even though the JCA architecture has explicitly specified that it integrates with the JDBC programming model). These gaps cause some incompatibility between the JDBC and JCA programming models.

When getting and using shareable connections in a global transaction, it is not valid to change a property on the connection after you obtain it. Changes can unknowingly affect other users who share the same connection.

The J2EE Connector Architecture (JCA) Specification supports telling the resource adapter the specific properties settings at the time you request the connection (using the *getConnection* method) by passing in a *ConnectionSpec*. The *ConnectionSpec* contains the necessary connection properties used to get a connection. After you obtain a connection from this environment, your application does not need to alter the properties.

The JDBC programming model does not have the same interface to specify the connection properties. Instead, it gets the connection first, then sets the properties on the connection. In the case of a shareable connection, changing the connection properties impacts all the connections shared with the same physical connection.

WebSphere Application Server provides the following extensions to fill in the gaps between these two specifications.

- **WSDatasource interface** - this interface extends *javax.sql.DataSource*, and enables a component or an application to specify the connection properties through the WebSphere Application Server *JDBCConnectionSpec* to get a specific connection.
  - *getConnection(JDBCConnectionSpec)* - this method returns a specific connection which has the JCA compliant connection behavior.
  - For more information see the Javadoc **wsdatasource** in the Javadoc index.
- **JDBCConnectionSpec interface** - this interface extends the *com.ibm.websphere.rsadapter.WSConnectionSpec*, which extends *javax.resources.cci.ConnectionSpec*. The standard *ConnectionSpec* interface provides only the interface marker without any get and set methods. The *WSConnectionSpec* and *JDBCConnectionSpec* define a set of get and set methods used by the WebSphere Application Server run time. This interface enables the application to specify all the essential connection properties in order to get an appropriate connection. You can create this class from the WebSphere *WSRRAFactory*. For more information see the Javadoc **JDBCConnection** in the Javadoc index.
- **WSRRAFactory** - this is the Relational Resource Adapter Factory which allows the user to create a *JDBCConnectionSpec* or other resource adapter related object. For more information see the Javadoc **wsrrafactory** in the Javadoc index

### Example: Accessing data using IBM extended APIs for connections

If your application runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

You can access an extended API in your JDBC application. Instead of using the *DataSource* interface, you use the *WSDatasource* interface. The following code segment illustrates how to get the connection.

```
import com.ibm.websphere.rsadapter.*;
```

```
...
```

```
// Create a JDBCConnectionSpec and set connection properties. If this connection is shared with  
the CMP bean, make sure that the isolation level is the same as the isolation level that is mapped by
```

```
JDBCConnectionSpec connSpec = WSRRAFactory.createJDBCConnectionSpec();
```

```
connSpec.setTransactionIsolation(CONNECTION.TRANSACTION_REPEATABLE_READ);
```

```
connSpec.setCatalog("DEPT407");
```

```
//Use WSDatasource to get the connection
```

```
Connection conn = ((WSDatasource)datasource).getConnection(connSpec);
```

### **Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans**

If your application runs with a shareable connection that might be shared with other container-managed persistence (CMP) beans within a transaction, it is recommended that you use the WebSphere Application Server extended APIs to get the connection. When you use these APIs, you cannot port your application to other application servers.

You can access an extended API in your JDBC application. Instead of using the `DataSource` interface, you use the `WSDataSource` interface.

To ensure that both CMP and bean-managed persistence (BMP) beans are sharing the same physical connection, you can define the same Access Intent profile on both the CMP and BMP beans. Inside your BMP method, you can get the right isolation level from the relational resource adapter helper class.

```
package fvt.example;

import java.sql.Connection;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;

import javax.ejb.CreateException;
import javax.ejb.DuplicateKeyException;
import javax.ejb.EJBException;
import javax.ejb.ObjectNotFoundException;
import javax.sql.DataSource;

// following imports are used by the IBM extended API
import com.ibm.websphere.appprofile.accessintent.AccessIntent;
import com.ibm.websphere.appprofile.accessintent.AccessIntentService;
import com.ibm.websphere.rsadapter.JDBCConnectionSpec;
import com.ibm.websphere.rsadapter.WSCallHelper;
import com.ibm.websphere.rsadapter.WSDataSource;
import com.ibm.websphere.rsadapter.WSRRAFactory;

## **Container-managed persistence features**

The container-managed persistence (CMP) features include those defined by the EJB 2.0 Specification, as well as capabilities that are beyond the specification.

### **EJB 2.0 specified capabilities**

*Container-Managed Relationships* (CMR) is one of the most significant new features added by the EJB 2.0 Specification. Like *Inheritance*, relationships are a key component of object-oriented software development and non-trivial object models can form complex networks with these relationships. The EJB 2.0 Specification adds relationships to the EJB programming model and requires that the container be responsible for their maintenance.

The container automatically manages the state of CMP entity beans. This management includes synchronizing the state of the bean with the underlying database when necessary and also managing any relationships (CMRs) with other entity beans. The bean developer is relieved of writing any database specific code and, instead, can focus on business logic.

*Local interfaces* are another feature introduced in the EJB 2.0 Specification. Local component interfaces allow co-located beans to interact without the overhead associated with remote access.

### **Value-add features**

Several capabilities are provided to enhance the function of CMP entity beans that go beyond those capabilities defined by the specification. These include:

#### **Entity bean inheritance**

Inheritance is a key aspect of object-oriented software development and is a capability currently missing from the EJB 2.0 Specification.

The use of inheritance enables a developer to define fields, relationships, and business logic in a superclass entity bean that are inherited by all subclasses. See the section *EJB inheritance* of the WebSphere Studio Application Developer (WSAD) documentation for details on using inheritance with WebSphere Application Server and entity beans.

#### **Access Intent Policies**

Access intent policies provide J2EE application developers the mechanism by which they can indicate the intent of an application’s interaction with the essential state for entity beans in order that the persistence mechanisms

can make appropriate optimizations. For example, if it is known that an entity is not updated during the course of a transaction, then the persistence management is able to ease up on the concurrency control and still maintain data integrity by disallowing update operations on that bean for the duration of the transaction.

#### **Caching data across transactions**

Data caching across transactions is a configurable option set by the bean deployer that can greatly improve performance. Essentially, this is for data that changes infrequently. The option is known as *LifetimeInCache*. The data for an entity configured for lifetime in cache is stored in a cache until its specified lifetime expires. Requests on the entity during that configured lifetime use the cached data, and do not result in the execution of queries against the underlying data store. Lifetime can be expressed as time elapsed since the data was retrieved from the data store or until a specific time of day or week. See the *LifetimeInCache* help sections of the Application Assembly Tool (AAT) for more details.

#### **Related concepts**

Access intent policies

An access intent policy is a named set of properties (access intents) that governs data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. If you have the WebSphere Application Server Enterprise product installed, you can assign these during development as well. Access intents are settable only within EJB Version 2.x-compliant modules for entity beans with bean-managed persistence or with CMP Version 2.x.

## **Looking up data sources with resource references for relational access**

Using a resource reference to access your data source or connection factory is required when running in WebSphere Application Server. Some of the reasons follow:

- If a data source is looked up directly, the connection gets all default properties for the missing resource reference. For example, the *sharing-scope* is a shareable connection resulting in the possibility that the physical connection is the same each time the connection is requested from the data source. This situation can cause a multitude of problems if you expect unshareable connections.
- It relieves the programmer from having to know the name of the actual data source at the target application server.
- You can set the default isolation level for the data source through resource references. With no resource reference you get the default for the JDBC driver you use.

Use a resource reference (resource-ref) for looking up a data source through the standard Java Naming and Directory Interface (JNDI) naming interface. The JNDI name defined in the resource-ref is a logical name of the data source. Have your application use this JNDI name to look up a data source instead of using the JNDI name that is defined on the data source.

Later, you can substitute the real name, either by using the Application Assembly Tool (AAT) or during installation of the application EAR file onto the server.

For example, assume that you use a `DataSource jdbc/Section` as illustrated in the code below.

```
javax.sql.DataSource specificDataSource =  
    (javax.sql.DataSource) javax.rmi.PortableRemoteObject.narrow( (new InitialContext()).lookup("j  
                                                                    javax.sql.DataSource.class);
```

In the AAT, specify the name (*jdbc/Section*) as the resource reference. If you know the name of the `DataSource`, you specify it in the resource references Bindings page.

### **Isolation level and resource reference**

In a J2EE 1.2 module, you can specify the isolation level at an enterprise bean method level, bean level, or module level. This capability has been removed from the J2EE 1.3 module. WebSphere Application Server Version 5.0 is compliant with the J2EE 1.3 specification; therefore you cannot specify isolation level on the EJB method level or bean level. Also, if a JDBC application, a bean-managed persistence (BMP) bean, or a servlet runs in a global transaction, and you are using shareable connections, you cannot set the isolation level on a connection.

When a container-managed persistence (CMP) bean uses a new data source to access a backend database, the isolation level is determined by the WebSphere Application Server run time based on the type of access intent that this method or the bean has chosen. All other connection users can also use the access intent and application profile support to manage their concurrency control.

For all JDBC connections (excluding those used by CMP beans), you can specify an isolation level default on the resource reference. For shareable connections that run in global transactions, this default is the only way to set the *isolationLevel* for connections. Trying to directly set the isolation level through the *setTransactionIsolation()* method on a shareable connection that runs in a global transaction is not allowed. To use a different isolation level on connections, you must provide a different resource reference. Set these defaults through the Application Assembly Tool (AAT).

Each resource reference associates with one isolation level. When your application uses this resource reference Java Naming and Directory Interface (JNDI) name to look up a data source, every connection returned from this data source using this resource reference has the same isolation level.

Components needing to use shareable connections with multiple isolation levels can create multiple resource references, giving them different JNDI names, and have their code look up the appropriate data source for the isolation level they need. In this way, you use separate connections with the different isolation levels enabled on them.

It is possible to map these multiple resource references to the same configured data source. The connections still come from the same underlying pool, however, the connection manager does not allow sharing of connections requested by resource references with different isolation levels.

For example, a data source is bound to two resource references: *jdbc/RRResRef* and *jdbc/RCResRef*. *RRResRef* has the *RepeatableRead* isolation level defined. *RCResRef* has the *ReadCommitted* isolation level defined. If your application wants to update the tables or a BMP bean updates some attributes, it can use the *jdbc/RRResRef* JNDI name to look up the data source instance. All connections returned from the data source instance have a *RepeatableRead* isolation level. If the application wants to perform a query for read only, then it is better to use the *jdbc/RCResRef* JNDI name to look up the data source.

#### **Creating or changing a resource reference:**

A resource reference supports application provider access to a resource (such as a data source, URL, or mail provider) using a logical name rather than the actual name in the run time environment. This ability insulates the application provider from the run time configuration, and simplifies the process of changing the run time configuration.

Resource references are declared in the deployment descriptor by the application provider. At some point in the application deployment process, you must bind the resource reference to the actual name of the resource in the run time environment.

1. Start the Application Assembly Tool. Cancel the *Welcome to the Application Assembly Tool* window.
2. Click **File > Open**. Find the EAR file you want to change, click the file name, and click **Open**.
3. Display the resource references for the type of application component:
  - If an enterprise bean uses the resource reference:
    - Expand the name of the EAR file
    - Expand **EJB Modules**
    - Expand the EJB module wanted
    - Expand the section for the appropriate type of enterprise bean (**Session Beans** or **Entity Beans**)
    - Expand the enterprise bean
  - If a servlet uses the resource reference:
    - Expand the name of the EAR file
    - Expand **Web Modules**
    - Expand the Web module wanted
  - If an application client uses the resource reference:

- Expand the name of the EAR file
  - Expand **Application Clients**
  - Expand the application client module wanted
4. Click **Resource References**.
  5. Right-click **Resource References** and click **New** to display the new Resource Reference window.
  6. Specify settings.
  7. Click **IBM Extensions** and select the *Isolation level*.
  8. Click **Bindings** and fill in the *JNDI name*. You can choose to skip this step, as you are allowed to fill in or change this field during installation of the EAR file.
  9. Click **OK**.
  10. Save the EAR file. See Saving applications after assembly.
  11. Generate the code. See Generating code for deployment.

*Bean-managed persistence bean:* When developing your bean-managed persistence (BMP) bean you generally lack knowledge about the name of the data source on the target application server. In your code, do not look up the data source directly. Instead, you look up the resource reference from the *java:comp/env namespace* file. Let us assume that you look up the resource reference named *ref/ds* as illustrated in the code below.

```
javax.sql.DataSource dSource = (javax.sql.DataSource)((new InitialContext()).lookup("java:/comp/env/
(javax.sql.DataSource)javax.rmi.PortableRemoteObject.narrow( (new InitialContext()).lookup("jdbc/Se
```

In the AAT, you specify the name **ref/ds** in the Resource Reference page on the General Tab. If you know the name of the data source you can specify it in this

Resource References page on the Bindings Tab. Note that if you do not specify it here, you must provide this Java Naming and Directory Interface (JNDI) name when you install the application EAR file.

*Container-managed persistence bean:* In a container-managed persistence (CMP) bean you do not specify the DataSource in the code. Instead you specify the JNDI name of the DataSource during assembly using the AAT, this is the setting in the Bean Binding panel. In this example, the JNDI name *jdbc/Section* is used.

*Servlets and JavaServer Pages Files:* In a servlet application, you look up the DataSource exactly as you look it up in the BMP bean case.

**Access intent and isolation level:**

The *access intent* service enables developers to precisely tune the management of application persistence.

**Related concepts**

Access intent policies

An access intent policy is a named set of properties (access intents) that governs data access for Enterprise JavaBeans (EJB) persistence. You can assign policies to an entity bean and to individual methods on an entity bean's home, remote, or local interfaces during assembly. If you have the WebSphere Application Server Enterprise product installed, you can assign these during development as well. Access intents are settable only within EJB Version 2.x-compliant modules for entity beans with bean-managed persistence or with CMP Version 2.x.

**Related tasks**

Applying access intent policies to methods

*Access intent -- isolation levels and update locks:* The combination of concurrency and access type determines the isolation level for the persistence manager. The actual isolation level depends upon the particular database, as shown in the following table.

AccessIntent profile	Isolation level						For Update
	DB2	Oracle*	SyBase	Informatica	Cloudscape	SQL Server	
wsPessimisticUpdateWeakest LockAtLoad (Default policy)	RR	RC	RR	RR	RR	RR	No (*Oracle, Yes)
wsPessimisticUpdate	RR	RC	RR	RR	RR	RR	Yes
wsPessimisticRead	RR	RC	RR	RR	RR	RR	No
wsOptimisticUpdate	RC	RC	RC	RC	RC	RC	No
wsOptimisticRead	RC	RC	RC	RC	RC	RC	No
wsPessimisticUpdateNo-Collisions	RC	RC	RC	RC	RC	RC	No
wsPessimisticUpdateExclusive	S	RC	S	S	S	S	Yes

- RC = JDBC Read committed
- RR = JDBC Repeatable read
- S = JDBC Serializable

## Data access from J2EE Connector Architecture applications

To access data from a J2EE Connector Architecture (JCA) compliant application in WebSphere Application Server, you can use encapsulated session beans and JCA connectors.

Use WebSphere Studio Application Developer Integration Edition (WSADIE) 4.1.1 to create a SessionBean that encapsulates the access to the backend. To find help on this subject, see the documentation for WSADIE.

## Accessing data using J2EE Connector Architecture connectors

As indicated in the J2EE Connector Architecture (JCA) Specification, each enterprise information system (EIS) needs a resource adapter and a connection factory. This connection factory is then accessed through the following programming model. If you use WebSphere Studio Application Development (WSAD) tools, most of the following deployment descriptors and code are generated for you. This example shows the manual method of accessing an EIS resource.

For each EIS connection, do the following:

1. Declare a connection factory resource reference in your application component's deployment descriptors, as described in this example:

```
<resource-ref>
  <description>description</description>
  <res-ref-name>eis/myConnection</res-ref-name>
  <res-type>javax.resource.cci.ConnectionFactory</res-type>
  <res-auth>Application</res-auth>
</resource-ref>
```

2. Configure, during deployment, each resource adapter and associated connection factory through the console. See *Configuring J2C resource adapters* and *Configuring J2C connection factories* for more information.
3. Locate the corresponding connection factory for the EIS resource adapter using Java Naming and Directory Interface (JNDI) lookup in your application component, during run time.
4. Get the connection to the EIS from the connection factory.
5. Create an interaction from the Connection object.
6. Create an *InteractionSpec* object. Set the function to execute in the *InteractionSpec* object.
7. Create a Record instance for the input and output data used by function.
8. Execute the function through the Interaction object.
9. Process the record data from the function.
10. Close the connection.

The following code segment shows how an application component might create an interaction and execute it on the EIS:

```
javax.resource.cci.ConnectionFactory connectionFactory = null;
javax.resource.cci.Connection connection = null;
javax.resource.cci.Interaction interaction = null;
javax.resource.cci.InteractionSpec interactionSpec = null;
javax.resource.cci.Record inRec = null;
javax.resource.cci.Record outRec = null;
```

```

try {
// Locate the application component and perform a JNDI lookup
    javax.naming.InitialContext ctx = new javax.naming.InitialContext();
    connectionFactory = (javax.resource.cci.ConnectionFactory)
ctx.lookup("java:comp/env/eis/myConnection");

// create a connection
    connection = connectionFactory.getConnection();

// Create Interaction and an InteractionSpec
    interaction = connection.createInteraction();
    interactionSpec = new InteractionSpec();
    interactionSpec.setFunctionName("GET");

// Create input record
    inRec = new javax.resource.cci.Record();

// Execute an interaction
    interaction.execute(interactionSpec, inRec, outRec);

// Process the output...

} catch (Exception e) {
    // Exception Handling
}
finally {
    if (interaction != null) {
        try {
            interaction.close();
        }
        catch (Exception e) { /* ignore the exception*/ }
    }
    if (connection != null) {
        try {
            connection.close();
        }
        catch (Exception e) { /* ignore the exception */ }
    }
}

```

## J2EE Connector Architecture migration tips

Previous WebSphere Application Server versions provided an initial implementation of the J2EE Connector Architecture (JCA) specification, Version 1.0. This implementation provided basic run time support based on the final JCA 1.0 Specification, but it was not a complete implementation.

The product now provides a complete implementation of the JCA 1.0 Specification, which supports:

- Connection sharing (*res-sharing-scope*).
- Get/use/close programming model for connection handles.
- Get/use/cache programming model for connection handles.
- *XA*, *Local*, and *No Transaction* models of resource adapters, including XA recovery.
- Security options A and C per the specification.

If you move from one of the earlier implementations of the J2EE Connector Architecture to the current implementation, be aware of the following:

- This version supports the *res-sharing-scope* tag within the resource reference (resource-ref) element. This tag was not available in previous versions and defaulted to *shareable* connections. Version 5.0 supports **both** shareable and unshareable connections.
- The current product supports the Web container. Both enterprise bean and Web components can utilize the J2EE Connector Architecture.
- Both connection handle usage patterns (get/use/close and get/use/cache) are supported. The get/use/close pattern indicates that a connection is retrieved, used, and closed all within the same transaction or method boundary. The get/use/cache pattern indicates that you can cache a connection across transaction or method boundaries.
- The current version supports additional authentication mechanisms. The capability to support Options A and C per the JCA specification is provided, as well as support for *res-auth* settings of either *Application* or *Container*. In previous versions, the *res-auth* setting was basically ignored, therefore it was treated as if *res-auth* was set to *Application*. If your existing applications had *res-auth* set to *Container*, they might behave differently if you install them into a current environment without any changes.
- You can no longer specify pool and subpool names. The pool name is based on the data source or connection factory's Java Naming and Directory Interface (JNDI) name. Subpools were eliminated to provide better performance.

For applications that use WebServices and JCA Connectors, there are some additional points to be aware of:

- Applications generated on WebSphere Studio Application Developer -- Integration Edition Version 4.1.1 can run on WebSphere Application Server Version 4.0.4 and WebSphere Application Server Enterprise Version 4.1.
- Applications generated on WebSphere Studio Application Developer -- Integration Edition Version 5.0 can run on WebSphere Application Server Version 5.0 and WebSphere Application Server Enterprise Version 5.0.
- Applications generated on WebSphere Studio Application Developer -- Integration Edition Version 4.1.1 can run unchanged on WebSphere Application Server Enterprise Version 5.0, but can only run on WebSphere Application Server Version 5.0 if the applications are regenerated using WebSphere Studio Application Developer -- Integration Edition Version 5.0 tools.

This limitation is because of the *wsd14j.jar* file. As delivered in WebSphere Application Server Enterprise Version 4.1, the file is not fully compliant with JSR 110 (JSR 110 was not final at the time that 4.1 shipped). The *wsd14j.jar* file shipped with WebSphere Application Server Version 5.0 is compliant. However, because most of the classes have the same package names and interfaces, BUT NOT ALL, the two *wsd14j.jar* files cannot co-exist in the same WebSphere Application Server installation.

## Data access from an enterprise entity bean

Container-managed persistence (CMP) developers can use *access intent* to provide hints on how the application server run time should manage the details of persistence without having to explicitly manage any of the persistence logic from within their application.

However, there are still situations where developers must develop bean-managed persistence (BMP) entity beans. Because the only meaningful difference between BMP and CMP components is who provides the persistence logic, BMP beans should leverage access intent hints just the same as the application server does on behalf of CMP beans. This ability becomes especially important when BMP entities and CMP entities want to share connections. BMP beans configured with the same concurrency as the CMP beans and implemented to the same isolation level mapping as the CMP can share connections.

### Related tasks

Enterprise beans

An enterprise bean is a Java component that can be combined with other resources to create J2EE applications. There are three types of enterprise beans, entity beans, session beans, and message-driven beans.

### Related reference

“Example: Accessing data using IBM extended APIs to share connections between container-managed and bean-managed persistence beans” on page 183

## Data access bean types

Data access beans are essentially a class library that makes it easier to access a database. The library contains a set of beans with methods that access the database through the JDBC API. There are several sets of classes referred to as data access beans. To make things clearer, you can refer to the classes by the name of the JAR file that contains them:

*databeans.jar* - This JAR file ships with the WebSphere Application Server. This file contains classes that enable you to access the database using the JDBC API.

*ivjdab.jar* - This JAR file ships with Visual Age for Java (VAJ). This file contains all of the classes in the *databeans.jar* file and classes that support easy use of the data access beans from the VAJ Visual Composition Editor.

*dbbeans.jar* - This JAR file ships with WebSphere Studio Site Developer (WSSD) and WebSphere Studio Application Developer (WSAD). This file contains a set of data access beans to more closely conform to the JDBC 2.0 *RowSet* standard.

For the current product, data access beans remain unchanged from WebSphere Application Server Version 4.0. The *com.ibm.db* package is provided to support existing applications that use data access beans.

IBM strongly suggests that any **new** applications using data access beans be developed using the *com.ibm.db.beans* package that is provided with WebSphere Studio Application Developer (WSAD).

If you want to continue using applications that use the *com.ibm.db* package, see the WebSphere Application Server Version 4.0 documentation concerning data access beans. An example is shown here: Example: Using data access beans in Version 4.0.

If you want to create new applications that use the *com.ibm.db.beans* package, see the WSAD documentation concerning data access beans. An example is shown here: Example: Using data access beans in Version 5.0

 */
public SelectStatementExample() {
    super();
}
/**
 * Starts the application.
 * @param args an array of command-line arguments
 */
public static void main(java.lang.String[] args) {
    // Objects

    SelectStatement stmt = new SelectStatement();
    DatabaseConnection conn = new DatabaseConnection();
    StatementMetaData metaData = new StatementMetaData();
    SelectResult result;

    // Set properties for connection
    conn.setDriverName("COM.ibm.db2.jdbc.app.DB2Driver");
    conn.setDataSourceName("jdbc:db2:Sample");
    conn.setUserID("userid");
    conn.setPassword("password");

    // Set SQL statement
    metaData.setSQL("SELECT * FROM DEPARTMENT");

    // Associate connection and metadata with stmt
    stmt.setConnection(conn);
    stmt.setMetaData(metaData);

    try {
        // Execute SQL statement
        stmt.execute();

        // Process results
        result = stmt.getResult();
        for (int i = 1; i <= result.getNumRows(); i++) {
            System.out.println(result.getColumnValueToString(1));
            System.out.println(result.getColumnValueToString(2));
            result.nextRow();
        }
    }
}
```

```

    }

    // Release JDBC resources
    result.close();

    // Close the database connection
    conn.disconnect();

    } catch (DataException ex) {
        ex.printStackTrace();
    }
}
}

```

### Example: Using data access beans in Version 5.0

```

package example;
import com.ibm.db.beans.*;
import java.sql.SQLException;

public class DBSelectExample {

    public static void main(String[] args) {

        DBSelect select = null;

        select = new DBSelect();
        try {

            // Set database connection information
            select.setDriverName("COM.ibm.db2.jdbc.app.DB2Driver");
            select.setUrl("jdbc:db2:SAMPLE");
            select.setUsername("userid");
            select.setPassword("password");

            // Specify the SQL statement to be executed
            select.setCommand("SELECT * FROM DEPARTMENT");

            // Execute the statement and retrieve the result set into the cache
            select.execute();

            // If result set is not empty
            if (select.onRow()) {
                do {
                    // display first column of result set
                    System.out.println(select.getColumnAsString(1));
                    System.out.println(select.getColumnAsString(2));
                } while (select.next());
            }

            // Release the JDBC resources and close the connection
            select.close();

        } catch (SQLException ex) {
            ex.printStackTrace();
        }
    }
}

```

## Accessing data from application clients

To access a database directly from a J2EE application client, you retrieve a *javax.sql.DataSource* object from a resource reference configured in the client deployment descriptor. This resource reference is configured as part of the deployment descriptor for the client application, and provides a reference to a preconfigured data source object.

Note that data access from an application client uses the JDBC driver connection functionalities directly from the client side. It does not take advantage of the additional pooling support available in the application server run time. For this reason, your client application should utilize an enterprise bean running on the server side to perform data access. This enterprise bean can then take advantage of the connection reuse and additional added functionality provided by the product run time.

1. Import the appropriate JDBC API and naming packages:

```
import java.sql.*;
import javax.sql.*;
import javax.naming.*;
```

2. Create the initial naming context:

```
InitialContext ctx = new InitialContext();
```

3. Use the *InitialContext* to look up a data source object from a resource reference.

```
javax.sql.DataSource ds = (DataSource)ctx.lookup("java:comp/env/jdbc/myDS");
//where jdbc/myDS is the name of the resource reference
```

4. Get a *java.sql.Connection* from the data source.

- If no user ID and password are required for the connection, or if you are going to use the *defaultUser* and *defaultPassword* that are specified when the data source is created in the Application Client Resource Configuration tool (ACRCT) in a future step:

```
java.sql.Connection conn = ds.getConnection();
```

- Otherwise, you should make the connection with a specific user ID and password:

```
java.sql.Connection conn = ds.getConnection("user", "password");
//where user and password are the user id and password for the connection
```

5. Run a database query using the *java.sql.Statement*, *java.sql.PreparedStatement*, or *java.sql.CallableStatement* interfaces as appropriate.

```
Statement stmt = conn.createStatement();
String query = "Select FirstNme from " + owner.toUpperCase() + ".Employee where LASTNAME = '";
ResultSet rs = stmt.executeQuery(query);
while (rs.next()) {    firstNameList.addElement(rs.getString(1));
}
}
```

6. Close the database objects used in the previous step, including any *ResultSet*, *Statement*, *PreparedStatement*, or *CallableStatement* objects.

7. Close the connection. Ideally, you should close the connection in a *finally* block of the *try...catch* wrapped around the database operation. This action ensures that the connection gets closed, even in the case of an exception.

```
conn.close();
```

## **Connection thread identity**

WebSphere Application Server for z/OS allows you to assign a thread identifier as an owner of a connection, when you first obtain the connection. The *thread identity* function only applies to J2EE Connector Architecture (JCA) resource adapters and Relational Resource Adapter (RRA) wrapped Java Database Connectivity (JDBC) providers that support the use of thread identity for connection ownership.

The following table lists the JCA resource adapter and JDBC provider processes that support thread identity and thread security. It also provides the level of thread identity support:

Connectors	Thread identity support	Thread Security
IMS Connector - local ConnectionFactory configuration	ALLOWED	Not supported
IMS Connector - remote ConnectionFactory configuration	NOTALLOWED	Not supported
CTG CICSECICConnector - local ConnectionFactory configuration	ALLOWED	Not supported
CTG CICSECICConnector - remote ConnectionFactory configuration	NOTALLOWED	Not supported
IMS JDBC Connector - local ConnectionFactory configuration (By default, IMS JDBC only supports this type of configuration.)	REQUIRED	True
RRA DB2 for z/OS local JDBC provider - data sources configured to the local DB2	ALLOWED	True

WebSphere Application Server for z/OS allows resource adapters and JDBC providers to define the level of thread identity support for the defined connection factories or data sources. The level of support can be:

- **ALLOWED**, which indicates thread identity for connection ownership is allowed for this configuration.
- **NOTALLOWED**, which indicates thread identity for connection ownership is not allowed for this configuration.
- **REQUIRED**, which indicates thread identity for connection ownership is required.

The thread identity function is only available in those server configurations where JCA connectors or JDBC providers access local z/OS resources through callable (not TCP/IP) interfaces. So, for example, CICS and IMS provide thread identity support only if the target CICS or IMS is configured on the same system as the z/OS WebSphere Application Server.

To use thread identity when getting connections to a connection factory or JDBC data source for your application, you must specify **resauth=Container** for the connection factory or JDBC data source. Use the the Application Assembly Tool (AAT) or WebSphere Studio Application Developer Integration Edition (WSADIE) to indicate the **resauth=Container** setting.

When the level of thread identity support provided by the connector configuration is **ALLOWED**, if you want to use thread identity for the connections, you cannot specify a Container-managed alias when you define the connection factory or JDBC data source. If you specify a Container-managed alias, the userid defined by the alias is assigned as the owning id for the connections obtained by the application.

When the JDBC provider supports thread identity, the thread identity function is only used when data sources configured for that provider are used by Version 2.0 EJB modules and Version 2.3 servlets.

WebSphere Application Server for z/OS also allows supported resource adapters and JDBC providers to enable *OS thread security* in conjunction with thread identity support. You can use OS thread security when:

- The server configuration supports both thread identity and thread security.
- The **Enable Synch to Thread** property is set to **true**.

You can configure the server to allow **Enable Synch to Thread** support by navigating through the following panels in the administrative console:

**Security > Global Security**

On the **Global Security** panel, check the box entitled, **Enable Synch to Thread**, and then select **Apply**.

If these conditions are met, the system creates an access control environment element (ACEE) for the user associated with the thread.

#### **Related tasks**

“Using thread identity support”

#### **Related reference**

“Security states with thread identity support” on page 204

## **Using thread identity support**

Perform the following steps to enable the thread identity function for the connection factories or JDBC provider data sources created with the supported JCA resource adapters and JDBC providers:

1. Define **resauth=Container** for the application resource.
2. Ensure the JCA resource adapters or JDBC providers support the thread identity function.

Review the supported resource adapters and datasource providers, and the level of support: **REQUIRED**, **ALLOWED**, and **NOTALLOWED**.

If the adapter or provider is not listed, then thread identity support is **NOTALLOWED**, by default.

3. Set the **Container-managed authentication alias** to **NULL**, if you configure the connector locally.

When the connector is configured locally, the resource adapter determines the level of thread identity support as **ALLOWED**. If thread identity support is allowed and you specify **Container-managed authentication alias** as **NULL**, the connector uses the current thread identity as the owner for each connection that is created.

When the resource adapter or JDBC provider determines that the level of thread identity support is **REQUIRED**, any specification for the **Container-managed authentication alias** is ignored. Thread identity support in this case always applies.

4. Determine connector behavior when global security is a factor.

If you want the thread identity associated with a connection to be the **RunAs** identity, then you must enable global security. In the case of JDBC providers that support the thread identity function and require the thread to be pushed to the z/OS thread of execution, you must set the server **Enable Synch to Thread** property to **true**.

**Note:** With Bean Managed Persistence (BMP) beans, if you obtain a connection under the `ejbLoad()` or `ejbStore()` functions during pre-invoke or post-invoke method processing, your thread identity support does not become the **RunAs** identity because the container during this processing is running under server identity. With BMP beans, instead of using thread identity, specify a Container-managed alias to associate the user with the connection.

**Related concepts**

“Connection thread identity” on page 201

**Security states with thread identity support**

The combinations of global security, server configurations, connector configurations, and container-managed alias support determine the processing that results when you use the thread identity function. Thread identity support is only available with specific resource adapters and JDBC providers. Review the supported resource adapters and JDBC providers to determine if you can use thread identity. If your resource adapter or JDBC provider is in the supported list, use the following tables to determine the processing that occurs, based on the settings of the specified properties:

*Table 2. State of the connectors when global security is enabled*

Container-managed alias state	Connector thread identity support	Connector requires thread security	Server "Enable Synch to Thread" setting	Results
Not specified	NOTALLOWED	Not applicable	Not applicable	Processing depends on the connector: <ul style="list-style-type: none"> <li>• Connector might throw an exception.</li> <li>• Connector might use userid and password from the custom property settings.</li> </ul>
Not specified	ALLOWED	Not supported	Not applicable	Uses identity associated with current thread.
Not specified	ALLOWED	True	Not enabled	Uses server identity.
Not specified	ALLOWED	True	Enabled	Uses identity associated with current thread.
Not specified	REQUIRED	Not supported	Not applicable	Uses identity associated with current thread.
Not specified	REQUIRED	True	Not enabled	Uses server identity.
Not specified	REQUIRED	True	Enabled	Uses identity associated with current thread.
Specified	NOTALLOWED	Not applicable	Not applicable	Uses specified alias.

Table 2. State of the connectors when global security is enabled (continued)

Container-managed alias state	Connector thread identity support	Connector requires thread security	Server "Enable Synchron to Thread" setting	Results
Specified	REQUIRED	Not supported	Not applicable	Uses identity associated with current thread.
Specified	REQUIRED	True	Not enabled	Uses server identity.
Specified	REQUIRED	True	Enabled	Uses identity associated with current thread.

Table 3. State of the connectors when global security is not enabled

Container-managed alias state	Connector thread identity support	Results
Not specified	NOTALLOWED	Processing depends on the connector: <ul style="list-style-type: none"> <li>• Connector might throw an exception.</li> <li>• Connector might use userid and password from the custom property settings.</li> </ul>
Not specified	ALLOWED	Uses server identity.
Not specified	REQUIRED	Uses server identity.
Specified	NOTALLOWED	Uses specified alias.
Specified	ALLOWED	Uses specified alias.
Specified	REQUIRED	Uses server identity.

## Exceptions pertaining to data access

All enterprise bean container-managed persistence (CMP) beans under the EJB 2.0 Specification receive a standard *EJBException* when an operation fails.

JDBC applications receive a standard *SQLException* if any JDBC operation fails.

The product provides special exceptions for its relational resource adapter (RRA), to indicate that the connection currently held is no longer valid. The *ConnectionWaitTimeoutException* indicates that the application timed out trying to get a connection. The *StaleConnectionException* indicates that the connection is no longer valid.

#### Related concepts

"Resource adapter" on page 153

### Connection wait timeout

The *ConnectionWaitTimeoutException* indicates that the application has waited for the number of seconds specified by the connection timeout setting and has not received a connection. This situation can occur when the pool is at maximum size and all of the connections are in use by other applications for the duration of the

wait. In addition, there are no connections currently in use that the application can share because either the connection properties do not match, or the connection is in a different transaction.

When using a Version 4.0 data source, the `ConnectionWaitTimeout` throws an exception whose class is `com.ibm.ejs.cm.pool.ConnectionWaitTimeoutException`.

For connection factories, the `ConnectionWaitTimeout` throws a `ResourceException` whose class is `com.ibm.websphere.ce.j2c.ConnectionWaitTimeoutException`.

Finally, Version 5.0 data sources throw an `SQLException` subclass called `com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException`.

**Example: Handling data access exception - `ConnectionWaitTimeoutException` (for the JDBC API):** In all cases in which the `ConnectionWaitTimeoutException` is caught, there is very little to do for recovery.

The following code fragment shows how to use this exception in the JDBC API:

```
public void test1() {
    java.sql.Connection conn = null;
    java.sql.Statement stmt = null;
    java.sql.ResultSet rs = null;

    try {
        // Look for datasource
        java.util.Properties props = new java.util.Properties();
        props.put(
            javax.naming.Context.INITIAL_CONTEXT_FACTORY,
            "com.ibm.websphere.naming.WsnInitialContextFactory");
        ic = new javax.naming.InitialContext(props);
        javax.sql.DataSource ds1 =
            (javax.sql.DataSource) javax.rmi.PortableRemoteObject.narrow(
                ic.lookup(jndiString),
                javax.sql.DataSource.class);

        // Get Connection.
        conn = ds1.getConnection();
        stmt = conn.createStatement();
        rs = stmt.executeQuery("select * from mytable where this = 54");
    }
    catch (com.ibm.websphere.ce.cm.ConnectionWaitTimeoutException cwte) {
        //notify the user that the system could not provide a
        //connection to the database. This usually happens when the
        //connection pool is full and there is no connection
        //available for to share.
    }
    catch (java.sql.SQLException sqle) {
        // handle other database problems.
    }
    finally {
        if (rs != null)
            try {
```

```

        rs.close();
    }
    catch (java.sql.SQLException sqle1) {
    }
    if (stmt != null)
    try {
        stmt.close();
    }
    catch (java.sql.SQLException sqle1) {
    }
    if (conn != null)
    try {
        conn.close();
    }
    catch (java.sql.SQLException sqle1) {
    }
}
}

## Stale connections

The product provides a special subclass of *java.sql.SQLException* when using connection pooling to access a relational database. This *com.ibm.websphere.ce.cm.StaleConnectionException* subclass exists in both a WebSphere 4.0 data source and in the new data source using the relational resource adapter, and is used to indicate that the connection currently held is no longer valid. This situation can occur for many reasons, including the following:

- The application tries to get a connection and fails, as when the database is not started.
- A connection is no longer usable because of a database failure. When an application tries to use a previously obtained connection, the connection is no longer valid. In this case, all connections currently in use by the application can get this error when they try to use the connection.
- The connection is orphaned (because the application had not used it in at most two times the value of the *unused timeout* setting) and the application tries to use the orphaned connection. This case applies only to Version 4.0 data sources.
- The application tries to use a JDBC resource, such as a statement, obtained on a stale connection.
- A connection is closed by the Version 4.0 data source *auto connection cleanup* and is no longer usable. Auto connection cleanup is the standard mode in which connection management operates. This mode indicates that at the end of a transaction, the transaction manager closes all connections enlisted in that transaction. This enables the transaction manager to ensure that connections are not held for excessive periods of time and that the pool does not reach its maximum number of connections prematurely.

One ramification of having the transaction manager close the connections and return the connection to the free pool after a transaction ends, is that an application cannot obtain a connection in one transaction and try to use it in another transaction. If the application tries this, a *StaleConnectionException* is thrown because the connection is already closed.

In the case of trying to use an orphaned connection or a connection cleaned up by auto connection cleanup, a *StaleConnectionException* indicates that the application has attempted to use a connection already returned to the connection pool. It does not indicate an actual problem with the connection. However, other cases of a *StaleConnectionException* indicate that the connection to the database has gone bad,

or *stale*. Once a connection has gone stale, you cannot recover it, and you must completely close the connection rather than returning it to the pool.

### Detecting stale connections

When a connection to the database becomes stale, operations on that connection result in an *SQLException* from the JDBC driver. Because an *SQLException* is a rather generic exception, it contains state and error code values that you can use to determine the meaning of the exception. However, the meanings of these states and error codes vary depending on the database vendor. The connection pooling run time maintains a mapping of which SQL state and error codes indicate a *StaleConnectionException* for each database vendor supported. When the connection pooling run time catches any *SQLException*, it checks to see if this *SQLException* is considered a *StaleConnectionException* for the database server in use.

### Recovering from stale connections

Recovering from stale connections is a joint effort between the application server run time and the application developer. From an application server perspective, the connection pool is purged based on its *PurgePolicy* setting.

Explicitly catching a *StaleConnectionException* is not required in an application. Because applications are already required to catch *java.sql.SQLException*, and *StaleConnectionException* extends *SQLException*, *StaleConnectionException* can be thrown from any method that is declared to throw *SQLException*, and is caught automatically in the general catch-block. However, explicitly catching *StaleConnectionException* makes it possible for an application to recover from bad connections. When application code catches *StaleConnectionException*, it should take explicit steps to handle the exception.

**Handling data access exception - *StaleConnectionException*:** When an application receives a *StaleConnectionException* on a database operation, it indicates that the connection currently held is no longer valid. While it is possible to get a *StaleConnectionException* on any database operation, the most common time to see a *StaleConnectionException* thrown is the first time that a connection is used, just after it is retrieved. Because connections are pooled, a database failure is not detected until the operation immediately following its retrieval from the pool, which is the first time communication to the database is attempted. It is only when a failure is detected that the connection is marked stale. *StaleConnectionException* occurs less often if each method that accesses the database gets a new connection from the pool.

Many *StaleConnectionExceptions* are caused by intermittent problems with the network of the database server. Obtaining a new connection and retrying the operation can result in successful completion without exceptions to the end user. In some cases it is advantageous to add a small wait time between the retries to give the database server more time to recover. However, applications should not retry operations indefinitely, in case the database is down for an extended period of time.

Before the application can obtain a new connection for a retry of the operation, roll back the transaction in which the original connection was involved and begin a new transaction. You can break down details on this action into two categories: **Objects operating in a bean-managed global transaction context begun in the same method as the database access.**

A servlet or session bean with bean-managed transactions (BMT) can start a global transaction explicitly by calling *begin()* on a *javax.transaction.UserTransaction* object, which you can retrieve from naming or from the bean *EJBContext* object. To commit a bean-managed transaction, the application calls *commit()* on the *UserTransaction* object. To roll back the transaction, the application calls *rollback()*. Entity beans and non-BMT session beans cannot explicitly begin global transactions.

If an object that explicitly started a bean-managed transaction receives a *StaleConnectionException* on a database operation, close the connection and roll back the transaction. At this point, the application developer can decide to begin a new transaction, get a new connection, and retry the operation.

The following code fragment shows an example of handling *StaleConnectionExceptions* in this scenario:

```
//get a userTransaction
javax.transaction.UserTransaction tran = getSessionContext().getUserTransaction();
//retry indicates whether to retry or not
//numOfRetries states how many retries have
// been attempted
boolean retry = false;
int numOfRetries = 0;
java.sql.Connection conn = null;
java.sql.Statement stmt = null;
do {
    try {
        //begin a transaction
        tran.begin();
        //Assumes that a datasource has already been obtained
        //from JNDI
        conn = ds.getConnection();
        conn.setAutoCommit(false);
        stmt = conn.createStatement();
        stmt.execute("INSERT INTO EMPLOYEES VALUES
            (0101, 'Bill', 'R', 'Smith')");
        tran.commit();
        retry = false;
    } catch (com.ibm.websphere.ce.cm.StaleConnectionException
        sce)
    {
        //if a StaleConnectionException is caught
        // rollback and retry the action
        try {
            tran.rollback();
        } catch (java.lang.Exception e) {
            //deal with exception
            //in most cases, this can be ignored
        }
        if (numOfRetries < 2) {
            retry = true;
            numOfRetries++;
        } else {
            retry = false;
        }
    } catch (java.sql.SQLException sqle) {
        //deal with other database exception
        retry = false
    } finally {
```

```

//always cleanup JDBC resources
try {
    if(stmt != null) stmt.close();
} catch (java.sql.SQLException sqle) {
    //usually can ignore
}
try {
    if(conn != null) conn.close();
} catch (java.sql.SQLException sqle) {
    //usually can ignore
}
}
} while (retry) ;

```

### Objects operating in a global transaction context and transaction not begun in the same method as the database access.

When the object which receives the `StaleConnectionException` does not have direct control over the transaction, such as in a container-managed transaction case, the object must mark the transaction for rollback, and then indicate to its caller to retry the transaction. In most cases, you can do this by throwing an application exception which indicates to retry that operation. However this action is not always allowed, and often a method is defined only to throw a particular exception. This is the case with the `ejbLoad` and `ejbStore` methods on an enterprise bean. The next two examples explain each of these scenarios.

#### Example 1: Database access method can throw application exception.

When the method that accesses the database is free to throw whatever exception is required, the best practice is to catch `StaleConnectionException` and rethrow some application exception that you can interpret to retry the method. The following example shows an EJB client calling a method on an entity bean with transaction demarcation `TX_REQUIRED`, which means that the container begins a global transaction when `insertValue` is called:

```

public class MyEJBClient {
    //... other methods here ...
    public void myEJBClientMethod()
    {
        MyEJB myEJB = myEJBHome.findByPrimaryKey("myEJB");
        boolean retry = false;
        do {
            try {
                retry = false;
                myEJB.insertValue();
            }
            catch(RetryableConnectionException retryable) {
                retry = true;
            }
            catch(Exception e) { /* handle some other problem */ }
        } while (retry);
    }
    //end MyEJBClient

    public class MyEJB implements javax.ejb.EntityBean {
        //... other methods here ...
        public void insertValue() throws RetryableConnectionException,
            java.rmi.RemoteException {
            try
            {
                conn = ds.getConnection();
                stmt = conn.createStatement();
                stmt.execute("INSERT INTO my_table VALUES (1)");
            }
            catch(com.ibm.websphere.ce.cm.StaleConnectionException
                sce) {

```

```

getSessionContext().setRollbackOnly();
throw new RetryableConnectionException();
}
catch(java.sql.SQLException sqle) {
//handle other database problem
}
finally {
21
//always cleanup JDBC resources
try {
if(stmt != null) stmt.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
try {
if(conn != null) conn.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
}
} //end MyEJB

```

*MyEJBClient* first gets a *MyEJB* bean from the home interface, assumed to have been previously retrieved from the Java Naming and Directory Interface (JNDI). It then calls *insertValue()* on the bean. The method on the bean gets a connection and tries to insert a value into a table. If one of the methods fails with a *StaleConnectionException*, it marks the transaction for *rollbackOnly* (which forces the caller to roll back this transaction) and throws a new *RetryableConnectionException*, cleaning up the resources before the exception is thrown. The *RetryableConnectionException* is simply an application-defined exception that tells the caller to retry the method. The caller monitors *RetryableConnectionException* and, if it is caught, retries the method. In this example, because the container is beginning and ending the transaction, no transaction management is needed in the client or the server. Of course, the client could start a bean-managed transaction and the behavior would still be the same, provided that the client also committed or rolled back the transaction.

**Example 2: Database access method can throw only RemoteException or EJBException.**

Not all methods are allowed to throw exceptions defined by the application. If you use bean-managed persistence (BMP), use the *ejbLoad()* and *ejbStore()* methods to store the bean state. The only exceptions thrown from these methods are *java.rmi.RemoteException* or *javax.ejb.EJBException*, so you cannot use something similar to the previous example.

If you use container-managed persistence (CMP), the container persists the bean, and it is the container that sees *StaleConnectionException*. If a stale connection is detected, by the time the exception is returned to the client it is simply a *RemoteException*, and so a simple catch-block does not suffice. There is a way to determine if the root cause of a *RemoteException* is a *StaleConnectionException*. When *RemoteException* is thrown to wrap another exception, the original exception is usually retained. All *RemoteException* instances have a detail property, which is of type *java.lang.Throwable*. With this detail, you can trace back to the original exception and, if it is a *StaleConnectionException*, retry the

transaction. In reality, when one of these RemoteExceptions flows from one Java Virtual Machine API to the next, the detail is lost, so it is better to start a transaction in the same server as the database access occurs. For this reason, the following example shows an entity bean accessed by a session bean with bean-managed transaction demarcation.

```
public class MySessionBean extends javax.ejb.SessionBean {
    ... other methods here ...
    public void mySessionBMTMethod() throws
    java.rmi.RemoteException
    {
        javax.transaction.UserTransaction tran =
        getSessionContext().getUserTransaction();
        boolean retry = false;
        do {
            try {
                retry = false;
                tran.begin();
                // causes ejbLoad() to be invoked
                myBMPBean.myMethod();
                // causes ejbStore() to be invoked
                tran.commit();
            }
            catch(java.rmi.RemoteException re) {
                try { tran.rollback();
                }
                catch(Exception e) {
                    //can ignore
                }
                if (causedByStaleConnection(re))
                    retry = true;
                else
                    throw re;
            }
            catch(Exception e) {
                // handle some other problem
            }
            finally {
                //always cleanup JDBC resources
                try {
                    if(stmt != null) stmt.close();
                } catch (java.sql.SQLException sqle) {
                    //usually can ignore
                }
                try {
                    if(conn != null) conn.close();
                } catch (java.sql.SQLException sqle) {
                    //usually can ignore
                }
            }
        } while (retry);
    }

    public boolean causedByStaleConnection(java.rmi.RemoteException
    remoteException)
    {
        java.rmi.RemoteException re = remoteException;
        Throwable t = null;
        while (true) {
            t = re.detail;
            try { re = (java.rmi.RemoteException)t; }
            catch(ClassCastException cce) {
                return (t instanceof
                com.ibm.websphere.ce.cm.StaleConnectionException);
            }
        }
    }
}
```

```

}
}
public class MyEntityBean extends javax.ejb.EntityBean {
... other methods here ...
public void ejbStore() throws java.rmi.RemoteException
{
try {
conn = ds.getConnection();
stmt = conn.createStatement();
stmt.execute("UPDATE my_table SET value=1 WHERE
primaryKey=" + myPrimaryKey);
}
catch(com.ibm.websphere.ce.cm.StaleConnectionException
sce) {
//always cleanup JDBC resources
try {
if(stmt != null) stmt.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
try {
if(conn != null) conn.close();
} catch (java.sql.SQLException sqle) {
//usually can ignore
}
// rollback the tran when method returns
getEntityContext().setRollbackOnly();
throw new java.rmi.RemoteException("Exception occurred in
ejbStore", sce);
}
catch(java.sql.SQLException sqle) {
// handle some other problem
}
}
}
}

```

In *mySessionBMTMethod()*:

- the session bean first retrieves a *UserTransaction* object from the session context and then begins a global transaction.
- Next, it calls a method on the entity bean, which calls the *ejbLoad()* method. If *ejbLoad()* runs successfully, the client then commits the transaction, causing the *ejbStore()* method to be called.
- In *ejbStore()*, the entity bean gets a connection and writes its state to the database; if the connection retrieved is stale, the transaction is marked *rollbackOnly* and a new *RemoteException* that wraps the *StaleConnectionException* is thrown. That exception is then caught by the client, which cleans up the JDBC resources, rolls back the transaction, and calls *causedByStaleConnection()*, which determines if a *StaleConnectionException* is buried somewhere in the exception.
- If the method returns true, the retry flag is set and the transaction is retried; otherwise, the exception is rethrown to the caller.
- The *causedByStaleConnection()* method looks through the chain of detail attributes to find the original exception. Multiple wrapping of exceptions can occur by the time the exception finally gets back to the client, so the method keeps searching until it encounters a *non-RemoteException*. If this final exception is a *StaleConnectionException*, you found it and true is returned;

otherwise, there is no *StaleConnectionException* in the list (because *StaleConnectionException* can never be cast to a *RemoteException*), and false is returned.

- If you are talking to a CMP bean instead of to a BMP bean, the session bean is exactly the same. The CMP bean's *ejbStore()* method would most likely be empty, and the container after calling it would persist the bean with generated code.
- If a stale connection exception occurs during persistence, it is wrapped with a *RemoteException* and returned to the caller. The *causedByStaleConnection()* method would again look through the exception chain and find the root exception, which would be *StaleConnectionException*.

### Objects operating in a local transaction context.

When a database operation occurs outside of a global transaction context, a local transaction is implicitly begun by the container. This includes servlets or JSPs which do not begin transactions with the *UserTransaction* interface, as well as enterprise beans running in unspecified transaction contexts. As with global transactions, you must roll back the local transaction before the operation is retried. In these cases, the local transaction containment usually ends when the business method ends. The one exception is if you are using activity sessions. In this case the activity session must end before attempting to get a new connection.

When the local transaction occurs in an enterprise bean running in an unspecified transaction context, the enterprise bean client object, outside of the local transaction containment, could use the method described in the previous bullet to retry the transaction. However, when the local transaction containment takes place as part of a servlet or JSP file, there is no client object available to retry the operation. For this reason, it is recommended to avoid database operations in servlets and JSP files unless they are a part of a user transaction.

*StaleConnectionException on Linux systems:* The *StaleConnectionException* **SQL1224** is related to extension shared memory attachment. Linux systems have a semaphore problem causing the DB2 SQL1224 error.

To work around the problem, set the loopback for your database. For example, if your database is *WAS*, host name is *LHOST*, and database service port number is *50000*, issue the following commands from the DB2 command line window:

```
db2 catalog TCPIP node RHOST remote LHOST server 50000
db2 catalog WAS as WASAlias
db2 uncatalog db WAS
db2 catalog WASAlias as WAS at node RHOST
```

Verify this by issuing the following commands from the DB2 command line window:

```
db2 connect to WAS user xxx
passwd: xxx
```

*Example: Developing servlet with user transaction:*

```

## Handling data access exception - error mapping in DataStoreHelper

Error mapping is necessary because various database vendors can provide differing SQL errors and codes that might mean the same things. For example, the *StaleConnectionException* has different codes in different databases. The **DB2** SQLCODEs of *1015*, *1034*, *1036* and so on, indicate that the connection is no longer available because of a temporary database problem. The **Oracle** SQLCODEs of *28*, *3113*, *3114* and so on indicate the same situation.

To provide portability for applications, WebSphere Application Server provides a *DataStoreHelper* interface to enable mapping of these codes to the WebSphere Application Server exceptions. The following code segment illustrates how to add two error codes into the error map:

```

public class NewDSHelper extends GenericDataStoreHelper
{
    public NewDSHelper()
    {
        super(null);
        java.util.Hashtable myErrorMap = null;
        myErrorMap = new java.util.Hashtable(2);
        myErrorMap.put(new Integer(-803), myDuplicateKeyException.class);
        myErrorMap.put(new Integer(-1015), myStaleConnectionException.class);
        myErrorMap.put("S1000", MyTableNotFoundException.class);
        setUserDefinedMap(myErrorMap);
        ...
    }
}

```

## Embedded Structured Query language in Java (SQLJ) support

Structured Query Language in Java (SQLJ) is a set of programming extensions that allow a programmer, using the Java programming language, to embed statements that provide SQL (Structured Query Language) database requests.

Advantages of developing applications with SQLJ include improved performance and a shorter, more efficient development cycle:

- You improve performance by using static SQL statements.

- You reduce the development cycle because:
  - You write less code with the simpler SQLJ syntax, which reduces the number of lines of code required to execute statements, and to set and retrieve parameters.
  - You detect programming errors earlier in the development phase with the onlinecheck function, which performs data type and schema validation.

“Using Structured Query Language in Java (SQLJ) for Enterprise Java Bean (EJB) Bean Managed Persistence (BMP) entity beans, session beans, and servlets” on page 245

## **Using embedded Structured Query Language in Java (SQLJ) support**

WebSphere Application Server Version 5.0.1 introduces support for Structured Query Language in Java (SQLJ ) with the DB2 universal Java Database Connectivity (JDBC) driver provider and the DB2 Legacy CLI-based Type 2 JDBC driver for DB2 Version 8 FixPak1 (FP1).

Only the WebSphere Application Server Version 5.0.1 data source supports the DB2 universal JDBC driver provider. The WebSphere Application Server Version 4.0.x data source does not support this driver provider. In addition, the universal JDBC driver currently only supports a single phase data source.

Perform the following steps to convert existing JDBC applications to SQLJ in WebSphere Application Server:

1. Acquire the required drivers to run SQLJ.
  - DB2 Legacy CLI-based JDBC driver  
You must have the db2java.zip and db2jcc.jar files in your classpath. Define these files in the classpath of the Websphere Application Server Version 5.0.1 DB2 Legacy CLI-based JDBC Driver Provider.
  - DB2 Universal JDBC driver  
You only need the db2jcc.jar file.
  - WebSphere Application Server driver  
WebSphere Application Server must be at the Version 5.0.1 level.
2. Review the appropriate task file for instructions on using SQLJ with either Enterprise Java Bean (EJB) Container Managed Persistence (CMP) beans, or with EJB Bean Managed Persistence (BMP) entity beans, session beans, and servlets.

#### **Related concepts**

“Embedded Structured Query language in Java (SQLJ) support” on page 239

## **Using Structured Query Language in Java (SQLJ) for Enterprise Java Bean (EJB) Container Managed Persistence (CMP) beans**

Structured Query Language in Java (SQLJ) for EJB Persistence requires DB2 Version 8 FixPak1. You need DB2 UDB Application Development Client Version 8 FixPak1 on the machine where you generate the deployed code, and DB2 UDB Server

(Version 8 FixPak1 for UNIX and Windows, and Version 6 or Version 7 for z/OS and OS/390) on the machine containing the database for running the scenario.

SQLJ support requires Version 2.0 CMP Enterprise Java Beans. If you mix EJB 1.1 and 2.0 beans in an EJB 2.0 module, then only the EJB 2.0 beans are deployed to use SQLJ. The EJB 1.1 beans continue using JDBC for data access.

The deployment command for Enterprise Java Beans (EJBDeploy) only provides SQLJ support for the Version 2.0 CMP beans. It is the user's responsibility to manually translate and customize the profile on the database for the Bean Managed Persistence (BMP) entity beans, session beans, and servlet SQLJ applications. See the Using SQLJ for Enterprise Java Bean (EJB) Bean Managed Persistence (BMP) entity beans, session beans, and Servlets article for more information.

WebSphere Application Server Version 5.0.1 provides tools for using SQLJ as the persistence mechanism for CMP Enterprise Java Beans. You can deploy the CMP beans to use SQLJ either by using the EJB deploy tool in WebSphere Studio Application Developer (WSAD), or by using the command utility **ejbdeploy** with the **-sqlj** option.

**Note:** You cannot deploy a CMP bean with the **sqlj** option from the administrative console or the Application Assembly Tool (AAT) in Version 5.01.

When you install an application comprised of CMP beans, you have the following choices:

- For data access with SQLJ, deploy the CMP beans to use SQLJ before installing the application in WebSphere Application Server. Perform deployment within the WSAD environment, or by using the command utility **ejbdeploy** with the **-sqlj** option.

Do not deploy this bean again in the administrative console when you install the application. If you pre-deploy this bean with the **-sqlj** option and then re-deploy it from the administrative console when you install the application, this bean is then deployed with JDBC access.

- For JDBC access, use the **ejbdeploy** command or the administrative console to deploy the CMP bean.

If the bean is not deployed, the installation of the application will fail.

1. Deploy the EAR file.

- a. Ensure directory `<was_home>/bin` is in your PATH.
- b. Verify the `ws_ant.bat` file is available on your system.

You need the `ws_ant.bat` file to run the rest of the commands.

**Note:** On Windows, the Apache Ant tool is `ws_ant.bat`. On UNIX systems, the Ant tool is `ws_ant`.

- c. Run the **ejbdeploy** command utility with the **-sqlj** option.

You must supply the location of the SQLJ translator `sqlj.zip` file with the **-cp** (classpath) option:

```
ejbdeploy d:\MyApplication.ear working d:\deployedMyApplication.ear -sqlj -dbvendor DB2UDF
```

The **ejbdeploy** command will not access `sqlj.zip` from your system classpath. The **ejbdeploy** command will generate an EAR file with the name you specify as, for example, `deployedMyApplication.ear` and an Ant script with the name `<InputEarName>.ear.xml`, or in this example, `deployedMyApplication.ear.xml`.

If you create the EAR file using WebSphere Studio Application Developer (WSAD), you can associate SQLJ with a particular database backend in the mapping editor. If you use the mapping editor, you do not have to specify the **-sqlj** option in the **ejbdeploy** command.

2. Perform the SQLJ profile customization steps if your application is running in a clustered environment.

If your application is not running in a clustered environment, go to the Ant tool properties description.

Perform customization once, on a single host.

- a. Run the DB2 SQLJ customizer, **db2sqljcustomize**, against the serialized profiles.

One serialized profile exists for each EJB .jar file. You can find the serialized profile in the EJB .jar file. One example of a serialized profile file name is FS\_TopDown1\_SJProfile0.ser.

When you run the DB2 SQLJ customizer with the **"-automaticbind yes"** default option against the serialized profiles, you create static SQL in the database, which is used at runtime. The customization phase creates four database packages that contain static SQL, one for each isolation level.

- b. Include the customized profiles in the EJB .jar files installed on WebSphere Application Server.

The customization step also updates the generated customized profiles. To make these updated customized profiles available to the generated code at runtime, include the profiles in the EJB .jar file, which is installed in WebSphere Application Server.

**Note:** If you omit the customization step, the EJB applications will run, but they will not use the static SQL stored in the database, and you lose all the benefits of SQLJ.

- c. Use the Ant script to make customization easier.

When you run batch SQLJ `ejbDeploy` against an EAR file, it produces an Ant script. Use this script file to run the DB2 customizer against every serialized profile in every EJB .jar file in the associated EAR file. The script updates each EJB .jar file with a serialized profile, and replaces the .jar files in the EAR file with the modified versions. The Ant script is specific to the corresponding EAR file.

**Note:** This script modifies the existing EAR file.

The script also uses a set of default names for the packages created in the database. Change the names used by the script file to ensure the names for each customization profile do not conflict with existing package names in the database. Ant scripts, generated for different EAR files, by default use the same package names, and will overwrite existing packages unless the names are changed. Overwritten packages cause runtime errors.

- d. Change the values of the database URL, and the database userid and password properties in the generated Ant script.

The package names, database URLs, userids, and passwords are created in the script using Ant properties.

The Ant script defines the following global properties:

- for the database URL - `db.url`
- for the user - `db.user`
- for the password - `db.password`

- e. Change the values used by the Ant script and the serialized profile by specifying new values in a property file.

The Ant script uses the URL, userid, and password properties in the serialized profile to customize the profile. By default, the properties for the serialized profile are created from the global properties.

The script for a particular EAR file reads properties from two files:

- `ejbdeploy.sqlj.properties`

The `ejbdeploy.sqlj.properties` file is common to all Ant scripts generated by the **EJBDeploy** command. Use the `ejbdeploy.sqlj.properties` file to specify global properties, like the database userid and password.

- `<ear-name>.properties`

The `<ear-name>` value is the name of the EAR file. The `<ear-name>.properties` file is specific to the Ant script for the EAR file. If you want your Ant script to use a another file instead of `<ear-name>.properties`, specify the `script.property.file` property when you run the script.

- f. Use the DB2 Control Center to identify the packages installed in the database.

The DB2 SQLJ customizer requires a type 4 database URL in the form of:  
`jdbc:db2://<host-name>:<port>/<database-name>`

It also requires a userid and password. The value of the port is 50000, unless you changed it when you installed DB2.

3. Run the Ant script, specifying the **properties** target:

```
ws_ant -buildfile deployedMyApplication.ear.xml properties
```

This will create the properties file, `deployedMyApplication.ear.properties`. The `deployedMyApplication.ear.properties` file contains properties specifying default names for the packages corresponding to each serialized profile in the EAR file, as for example:

```
pkg.MyEJB1.jar.DB2UDBNT_V8_1=PKG1_  
pkg.MyEJB2.jar.DB2UDBNT_V8_1=PKG2_
```

```
.jarMyEJB1.jarMyEJB2.jar
```

4. Edit the generated properties file to change the package names.

You can also specify other properties in this file, such as the database URL, user, or password:

```
url.MyEJB1.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB1  
user.MyEJB1.jar.DB2UDBNT_V8_1=dbuser  
password.MyEJB1.jar.DB2UDBNT_V8_1=dbpassword  
pkg.MyEJB1.jar.DB2UDBNT_V8_1=TEST  
url.MyEJB2.jar.DB2UDBNT_V8_1=jdbc:db2://localhost:50000/MyDB2  
user.MyEJB2.jar.DB2UDBNT_V8_1=dbuser  
password.MyEJB2.jar.DB2UDBNT_V8_1=dbpassword  
pkg.MyEJB2.jar.DB2UDBNT_V8_1=WORK
```

DB2 uses the first seven characters of the package name. The DB2 customizer uses this name to create four packages in the database. For example, if you specify the name TEST, the customizer will create packages called:

```
TEST1, TEST2, TEST3, TEST4
```

5. Use the following **db2sqljcustomize** options to temporarily circumvent profile customization problems.

These options bypass errors during a profile customization and ensure a successful customization:

```
-onlinecheck NO and -bindoptions "VALIDATE RUN"
```

6. Run the Ant script.

The DB2 db2jcc.jar file must be on the classpath. This file should have been added to the classpath environment variable when DB2 V8 FixPak1 was installed.

7. Specify a working directory for the Ant script.

The script will create and delete files and sub-directories in this directory. If the working directory contains existing files and directories with the same name as the files and directories used by the script, the script will erase the files and directories.

Use the following command to specify a working directory:

```
ws_ant -Dwork.dir=tmp -buildfile MyApplication.ear.xml
```

```
tmpscript.property.file
```

```
ws_ant -Dwork.dir=tmp -Dscript.property.file=other.properties -buildfile MyApplication
```

8. If you rerun the **EJBDeploy** command, rerun the Ant script.

Generate a new properties file if any of the following conditions are true:

- You changed the number of .jar files in the EAR file.
- You changed the names of the .jar files in the EAR file.
- You changed the database backend ids in any of the .jar files

9. Install the updated EAR file in WebSphere Application Server.

10. Create a jdbc provider and data source in WebSphere Application Server:

To create a JDBC provider, in the administrative console:

- a. Click **Resources > JDBC providers > NEW**
- b. Choose the default value for DB2 universal JDBC Driver provider.
- c. Click Apply.

To create a data source under this JDBC provider in the administrative console:

- a. Scroll down to the **Additional Properties** panel.
- b. Click **DataSource > NEW**
- c. Define the Alias from the **J2C Authentication Data Entries**
- d. Return to the data source panel .
- e. Enter the alias in both the **Component** and **Container** managed authentication alias entries.
- f. Specify the **databaseName** on the **Custom Properties** panel.
- g. For a data source using the universal driver, specify the **portNumber** and **serverName** on the **Custom Properties** panel.

11. Install your application through the administrative console but do not re-deploy the EJB. If you check the **EJBDeploy** box, your application is redeployed to JDBC access.

12. Stop the server.

13. Start the server.

You are now ready to run your application.

## Using Structured Query Language in Java (SQLJ) for Enterprise Java Bean (EJB) Bean Managed Persistence (BMP) entity beans, session beans, and servlets

This article describes how JDBC applications, comprised of Bean Managed Persistence (BMP) beans or servlets, are converted to SQLJ applications. It also describes how the SQLJ applications are then deployed in WebSphere Application Server.

Follow these steps precisely and in the right order to ensure a correct conversion:

1. Create a backup copy of your .java file. For example if your file is called MyServlet.java, copy MyServlet.java to MyServlet.java.bkup.
2. Rename your .java file to to a file name with a .sqlj extension. For example, if your application is a servlet named MyServlet.java, rename MyServlet.java to MyServlet.sqlj.

Now when you run the **sqlj** tool in the next step, the .java file that it creates will have the same name as your old .java file, providing you with a seamless transition to the SQLJ technology.

3. Edit the .sqlj file to convert the JDBC syntax to SQLJ syntax. When using SQLJ in WebSphere Application Server, if you want WebSphere Application Server connection management to function properly, you must specify correct connection contexts.

For example, convert the following JDBC operation:

```
Connection con = dataSource.getConnection();
Statement stmt = con.createStatement();
stmt.execute("INSERT INTO users VALUES (1, 'user1')");
con.commit();
```

to the following SQLJ:

```
// At the top of the file and just below the import statements, define Connection
#sql context Connection_context;
.
.
Connection con = dataSource.getConnection();
.
.
Connection_context ctx1 = new Connection_context(con);
.
.
#sql [ctx1] {INSERT INTO users VALUES (1, 'user1')};
.
.
con.commit();
ctx1.close();
```

4. Run the DB2 **sqlj** translator. This tool creates a .java version of your .sqlj file as well as a .ser profile that is used later in the processing. Refer to the DB2 documentation for more information on this tool.
5. Package your EJB jar and deploy it in the usual manner.
6. After the EJB files are deployed, run the **db2sqljcustomize** tool to customize your .ser file. One serialized profile exists for each EJB .jar file. You can find the profile in the EJB .jar file. One example of a serialized profile file name is MyBMPBeanProfile.ser.

When you run the DB2 SQLJ customizer against the serialized profiles, you create static SQL in the database, which is used at runtime. The customization phase creates four database packages that contain static SQL, one for each isolation level.

7. Configure your database.
8. Update your EJB jar with the .ser file.
9. Package your EJB jar and servlets, along with .ser files, into an .ear file.
10. Install the application in the usual manner.

---

## **Assembling data access applications**

1. Define the resource reference attributes through the Application Assembly Tool.
2. Bind this resource reference to a resource like a J2EE Connector Architecture (JCA) connection factory or a data source.
3. Configure isolation level, access intent assembly settings.
4. Map to EJB deployment tool schema

#### **Related concepts**

“Data sources” on page 164

“Binding to a data source” on page 191

#### **Related tasks**

“Creating or changing a resource reference” on page 190

#### **Related reference**

Access intent assembly settings

Access intent policies contain data-access settings for use by the persistence manager. Default access intent policies are configured on the entity bean.

Optionally, you can associate access intent policies with one or more methods.

“Data access : Resources for learning” on page 340

## **Example: Configuring isolation level on a resource reference during assembly**

Specify the appropriate *isolation level* for each of your resource references. The isolation level is used only by JDBC users. For information about setting isolation levels on a resource reference, see Isolation level and resource reference.

You can define multiple resource references for the same bean-managed persistence (BMP) bean or servlet. Each resource reference has its own Java Naming and Directory Interface (JNDI) logical name. You can also bind multiple resource references to the same data source. Each JNDI resource reference naming lookup returns the connections from the data source that has the same isolation level.

For example, an account bean has two resource references defined:

```
jdbc/RRResRef:  
resource_ref has RepeatableRead isolation level  
jdbc/RResRef:  
resource_ref has ReadCommitted isolation level
```

If your application uses *RRResRef* to get the data source instance, all connections that are acquired from this data source instance have the RepeatableRead isolation level.

If your application uses *RResRef* to get the data source instance, all connections that are acquired from this data source instance have the ReadCommitted isolation level.

#### **Related concepts**

“Data sources” on page 164

## **Enterprise bean deployment tool schema**

There are three options for mapping entity beans to a backend database schema: top-down, meet-in-the-middle, and bottom-up.

With the top-down option, the deployment tools generate a backend schema directly from the provided abstract persistence schema (abstract accessor methods plus the deployment descriptor elements) and then map the elements in the abstract persistence schema to the generated backend schema. See the section *Generating a top-down mapping* of the WebSphere Studio Application Developer (WSAD) documentation for details.

With meet-in-the-middle mapping, you employ a tool to manually map elements from the abstract persistence schema to elements in an existing backend schema. WSAD provides a meet-in-the-middle mapping tool. See the section *Generating a meet-in-the-middle mapping* of the WSAD documentation for details.

With the bottom-up approach, the tools take, as input, an existing backend database schema and generate equivalent entity beans and then map the elements of the two schemas. See the section *Generating a bottom-up mapping* of the WSAD documentation for details.

## **Migrating a version 4.0 data access application to version 5.0**

In order to utilize the connection management infrastructure in WebSphere Application Server Version 5.0, you must package your application as a J2EE 1.3 application. This means repackaging your web modules to the 2.3 Specification and your EJB modules to the 2.0 Specification before installing them into WebSphere Application Server.

Applications left at the J2EE 1.2 level will continue to run fine using the connection management support that was available at V4.0.

Note that with this repackaging comes the need to use Version 5.0 data sources. With the repackaging process, you cannot use a Version 4.0 data source. The 4.0 data source case is very simple, though, you just create the JDBC provider and data source, and install the 4.0 application as-is.

## Converting a 2.2 web module to a 2.3 web module

Use the following steps to migrate each of your web modules.

1. Open the Application Assembly Tool.
2. Create a new Web Module by selecting **File -> New -> Web Module**.
3. Add any required class files to the new module.
  - a. Expand the **Files** portion of the tree.
  - b. Right click **Class Files** and select **Add Files**.
  - c. In the Add Files window click **Browse**.
  - d. Navigate to your WebSphere 4.0 *EAR* file and click **Select**.
  - e. In the upper left pane of the Add Files window, navigate to your *WAR* file and expand the **WEB-INF** and **classes** directories.
  - f. Select each of the directories and files in the classes directory and click **Add**.
  - g. When you have added all of the required class files, click **OK**.
4. Add any required *JAR* files to the new module.
  - a. Expand the **Files** portion of the tree.
  - b. Right click **Jar Files** and select **Add Files**.
  - c. Navigate to your WebSphere 4.0 *EAR* file and click **Select**.
  - d. In the upper left pane of the Add Files window, navigate to your *WAR* file and expand the **WEB-INF** and **lib** directories.
  - e. Select each *JAR* file and click **Add**.
  - f. When you have added all of the required *JAR* files, click **OK**.
5. Add any required resource files, such as HTML files, JSP files, GIFs, and so on, to the new module.
  - a. Expand the **Files** portion of the tree.
  - b. Right click **Resource Files** and select **Add Files**.
  - c. Navigate to your WebSphere 4.0 *EAR* file and click **Select**.
  - d. In the upper left pane of the Add Files window, navigate to your *WAR* file.
  - e. Select each of the directories and files in the *WAR*, *excluding* **META-INF** and **WEB-INF**, and click **Add**.
  - f. When you have added all of the required resource files, click **OK**.
6. Import your Web Components.
  - a. Right click on **Web Components** and select **Import**.
  - b. In the Import Components window click **Browse**.
  - c. Navigate to your WebSphere 4.0 *EAR* file and click **Open**.
  - d. In the left top pane of the **Import Components** window highlight the *WAR* file you are migrating.
  - e. Highlight each of the components displayed in the right top pane and click **Add**.
  - f. When all of your web components show up in the Selected Components pane of the window, click **OK**.
  - g. Verify that your web components are correctly imported under the Web Components section of your new web module.
7. Add servlet mappings for each of your web components.
  - a. Right click **Servlet Mappings** and select **New**.
  - b. Fill in a URL pattern for the web component.

- c. Select the web component from the Servlet drop down box.
- d. Click **OK**.
8. Add any necessary resource references by following the instructions in Creating a resource reference.
9. Add any other web module properties that are required. Click **Help** for a description of the settings.
10. **Save** the web module.

### **Converting a 1.1 EJB module to a 2.0 EJB module**

Use the following steps to migrate each of your EJB modules.

1. Open the Application Assembly Tool.
2. Create a new EJB Module by selecting **File -> New -> EJB Module**.
3. Add any required class files to the new module.
  - a. Right click **Files object** and select **Add Files**.
  - b. In the Add Files window click **Browse**.
  - c. Navigate to your WebSphere 4.0 *EAR* file and click **Select**.
  - d. In the upper left pane of the Add Files window, navigate to your EJB *JAR* file.
  - e. Select each of the directories and class files and click **Add**.
  - f. When you have added all of the required class files, click **OK**.
4. Create your session beans and entity beans. To find help on this subject, see Migrating enterprise bean code to the supported specification, the documentation for WebSphere Studio Application Developer, or the documentation for WebSphere Studio Application Developer Integration Edition.
5. Add any necessary resource references by following the instructions in Creating a resource reference.
6. Add any other EJB module properties that are required. Click **Help** for a description of the settings.
7. **Save** the EJB module.
8. Generate the deployed code for the EJB by selecting **File -> Generate Code for Deployment**.
9. Fill in the appropriate fields and click **Generate Now**.

### **Add the EJB Modules and Web Modules to an EAR file**

1. Open the Application Assembly Tool.
2. Create a new Application by selecting **File -> New -> Application**.
3. Add each of your EJB modules.
  - a. Right click **EJB Modules** and select **Import**.
  - b. Navigate to your converted EJB Module and click **Open**.
  - c. Click **OK**.
4. Add each of your web modules.
  - a. Right click **Web Modules** and select **Import**.
  - b. Navigate to your converted web module and click **Open**.
  - c. Fill in a **Context root** and click **OK**.
5. Fill in any other Application properties. Click **Help** for a description of the settings.
6. Save the *EAR* file.

## Installing the Application in WebSphere

1. Create a JDBC provider and a Version 5.0 data source object following the instructions in Creating a JDBC provider and data source.
2. Install the application, following the instructions in Installing a new application and binding the resource references to the data source you created.

## Connection considerations when migrating servlets, JavaServer Pages, or enterprise session beans

If you are migrating from Websphere Application Server Version 3.5.x or Version 4.0.x to WebSphere Application Server Version 5.0.x, and you are running servlets, JavaServer Page (JSP) files, or enterprise session beans with bean managed transactions, a behavior change in the data access component can adversely affect the use of connections in your applications.

This change affects all applications that contain the following methods:

- `RequestDispatcher.include()`
- `RequestDispatcher.forward()`
- JSP includes (`<jsp:include>`)

Symptoms of the problem include:

- Session hang
- Session timeout
- Running out of connections

In Websphere Application Server Version 4.0.x and earlier releases, JSP files, servlets, and enterprise session beans with bean managed transactions are issued non-sharable connections, while all the other components are issued shareable connections.

Starting with Websphere Version 5.0.x, all connections that are accessed with a resource-reference, default to shareable unless specified unshareable in the resource-reference. This change is required for compliance with the J2EE 1.3 Specification. Using shareable connections in this context has the following effects:

- All connections received and used outside the scope of a user transaction are *not* returned to the free connection pool until the encapsulating method returns, even when the connection handle issues a `close()`.
- All connections received and used outside the scope of a user transaction are *not* shared with other component instances (that is, other servlets, JSP files, or enterprise java beans).

For example, if session bean 1 gets a connection and then calls session bean 2 that also gets a connection, even if all properties are identical, each session bean receives its own connection.

## Implications of the connection behavior change

If you did not anticipate this change in the connection behavior, the way you structure your application code could lead to excessive connection use, particularly in the cases of JSP includes, `RequestDispatcher.include()` routines, `RequestDispatcher.forward()` routines, session beans with bean managed transactions, or calls from these methods to other components.

## Examples of the connection behavior change

Servlet A gets a connection, completes the work, commits the connection, and calls `close()` on the connection. Next, servlet A calls the `RequestDispatcher.include()`

to include servlet B, which performs the same steps as servlet A. Since the servlet A connection did not return to the free pool until it returned from the current method, two connections are now busy. In this way, more connections might be in use than you intended in your application. If these connections are not accounted for in the **Max Connections** setting on the connection pool, this behavior might cause a lack of connections in the pool, which would result in `ConnectionWaitTimeoutExceptions`. If the **connection wait timeout** is not enabled, or if the **connection wait timeout** is set to a large number, these threads might appear to hang because they are waiting for connections that are never returned to the pool. Threads waiting for new connections will not return the ones they are currently using if new connections are not available.

### Alternatives to the connection behavior change

To resolve these problems:

1. Use unshared connections.

If you use an unshared connection and are not in a user transaction, the connection is returned to the free pool when you issue a `close()`, (assuming you committed or rolled back the connection).

2. Increase the maximum number of connections.

To calculate the number of required connections, multiply the number of configured threads by the deepest level of component call nesting (for those calls that use connections). See the Examples section for a description of call nesting.

## Resource adapter archive file

A Resource Adapter Archive (RAR) file is a Java archive (JAR) file used to package a resource adapter for the Java 2 Connector (J2C) Architecture for WebSphere Application Server.

A RAR file can contain the following:

- Enterprise information system (EIS) supplied resource adapter implementation code in the form of JAR files or other executables, such as dynamic link lists (DLL).
- Utility classes.
- Static documents, such as HTML files, images, and sound files.
- J2C common client interfaces, such as *cci.jar*.

The standard file extension of a RAR file is *.rar*.

#### Related concepts

“Resource adapter” on page 153

## Assembling Resource Adapter modules

The Resource Adapter Archive file contains code that implements a library for connecting with a backend Enterprise Information System (EIS). You may see the terms Resource Adapter *modules*, Resource Adapter *connectors* and Resource Adapter *archive files* used interchangeably.

1. Click **File>New> Resource Adapter**.

- If you are working with an existing file, click **File > Open**. Select the file you wish to modify.

The navigation pane displays a hierarchical structure used to build the contents of the archive. The icons represent the security permissions, configuration properties, and files for the archive. A property dialog box containing general information about the archive is displayed in the property pane.

2. Enter values for other properties as needed.

**Note:** The remaining information in this step only applies if you are creating *new* archive files.

By default, the archive file name and the module display name are the same. It is recommended that you change the display name in the property pane. Also by default, the temporary location of the Resource Adapter module is `installation_directory/bin`.

- a. Specify a new file name and location by clicking **File>Save**.

3. Enter the EIS type, vendor name, version, and specification (required).

- a. Click on the **Advanced** tab, and enter the implementation and interface class names for the EIS connection.
- b. Click **Browse** to locate the class files. By default, the root directory or archive is the current archive. If needed, browse the file system for the directory or archive where class files reside.
- c. Click **Select**. The archive's file structure is displayed in the window.
- d. Expand the structure and locate the files that you need. Select the file and click **OK**.

4. Define other properties for the resource adapter.

- a. Right-click the **Security Permissions** icon and click **New**. A property dialog box for Security Permissions is displayed.
- b. Enter values for each property and then click **OK**. Repeat to specify multiple security permissions. The top portion of the property pane lists each reference.
- c. Select the reference to view its corresponding property dialog box.
  - a. Right-click the **Configuration Properties** icon and click **New**.
  - b. A property dialog box for Configuration Properties is displayed.
  - c. Enter values for each property and then click **OK**.
  - d. Repeat to specify multiple configuration properties.

5. Add files for the Resource Adapter.

- a. In the navigation pane, right-click the **Files** icon and then choose **Add Files**. Use the file browser to locate files to add.
- b. First, browse for the root directory or archive where the files are located and click **Select**. If you are adding an entire archive, select the directory that contains the archive. The directory structure is displayed in the left pane.
- c. Browse the directory structure.

- d. From the right pane, select one or more files to be added and click **Add**. If you select a directory and click Add, all files in the directory, including the directory, are added. Relative path names are maintained.
  - e. The selected files are displayed in the Selected Files window. Click **OK**. The file names, extensions, modification dates, sizes, and path names are displayed in the property pane.
6. Review the contents of the archive and make any desired changes.

Save the EAR file. Verify archive files. Generate code for deployment.

Resource Adapter Archive file assembly settings

Use this page to set the resource adapter archive file properties.

---

## Deploying data access applications

Before installing a data access application into the WebSphere Application Server environment, you must first ensure that the appropriate database objects are available. This action includes creating and configuring any databases or tables required, setting necessary configuration parameters to handle expected load, and configuring any necessary JDBC providers and data source objects for servlets, enterprise beans, and client applications to use.

1. If your database configuration does not already exist:
  - a. Create a database to hold the data.
  - b. Create tables required by your application.

**If your application uses entity enterprise beans to access the data**  
You can create the tables using the data definition language (DDL) generated from the enterprise bean configuration. For more information, see Recreating database tables from the exported table data definition language.

**If your application does not use entity beans**  
You must use your database server interfaces to create the tables.
  - c. See Minimum required properties for vendor-specific data sources for certain vendor’s databases requirements.
2. Migrate Version 4.0 data access applications
3. See Creating a JDBC provider using the administrative console if your enterprise application contains a Web application or an EJB application that uses connection pooling to access a relational database.
4. See Configuring data access for application clients if your enterprise application contains an application client that accesses a relational database.

**Related concepts**

“JDBC providers” on page 164

“Data sources” on page 164

“Connection pooling” on page 167

## Relationship of assembly and administrative console data access settings

This article provides miscellaneous tips for using supported databases. See also the related links.

Always consult the product documentation for a list of the database brands and versions that are supported by your particular application server version, edition, and FixPak.

**Related concepts**

“Data sources” on page 164

**Related reference**

“Data access : Resources for learning” on page 340

**Notes about various databases**

- When using local DB2 databases for data access by session clients on AIX Version 4.3.3 or later versions, in some cases you cannot establish multiple connections for session clients. This is because AIX , by default, does not permit 32-bit applications to attach to more than 11 shared memory segments per process. Of these 11 shared segments, a maximum of 10 can be used for local DB2 connections. To use EXTSHM with DB2 and avoid stale connections when there are large numbers of session clients, do the following:

- In DB2 client environment (that is the WebSphere Application Server run time environment in this case):

```
export EXTSHM=ON
```

- In DB2 UDB Server environment:

```
export EXTSHM=ON
db2set DB2ENVLIST=EXTSHM
```

- When using Sybase 11.x, you might encounter the following error when HttpSession persistence is enabled:

```
DBPortability W Could not create database table: "sessions"
com.sybase.jdbc2.jdbc.SybSQLException: The 'CREATE TABLE' command is not
allowed within a multi-statement transaction in the 'database_name' database
```

where *database\_name* is the name of the database for holding sessions.

If you encounter the error, issue the following commands at the Sybase command line:

```
use database_name
go
sp_dboption db,"ddl in tran ",true
go
```

- Sybase 12.0 does not support local transaction modes with a JTA enabled data source. To use a connection from a JTA enabled data source in a local transaction, install Sybase patch EBF9422.

**Additional administrative tasks for specific databases**

For your convenience, this article provides instructions for enabling some popular database drivers, and performing other administrative tasks often required to provide data access to applications running on WebSphere Application Server. These tasks are performed outside of the WebSphere Application Server administrative tools, often using the database product tools. Always refer to the documentation accompanying your database driver as the authoritative and complete source of driver information.

See the Supported hardware, software, and APIs for the latest information about supported databases, drivers, and operating systems.

**Enabling JDBC 2.0:** Ensure that your operating system environment is set up to support JDBC 2.0. This action is required to use data sources created through WebSphere Application Server.

The following steps make it possible to find the appropriate JDBC 2.0 driver for use with WebSphere Application Server administration:

*Enabling JDBC 2.0 with DB2 on Windows NT systems:* To enable JDBC 2.0 use on Windows NT systems:

- For DB2 Version 7.2
  1. Stop the DB2 JDBC Applet Server service.
  2. Run the following batch file:  
SQLLIB\java12\usejdbc2.bat
  3. Stop WebSphere Application Server (if it is running) and start it again.
- For DB2 Version 8.1
  - JDBC 2.0 is supported by default, there are no additional steps for you to perform.

Perform the steps once for each system.

*Determining the level of the JDBC API in use for DB2 on Windows NT systems:* To determine the JDBC level in use on your system:

- For DB2 Version 7.2
  - If JDBC 2.0 is in use, this file exists:  
SQLLIB\java12\inuse
  - If JDBC 1.0 is in use, this file exists:  
SQLLIB\java11\inuse

or no *java11* directory exists.
- For DB2 Version 8.1
  - Go to directory *SQLLIB\samples\java*, compile and run the class *db2JDBCVersion.java*.

*Enabling JDBC 2.0 with DB2 on UNIX systems:*

- For DB2 Version 7.2
  - Before starting WebSphere Application Server, call *\$INSTHOME/sqlib/java12/usejdbc2* to use JDBC 2.0. For convenience, you might want to put this in your root user's startup script. For example, on AIX, add the following to the root user's *.profile*:

```
if [ -f /usr/lpp/db2_07_01/java12/usejdbc2 ] ; then
. /usr/lpp/db2_07_01/java12/usejdbc2
fi
```
- For DB2 Version 8.1
  - JDBC 2.0 is supported by default, there are no additional steps for you to perform.

*Determining the level of the JDBC API in use for DB2 on UNIX systems:*

- For DB2 Version 7.2
  - To determine if you are using JDBC 2.0, you can echo *\$CLASSPATH*. If it contains  
*\$INSTHOME/sqlib/java12/db2java.zip*  
  
then JDBC 2.0 is in use.  
  
If it contains  
*\$INSTHOME/sqlib/java/db2java.zip*  
  
then JDBC 1.0 is in use.
- For DB2 Version 8.1

- Go to directory *sqllib/samples/java*, compile and run the class *db2JDBCVersion.java*.

**Sourcing the db2profile script on UNIX systems:** Before starting WebSphere Application Server to host applications requiring data access, source the *db2profile*:  
`. ~db2inst1/sqllib/db2profile`

where *db2inst1* is the user created during DB2 installation.

**Using Java Transaction API drivers:** Instructions are available for using Java Transaction API (JTA) drivers on particular operating systems. See your operating system documentation for more information.

The goal of this section is to provide information about the steps that make DB2 work well with applications utilizing XA classes -- that is, those whose *dataSourceClasses* implement *javax.sql.XADataSource*.

*Using Java Transaction API drivers for DB2 on Windows NT systems:* To enable JTA drivers for DB2 on Windows NT systems, follow these steps:

1. Bind the necessary packages to the database. From the **DB2 Command Line Processor** window, issue the following commands:

```
db2=> connect to mydb2jta
db2=> bind db2home\bnd\@db2cli.lst
db2=> bind db2home\bnd\@db2ubind.lst
db2=> disconnect mydb2jta
```

where *mydb2jta* is the name of the database to enable for the JTA, and *db2home* is the DB2 root installation directory path (for example, *D:\ProgramFiles\SQLLIB\bnd\@db2cli.lst*).

2. Specify the following settings when you use an IBM WebSphere Application Server administrative client (such as the WebSphere Administrative Console) to configure a JDBC driver:
  - **Server class path** = %DB2\_ROOT%/SqlLib/java/db2java.zip
  - **Implementation class name** = COM.ibm.db2.jdbc.DB2XADataSource

*Using Java Transaction API drivers for DB2 on UNIX systems:* To enable JTA drivers on UNIX systems, follow these steps:

1. Stop all DB2 services.
2. Stop the IBM WebSphere Application Server administrative service.
3. Stop any other processes that use the *db2java.zip* file.
4. Make sure that you already enabled JDBC 2.0.
5. Start the DB2 services.
6. Bind the necessary packages to the database. From the DB2 command-line process or window, issue the following commands:

```
db2=> connect to mydb2jta
db2=> bind db2home\bnd\@db2cli.lst
db2=> bind db2home\bnd\@db2ubind.lst
db2=> disconnect mydb2jta
```

7. Specify the following settings when you use an IBM WebSphere Application Server administrative client (such as the WebSphere Administrative Console) to configure a JDBC driver:
  - **Server class path** = \$INSTHOME/sqlLib/java12/db2java.zip  
 For example, if *\$INSTHOME* is */home/test*, the path will be */home/test/sqlLib/java12/db2java.zip*
  - **Implementation class name** = COM.ibm.db2.jdbc.DB2XADataSource

*For Oracle 8.1.7 two phase commit support:* You can use the Oracle 8.1.7 thin driver for JTA two-phase support with the following restrictions:

- The thin driver that comes shipped with 8.1.7 might or might not work. Future patches from Oracle might work as well, but are not tested. The driver that was available from the Oracle Technology Network Web site as of February 20, 2001 does work and is the recommended driver. Later versions on this Web site are expected to work, but are not tested.

To obtain the driver from the Oracle support Web site, visit:

<http://technet.oracle.com/>

You need to be a registered user for the Oracle Technology Network to get the driver from this site. Contact Oracle for access. After you have access download the 8.1.7 driver for the platforms you use and follow the instructions for installing the new driver.

- You must use the 8.1.7 driver with 8.1.7 databases, 8.1.6 databases do not support the `recover()` and `forget()` methods and other problems are encountered running with 8.1.6. Oracle does not support JTA with 8.1.6.
- For Oracle, you can only use JTA with container-managed persistence (CMP) beans.
- For the bean to create the table, you must start the bean with the JTA set to *false*. After the bean creates the table, you can set the JTA back to *true*.
- Configure an entity bean that accesses Oracle with JTA set to *true* as follows:
  - Click **deployment descriptor properties** > **Transactions** > Remote tab. Set the Transaction Attribute to *TX\_REQUIRED*.
  - Click **Isolation** > Remote tab. Set the Isolation Level to *TRANSACTION\_READ\_COMMITTED*.
- Configure a session bean that is used with an entity bean that accesses Oracle with JTA set to *true* as follows:
  - Click **deployment descriptor properties** > **Transactions** > Remote tab. Set the Transaction Attribute to *TX\_BEAN\_MANAGED*.
  - Click **Isolation** > Remote tab. Set the Isolation Level to *TRANSACTION\_READ\_COMMITTED*.

*Using Java Transaction API drivers for Sybase products on AIX systems:* To enable Java Transaction API (JTA) drivers for use with Sybase products on the AIX operating system, follow these steps:

1. Enable the Data Transaction Manager (DTM) by issuing these commands (one per line) at a command prompt:

```
isql -Usa -Ppassword -Sservername
sp_configure "enable DTM", 1
go
```

2. Stop the Sybase Adaptive Server database and start it again.

3. Grant the appropriate role authorization to the enterprise bean user at a command prompt:

```
isql -Usa -Ppassword -Sservername
grant role dtm_tm_role to EJB
go
```

*Notes about Sybase Java Transaction API drivers:* Do not use a Sybase Java Transaction API (JTA) connection in an enterprise bean method with an unspecified transaction context. A Sybase JTA connection does not support the local transaction mode. The implication is that you must use the Sybase JTA connection in a global transaction context.

## Recreating database tables from the exported table data definition language

When an EAR file deploys the target database is selected. Then an appropriate *Table.ddl* file is created that contains the SQL statements to create the table for the bean. To create your table, using the *Table.ddl* file for DB2:

1. The container-managed bean (CMP) enterprise bean JAR file has a *Table.ddl* file that the Application Assembly Tool (AAT) generates. Extract the *Table.ddl* file to a working directory such as *C:\temp*.
2. Run this command -- **C:\temp>db2cmd** A new command window appears in which you enter the following commands.
3. Run this command -- **C:\temp>db2 connect <dbname>**
4. Run this command -- **C:\temp>db2 -tf Table.ddl** The command runs and creates tables for your CMP enterprise bean.
5. Run this command -- **C:\temp>db2 disconnect all**

## Installing Java 2 Connector resource adapters

1. Click **Resources**.
2. Click **Resource Adapters**.
3. Click **Install RAR**. The Install RAR button opens a dialog that enables you to install a J2EE Connector Architecture (JCA) connector and create a resource adapter for it. You can also use the **New** button, but the New button creates only a new resource adapter (the JCA connector must already be installed on the system).

**Note:** When installing a RAR file using this dialog, the scope you define on the Resource Adapters page has no effect on where the RAR file is installed. You can install RAR files only at the *node* level, and the node the file is installed on is determined by the scope on the **Install RAR** page. The scope you set on the Resource Adapters page determines the scope of the new resource adapters, which you can install at the server, node, or cell level.

4. Browse to find the appropriate RAR file.
5. Click **Next**.
6. Enter the resource adapter name and any other properties needed under *General Properties*. If you install a J2C Resource Adapter that includes *Native path* elements, consider the following: If you have more than one native path element, and one of the native libraries (native library A) is dependent on another library (native library B), then you must copy native library B to a *system* directory. Because of limitations on Windows NT and most Unix platforms, an attempt to load a native library does not look in the current directory.
7. Click **OK**.

### Related concepts

“Resource adapter” on page 153

## Installing resource adapters within applications

1. Assemble an application with resource adapter archive (RAR) modules in it. See *Assembling applications*.
2. Install the application following the steps in *Installing a new application*. In the **Map modules to application servers** step, specify target servers or clusters for

each RAR file. Be sure to map all other modules that use the resource adapters defined in the RAR modules to the same targets.

3. Click **Finish** > **Save** to save the changes.
4. Create connection factories for the newly installed application.
  - a. Open the administrative console.
  - b. Click **Applications** > **Enterprise Applications** > *application name*.
  - c. Click **Connector Modules** in the Related Items section of the page.
  - d. Click *filename.rar*.
  - e. Click **Resource adapter** in the Additional Properties section of the page.
  - f. Click **J2C Connection Factories** in the Additional Properties section of the page.
  - g. Click on an existing connection factory to update it, or **New** to create a new one.

If you install a J2C Resource Adapter that includes *Native path* elements, consider the following: If you have more than one native path element, and one of the native libraries (native library A) is dependent on another library (native library B), then you must copy native library B to a *system* directory. Because of limitations on Windows NT and most Unix platforms, an attempt to load a native library does not look in the current directory.

After you create and save the connection factories, you can modify the resource references defined in various modules of the application and specify the Java Naming and Directory Interface (JNDI) names of the connection factories wherever appropriate.

**Note:** A given native library can only be loaded one time for each instance of the Java virtual machine (JVM). Because each application has its own classloader, separate applications with embedded RAR files cannot both use the same native library. The second application receives an exception when it tries to load the library.

If any application deployed on the application server uses an embedded RAR file that includes native path elements, then you must always ensure that you shut down the application server cleanly, with no outstanding transactions. If the application server does not shut down cleanly it performs *recovery* upon server restart and loads any required RAR files and native libraries. On completion of recovery, do not attempt any application-related work. Shut down the server and restart it. No further recovery is attempted by the application server on this restart, and normal application processing can proceed.

### Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

### Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

#### *Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

WebSphere 5.0 allows resources such as JDBCProviders, Namespace Bindings, or Shared Libraries at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they have been overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they have been overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope that is selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

#### *Name:*

Specifies the name of the resource provider.

A string with no spaces meant to be a meaningful text identifier for the resource provider.

**Data type** String

#### *Description:*

Specifies a text description of the resource factory.

A free-form text string to describe the resource factory and its purpose.

**Data type** String

#### *Archive path:*

Specifies the path to the .RAR file containing the module for this resource adapter.

**Data type** String

*Classpath:*

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

This includes any additional libraries needed by the resource adapter. The resource adapter code base itself is automatically added to the classpath, but if anything outside the .RAR is needed it can be specified here.

**Data type** String

*Native path:*

Specifies a list of paths which forms the location for the resource provider native libraries.

The resource adapter code base itself is automatically added to the classpath, but if anything outside the .RAR is needed it can be specified here.

**Data type** String

## Creating and configuring a JDBC provider and data source

1. Decide which data source to use: Data source (Version 4.0) or a Version 5.0 data source.

2. Create a JDBC provider.

From the administrative console, see [Creating a JDBC provider using the administrative console](#).

**OR**

Using the Java Management Extensions (JMX) API, see [Creating a JDBC provider and data source using the Java Management Extensions API](#).

3. Create a data source.

From the administrative console, see [Creating a data source using the administrative console](#).

**OR**

Using the JMX API, see [Creating a JDBC provider and data source using the Java Management Extensions API](#).

4. Bind the resource reference.

5. **5.0.1 +** Test the connection (for non-container-managed persistence usage).

**Related concepts**

## Verifying a connection

User errors cause most test connection problems. This article provides a checklist of steps that you must complete to enable a successful connection. Click on the link for more information on a specific step.

If, after completing these steps and reviewing the applicable information, your connection is still not successful, check the SystemOut.log for warning or exception messages. Then use the technical support search function to find known problems.

1. Create the authentication data alias.
2. Create the JDBC provider.
3. Create a Version 5.0 or 4.0 data source.
4. Save the data source.
5. Restart the server.

If you are running Websphere Application Server Version 5.0.2, you do not have to complete this step unless you also created a new Java Authentication and Authorization Service (JAAS) entry.

6. Test the connection

You can test your connection from the data source collection view or the data source details view. Access either view in the administrative console, and then select a connection from the list. Click the **test connection** button on the connection.

You must complete all the steps and restart the server before you test the connection. Neither the authentication data alias nor the WebSphere Application Server environment variables (in Version 5.0.1) are available before a server restart.

## Creating and configuring a JDBC provider using the administrative console

To access a database you must first create a JDBC provider. You can do this from the administrative console. You need to know where your database software is installed and where the drivers are located.

1. Open the administrative console.
2. Click **Resources > JDBC Providers**.
3. Select the *scope* of your definition.
4. Click **New**.
5. Use the drop-down list to select the type of JDBC provider to create. If the list of supported JDBC provider types does not include the JDBC provider that you want to use, select the **User-Defined JDBC Provider**. Consult the JDBC provider vendor's documentation for information on specific required properties.

Do not change the name of the JDBC provider if you create it by selecting an existing JDBC provider from the drop-down list. This restriction does not apply if you are using the **User-Defined JDBC Provider** feature and supplying the provider information.

**Note:** Using the administrative console to create a DB2 JDBC provider for a zSeries server causes an exception to occur.

When you use the administrative console to create a **DB2 for z/OS JDBC Provider** or a **DB2 for z/OS JDBC Provider (XA)**, an exception occurs with the message *Name is not a valid entry*. To work around this problem, choose the normal **DB2 JDBC Provider** to create a JDBC provider. They both use the same implementation class. When you create a data source under this provider, change the data store helper value from *DB2DataStoreHelper* to *DB2390DataStoreHelper*. Otherwise, your database access does not work.

6. Click **Apply** to view the settings page for your JDBC provider.
7. Enter the properties for your JDBC provider. For more information, see JDBC Provider settings.
8. Click **Apply** to view the page with your new JDBC provider settings. Note that there is now an *Additional Properties* section on this page. To set up a data source, click one of the data sources links. For more information about creating a data source, see *Creating a data source with the administrative console*.
9. Click **OK** to return to the JDBC providers page, where your new JDBC provider appears in the list.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

“Data Sources (Version 4)” on page 274

“Data Source collection” on page 269

*Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource’s properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

*Name:*

Specifies the name of the resource provider.

**Data type** String

*Description:*

Specifies a text description for the resource provider.

**Data type** String

*Classpath:*

Specifies a list of paths or JAR file names which together form the location for the resource provider classes.

For example *D:/SQLLIB/java/db2java.zip*.

Classpath entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Classpaths contain variable (symbolic) names which you can substitute using a variable map. Check the driver installation notes for the specific required JAR file names.

**Data type** String

*Native Library Path:*

Specifies a list of paths that forms the location for the resource provider native libraries.

Native path entries are separated by using the ENTER key and must not contain path separator characters (such as ';' or ':'). Native paths can contain variable (symbolic) names which you can substitute using a variable map.

**Data type** String

*Implementation Classname:*

Specifies the Java class name of the JDBC driver implementation.

This class is available in the driver file mentioned in the Classpath description above. For example *COM.ibm.db2.jdbc.DB2XDataSource*.

**Data type** String

*New JDBC Provider:*

Use this page to choose a type of JDBC Provider to create.

To view this administrative console page, click **Resources >JDBC Providers > New**.

**Related concepts**

"JDBC providers" on page 164

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

*JDBC Providers:*

Specifies the names of the supported JDBC Provider types.

If the list of supported JDBC Provider types does not include the JDBC Provider that you want to use, select the *User-Defined JDBC Provider*. You might need to consult the documentation for the JDBC Provider for more information on specific properties required by that provider.

Data type

Drop-down list

## Creating and configuring a data source using the administrative console

After you create a JDBC provider, you must create a data source to access the backend data store. Follow these steps to create either a new Version 5.0 data source or a Version 4.0 data source.

1. Open the administrative console.
2. Click **Resources > JDBC Providers**.
3. You might need to change the **Scope** selection to find the JDBC provider for which you want to create a data source. Scope settings are used to limit the availability of resources to a particular cell, node, or server. When new items are created in this view, they are created within the current scope.
4. Choose the JDBC resource provider in which you want to create the data source. The detail page for this provider appears.
5. Click **Data Sources** in Additional Properties if you want to create a Version 5.0 data source. If you want to create a Version 4.0 data source, click **Data Sources (Version 4)** in Additional Properties. The *Data Sources* or *Data Sources (Version 4)* page appears.
6. Click **New** to display the settings page for your V5.0 or V4.0 data source.
7. Enter the properties for your data source.

**For your Version 5.0 data source:**

- Optionally choose an existing **Component-managed Authentication Alias** or **Container-managed Authentication Alias** from the lists. These aliases are used for database authentication in run time. If you do not set one of these fields and your database requires the user ID and password to get a connection, then you receive an exception during run time.

If your resource authentication (res-auth) is set to *Application*, set the alias in the Component-managed Authentication Alias. If your res-auth is set to *Container*, set the Container-managed Authentication Alias. If your database does not support a *user ID* and *password* on a connection (for example, Cloudscape), then do not specify the alias in either one of these entries.

Because defining a *user ID* and *password* in the Custom Properties page is not always desirable (your password can be seen by anyone who accesses the *resources.xml* file), you can define the user ID and password as an alias. To define a new alias from the J2C Authentication Data Entries choice, follow these steps:

- a. Click **Apply**. The J2C Authentication Data Entries choice does not appear on the "New" data source page, but does appear on an existing

data source's page. Because you were just creating a new data source, you must click on the apply button for the J2C Authentication Data Entries choice to show. This also saves the properties that you have already applied to this data source.

- b. Click **J2C Authentication Data Entries** in the Related Items section.
- c. Click **New** on the J2C Authentication Data Entries page.
- d. Fill in the fields on the resulting page. Click **Apply**.
- e. Return to the data source page.
- f. If the new alias does not appear in the picklists for Component- or Container-managed Authentication Alias, close the page and re-open it.

For more information, see *Data source settings*, *Data source (Version 4) settings*, and *Minimum required properties for vendor-specific data sources*

8. Click **Apply** to view a page with your new data source settings. Note that there are now *Additional Properties* and *Related Items* sections on this page. *Additional Properties* contains the *Connection Pool* and *Custom Properties* choices. Some database vendors might require additional custom properties for data sources that access the database. Click on either or both of these to modify their properties.

The Related Items section contains the *J2C Authentication Data Entries* choice. Here, you can specify a list of user IDs and passwords for use by Java 2 Connector (J2C) security.

9. Click **Save**.
10. Return to the data source page to confirm that your new data source appears in the list.

Tuning parameter index

### Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource’s properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type**

String

*Name:*

Specifies the display name for the data source.

For example you can set this field to *Test Data Source*.

**Data type** String

*JNDI Name:*

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of *markSection* generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run *dumpnamespace*.

**Data type** String

*Container managed persistence:*

Specifies if this data source is used for container managed persistence of enterprise beans.

If the checkbox is selected, a CMP Connector Factory that corresponds to this data source is created for the relational resource adapter.

**Data type** Checkbox  
**Default** Not checked

*Description:*

Specifies a text description for the resource.

**Data type** String

*Category:*

Specifies a category string you can use to classify or group the resource.

**Data type** String

*Statement Cache Size:*

Specifies the number of free statements that are cached per connection.

The WebSphere Application Server data source optimizes the processing of prepared statements. A prepared statement is a precompiled SQL statement that is stored in a prepared statement object. This object is used to efficiently execute the given SQL statement multiple times.

If the cache is not large enough, useful entries are discarded to make room for new entries. To determine the largest value for your cache size to avoid any cache discards, add the number of uniquely prepared statements, callable statements (as determined by the *sql* string, concurrency, and the scroll type) for each application that uses this data source on a particular server. This value is the maximum number of possible prepared statements that are cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. In general, the more statements your application has, the larger the cache should be. For example, if the application has 5 SQL statements, set the statement cache size to 5, so that each connection has 5 statements.

In test applications, tuning the statement cache improved throughput by 10-20%. However, because of potential resource limitations, this might not always be possible.

**Data type**

Integer

**Default**

Depends on the database. Most are 10. Informix Version 7.3, 9.2, or 9.3 without latest fix must also be 0. A default of 0 means there is no cache statement.

*Datasource Helper Classname:*

Specifies the datastore helper that is used to perform database specific functions.

This is used by the Relational Resource Adapter at runtime. The default DataStoreHelper implementation class is set based on the JDBC driver implementation class, using the structure:

*com.ibm.websphere.rsadapter.<database>DataStoreHelper*. For example, if the JDBC provider is DB2, then the default DataStoreHelper class is *com.ibm.websphere.rsadapter.DB2DataStoreHelper*. You can change to your subclass of this DataStoreHelper if necessary.

**Data type**

String

**Default**

Dependent on JDBC driver implementation class

*Component-managed Authentication Alias:*

This alias is used for database authentication in run time.

If your resource authentication (res-auth) is set to *Application*, set the alias in the Component-managed Authentication Alias.

If you do not set this field and your database requires the user ID and password to get a connection, then you receive an exception during run time.

If your database (for example, Cloudscape) does not support *user ID* and *password*, then do not set the alias in the Component-managed authentication alias or Container-managed authentication alias fields. Otherwise, you see the warning message in the system log to indicate that the user and password are not valid properties. This message is a only warning message, therefore the data source is created successfully.

**Data type** Pick-list

#### *Container-managed Authentication Alias:*

This alias is used for database authentication in run time.

If your res-auth is set to *Container*, set the Container-managed Authentication Alias.

If you do not set this field and your database requires the user ID and password to get a connection, then you receive an exception during run time.

If your database (for example, Cloudscape) does not support *user ID* and *password*, then do not set the alias in the Component-managed authentication alias or Container-managed authentication alias fields. Otherwise, you see the warning message in the system log to indicate that the user and password are not valid properties. This message is a only warning message, therefore the data source is created successfully.

**Data type** Pick-list

#### *Mapping-Configuration Alias:*

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations.

**Data type** Pick-list

#### **Data Sources (Version 4):**

Use this page to view the settings of a Version 4.0 style data source.

These Version 4.0 data sources use the WebSphere Application Server Version 4.0 Connection Manager architecture. All EJB 1.1 modules must use a Version 4.0 data source.

To view this administrative console page, click **Resources > JDBC Providers > JDBC\_provider > Data Sources (Version 4)**.

#### *Scope:*

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource’s properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

#### *Name:*

Specifies the display name for the resource.

For example you can set this field to *Test Data Source*.

**Data type** String

*JNDI Name:*

Specifies the Java Naming and Directory Interface (JNDI) name.

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects.

There are many naming and directory service implementations, and the interfaces to them vary. JNDI provides a common interface that is used to access the various naming and directory services.

For example, you can use the name *jdbc/markSection*.

If you leave this field blank a JNDI name is generated from the name of the data source. For example, a data source name of *markSection* generates a JNDI name of *jdbc/markSection*.

After you set this value, save it, and restart the server, you can see this string when you run *dumpnamespace*.

**Data type** String

*Description:*

Specifies a text description for the resource.

**Data type** String

*Category:*

Specifies a category string that you can use to classify or group the resource.

**Data type** String

*Database Name:*

Specifies the name of the database that this data source accesses.

For example, you can call the database *SAMPLE*.

**Data type** String

*Default User ID:*

Specifies the user name to use for connecting to the database.

For example, you can use the ID *db2admin*.

**Data type** String

*Default Password:*

Specifies the password used for connecting to the database.

For example, you can use the password *db2admin*.

**Data type** String

### **Custom Properties collection:**

Use this page to view the custom properties.

Custom properties are unique to each resource, zero or more can be required.

**Note:** After you enter this page, the first thing to do is click on the *Required* field to sort in descending order. All of the required (true) values are then sorted at the beginning of the page. You must repeat this process until all the required properties are set.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource's properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

*Required:*

Specifies properties that are required for this resource.

Setting can be *true* or *false*.

**Data type** String

*Name:*

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

**Data type** String

*Value:*

Specifies the value associated with this property in this property set.

**Data type** Integer

*Description:*

Specifies text to describe any bounds or well-defined values for this property.

**Data type** String

*Type:*

Specifies the fully qualified Java data type of this property .

There are specific types that are valid:

- java.lang.Boolean
- java.lang.String
- java.lang.Integer
- java.lang.Double
- java.lang.Byte
- java.lang.Short
- java.lang.Long
- java.lang.Float
- java.lang.Character

**Data type**

Pick file

### **Custom Properties (Version 4) collection:**

Use this page to view properties for a Version 4.0 datasource.

To view this administrative console page, click **Resources > JDBC Providers > JDBC\_provider > Data Sources (Version 4) > data\_source > Custom Properties**

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

Administrative console filter settings

Use the Filter settings to specify how to filter entries shown in a collection view.

Administrative console preference settings

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

*Name:*

Specifies the name of the custom property

Insure that the data source has the setter of this property.

**Data type** String

*Value:*

Specifies the value of the custom property.

**Data type** Integer

*Description:*

Specifies text to describe any bounds or well-defined values for this property.

**Data type** String

*Required:*

Specifies properties that are required for this resource.

**Data type** String

*Custom property (Version 4) settings:*

Use this page to add properties for a Version 4.0 datasource.

To view this administrative console page, click **Resources >JDBC Providers> JDBC\_provider > Data Sources (Version 4) > data\_source > Custom Properties > custom\_property**.

Specifies the name associated with this property (PortNumber, ConnectionURL, etc).

Insure that the data source has the setter of this property.

**Data type** String

*Value:*

Specifies the value associated with this property in this property set.

**Data type** Integer

*Description:*

Specifies text to describe any bounds or well-defined values for this property.

**Data type** String

Type:

Specifies the fully qualified Java type of this property (java.lang.Integer, java.lang.Byte).

Data type String

## Creating a JDBC driver on multiple nodes

These are the instructions to create a JDBC Driver in a Network Development (ND) environment. This sample configuration involves two base nodes: node A and node B added to ND on node C.

1. Open the administrative console.
2. Click **Resources > JDBC Drivers**. The default listing is at the *node* level.
3. Leave the node text field blank and click **Apply** to change the scope to the *cell* level.
4. Click **New** to create a new JDBC Driver at the cell level. For the classpath filed while creating the data source, the default is `${DB2_JDBC_DRIVER_PATH}\db2java.zip`. Leave it at the default.
5. Finish creating the JDBC Driver.
6. Click **Environment**.
7. Click **Manage WebSphere Variables**.
8. Select each node.
9. Click **DB2\_JDBC\_DRIVER\_PATH** (this already exists by default). Here provide the path (in the *value* field) where `db2java.zip` exists on the selected node.
10. Click **Apply** and save the changes. If you provided a different variable (like `${DB2PATH}`) when creating the JDBC Driver, you must create a new variable by clicking **New**.

**Note:** This variable must be defined on each node under the cell.

## Creating and configuring a JDBC provider and data source using the Java Management Extensions API

You need two JAR files in your classpath -- `wsexception.jar` and `wasjmx.jar`. The following command suffices for most invocations:

```
set classpath=%classpath%;D:\WebSphere\AppServer\lib\wsexception.jar;D:\WebSphere\AppServer\lib\wasjmx.jar
```

The usual program follows these main points:

1. Look up the host and get an administration client handle.
2. Get a configuration service handle.
3. Update the `resource.xml` file using the configuration service as desired.
  - a. Add a JDBC provider
  - b. Add the data source
  - c. Add the connection factory (for container-managed persistence)
4. Reload the `resource.xml` file to bind the newly created data source into the JNDI namespace. Perform this step if you want to use the newly created data source right away without restarting the application server.
  - a. Locate the DataSourceConfigHelper MBean using the name.
  - b. Put together the signature and parameters for the call.

c. Invoke the reload() call.

**Example: Test a connection to a data source:** This resource adapter test program ensures that the MBean interfaces work. The following interfaces are tested:

- `getPropertiesForDataSource()`
- `reload()`
- `testConnectionToDataSource()`

You need the following to run: set the classpath to *classpath=%classpath%; was\_home\lib\wsexception.jar; was\_home\lib\wasjmx.jar; was\_home\lib\j2ee.jar; was\_home\lib\admin.jar; was\_home\lib\jmx.jar; was\_home\lib\utils.jar*. Replace the variable *was\_home* with the directory where you installed WebSphere Application Server.

**Example: Creating a JDBC provider and data source using Java Management Extensions API and the scripting tool:** Following is a JAAS (WSadmin - scripting tool) script used to create a data source and test the connection. This script:

- Creates a data source fvtDS\_1
- Creates a 4.0 data source fvtDS\_3
- Creates a container-managed persistence (CMP) data source linked to fvtDS\_1
- Tests the connection

```
#AWE -- Set up XA DB2 data sources, both 5.0 and 4.0
```

```
#UPDATE THESE VALUES:
```

```
#The classpath that will be used by your database driver
```

```
set driverClassPath "c:/sqllib/java/db2java.zip"
```

```
set server "server1"
```

```
set fvtbase "c:/wssb/fvtbase"
```

```
#Users and passwords..
```

```
set defaultUser1 "dbuser1"
```

```
set defaultPassword1 "dbpwd1"
```

```
set aliasName "alias1"
```

```
set databaseName1 "jtest1"
```

```
set databaseName2 "jtest2"
```

```
#END OF UPDATES
```

```
puts "Add an alias alias1"
```

```
set cell [${AdminControl getCell}]
```

```
set sec [${AdminConfig getid /Cell:$cell/Security:/}]
```

```
#-----
```

```
# Create a JAASAuthData object for component-managed authentication
```

```
#-----
```

```
puts "create JAASAuthData object for alias1"
```

```
set alias_attr [list alias $aliasName]
```

```

set desc_attr    [list description "Alias 1"]

- “JDBC providers” on page 164
- “Data sources” on page 164
- “Connection pooling” on page 167

## Configuring Java 2 Connector connection factories in the administrative console

1. Click **Resources**.
2. Click **Resource Adapters**.
3. Select a resource adapter under Resource Adapters.
4. Click **J2C Connection Factories** under Additional Properties .
5. Click **New**.
6. Specify *General Properties* .
7. Select the authentication preference.
8. Select aliases for **component-managed authentication, container-managed authentication**, or both. If none are available, or you want to define a different one, click **Apply > J2C Authentication Data Entries** under Related Items.
  - a. Click **J2C Auth Data Entries** under Related Items.
  - b. Click **New**.
  - c. Specify General Properties.
  - d. Click **OK**.
9. Click **OK**.
10. Click the J2C connection factory you just created.
11. Under *Additional Properties* click **Connection Pool**.
12. Change any values desired by clicking the property name.
13. Click **OK**.
14. Click **Custom Properties** under *Additional Properties*.

15. Click any property name to change its value. Note that **UserName** and **Password** if present, are overridden by the **component-managed authentication** alias you specified in a previous step.
16. Click **Save**.

## **Connection pool settings**

Use this page to configure connection pool settings.

This administrative console page is common to a range of resource types; for example, JDBC data sources and JMS queue connection factories. To view this page, the path depends on the type of resource, but generally you select an instance of the resource provider, then an instance of the resource type, then click **Connection Pool**. For example: click **Resources** > **JDBC Providers** > *JDBC\_provider* > **Data Sources** > *data\_source* > **Connection Pool**.

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

Tuning parameter index

### **Scope:**

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource’s properties only apply at an individual server level. For example, if you define the scope of a

data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

#### **Connection Timeout:**

Specifies the interval, in seconds, after which a connection request times out and a `ConnectionWaitTimeoutException` is thrown.

The wait is necessary when the maximum value of connections (*Max Connections*) to a particular connection pool is reached. For example, if *Connection Timeout* is set to 300 and the maximum number of connections is reached, the Pool Manager waits for 300 seconds for an available physical connection. If a physical connection is *not* available within this time, the Pool Manager throws a `ConnectionWaitTimeoutException`. It usually does not make sense to retry the `getConnection()` method, because if a longer wait time is required, you should set the *Connection Timeout* setting to a higher value. Therefore, if this exception is caught by the application, the administrator should review the expected usage of the application and tune the connection pool and the database accordingly.

If *Connection Timeout* is set to 0, the Pool Manager waits as long as necessary until a connection is allocated (which happens when the number of connections falls below the value of *Max Connections*).

If *Max Connections* is set to 0, which enables an infinite number of physical connections, then the *Connection Timeout* value is ignored.

**Data type** Integer  
**Units** Seconds  
**Default** 180  
**Range** 0 to max int

#### **Max Connections:**

Specifies the maximum number of physical connections that you can create in this pool.

These are the physical connections to the backend resource. Once this number is reached, no new physical connections are created and the requester waits until a physical connection that is currently in use returns to the pool, or a `ConnectionWaitTimeoutException` is thrown.

For example, if the Max Connections value is set to 5, and there are five physical connections in use, the pool manager waits for the amount of time specified in Connection Timeout for a physical connection to become free.

If Max Connections is set to 0, the Connection Timeout value is ignored.

For better performance, set the value for the connection pool lower than the value for the Max Connections option in the Web container. Lower settings, such as 10-30 connections, perform better than higher settings, such as 100.

If clones are used, one data pool exists for each clone. Knowing the number of data pools is important when configuring the database maximum connections.

#### **Min Connections:**

Specifies the minimum number of physical connections to maintain.

Until this number is reached, the pool maintenance thread does not discard physical connections. However, no attempt is made to bring the number of connections up to this number. If you set a value for Aged Timeout, the minimum is not maintained. All connections with an expired age are discarded.

For example if the Min Connections value is set to 3, and one physical connection is created, the Unused Timeout thread does not discard that connection. By the same token, the thread does not automatically create two additional physical connections to reach the Min Connections setting.

<b>Data type</b>	Integer
<b>Default</b>	1
<b>Range</b>	0 to max int

#### **Reap Time:**

Specifies the interval, in seconds, between runs of the pool maintenance thread.

For example, if Reap Time is set to 60, the pool maintenance thread runs every 60 seconds. The *Reap Time* interval affects the accuracy of the *Unused Timeout* and *Aged Timeout* settings. The smaller the interval, the greater the accuracy. If the pool maintenance thread is enabled, set the Reap Time value less than the values of Unused Timeout and Aged Timeout. When the pool maintenance thread runs, it discards any connections remaining unused for longer than the time value specified in Unused Timeout, until it reaches the number of connections specified in *Min Connections*. The pool maintenance thread also discards any connections that remain active longer than the time value specified in Aged Timeout.

The Reap Time interval also affects performance. Smaller intervals mean that the pool maintenance thread runs more often and degrades performance.

To disable the pool maintenance thread set Reap Time to 0, or set both Unused Timeout and Aged Timeout to 0. The recommended way to disable the pool maintenance thread is to set Reap Time to 0, in which case Unused Timeout and Aged Timeout are ignored. However, if Unused Timeout and Aged Timeout are set to 0, the pool maintenance thread runs, but only physical connections which timeout due to non-zero timeout values are discarded.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	180
<b>Range</b>	0 to max int

#### **Unused Timeout:**

Specifies the interval in seconds after which an unused or idle connection is discarded.

Set the Unused Timeout value higher than the Reap Timeout value for optimal performance. Unused physical connections are only discarded if the current number of connections not in use exceeds the Min Connections setting. For example, if the unused timeout value is set to 120, and the pool maintenance thread is enabled (Reap Time is not 0), any physical connection that remains unused for two minutes is discarded. Note that accuracy of this timeout, as well as performance, is affected by the Reap Time value. See Reap Time for more information.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	1800
<b>Range</b>	0 to max int

#### **Aged Timeout:**

Specifies the interval in seconds before a physical connection is discarded.

Setting *Aged Timeout* to 0 supports active physical connections remaining in the pool indefinitely. Set the Aged Timeout value higher than the Reap Timeout value for optimal performance. For example, if the Aged Timeout value is set to 1200, and the Reap Time value is not 0, any physical connection that remains in existence for 1200 seconds (20 minutes) is discarded from the pool. Note that accuracy of this timeout, as well as performance, are affected by the Reap Time value. See Reap Time for more information.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	0
<b>Range</b>	0 to max int

#### **Purge Policy:**

Specifies how to purge connections when a *stale connection* or *fatal connection error* is detected.

Valid values are **EntirePool** and **FailingConnectionOnly**. JCA data sources can have either option. WebSphere Version 4.0 data sources always have a purge policy of **EntirePool**.

**Data type**  
**Default**  
**Range**

String  
EntirePool

**EntirePool**

All connections in the pool are marked stale. Any connection not in use is immediately closed. A connection in use is closed and throws a *StaleConnectionException* during the next operation on that connection. Subsequent *getConnection* requests from the application result in new connections to the database opening. When using this purge policy, there is a slight possibility that some connections in the pool are closed unnecessarily when they are not stale. However, this is a rare occurrence. In most cases, a purge policy of EntirePool is the best choice.

**FailingConnectionOnly**

Only the connection that caused the *StaleConnectionException* is closed. Although this setting eliminates the possibility that valid connections are closed unnecessarily, it makes recovery from an application perspective more complicated. Because only the currently failing connection is closed, there is a good possibility that the next *getConnection* request from the application can return a connection from the pool that is also stale, resulting in more stale connection exceptions.

## Connection pool (Version 4) settings

Use this page to create a connection pool for a Version 4.0 data source.

To view this administrative console page, click **Resources > JDBC Providers > JDBC\_provider > Data Sources (Version 4) > data\_source > Connection Pool**.

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

**Scope:**

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource’s properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

**Minimum Pool Size:**

Specifies the minimum number of connections to maintain in the pool.

The minimum pool size can affect the performance of an application. Smaller pools require less overhead when the demand is low because fewer connections are held open to the database. When the demand is high, the first applications experience a slow response because new connections are created if all others in the pool are in use.

<b>Data type</b>	Integer
<b>Default</b>	1
<b>Range</b>	Any non-negative integer.

### Maximum Pool Size:

Specifies the maximum number of connections to maintain in the pool.

If the maximum number of connections is reached and all connections are in use, additional requests for a connection wait up to the number of seconds specified as the connection timeout. The maximum pool size can affect the performance of an application. Larger pools require more overhead when demand is high because there are more connections open to the database at peak demand. These connections persist until idled out of the pool. If the maximum value is smaller, longer wait times or possible connection timeout errors during peak times can occur. Ensure that the database can support the maximum number of connections in the application server, in addition to any load that it has outside of the application server.

<b>Data type</b>	Integer
<b>Default</b>	10
<b>Range</b>	Any positive integer

### Connection Timeout:

Specifies the maximum number of seconds an application waits for a connection from the pool before timing out and throwing a `ConnectionWaitTimeoutException` to the application.

Setting this value to 0 disables the connection timeout.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	180
<b>Range</b>	Any non-negative integer

### Idle Timeout:

Specifies the maximum number of seconds that an idle (unallocated) connection can remain in the pool before being removed to free resources.

Connections need to idle out of the pool because keeping connections open to the database can cause database memory problems. However, not all connections are idled out of the pool, even if they are older than the Idle Timeout setting. A connection is not idled if removing the connection would cause the pool to shrink below its minimum size. Setting this value to 0 disables the idle timeout.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	1800
<b>Range</b>	Any non-negative integer

### Orphan Timeout:

Specifies the maximum number of seconds that an application can hold a connection without using it before the connection returns to the pool

If there is no activity on an allocated connection for longer than the Orphan Timeout setting, the connection is marked for orphaning. After another Orphan Timeout number of seconds, if the connection still has no activity, the connection returns to the pool. If the application tries to use the connection again, it is thrown a `StaleConnectionException`. Connections that are enlisted in a transaction are not orphaned. Setting this value to 0 disables the orphan timeout.

<b>Data type</b>	Integer
<b>Units</b>	Seconds
<b>Default</b>	1800
<b>Range</b>	Any non-negative integer

#### **Statement Cache Size:**

Specifies the number of cached prepared statements to keep per connection.

The largest value you would need to set your cache size to if you do not want any cache discards is determined as follows: for each application that uses this data source on a particular server, add up the number of unique prepared statements (as determined by the `sql` string, concurrency, and the scroll type). This is the maximum number of possible prepared statements that can be cached on a given connection over the life of the server. Setting the cache size to this value means you never have cache discards. This provides better performance. However, because of potential resource limitations, this might not always be possible.

<b>Data type</b>	Integer
<b>Default</b>	10
<b>Range</b>	Any non-negative integer

#### **Auto Connection Cleanup:**

Specifies whether or not the connection pooling software automatically closes connections from this data source at the end of a transaction.

The default is *false*, which indicates that when a transaction completes, WebSphere Application Server closes the connection and returns it to the pool. Any use of the connection after the transaction has ended results in a `StaleConnectionException` because the connection is closed and has returned to the pool. This mechanism ensures that connections are not held indefinitely by the application. If the value is set to *true*, the connection is not returned to the pool at the end of a transaction. In this case, the application must return the connection to the pool by calling `close()`. If the application does not close the connection, the pool can run out of connections for other applications to use.

<b>Data type</b>	Check box
<b>Default</b>	False (clear)

### **Configuring connection factories for resource adapters within applications**

1. Click **Applications**.
2. Click **Install New Application**.

3. Browse to find the appropriate EAR file, which contains an RAR file.
4. Click **Next**.
5. Select **resource ref mapping to a J2C Connection Factory**, then click **Next**.
6. After the application installs, click **Applications**.
7. Select the application just installed.
8. Click **Connector Modules** under Related Items.
9. Select an RAR file name on the Connector Modules page.
10. Click **Resource Adapter** under Additional Properties.
11. Click **J2C Connection Factories** under Additional Properties.
12. Click **New**.
13. Specify General Properties.
14. Select the authentication preference.
15. Select aliases for **component-managed authentication**, **container-managed authentication**, or both. If none are available, or you want to define a different one, click **Apply > J2C Authentication Data Entries** under Related Items.
  - a. Click **J2C Auth Data Entries** under Related Items.
  - b. Click **New**.
  - c. Specify General Properties.
  - d. Click **OK**.
16. Click **OK**.
17. Click the J2C connection factory you just created.
18. Click **Connection Pool** under Additional Properties .
19. Change any values desired by clicking on the property name.
20. Click **OK**.
21. Click **Custom Properties** under Additional Properties.
22. Click any property name to change its value. Note that **UserName** and **Password** if present, are overridden by the **component-managed authentication** alias you specified in a previous step.
23. Click **Save**.

### **J2C Connection Factories collection**

Use this page to select a connection factory, which represents one set of connection configuration values.

Application components such as enterprise beans have resource reference descriptors that refer to the connection factory, not the resource adapter. The connection factory is really a configuration properties list holder. In addition to the arbitrary set of configuration properties defined by the vendor of the resource adapter, there are several standard configuration properties that apply to the connection factory. These standard properties are used by the Java 2 Connectors

connection pool manager in the application server run time and are not known by the vendor supplied resource adapter code.

To view this administrative console page, click **Resources > Resource Adapters > resource\_adapter > J2C Connection Factories**.

### Scope:

Specifies the level to which this resource definition is visible -- the cell, node, or server level.

Resources such as JDBC Providers, Namespace bindings, or shared libraries can be defined at multiple scopes, with resources defined at more specific scopes overriding duplicates which are defined at more general scopes.

Note that no matter what the scope of a defined resource, the resource’s properties only apply at an individual server level. For example, if you define the scope of a data source at the Cell level, all users in that Cell can look up and use that data source, which is unique within that Cell. However, resource property settings are local to each server in the Cell. For example, if you define *max connections* to 10, then each server in that Cell can have 10 connections.

**Cell** The most general scope. Resources defined at the Cell scope are visible from all Nodes and servers, unless they are overridden. To view resources defined in the cell scope, do not specify a server or a node name in the scope selection form.

**Node** The default scope for most resource types. Resources defined at the Node scope override any duplicates defined at the Cell scope and are visible to all servers on the same node, unless they are overridden at a server scope on that node. To view resources defined in a node scope, do not specify a server, but select a node name in the scope selection form.

**Server** The most specific scope for defining resources. Resources defined at the Server scope override any duplicate resource definitions defined at the Cell scope or parent Node scope and are visible only to a specific server. To view resources defined in a server scope, specify a server name as well as a node name in the scope selection form.

When resources are created, they are always created into the current scope selected in the panel. To view resources in other scopes, specify a different node or server in the scope selection form.

**Data type** String

*Name:*

Specifies a list of connection factory display names.

**Data type** String

*JNDI Name:*

Specifies the JNDI name of this connection factory.

For example, the name could be *eis/myECIConnection*.

After you set this value, save it and restart the server. You can see this string when you run *dumpNameSpace*.

**Data type** String  
**Default** *eis/display name*

*Description:*

Specifies a text description of this connection factory.

**Data type** String

*Category:*

Specifies a string that you can use to classify or group this connection factory.

**Data type** String

*Authentication Preference:*

Specifies the authentication mechanisms defined for this connection factory.

This setting specifies which of the authentication mechanisms defined for the corresponding resource adapter applies to this connection factory. Common values, depending on the capabilities of the resource adapter, are: *KERBEROS*, *BASIC\_PASSWORD*, and *None*.

If *None* is chosen, the application component is expected to manage authentication (<res-auth>Application</res-auth>). In this case, the user ID and password are taken from one of the following:

- The component-managed authentication alias
- UserName, Password Custom Properties
- Strings passed on the getConnection method

For example, if two authentication mechanism entries are defined for a resource adapter in the *ra.xml* document:

- <authentication-mechanism-type>BasicPassword</authentication-mechanism-type>
- <authentication-mechanism-type>Kerbv5</authentication-mechanism-type>

the authentication preference specifies the mechanism to use for container-managed authentication. An exception is thrown during server startup if

a mechanism that is not supported by the resource adapter is selected.

<b>Data type</b>	Pick-list
<b>Default</b>	BASIC_PASSWORD

*Component-managed Authentication Alias:*

Specifies authentication data for component-managed signon to the resource.

### **SecurityJAAS ConfigurationJ2C Authentication Data**

To define a new alias not already appearing in the pick list:

- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.
- Select the alias.

<b>Data type</b>	Pick-list
------------------	-----------

*Container-managed Authentication Alias:*

Specifies authentication data (a string path converted to userid and password) for container-managed signon to the resource.

### **SecurityJAAS ConfigurationJ2C Authentication Data**

To define a new alias not already appearing in the pick list:

- Click **Apply** to expose Related Items.
- Click **J2C Authentication Data Entries**.
- Define an alias.
- Click the connection factory name at the top of the *J2C Authentication Data Entries* page to return to the connection factory page.
- Select the alias.

<b>Data type</b>	Pick-list
------------------	-----------

*Mapping-Configuration Alias:*

Allows users to select from the **Security > JAAS Configuration > Application Logins Configuration** list.

The **DefaultPrincipalMapping** JAAS configuration maps the authentication alias to the userid and password. You may define and use other mapping configurations.

<b>Data type</b>	Pick-list
------------------	-----------

### **Connection factory JNDI name tips**

Distributed computing environments often employ naming and directory services to obtain shared components and resources. Naming and directory services associate names with locations, services, information, and resources.

Naming services provide name-to-object mappings. Directory services provide information on objects and the search tools required to locate those objects. There are many naming and directory service implementations, and the interfaces to them vary.

Java Naming and Directory Interface (JNDI) provides a common interface that is used to access the various naming and directory services. After you have set this value, saved it, and restarted the server, you should be able to see this string when you run *dumpnamespace*.

For WebSphere Application Server specifically, when you create a data source the default JNDI name is set to *jdbc/data\_source\_name*. When you create a connection factory, its default name is *eis/j2c\_connection\_factory\_name*. You can, of course, override these values by specifying your own.

In addition, if you click the checkbox *Use this data source for container managed persistence (CMP)* when you create the data source, another reference is created with the name of *eis/jndi\_name\_of\_datasource\_CMP*. For example, if a data source has a JNDI name of *jdbc/myDataSource*, the CMP JNDI name is *eis/jdbc/myDataSource\_CMP*. This name is used internally by CMP and is provided simply for informational purposes.

When creating a connection factory or data source, a JNDI name is given by which the connection factory or data source can be looked up by a component. Generally an "indirect" name with the *java:comp/env* prefix should be used. This makes any resource-reference data associated with the application available to the connection management runtime, to better manage resources based on the *res-auth*, *res-isolation-level*, *res-sharing-scope*, and *res-resolution-control* settings.

While the use of a direct JNDI name is supported, such use results in default values of these resource-ref data. You will see an informational message logged such as this:

```
J2CA0122I: Resource reference abc/myCF could not be located, so default values of the following are
    res-auth: 1 (APPLICATION)
    res-isolation-level: 0 (TRANSACTION NONE)
    res-sharing-scope: true (SHAREABLE)
    res-resolution-control: 999 (undefined)
```

#### **Related concepts**

"Connection factory" on page 160

"Data sources" on page 164

## **Security of lookups with component managed authentication**

External Java clients (stand alone clients or servers from other cells) with Java Naming and Directory Interface (JNDI) access can look up a Java 2 Connector (J2C) resource such as a data source or Java Message Service (JMS) queue. However, they are not permitted to take advantage of the component managed *authentication alias* defined on the resource. This alias is a default value used when the *user* and *password* are not supplied on the *getConnection* call. Therefore, if an external client needs to get a connection, it must assume responsibility for the authentication data. It can either pass the *user* and *password* on the *getConnection* call, or it can use the no-argument *getConnection* call and define the alias with the corresponding *user* and *password* in a file on each system on which the client is expected to run.

Any client running in the WebSphere Application Server process (such as a Servlet or an enterprise bean) within the same cell that can look up a resource in the JNDI

namespace can obtain connections without providing authentication data. It is important to note that J2C authentication alias is per **cell**. An enterprise bean or Servlet in one application server cannot look up a resource in another server process which is in a different cell, because the alias would not be resolved.

## Passing user and password on the getConnection call

If the *user* and *password* are supplied on the *getConnection* call by a client running outside the WebSphere Application Server process, the connection factory or datasource looked up for obtaining connections must not have a component managed authentication alias defined on it.

Make sure the connection factory or datasource does not have a component managed authentication alias defined on it. See Configuring Java 2 Connector connection factories in the administrative console for details.

## Using the no-argument getConnection() call

If a client running outside the WebSphere Application Server process does not pass the *user* and *password* on the *getConnection* call, you must define a text file on each system on which the client runs. This file, whose name is defined by the system property *WAS\_AuthDataFile*, has records of the form:

```
alias1,user1,pw1
```

For each unique component managed *authentication alias* defined on a connection factory or datasource and used by the remote client, you must define the alias and corresponding *user* and *password* to match the definition of the alias in the WebSphere Application Server.

To create the remote client text file:

1. Run `%WAS_HOME%\bin\EncAuthDataFile.bat` to encode the password as follows: `EncAuthDataFile c:\client0.txt c:\client1.txt` Be sure to fully qualify the filenames. The file `client1.txt` for the above alias, user, and password should now look like this:

```
alias1,user1,{xor}Lyhu
```

2. You must have the client specify the location of the text file in the system property *WAS\_AuthDataFile*. This is done on the *launchClient* invocation by passing the following, for example:

```
%WAS_HOME%\bin\launchClient.bat myApp.ear -CCDWAS_AuthDataFile=c:\client1.txt
```

## Disabling lookup security

By default, all lookups are secure as described in Security of lookups with component managed authentication.

Although it is **not recommended**, it is possible to turn off the secure mode for a particular datasource or connection factory.

Edit `%WAS_HOME%\properties\j2c.properties` (or `$WAS_HOME/properties/j2c.properties` on UNIX platforms).

Change this:

```
<!-- The security-properties are in a comment block. Uncomment to use -->
<!--
  <security-properties connectionFactoryJNDIName="myDataSource">
    <secureMode>>false</secureMode>
  </security-properties>
-->
```

to this, for example:

```
<!-- The security-properties are in a comment block. Uncomment to use -->
```

```
<security-properties connectionFactoryJNDIName="myDataSource">  
  <secureMode>false</secureMode>  
</security-properties>
```

Where "myDataSource" is the JNDI name of the datasource or connection factory you want to run unsecure.

## Configuring data access for application clients

Configuring data access for application clients involves specifying the resource reference and associated database information required for data access. This specification is done as part of the assembly and deployment steps for the application client.

There are two essential tools needed to configure data sources used by J2EE Application Clients: the Application Assembly Tool (AAT) for defining the resource reference in the deployment descriptor, and the Application Client Resource Configuration Tool (ACRCT) for defining the connection to the database in the client deployment environment.

Data access from an application client uses the JDBC drive connection functions directly from the client side. It does not take advantage of the additional pooling support available in the WebSphere Application Server run time. Configuring data access for an application client does not require configuration of a JDBC provider and data source on the WebSphere Application Server server machine.

If you want to take advantage of the pooling and additional database functions provided by WebSphere Application Server, it is recommended that your client application utilize an enterprise bean running on the server side to perform data access.

### Defining an application client resource reference in the Application Assembly Tool

1. Assemble your application client module as described in *Assembling Application Client Modules*. When you reach the step for creating a resource reference, continue with these steps.
2. Create a new resource reference.
3. Do the following on the **New Resource Reference General Tab**:
  - a. Enter the **Name** of this resource reference. The WebSphere Application client run time uses this name for two purposes: to bind the object into the *java:comp/env* portion of the JNDI namespace, and to find client specific configuration information. If the code for the application client performs a lookup for *java:comp/env/jdbc/myDB*, the Name of the resource reference should be *jdbc/myDB*.
  - b. Use the pull-down in the **Type** field and select *javax.sql.DataSource* for JDBC connections.
  - c. Set the **authentication** field to *Application* if your client application intends to provide authentication information. If the WebSphere Application Client run time provides the authentication information (as configured by the Application Client Resource Configuration tool), then set this field to *Container*.

- d. Ignore the **sharing scope** setting, it is unused in an application client resource reference. All WebSphere Application Client resources are currently unsharable.
4. Ignore the **JNDI name** field on the *Binding Tab*. It is not used in an application client resource reference. The required information is provided in the ACRCT.

Deploying application clients on workstation platforms

## Client configuration with the ACRCT

There are two client resources for you to configure in the Application Client Resource Configuration Tool (ACRCT) to enable data access from an application client: a data source provider and a data source.

1. Configure a new data source provider as described in Configuring new data source providers. This provider describes the JDBC database implementation for your client application.
2. Enter the following information on the General Tab:
  - a. A **name** for this data source provider.
  - b. A **description** (this is optional).
  - c. The **classpath** to the data source provider implementation classes or JAR files. This is optional if the implementation classes or JAR files are already in the classpath configuration of the client.
  - d. The name of the **implementation class**. For example, for DB2 this value is `COM.ibm.db2.jdbc.DB2DataSource`. Remember this class must implement the `javax.sql.DataSource` class. The ACRCT does not verify this class and you receive an error when you run your client application if the class does not implement `javax.sql.DataSource`.

Use the *Custom Tab* to configure non-standard properties of the data source provider. This panel enables you to enter property-value pairs. During run time the *implementation classname* is created and any custom properties added on this panel are set on the newly created data source object using reflection. Any properties configured on this panel must have an appropriate set method on the data source class. For example, assume there is a property called `use2Phase` and its value should be 1. On the custom panel you enter the value `use2Phase` into the **name** column and the value `1` into the **value** column. The WebSphere Application Client run time then uses reflection to find a property on the data source class called, typically `setUse2Phase` and call that method passing the value of 1. See your database product documentation for valid properties on your data source implementation.

3. Click **OK**.
4. Configure a new data source as described in Configuring new data sources for application clients. This describes the client properties of the database your client application uses.
5. Enter the following information on the General Tab:

- a. A **Name**. This field is required and identifies a name for the Application Client Resource Configuration Tool to use. This name is **not** used by your client application program.
- b. A **description** (this field is optional).
- c. The **JNDI name**. This field is required and must match the value entered in the **Name** field of the General Tab of the Application Assembly Tool. In the example above, set this value to *jdbc/myDB*.
- d. The **Database Name** (this field is optional).
- e. Your *userid* in the **User** field. This field is optional.
- f. Your *password* in the **Password** field. This password does not display. This field is optional.
- g. Your password again to confirm in the **Re-Enter password** field. Note: The User and password fields are only used when the Authentication field on the General tab of the Application Assembly Tool is set to *Container*.

Notes The following WebSphere objects, which can be bound into the server namespace, are not supported on the client:

- Java 2 Connector (J2C) objects
- Connection manager objects

The WebSphere Application Server Client does not provide client database drivers. If your client application uses a database directly, rather than using an enterprise bean, you must provide the database drivers on the client machine. This action can involve contacting your database vendor to acquire client database driver code and licenses.

Instead of accessing the database directly, it is recommended that your client application use an enterprise bean. Accessing a database through an enterprise bean eliminates the need to have database drivers on the client machine because the database access is handled by the enterprise bean running on the WebSphere Application Server. Enterprise beans can also take advantage of the additional database functions provided by the WebSphere Application Server run time.

## Configuring Cloudscape Version 5.1

When you install WebSphere Application Server, Cloudscape Version 5.0 is installed by default. To install Cloudscape Version 5.1, run the `Cloudscape51.bat` file on Windows or `Cloudscape51.sh` file on UNIX platforms. You can find this file in the `WAS_HOME/cloudscape51` directory.

The installer replaces the Cloudscape Version 5.0 files with the files from the `WAS_HOME/cloudscape51` directory. It also replaces the Cloudscape `.jar` files, which are located in the `WAS_HOME/lib` directory, with Cloudscape Version 5.1 `.jar` files. The installer launches a WebSphere specific Cloudscape installer and defines some Websphere environment variables. The installer also creates an uninstaller, which can undo these changes. You cannot use any Version 4.0 data sources with Cloudscape. Cloudscape Version 5.0 is *deprecated* in WebSphere Application Server Version 5.0.2.

**Note:** After you install Cloudscape Version 5.1, you cannot run or have any Cloudscape Version 5.0 defined data sources. If you want to run Cloudscape Version 5.0, you must first uninstall Cloudscape Version 5.1, and then remove Cloudscape Version 5.1 data sources or change them to Cloudscape Version 5.0 data sources.

Cloudscape Version 5.1 provides the following two separate frameworks for running Cloudscape with WebSphere Application Server:

- **Embedded:** This framework is the same as the one for Cloudscape Version 5.0. To use this framework, define a Cloudscape JDBC provider. See the Cloudscape section in the minimum required settings article for more information.  
You must use the embedded framework if you are running XA. Cloudscape does not support XA on Network Server.
- **Network Server:** This framework is a new feature in Cloudscape Version 5.1, and removes these limitations that existed in earlier versions of Cloudscape:
  - inability to access a remote Cloudscape instance
  - only one JVM can boot up the same database instance

The following steps describe how to configure and run the Network Server framework.

1. Start the Network Server on the machine that hosts the database instance.  
To start the Network Server, run the **startNetworkServer.bat** file, which is located in the `WAS_HOME/cloudscape51/bin/networkserver` directory. On UNIX platforms, the file is **startNetworkServer.sh**.
2. Update the **db2j.properties** file, which is located in the `WAS_HOME/cloudscapeCommon` directory, if necessary.  
Cloudscape should work without any modifications to this file.  
Use the entries in the **db2j.properties** file to turn on trace, change the port number on which Network Server listens, and enable other functions of the Network Server framework. The default port number on which the Network Server listens is port 1527.  
For more information on this file, see the Cloudscape documentation at [www.ibm.com/software/data/cloudscape/pubs/collateral.html](http://www.ibm.com/software/data/cloudscape/pubs/collateral.html).
3. Define a Cloudscape Network Server using Universal JDBC driver to connect Cloudscape Version 5.1 with WebSphere Application Server using the Network Server framework.
4. Stop the Network Server by invoking the **stopNetworkServer.bat** file.  
You can find this file in the `WAS_HOME/cloudscape51/bin/networkserver` directory. On UNIX platforms, the file is **stopNetworkServer.sh**.
5. Review additional tools available in the Network Server framework.  
Find these tools in the `WAS_HOME/cloudscape51/bin/networkserver` directory.  
These tools are:
  - `sysinfo`
  - `cview`
  - `ijf`
  - `dropSYSIBM` Use this tool to drop the SYSIBM schema and its contents.
6. Create a SYSIBM schema.  
If you do not create the SYSIBM schema, you cannot see the datatypes when you create tables using the `cview` graphical user interface. The **db2j.drda.loadSYSIBM** property in the **db2j.properties** file controls whether the schema is created on the first connection to the database. The **db2j.drda.loadSYSIBM** property default value is true.  
**Note:** You cannot run a new version and an older version of Cloudscape in the same WebSphere Application Server environment. For datasources created under the old version of Cloudscape, you must change the classpath in these datasources to point to the new version of Cloudscape; otherwise, the jar files from both versions of Cloudscape are loaded in the same environment. This might result in undesirable consequences or exception situations.

## Cloudscape Version 5.1 post install instructions

After installing Cloudscape Version 5.1, you must complete the following steps before you can access the database.

1. Upgrade or migrate any existing database instances.
  - a. Backup an existing database.

You must complete a backup in case you have to access the previous version of Cloudscape. After you migrate a database, you cannot access your old database unless you perform a backup.
  - b. Migrate an existing database by doing the following:
    - Set the *connectionAttributes* custom property to **upgrade=true**.

The data source is located in the WebSphere Application Server administrative console under the JDBC providers.
    - If you are using cview, located in the WAS\_HOME/cloudscape51/bin/embedded directory, click **yes** when you see the *upgrade database* prompt.

**Note:** Ensure you migrate **defaultDB**, which is located in the WAS\_HOME/bin/DefaultDB directory.
2. Use the administrative console to add the following WebSphere Application Server environment variables, if they do not exist, or to modify the ones that do exist:
  - **DB2UNIVERSAL\_JDBC\_DRIVER\_PATH** Enter the location of the **db2jcc.jar** file as the value for this environment variable. For example, if your **db2jcc.jar** file is located in the java directory on the C drive, enter `c:\sql11ib\java`.

If you install DB2 and you run WebSphere Application Server with DB2, use the **db2jcc.jar** file from DB2.

If you run a Type 4 universal driver and DB2 is not installed, as for example a client machine, copy the **db2jcc.jar** file from the DB2 machine to the client machine, and set the value of this environment variable to the location of the file on the client machine.

If DB2 is not installed and you run Websphere Application Server with another database, as for example Oracle, Sybase or Informix, set the value of this variable to the location of the **db2jcc.jar** that ships with WebSphere Application Server, which is `WAS_HOME/universalDriverforCloudscape`.
3. Set or change the classpath definitions in any existing JDBC providers, which are defined to use Cloudscape. Cloudscape jar files will not load when WebSphere Application Server is active.

Use the WebSphere Application Server environment variable **#{CLOUDSCAPE51\_JDBC\_DRIVER\_PATH}\db2j.jar** to point to the new version of Cloudscape.

The **CLOUDSCAPE51\_JDBC\_DRIVER\_PATH** environment variable is defined in Websphere Application Server with a value of `WAS_HOME/cloudscape51/lib`.

## DB2 tuning parameters

DB2 has many parameters that you can configure to optimize database performance. For complete DB2 tuning information, refer to the DB2 UDB Administration Guide: Performance.

### DB2 logging

- **Description:** DB2 has corresponding log files for each database that provides services to administrators, including viewing database access and the number of connections. For systems with multiple hard disk drives, you can gain large performance improvements by setting the log files for each database on a different hard drive from the database files.
- **How to view or set:** At a DB2 command prompt, issue the command: **db2 update db cfg for [database\_name] using newlogpath [fully\_qualified\_path]**.
- **Default value:** Logs reside on the same disk as the database.
- **Recommended value:** Use a separate high-speed drive, preferably performance enhanced through RAID.

### DB2 configuration advisor

Located in the DB2 Control Center, this advisor calculates and displays recommended values for the DB2 buffer pool size, the database, and the database manager configuration parameters, with the option of applying these values. See more information about the advisor in the online help facility within the Control Center.

### Use TCP/IP sockets for DB2 on Linux

- **Description:** On Linux platforms, whether the DB2 server resides on a local machine with WebSphere Application Server or on a remote machine, configure the DB2 application databases to use TCP/IP sockets for communications with the database.
- **How to view or set:** Locate the directions for configuring DB2 on Linux in the WebSphere Application Server installation documentation for the various operating systems. This document specifies setting DB2COMM for TCP/IP and corresponding changes required in the etc/service file.
- **Default value:** Shared memory for local databases
- **Recommended value:** On Linux, change the specification for the DB2 application databases and any session databases from shared memory to TCP/IP sockets.

### Number of connections to DB2 - MaxAppls and MaxAgents

When configuring the data source settings for the databases, confirm the DB2 MaxAppls setting is greater than the maximum number of connections for the data source. If you are planning to establish clones, set the MaxAppls value as the maximum number of connections multiplied by the number of clones. The same relationship applies to the session manager number of connections. The MaxAppls setting must be equal to or greater than the number of connections. If you are

using the same database for session and data sources, set the MaxAppls value as the sum of the number of connection settings for the session manager and the data sources.

For example, MaxAppls = (# of connections set for data source + # of connections in session manager) x # of clones.

After calculating the MaxAppls settings for the WebSphere database and each of the application databases, verify that the MaxAgents setting for DB2 is equal to or greater than the sum of all of the MaxAppls values, for example, MaxAgents = sum of MaxAppls for all databases.

### DB2 buffpage

- **Description:** Improves database system performance. Buffpage is a database configuration parameter. A buffer pool is a memory storage area where database pages containing table rows or index entries are temporarily read and changed. Data is accessed much faster from memory than from disk.
- **How to view or set:** To view the current value of buffpage for database *x*, issue the DB2 command **get db cfg for x** and look for the value **BUFFPAGE**. To set **BUFFPAGE** to a value of *n*, issue the DB2 command **update db cfg for x** using **BUFFPAGE n** and set **NPAGES** to -1 as follows:

```
db2 <-- go to DB2 command mode, otherwise the following "select" does not work as is
connect to x <-- (where x is the particular DB2 database name)
select * from syscat.bufferpools
      (and note the name of the default, perhaps: IBMDEFAULTBP)
      (if NPAGES is already -1, there is no need to issue following command)
alter bufferpool IBMDEFAULTBP size -1
      (re-issue the above "select" and NPAGES now equals -1)
```

You can collect a snapshot of the database while the application is running and calculate the buffer pool hit ratio as follows:

1. Collect the snapshot:
    - a. Issue the **update monitor switches using bufferpool on** command.
    - b. Make sure that bufferpool monitoring is on by issuing the **get monitor switches** command.
    - c. Clear the monitor counters with the **reset monitor all** command.
  2. Run the application.
  3. Issue the **get snapshot for all databases** command before all applications disconnect from the database, otherwise statistics are lost.
  4. Issue the **update monitor switches using bufferpool off** command.
  5. Calculate the hit ratio by looking at the following database snapshot statistics:
    - Buffer pool data logical reads
    - Buffer pool data physical reads
    - Buffer pool index logical reads
    - Buffer pool index physical reads
- **Default value:** 250
  - **Recommended value:** Continue increasing the value until the snapshot shows a satisfactory hit rate.

The buffer pool hit ratio indicates the percentage of time that the database manager did not need to load a page from disk to service a page request. That is, the page was already in the buffer pool. The greater the buffer pool hit ratio, the lower the frequency of disk input and output. Calculate the buffer pool hit ratio as follows:

- P = buffer pool data physical reads + buffer pool index physical reads
- L = buffer pool data logical reads + buffer pool index logical reads

- Hit ratio =  $(1-(P/L)) * 100\%$

### DB2 query optimization level

- **Description:** Sets the amount of work and resources that DB2 puts into optimizing the access plan. When a database query is executed in DB2, various methods are used to calculate the most efficient access plan. The range is from zero to 9. An optimization level of 9 causes DB2 to devote a lot of time and all of its available statistics to optimizing the access plan.
- **How to view or set:** The optimization level is set on individual databases and can be set with either the command line or with the DB2 Control Center. Static SQL statements use the optimization level specified on the **prep** and **bind** commands. If the optimization level is not specified, DB2 uses the default optimization as specified by the `dft_queryopt` setting. Dynamic SQL statements use the optimization class specified by the current query optimization special register, which is set using the SQL Set statement. For example, the following statement sets the optimization class to 1:

```
Set current query optimization = 1
```

If the current query optimization register is not set, dynamic statements are bound using the default query optimization class.

- **Default value:** 5
- **Recommended value:** Set the optimization level for the needs of the application. Use high levels only when there are very complicated queries.

### DB2 reorgchk

- **Description:** Obtains the current statistics for data and rebinding. Use this parameter because SQL statement performance can deteriorate after many updates, deletes or inserts.
- **How to view or set:** Use the **DB2 reorgchk update statistics on table all** command to issue runstats on all user and system tables for the database to which you are currently connected. Rebind packages using the **bind** command. If runstats exists, issue the **db2 -v "select tname, nleaf, nlevels, stats\_time from sysibm.sysindexes"** command on DB2 CLP. If no runstats exist, nleaf and nlevels are -1, and stats\_time has an empty entry, for example "-". If runstats was previously done, the real-time stamp from completion of the runstats also displays under stats\_time. If you think the time shown for the previous runstats is too old, execute runstats again.
- **Default value:** None
- **Recommended value:** None

### DB2 MinCommit

- **Description:** Delays the writing of log records to a disk until a minimum number of commits is performed, reducing the database manager overhead associated with writing log records. For example, if MinCommit is set to 2, a second commit causes output to the transaction log for the first and second commits. The exception occurs when a one-second timeout forces the first commit to be output if a second commit does not occur within one second. In test applications, up to 90% of the disk input and output was related to the DB2 transaction log. Changing MinCommit from 1 to 2 reduced the results to 45%.

Adjust this parameter if the disk input and output wait is more than 5% and there is DB2 transaction log activity from multiple sources. When a lot of activity occurs from multiple sources, it is less likely that a single commit has to wait for another commit, or the one second timeout. Do not adjust this parameter if you

have an application with a single thread performing a series of commits because each commit can hit the one second delay.

- **How to view or set:**
  1. Issue the DB2 **get db cfg for xxxxxx** command, where *xxxxxx* is the name of the application database, to list database configuration parameters.
  2. Look for "Group commit count (MINCOMMIT)".
  3. Set a new value by issuing the DB2 **update db cfg for xxxxxx using mincommit n** command, where *xxxxxx* is the name of the application database and *n* is a value between 1 and 25 inclusive.

The new setting takes effect immediately.

The following are several metrics that are related to DB2 MinCommit:

- The disk input and output wait can be observed on AIX with the command **vmstat 5**. This shows statistics every 5 seconds. Look for the *wa* column under the CPU area.
  - The percentage of time a disk is active can be observed on AIX with the command **iostat 5**. This shows statistics every 5 seconds. Look for the *%tm\_act* column.
  - The DB2 **get snapshot for db on xxxxxx** command, where *xxxxxx* is the name of the application database, shows counters for log pages read and log pages written.
- **Default value:** 1.
  - **Recommended value:** 1 or 2, if the circumstance permits.

## Vendor-specific data sources minimum required settings

The following list contains descriptions for every JDBC provider supported in WebSphere Application Server Versions 5.0, 5.0.1, and 5.0.2. It also shows the supported data source classes and their required properties.

Specific fields are designated for the *user* and *password* properties. Inclusion of a property in the list does not imply that you should add it to the data source properties list. Rather, inclusion in the list means that a value is typically required for that field.

Use this list to find the provider information:

- DB2
- DB2 UDB for iSeries
- DB2 for z/OS
- Cloudscape
- Informix
- Sybase
- Oracle
- MS SQL Server

### DB2

#### 1. DB2 legacy CLI-based Type 2 JDBC Driver

The DB2 legacy CLI-based Type 2 JDBC Driver Provider is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers.

DB2 legacy CLI-based Type 2 JDBC Driver supports one phase data source:

**COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource**

Requires JDBC driver files: **db2java.zip** (Note: If you run SQLJ in DB2 Version 8, **db2jcc.jar** is also required.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2DataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

## 2. DB2 legacy CLI-based Type 2 JDBC Driver (XA)

The DB2 legacy CLI-based Type 2 JDBC Driver (XA) is built on top of DB2 CLI (Call Level Interface). It uses the DB2 CLI interface to communicate with DB2 UDB servers.

DB2 legacy CLI-based Type 2 JDBC Driver (XA) supports two phase data source:

**COM.ibm.db2.jdbc.DB2XADataSource**

Requires JDBC driver files: **db2java.zip** (Note: If you run SQLJ in DB2 Version 8, **db2jcc.jar** is also required.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2DataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

## 3. DB2 JDBC Provider -- *Deprecated*

This JDBC provider is the same as the DB2 Legacy CLI-based Type 2 JDBC Driver. This JDBC driver is *deprecated*. Use the DB2 Legacy CLI-based Type 2 JDBC Driver instead of this one.

DB2 JDBC Provider supports one phase data source:

**COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource**

Requires JDBC driver files: **db2java.zip** (Note: If you run SQLJ in DB2 Version 8, **db2jcc.jar** is also required.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2DataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

## 4. DB2 JDBC Provider (XA) -- *Deprecated*

This JDBC provider is the same as the DB2 Legacy CLI-based Type 2 JDBC Driver (XA). This JDBC driver is *deprecated*. Use the DB2 Legacy CLI-based Type 2 JDBC Driver (XA) instead of this one.

DB2 JDBC Provider (XA) supports two phase data source:

**COM.ibm.db2.jdbc.DB2XADataSource**

Requires JDBC driver files: **db2java.zip** (Note: If you run SQLJ in DB2 Version 8, **db2jcc.jar** is also required.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2DataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on DB2, visit the DB2 Web site at:  
<http://www.ibm.com/software/data/db2/>.

## DB2 UDB for iSeries

### 1. DB2 UDB for iSeries (Native - Version 5 Release 2 and later)

The iSeries Developer Kit for Java contains this Type 2 JDBC driver that is built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R2, or later releases.

DB2 UDB for iSeries (Native V5R2 and later) supports one phase data source:

**com.ibm.db2.jdbc.app.UDBConnectionPoolDataSource**

Requires JDBC driver files: **db2\_classes.jar**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

Requires properties:

- **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is \*LOCAL.

### 2. DB2 UDB for iSeries (Native XA - Version 5 Release 2 and later)

The iSeries Developer Kit for Java contains this XA-compliant Type 2 JDBC driver built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R2 or later releases.

DB2 UDB for iSeries (Native XA - V5R2 and later) supports two phase data source:

**com.ibm.db2.jdbc.app.UDBXADatasource**

Requires JDBC driver files: **db2\_classes.jar**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

Requires properties:

- **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is \*LOCAL.

### 3. DB2 UDB for iSeries (Native - Version 5 Release 1 and earlier)

The iSeries Developer Kit for Java contains this Type 2 JDBC driver that is built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R1, or earlier releases.

DB2 UDB for iSeries (Native V5R1 and earlier) supports one phase data source:

**com.ibm.db2.jdbc.app.DB2StdConnectionPoolDataSource**

Requires JDBC driver files: **db2\_classes.jar**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

Requires properties:

- **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is \*LOCAL.

The V5R1 and earlier JDBC drivers, although still supported, will receive no further enhancements. We recommend that you replace them with the V5R2 JDBC driver providers.

#### 4. **DB2 UDB for iSeries (Native XA - Version 5 Release 1 and earlier)**

The iSeries Developer Kit for Java contains this XA-compliant Type 2 JDBC driver built on top of the iSeries DB2 Call Level Interface (CLI) native libraries. Only use this driver for local DB2 connections on iSeries. It is not recommended for remote access. Use this driver for iSeries V5R1, or earlier releases.

DB2 UDB for iSeries (Native XA - V5R1 and earlier) supports two phase data source:

**`com.ibm.db2.jdbc.app.DB2StdXADataSource`**

Requires JDBC driver files: **`db2_classes.jar`**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

Requires properties:

- **databaseName** The name of the relational database to which the data source connections are established. This name must appear in the iSeries Relational Database Directory. The default is \*LOCAL.

The V5R1 and earlier JDBC drivers, although still supported, will receive no further enhancements. We recommend that you replace them with the V5R2 JDBC driver providers.

#### 5. **DB2 UDB for iSeries (Toolbox)**

This JDBC driver, also known as iSeries Toolbox driver for Java, is provided in the DB2 for iSeries database server. Use this driver for remote DB2 connections on iSeries. We recommend you use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

DB2 UDB for iSeries (Toolbox) supports one phase data source:

**`com.ibm.as400.access.AS400JDBCConnectionPoolDataSource`**

Requires JDBC driver files: **`jt400.jar`**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

Requires properties:

- **serverName** The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

#### 6. **DB2 UDB for iSeries (Toolbox XA)**

This XA compliant JDBC driver, also known as iSeries Toolbox XA compliant driver for Java, is provided in the DB2 for iSeries database server. Use this

driver for remote DB2 connections on iSeries. We recommend you use this driver instead of the IBM Developer Kit for Java JDBC Driver to access remote DB2 UDB for iSeries systems.

DB2 UDB for iSeries (Toolbox XA) supports two phase data source:

**com.ibm.as400.access.AS400JDBCXADataSource**

Requires JDBC driver files: **jt400.jar**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2AS400DataStoreHelper`

Requires properties:

- **serverName** The name of the server from which the data source obtains connections. Example: *myserver.mydomain.com*.

For more information on DB2 UDB for iSeries, visit the DB2 Web site at: <http://www.ibm.com/software/data/db2/>

## DB2 for z/OS

### 1. DB2 for z/OS JDBC Provider

The DB2 for z/OS JDBC Provider provides remote JDBC access to DB2 for z/OS. The DB2 for z/OS JDBC Provider provides remote JDBC access to DB2 on z/OS. This is the Legacy CLI-based JDBC driver. You cannot use this driver locally on DB2 z/OS. Use the DB2 for z/OS Local JDBC Provider (RRS) on local z/OS systems. Do not use this JDBC provider to create DB2 for z/OS data sources. To create DB2 for z/OS data sources, use the DB2 Legacy CLI-based Type 2 JDBC Driver instead of this one, and change the DataStoreHelper class to **com.ibm.websphere.rsadapter.DB2390DataStoreHelper**.

DB2 for z/OS JDBC provider supports one phase data source:

**COM.ibm.db2.jdbc.DB2ConnectionPoolDataSource**

Requires JDBC driver files: **db2java.zip**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2390DataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

### 2. DB2 for z/OS JDBC Provider (XA)

The DB2 for z/OS JDBC Provider provides remote XA-compliant JDBC access to DB2 for z/OS. The DB2 for z/OS JDBC Provider provides remote JDBC access to DB2 on z/OS. This is the Legacy CLI-based JDBC driver. You cannot use this driver locally on DB2 z/OS. Use the DB2 for z/OS Local JDBC Provider (RRS) on local z/OS systems. Do not use this JDBC provider to create DB2 for z/OS XA data sources. To create DB2 for z/OS XA data sources, use the DB2 Legacy CLI-based Type 2 JDBC Driver (XA) instead of this one, and change the DataStoreHelper class to

**com.ibm.websphere.rsadapter.DB2390DataStoreHelper**.

DB2 for z/OS JDBC (XA) provider supports two phase data source:

**COM.ibm.db2.jdbc.DB2XADataSource**

Requires JDBC driver files: **db2java.zip**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2390DataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

### 3. DB2 for z/OS Local JDBC Provider (RRS)

The DB2 for z/OS JDBC Provider provides local JDBC access to DB2 for z/OS. The DB2 for z/OS Local JDBC Provider provides local JDBC access to DB2 on z/OS. This provider uses the native z/OS Resource Recovery Services (RRS) transaction manager to handle two phase commit transactions.

DB2 for z/OS Local JDBC provider supports two phase data source:

**com.ibm.db2.jcc.DB2ConnectionPoolDataSource**

Requires JDBC driver files: **db2j2classes.zip**

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.DB2390LocalDataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on DB2 for z/OS, visit the DB2 Web site at:

<http://www.ibm.com/software/data/db2/>.

## Cloudscape

### 1. Cloudscape JDBC Provider

The Cloudscape JDBC Provider provides the JDBC access to the Cloudscape database. This Cloudscape JDBC driver used the embedded framework. You cannot use any Version 4.0 data sources with Cloudscape.

Cloudscape JDBC Provider supports one phase data source:

**com.ibm.db2j.jdbc.DB2jConnectionPoolDataSource**

Requires JDBC driver files: **db2j.jar**. (This file ships with WebSphere Application Server. If you are running Cloudscape Version 5.1, you can find this file in the `WAS_HOME/cloudscape51/lib` directory).

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

### 2. Cloudscape JDBC Provider (XA)

The Cloudscape JDBC Provider (XA) provides the XA-compliant JDBC access to the Cloudscape database. This Cloudscape JDBC driver uses the embedded framework. You cannot use any Version 4.0 data sources with Cloudscape.

Cloudscape JDBC Provider (XA) supports two phase data source:

**com.ibm.db2j.jdbc.DB2jXADataSource**

Requires JDBC driver files: **db2j.jar** (This file ships with WebSphere Application Server. If you are running Cloudscape Version 5.1, you can find this file in the WAS\_HOME/cloudscape51/lib directory).

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample* or *c:\sample*.

### 3. Cloudscape JDBC Provider Version 5.0 -- *Deprecated*

This JDBC driver provider is the same as Cloudscape JDBC Provider. This JDBC driver provider is *deprecated*. Use the Cloudscape JDBC Provider instead of this one. You cannot use any Version 4.0 data sources with Cloudscape.

Cloudscape JDBC Provider 5.0 supports one phase data source:

**`com.ibm.db2j.jdbc.DB2jConnectionPoolDataSource`**

Requires JDBC driver files: **db2j.jar**. (This file ships with WebSphere Application Server. You can find this file in the WAS\_HOME/cloudscape50/lib directory).

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

### 4. Cloudscape JDBC Provider 5.0 (XA) -- *Deprecated*

This JDBC driver provider is the same as the Cloudscape JDBC Provider (XA). This JDBC driver provider is *deprecated*. Use the Cloudscape JDBC Provider (XA) instead of this one. You cannot use any Version 4.0 data sources with Cloudscape.

Cloudscape JDBC Provider 5.0 (XA) supports two phase data source:

**`com.ibm.db2j.jdbc.DB2jXADataSource`**

Requires JDBC driver files: **db2j.jar** (This file ships with WebSphere Application Server. You can find this file in the WAS\_HOME/cloudscape50/lib directory).

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.CloudscapeDataStoreHelper`

Requires properties:

- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on IBM Cloudscape, visit the Cloudscape Web site at: <http://www.ibm.com/software/data/cloudscape/>

## Informix

### 1. Informix JDBC Driver

The Informix JDBC Driver is a Type 4 JDBC driver that provides JDBC access to the Informix database.

Informix JDBC Driver supports one phase data source:

**com.informix.jdbcx.IfxConnectionPoolDataSource**

Requires JDBC driver files:

**ifxjdbc.jar**  
**ifxjdbcx.jar**

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.InformixDataStoreHelper

Requires properties:

- **serverName** The name of the Informix instance on the server. Example: *ol\_myserver*.
- **portNumber** The port on which the instances listen. Example: *1526*.
- **ifxIFXHOST** The physical name of the database server. Example: *myserver.mydomain.com*.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **informixLockModeWait** Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: *2*.

## 2. Informix JDBC Driver (XA)

The Informix JDBC Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Informix database.

Informix JDBC Driver (XA) supports two phase data source:

**com.informix.jdbcx.IfxXADataSource**

Requires JDBC driver files:

**ifxjdbc.jar**  
**ifxjdbcx.jar**

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.InformixDataStoreHelper

Requires properties:

- **serverName** The name of the Informix instance on the server. Example: *ol\_myserver*.
- **portNumber** The port on which the instances listen. Example: *1526*.
- **ifxIFXHOST** The physical name of the database server. Example: *myserver.mydomain.com*.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **informixLockModeWait** Although not required, this property enables you to set the number of seconds that Informix software waits for a lock. By default, Informix code throws an exception if it cannot immediately acquire a lock. Example: *2*.

For more information on Informix, visit the Informix Web site at:  
<http://www.ibm.com/software/data/informix/>

## Sybase

### 1. Sybase JDBC Driver

The Sybase JDBC Driver is a Type 4 JDBC driver that provides JDBC access to the Sybase database.

Sybase JDBC Driver supports one phase data source:

**com.sybase.jdbc2.jdbc.SybConnectionPoolDataSource**

Requires JDBC driver files: **jconn2.jar**.

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.SybaseDataStoreHelper

Requires properties:

- **serverName** The name of the database server. Example:  
*myserver.mydomain.com*.
- **5.0.1 + databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.

## 2. Sybase JDBC Driver (XA)

The Sybase JDBC Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Sybase database.

Sybase JDBC Driver (XA) supports two phase data source:

**com.sybase.jdbc2.jdbc.SybXADataSource**

Requires JDBC driver files: **jconn2.jar**.

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.SybaseDataStoreHelper

Requires properties:

- **serverName** The name of the database server. Example:  
*myserver.mydomain.com*
- **5.0.1 + databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.

## 3. Sybase 12.0 JDBC Driver -- *Deprecated*

This JDBC Driver provider is the same as Sybase JDBC Driver. This JDBC driver is *deprecated*. Use Sybase JDBC Driver instead of this one.

Sybase 12.0 JDBC Driver supports one phase data source:

**com.sybase.jdbc2.jdbc.SybConnectionPoolDataSource**

Requires JDBC driver files: **jconn2.jar**.

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.SybaseDataStoreHelper

Requires properties:

- **serverName** The name of the database server. Example:  
*myserver.mydomain.com*
- **5.0.1 + databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.

## 4. Sybase 12.0 JDBC Driver (XA) -- *Deprecated*

This JDBC Driver provider is the same as Sybase JDBC Driver (XA). This JDBC driver is *deprecated*. Use the Sybase JDBC Driver (XA) instead of this one.

Sybase 12.0 JDBC Driver (XA) supports two phase data source:

**com.sybase.jdbc2.jdbc.SybXADataSource**

Requires JDBC driver files: **jconn2.jar**.

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.SybaseDataStoreHelper

Requires properties:

- **serverName** The name of the database server. Example:  
*myserver.mydomain.com*
- **5.0.1 + databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.
- **portNumber** The TCP/IP port number through which all communications to the server take place. Example: *4100*.

For more information on Sybase, visit the Sybase Web site at:

<http://www.sybase.com/>

## Oracle

### 1. Oracle JDBC Driver

The Oracle JDBC Driver provides JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

Oracle JDBC Driver supports one phase data source:

**oracle.jdbc.pool.OracleConnectionPoolDataSource**

Requires JDBC driver files: **classes12.zip**. (Note: If you require Oracle trace, use **classes12\_g.zip**.)

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.OracleDataStoreHelper

Requires properties:

- **URL** The URL that indicates the database from which the data source obtains connections. Example: *jdbc:oracle:thin:@myServer:1521:myDatabase*, where *myServer* is the server name, *1521* is the port it is using for communication, and *myDatabase* is the database name.

### 2. Oracle JDBC Driver (XA)

The Oracle JDBC Driver (XA) provides XA-compliant JDBC access to the Oracle database. This JDBC driver supports both Type 2 JDBC access and Type 4 JDBC access.

Oracle JDBC Driver (XA) supports two phase data source:

**oracle.jdbc.xa.client.OracleXADataSource**

Requires JDBC driver files: **classes12.zip**. (Note: If you require Oracle trace, use **classes12\_g.zip**.)

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.OracleDataStoreHelper

Requires properties:

- **URL** The URL that indicates the database from which the data source obtains connections. Example: `jdbc:oracle:thin:@myServer:1521:myDatabase`, where `myServer` is the server name, `1521` is the port it is using for communication, and `myDatabase` is the database name.

### 3. Oracle JDBC Thin Driver -- *Deprecated*

Both the **Oracle JDBC Thin Driver** and the **Oracle JDBC oci8 Driver** are deprecated. Use the **Oracle JDBC Driver** instead of these two.

Oracle JDBC Thin Driver is a Type 4 JDBC driver that provides JDBC access to the Oracle database. Oracle JDBC Thin Driver is *deprecated*. Use the Oracle JDBC Driver instead of this one.

Oracle JDBC Thin Driver supports one phase data source:

`oracle.jdbc.pool.OracleConnectionPoolDataSource`

Requires JDBC driver files: **classes12.zip**. (Note: If you require Oracle trace, use **classes12\_g.zip**.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.OracleDataStoreHelper`

Requires properties:

- **URL**

<b>type</b>	<code>java.lang.String</code>
<b>value</b>	<code>" "</code>
<b>description</b>	This is a required property. The URL that indicates the database from which the data source obtains connections. Example: <code>jdbc:oracle:thin:@localhost:1521:sample</code> for thin driver and <code>jdbc:oracle:oci8:@sample</code> for thick driver, where <code>localhost</code> is the server name, <code>1521</code> is the port it is using for communication, and <code>sample</code> is the database name.

### 4. Oracle JDBC Thin Driver (XA) -- *Deprecated*

Both the **Oracle JDBC Thin Driver (XA)** and the **Oracle JDBC oci8 Driver (XA)** are deprecated. Use the **Oracle JDBC Driver (XA)** instead of these two.

Oracle JDBC Thin Driver (XA) is a Type 4 JDBC driver that provides XA-compliant JDBC access to the Oracle database. Oracle JDBC Thin Driver (XA) is *deprecated*. Use the Oracle JDBC Driver (XA) instead of this one.

Oracle JDBC Thin Driver (XA) supports two phase data source:

`oracle.jdbc.xa.client.OracleXADataSource`

Requires JDBC driver files: **classes12.zip**. (Note: If you require Oracle trace, use **classes12\_g.zip**.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.OracleDataStoreHelper`

Requires properties:

- **URL**

<b>type</b>	<code>java.lang.String</code>
<b>value</b>	<code>" "</code>

**description**

This is a required property. The URL that indicates the database from which the data source obtains connections. Example: *jdbc:oracle:thin:@localhost:1521:sample* for thin driver and *jdbc:oracle:oci8:@sample* for thick driver, where *localhost* is the server name, *1521* is the port it is using for communication, and *sample* is the database name.

**5. Oracle JDBC oci8 Driver -- *Deprecated***

Both the **Oracle JDBC Thin Driver** and the **Oracle JDBC oci8 Driver** are deprecated. Use the **Oracle JDBC Driver** instead of these two.

Oracle JDBC oci8 Driver is a Type 2 JDBC driver that provides JDBC access to the Oracle database. Oracle JDBC oci8 Driver is *deprecated*. Use the Oracle JDBC Driver instead of this one.

Oracle JDBC oci8 Driver supports one phase data source:

**oracle.jdbc.pool.OracleConnectionPoolDataSource**

Requires JDBC driver files: **classes12.zip**. (Note: If you require Oracle trace, use **classes12\_g.zip**.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.OracleDataStoreHelper`

Requires properties:

- **URL**

**type**

*java.lang.String*

**value**

" "

**description**

This is a required property. The URL that indicates the database from which the data source obtains connections. Example: *jdbc:oracle:thin:@localhost:1521:sample* for thin driver and *jdbc:oracle:oci8:@sample* for thick driver, where *localhost* is the server name, *1521* is the port it is using for communication, and *sample* is the database name.

**6. Oracle JDBC oci8 Driver (XA) -- *Deprecated***

Both the **Oracle JDBC Thin Driver (XA)** and the **Oracle JDBC oci8 Driver (XA)** are deprecated. Use the **Oracle JDBC Driver (XA)** instead of these two.

Oracle JDBC oci8 Driver (XA) is a Type 2 JDBC driver that provides XA-compliant JDBC access to the Oracle database. Oracle JDBC oci8 Driver (XA) is *deprecated*. Use the Oracle JDBC Driver (XA) instead of this one.

Oracle JDBC oci8 Driver (XA) supports two phase data source:

**oracle.jdbc.xa.client.OracleXADataSource**

Requires JDBC driver files: **classes12.zip**. (Note: If you require Oracle trace, use **classes12\_g.zip**.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.OracleDataStoreHelper`

Requires properties:

- **URL**

<b>type</b>	<i>java.lang.String</i>
<b>value</b>	" "
<b>description</b>	This is a required property. The URL that indicates the database from which the data source obtains connections. Example: <i>jdbc:oracle:thin:@localhost:1521:sample</i> for thin driver and <i>jdbc:oracle:oci8:@sample</i> for thick driver, where <i>localhost</i> is the server name, <i>1521</i> is the port it is using for communication, and <i>sample</i> is the database name.

For more information on Oracle, visit the Oracle Web site at:  
<http://www.oracle.com/>

### MS SQL Server

#### 1. DataDirect ConnectJDBC type 4 driver for MS SQL Server

DataDirect ConnectJDBC type 4 driver for MS SQL Server is a Type 4 JDBC driver that provides JDBC access to the MS SQL Server database. Only use this provider for the ConnectJDBC driver purchased from DataDirect Technologies. Do not use it with the Connect JDBC driver embedded in WebSphere.

This JDBC provider supports this data source:

**com.ddtek.jdbcx.sqlserver.SQLServerDataSource**

Requires JDBC driver files:

**sqlserver.jar**,  
**base.jar** and **util.jar**

(The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file is not in the same directory as the other three jar files. Instead, it is located in the `../spy/` directory.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication.  
Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

#### 2. DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA)

DataDirect ConnectJDBC type 4 driver for MS SQL Server (XA) is a Type 4 JDBC driver which provides XA-compliant JDBC access to the MS SQL Server database. Only use this provider for the ConnectJDBC driver purchased from DataDirect Technologies. Do not use it with the Connect JDBC driver embedded in WebSphere.

This JDBC provider supports this data source:

**com.ddtek.jdbcx.sqlserver.SQLServerDataSource.**

Requires JDBC driver files:

**sqlserver.jar**,  
**base.jar** and **util.jar**.

(The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file is not in the same directory as the other three jar files. Instead, it is located in the `../spy/` directory.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication.  
Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on the DataDirect ConnectJDBC driver, visit the DataDirect Web site at: <http://www.datadirect-technologies.com/>

### 3. WebSphere embedded ConnectJDBC driver for MS SQL Server

WebSphere embedded ConnectJDBC driver for MS SQL Server is a Type 4 JDBC driver that provides JDBC access to the MS SQL Server database. This JDBC driver ships with WebSphere Application Server. Only use this provider with the Connect JDBC driver embedded in WebSphere; it cannot be used with a Connect JDBC driver purchased separately from DataDirect Technologies.

This JDBC provider supports this data source:

`com.ibm.websphere.jdbcx.sqlserver.SQLServerDataSource`.

Requires JDBC driver files:

**sqlserver.jar**  
**base.jar** and  
**util.jar**.

(The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file for the WebSphere embedded Connect JDBC driver ships with WebSphere Application Server. All the files are located in the `WAS_HOME/lib/` directory.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.WSConnectJDBCDataStoreHelper`

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication.  
Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

### 4. WebSphere embedded ConnectJDBC driver for MS SQL Server (XA)

WebSphere embedded ConnectJDBC driver for MS SQL Server (XA) is a Type 4 JDBC driver which provides XA-complaint JDBC access to the MS SQL Server database. This JDBC driver ships with WebSphere Application Server. Use this

provider with the Connect JDBC driver embedded in WebSphere. Do not use it with a Connect JDBC driver purchased separately from DataDirect Technologies.

This JDBC provider supports this data source:

**com.ibm.websphere.jdbcx.sqlserver.SQLServerDataSource.**

Requires JDBC driver files:

**sqlserver.jar**  
**base.jar** and  
**util.jar.**

(The **spy.jar** file is optional. You need this file to enable spy logging. The **spy.jar** file for the WebSphere embedded Connect JDBC driver ships with WebSphere Application Server. All the files are located in the WAS\_HOME/lib/ directory.)

Requires **DataStoreHelper** class:

com.ibm.websphere.rsadapter.WSConnectJDBCDataStoreHelper

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication.  
Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

To view the instructions for installing *Stored Procedures for JTA* (required when enabling two-phase commit) on the WebSphere CD, refer to the following FTP site:

How to install "Stored Procedures for JTA" from the WebSphere CD

You can download the latest patches and upgrades to the WebSphere embedded ConnectJDBC drivers from the following FTP site:

<ftp://ftp.software.ibm.com/software/websphere/info/tools/DataDirect/datadirect.htm>

#### 5. **DataDirect SequeLink type 3 JDBC driver for MS SQL Server**

DataDirect SequeLink type 3 JDBC driver for MS SQL Server is a Type 3 JDBC driver that provides JDBC access to MS SQL Server via SequeLink server. This JDBC driver provider supports both the SequeLink type 3 JDBC driver shipped with WebSphere Application Server and the SequeLink type 3 JDBC driver purchased from DataDirect.

This JDBC provider supports this data source:

**com.ddtek.jdbcx.sequelink.SequeLinkDataSource**

Requires JDBC driver files:

**sljc.jar** and  
**spy-sl53.jar**

(The JDBC driver shipped with WebSphere Application Server requires the **sljc.jar** and the **spy-sl53.jar** files. The JDBC driver purchased from DataDirect requires the **sljc.jar** and the **spy.jar** files. The **spy.jar** and **spy-sl35.jar** files are optional. You need these files to enable spy logging.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.SequeLinkDataStoreHelper`

Requires properties:

- **serverName** The name of the server in which SequeLink Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that SequeLink Server uses for communication. By default, SequeLink Server uses port 19996.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

#### 6. DataDirect SequeLink type 3 JDBC driver for MS SQL Server (XA)

DataDirect SequeLink type 3 JDBC driver for MS SQL Server (XA) is a Type 3 JDBC driver which provides XA-compliant JDBC access to MS SQL Server via the SequeLink server. This JDBC driver provider supports both the SequeLink type 3 JDBC driver shipped with WebSphere Application Server and the SequeLink type 3 JDBC driver purchased from DataDirect.

This JDBC provider supports this data source:

`com.ddtek.jdbcx.sequelink.SequeLinkDataSource`

Requires JDBC driver files:

`sljc.jar` and  
`spy-s153.jar`

(The JDBC driver shipped with WebSphere Application Server requires the `sljc.jar` and the `spy-s153.jar` files. The JDBC driver purchased from DataDirect requires the `sljc.jar` and the `spy.jar` files. The `spy.jar` and `spy-s135.jar` files are optional. You need these files to enable spy logging.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.SequeLinkDataStoreHelper`

Requires properties:

- **serverName** The name of the server in which SequeLink Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that SequeLink Server uses for communication. By default, SequeLink Server uses port 19996.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

To view instructions for installing SequeLink Server from the WebSphere CD, refer to this FTP site:

How to install SequeLink Server from the WebSphere CD

Only install the SequeLink server from the WebSphere CD if you are using the SequeLink JDBC driver embedded in WebSphere. Otherwise, install the SequeLink server purchased from DataDirect Technologies.

You can download the latest patches and upgrades to the WebSphere embedded SequeLink type 3 JDBC drivers from the following FTP site:

<ftp://ftp.software.ibm.com/software/websphere/info/tools/DataDirect/datadirect.htm>

For more information on the DataDirect SequeLink type 3 JDBC driver, visit the DataDirect Web site at:

<http://www.datadirect-technologies.com/>

#### 7. **5.0.1 +** Microsoft JDBC driver for MSSQLServer 2000

Microsoft JDBC driver for MSSQLServer 2000 is a type 4 JDBC driver that provides JDBC access to the MS SQL Server database.

This JDBC provider supports this data source:

**com.microsoft.jdbcx.sqlserver.SQLServerDataSource**

Requires JDBC driver files:

**mssqlserver.jar**,  
**msbase.jar** and **msutil.jar**

(The **spy.jar** file is optional. You need it to enable spy logging. However, Microsoft does not ship the **spy.jar** file. Contact Microsoft about this issue.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication.  
Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

#### 8. **5.0.1 + Microsoft JDBC driver for MSSQLServer 2000 (XA)**

Microsoft JDBC driver for MSSQLServer 2000 (XA) is a type 4 JDBC driver that provides XA-complaint JDBC access to the MS SQL Server database.

This JDBC provider supports this data source:

**com.microsoft.jdbcx.sqlserver.SQLServerDataSource**

Requires JDBC driver files:

**mssqlserver.jar**,  
**msbase.jar** and **msutil.jar**

(The **spy.jar** file is optional. You need it to enable spy logging. However, Microsoft does not ship the **spy.jar** file. Contact Microsoft about this issue.)

Requires **DataStoreHelper** class:

`com.ibm.websphere.rsadapter.ConnectJDBCDataStoreHelper`

Requires properties:

- **serverName** The name of the server in which MS SQL Server resides.  
Example: *myserver.mydomain.com*
- **portNumber** The TCP/IP port that MS SQL Server uses for communication.  
Port 1433 is the default.
- **databaseName** The name of the database from which the data source obtains connections. Example: *Sample*.

For more information on the Microsoft JDBC driver, visit the Microsoft Web site at:  
<http://www.microsoft.com/sql>

## Connector Modules collection

Use this page to view connector module settings.

An instance of ConnectorModuleDeployment is created for every connector module (RAR) in the application.

To view this administrative console page, click **Applications >Enterprise Applications > application > Connector Modules**.

### Related reference

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console page features

This topic provides information about the basic elements of an administrative console page, such as the various tabs one can expect to encounter.

Administrative console filter settings

Use the Filter settings to specify how to filter entries shown in a collection view.

Administrative console preference settings

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

### URI

Specifies the logical path to the resource that will be serviced by the product.

**Data type** String

### Name

Specifies the display name of the connector module.

**Data type** String

## Connector module settings

Use this page to view connector modules.

To view this administrative console page, click **Applications > Enterprise Applications > application > Connector Modules > connector\_module**.

### Related reference

Administrative console buttons

The following button choices are available on various pages of the administrative console, depending on which product features you have enabled.

Administrative console filter settings

Use the Filter settings to specify how to filter entries shown in a collection view.

Administrative console preference settings

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

**Uri:**

Specifies the logical path to the resource that is serviced by WebSphere Application Server.

**Data type** String

**Name:**

Specifies the display name of the connector module.

**Data type** String

**altDD:**

Specifies the alternate DD of the connector module.

The alternate DD URI for a given module.

**Data type** String

**Starting weight:**

Specifies the startup priority of the connector module over others.

When your application contains multiple modules, the starting weight you specify determines this module's startup priority over other modules during server startup. Modules with lower startup order are started first.

**Data type** String

## Chapter 4. Using mail

Using JavaMail API, a code segment can be embedded in any Java 2 Enterprise Edition (J2EE) application component, such as an EJB or a servlet, allowing the application to send a message and save a copy of the mail to the Sent folder.

The following is a code sample that you would embed in a J2EE application:

```
javax.naming.InitialContext ctx = new javax.naming.InitialContext();

    javax.mail.Session mail_session = (javax.mail.Session) ctx.lookup("java:comp/env/mail/MailSession3");
    MimeMessage msg = new MimeMessage(mail_session);

    msg.setRecipients(Message.RecipientType.TO, InternetAddress.parse("bob@coldmail.net"));

    msg.setFrom(new InternetAddress("alice@mail.eedge.com"));

    msg.setSubject("Important message from eEdge.com");

    msg.setText(msg_text);

    Transport.send(msg);

    Store store = mail_session.getStore();

    store.connect();

    Folder f = store.getFolder("Sent");

    if (!f.exists()) f.create(Folder.HOLDS_MESSAGES);

    f.appendMessages(new Message[] {msg});
```

J2EE applications can use JavaMail APIs by looking up references to logically named mail connection factories through the `java:comp/env/mail` subcontext declared in the application deployment descriptor and mapped to installation specific mail session resources. As in the case of other J2EE resources, this can be done in order to eliminate the need for the application to hard code references to external resources.

Locate a resource through Java Naming and Directory Interface (JNDI). The J2EE specification considers a mail session instance as a resource, or a factory from which mail transport and store connections can be obtained. You should never *hardcode* mail sessions, namely fill up a Properties object, then use it to new up a `javax.mail.Session` object. Instead, you must follow the J2EE programming model of configuring resources through the system facilities and then locating them through JNDI lookups.

In the sample code above, the line `javax.mail.Session mail_session = (javax.mail.Session) ctx.lookup("java:comp/env/mail/MailSession3");` is an example of not hard coding a mail session and using a resource name located through JNDI. You can consider the lookup name `mail/MailSession3`, as a *soft link* to the real resource.

- Define resource references while assembling your application. You must define a resource reference for the mail resource in the deployment descriptor of the component, because a mail session is referenced

in the JNDI lookup. Typically, you can use the Application Assembly Tool (AAT) shipped with WebSphere Application Server. To learn more about using AAT see the InfoCenter article Starting the Application Assembly Tool.

When you create this reference, be sure that the name of the reference matches the name used in the code. For example, the code above uses `java:comp/env/mail/MailSession3` in its lookup, therefore the name of this reference must be `mail/Session3` and the type of the resource must be `javax.mail.Session`. After being defined, the deployment descriptor contains the following entry for the mail resource reference:

```
<resource-reference>
<description>description</description>
<res-ref-name>mail/MailSession3</res-ref-name>
<res-type>javax.mail.Session</res-type>
<res-auth>Container</res-auth>
```

- Configure mail providers and sessions.

The sample code references a mail resource, the deployment descriptor declares the reference, but the resource itself does not exist yet. Now you need to configure the mail resource that is referenced by your application component. Notice that the mail session you configure must have both its transport and mail access portions defined; the former required because the code is sending a message, the latter because it also saves a copy to the local mail store. When you configure the mail session, you will be asked to specify a JNDI name. This is an important name which you will require when you install your application and link up the resource references in your application with the real resources that you have configured.

- Install your application. You can install your application using either the administrative console or the scripting tool. One important step in the install process is that the system will go through all resource references, among other things, and expect you to supply a JNDI name for each of them. This is not an arbitrary JNDI name but the JNDI name given to a particular, configured resource which is the target of the reference.
- Manage existing mail providers and sessions.

You can update and remove mail providers and sessions.

To update mail providers and sessions:

1. Open the administrative console.
2. Click **Resources** > **Mail Providers** in the console navigation tree. Then, click **Mail Provider** > *mail\_provider* > **Mail Session**.
3. Click the *mail\_provider* or *mail\_session* that you want to modify. To remove a mail provider or mail session, click **Remove** after making your selection.
4. Click **Apply** or **OK**.
5. Save the configuration.

If your application has a client, you can update mail providers and mail sessions using the Application Client Resource Configuration Tool (ACRCT).

## Configuring mail providers and sessions

WebSphere Application Server includes a default mail provider called *built-in* provider. If you use the default mail provider you only have to configure the mail session, which is the last step in this task. To use the customized mail provider you must first create the mail provider and session:

1. Open the administrative console.
2. Click **Resources > Mail Providers**.
3. Create the mail provider.
  - a. Click **New**.
  - b. Type the name of the mail provider in the **Name** field.
  - c. Click **Apply** or **OK**.
4. Define the protocol provider for the mail provider.
  - a. Click *mail\_provider*.
  - b. Click **Protocol Providers**.
  - c. Click **New**.
  - d. Type the protocol name in the **Protocol** field.
  - e. Type the classname in the **Classname** field.
  - f. Click **Apply** or **OK**.

Ensure that every mail session is defined under a parent mail provider. Select a mail provider first and then create your new mail session.

5. Create the **mail session**.
  - a. Click *mail\_provider*.
  - b. Click **Mail Sessions**.
  - c. Click **New**.
  - d. Type the mail session name in the **Name** field.
  - e. Type the JNDI name in the **JNDI Name** field.
  - f. Click **Apply** or **OK**.
6. Configure the mail session.
  - a. Click *mail\_provider*.
  - b. Click **Mail Sessions**.
  - c. Click *mail\_session*.
  - d. Make changes to appropriate fields.
  - e. Click **Apply** or **OK**.

If your application has a client you can configure JavaMail providers and sessions using the Application Client Resource Configuration Tool (ACRCT).

Administrative console filter settings

Use the Filter settings to specify how to filter entries shown in a collection view.

Administrative console preference settings

Use the Preference settings to specify how you would like information to be displayed on an administrative console page.

### **Name**

Specifies the administrative name of the JavaMail session object.

### **JNDI Name**

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

This name provides the link between the platform binding information for resources defined in the client application deployment descriptor and the actual resources bound into JNDI by the platform.

### **Description**

Specifies an optional description for your administrative records.

### **Category**

Specifies an optional collection for classifying or grouping sessions.

## **Mail session settings**

Use this page to configure specific mail providers.

To view this administrative console page, click **Resources** > **Mail Providers** > *mail\_provider* > **Mail Sessions** > *mail\_session*.

### **Name**

Specifies the administrative name of the JavaMail session object.

### **JNDI Name**

Specifies the Java Naming and Directory Interface (JNDI) name for the resource, including any naming subcontexts.

This name provides the link between the platform binding information for resources defined in the client application deployment descriptor and the actual resources bound into JNDI by the platform.

### **Description**

Specifies an optional description for your administrative records.

### **Category**

Specifies an optional collection for classifying or grouping sessions.

### **Mail Transport Host**

Specifies the server accessed when sending mail.

### **Mail Transport Protocol**

Specifies the transport protocol used when sending mail.

### **Mail Transport User**

Specifies the user ID when the mail transport host requires authentication.

This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

### **Mail Transport Password**

Specifies the password when the mail transport host requires authentication. This setting is not generally used for most mail servers. Leave this field blank unless you use a mail server that requires a user ID and password.

### **Mail from**

Specifies the mail originator.

This value represents the Internet e-mail address that, by default, displays in the received message, as either the From or the Reply-To address. The recipient's reply comes to this address.

### **Mail Store Host**

Specifies the server accessed when receiving the mail.

This setting, combined with the mail store user ID and password, represents a valid mail account. For example, if the mail account is *john\_william@my.company.com* then the mail store host is *my.company.com*.

### **Mail Store Protocol**

Specifies the protocol used when receiving mail; it could be IMAP, POP3 or any store protocol for which the user has installed a provider.

### **Mail Store User**

Specifies the user ID for the given mail account.

For example, if the mail account is *john\_william@my.company.com* then the user is *john\_william*.

### **Mail Store Password**

Specifies the password for the given mail account .

For example, if the mail account is *john\_william@my.company.com* then enter the password for ID *john\_william*.

### **Debug**

Toggles debug mode on and off for this mail session.

---

## **JavaMail API**

The JavaMail APIs provide a platform and protocol-independent framework for building Java-based mail client applications.

WebSphere Application Server supports JavaMail, Version 1.2 and the JavaBeans Activation Framework (JAF) Version 1.0. In WebSphere Application Server, the JavaMail API is supported in all Web application components, namely:

- Servlets
- Java Server Pages (JSP) files
- Enterprise beans
- Application clients

The JavaMail APIs are generic for sending and reading mail. They require service providers, known in WebSphere Application Server as protocol providers, to interact with mail servers that run on pertaining protocols.

For example, Simple Mail Transfer Protocol (SMTP) is a popular transport protocol for sending mail. JavaMail applications can connect to an SMTP server and send mail through it by using this SMTP protocol provider.

In addition to service providers, the JavaMail API requires the Java Application Framework (JAF) to handle mail content that is not plain text, including Multipurpose Internet Mail Extensions (MIME), URL pages, and file attachments.

The JavaMail APIs, the JAF, the service providers and the protocols are shipped as part of WebSphere Application Server using the following Sun licensed packages:

- `mail.jar` - Contains the JavaMail APIs, and the SMTP, IMAP, and POP3 service providers.
- `activation.jar` - Contains the JavaBeans Activation Framework.

---

## Mail providers and mail sessions

A JavaMail service provider is a driver that supports JavaMail interaction with mail servers using a particular mail protocol. WebSphere Application Server includes service providers, also known as *protocol providers*, for mail protocols including Simple Mail Transfer Protocol (SMTP), Internet Message Access Protocol (IMAP), and Post Office Protocol 3 (POP3).

Mail provider encapsulates a collection of protocol providers. For example, WebSphere Application Server has a built-in mail provider that encompasses the three protocol providers: SMTP, IMAP and POP3. These protocol providers are installed as the default and suffice for most applications.

If you have a particular application that requires custom protocol providers, you must first follow the steps outlined in the "JavaMail API Design Specification, V1.2, Chapter 5 - The Mail Session" to install your own protocol providers. See the InfoCenter article, [Mail: Resources for learning](#), for a link to this documentation.

Mail sessions are represented by the `javax.mail.Session` class. A mail `Session` object authenticates users, and controls users' access to messaging systems.

To create platform-independent applications, use a resource factory reference to create a JavaMail session. A resource factory is an object that provides access to resources in the deployed environment of a program using the naming conventions defined by the Java Naming and Directory Interface (JNDI).

Ensure that every mail session is defined under a parent mail provider. Select a mail provider first and then create your new mail session.

## Mail migration tip

Specifications for Java Server Page(JSP) 1.2 changes the way the `EmailBean` class works with `Email.jsp`.

The specifications state that the JSP container creates a JSP page implementation class for each JSP page. The name of the JSP page implementation class is implementation dependent. The JSP page implementation object belongs to an implementation-dependent named package which can vary between one JSP and another, therefore minimal assumptions should be made. The unnamed package should not be used without explicit import of the class.

Following these specifications, you should place `EmailBean.class` in a package referred to it by the fully qualified `packageName` in `Email.jsp`. Otherwise, `Email.jsp` is unable to find `EmailBean.class`.

---

## JavaMail security permissions best practices

In many of its activities, the JavaMail API needs to access certain configuration files. The JavaMail and JavaBeans Activation Framework binary packages themselves already contain the necessary configuration files. However, JavaMail allows the user to define user-specific and installation-specific configuration files to meet special requirements.

The two locations where such configuration files can exist are `<user.home>` and `<java.home>/lib`. For example, if the JavaMail API needs to access a file named `mailcap` when sending a message, it first tries to access `<user.home>/mailcap`. If that attempt fails, either due to lack of security permission or a nonexistent file, the API continues to try `<java.home>/lib/mailcap`. If that attempt also fails, it will continue and try `META-INF/mailcap` in the classpath, which actually leads to the configuration files contained in the `mail.jar` and `activation.jar` files. WebSphere Application Server uses the general-purpose JavaMail configuration files contained in the `mail.jar` and `activation.jar` files and does not put any mail configuration files in `<user.home>` and `<java.home>/lib`. File read permission for both the `mail.jar` and `activation.jar` files is granted to all applications to ensure proper functioning of the JavaMail API, as shown in the following segment of the `app.policy` file:

```
grant codeBase "file:${application}" {
    // The following are required by Java mail
    permission java.io.FilePermission "${was.install.root}${java}${jre}${lib}${ext}${mail.jar}",
    permission java.io.FilePermission "${was.install.root}${java}${jre}${lib}${ext}${activation.
};
```

JavaMail code attempts to access configuration files at `<user.home>` and `<java.home>/lib` causing `AccessControlExceptions` to be thrown, since there is no file read permission granted for those two locations by default. This activity does not affect the proper functioning of the JavaMail API, but you might see a large amount of JavaMail-related security exceptions reported in the system log, which might swamp harmful errors that you are looking for. If this situation is a problem, consider adding two more permission lines to the permission block above. This should eliminate most, if not all, JavaMail-related harmless security exceptions from the log file. The application permission block in the `app.policy` file now looks like:

```
grant codeBase "file:${application}" {
    // The following are required by Java mail
    permission java.io.FilePermission "${was.install.root}${java}${jre}${lib}${ext}${mail.jar}",
    permission java.io.FilePermission "${was.install.root}${java}${jre}${lib}${ext}${activation.
    permission java.io.FilePermission "${user.home}${mailcap}", "read";
    permission java.io.FilePermission "${java.home}${lib}${mailcap}", "read";
};
```

---

## Chapter 5. Using URL resources within an application

Java 2 Enterprise Edition (J2EE) applications can use Uniform Resource Locators (URLs) by looking up references to logically named URL connection factories through the `java:comp/env/ur1` subcontext declared in the application deployment descriptor and mapped to installation specific URL resources. As in the case of other J2EE resources, this can be done in order to eliminate the need for the application to hard code references to external resources. The process is the same used with other J2EE resources, such as JDBC and JavaMail.

1. Develop an application that relies on naming features.
2. Define resource references while assembling your application. A URL resource that uses a built-in protocol, such as `http`, `ftp` or `file`, can use the default URL provider. URL resources that use other protocols need to use a custom URL provider.
3. Configure your URL resources within an application.
  - a. Open the administrative console.
  - b. Click **Resources>URL Providers** in the console navigation tree.
  - c. Click `URL_provider>URLs`.
4. (Optional) Configure URL providers and URLs within an application client using the Application Client Resource Configuration Tool (ACRCT).
5. Manage URL providers and URLs used by the deployed application. To update or remove existing URL configurations:
  - a. Open the administrative console.
  - b. Click **Resources > URL Providers** in the console navigation tree.
  - c. Click **URL Provider > URLs**.
  - d. Select the URL to modify.
  - e. Modify the URL properties.
  - f. Click **Apply** or **OK**.

To remove URL providers and URLs, after step 2, Click `URL_provider > URLs`. Select the URL you want to remove and click **Delete**. Then, click **Apply** or **OK**.

## URLs

A Uniform Resource Locator (URL) is an identifier that points to an electronically accessible resource, such as a directory file on a machine in a network, or a document stored in a database.

URLs appear in the format `scheme:scheme_information`.

You can represent a *scheme* as `http`, `ftp`, `file`, or another term that identifies the type of resource and the mechanism by which you can access the resource.

In a World Wide Web browser location or address box, a URL for a file available using HyperText Transfer Protocol (HTTP) starts with `http:`. An example is

`http://www.ibm.com`. Files available using File Transfer Protocol (FTP) start with `ftp:`. Files available locally start with `file:`.

The *scheme\_information* commonly identifies the Internet machine making a resource available, the path to that resource, and the resource name. The *scheme\_information* for HTTP, FTP and File generally starts with two slashes (`//`), then provides the Internet address separated from the resource path name with one slash (`/`). For example,

`http://www-4.ibm.com/software/webservers/appserv/library.html`.

For HTTP and FTP, the path name ends in a slash when the URL points to a directory. In such cases, the server generally returns the default index for the directory.

---

## URL provider collection

Use this page to create new URL providers to handle URL protocols that are not handled by the Java Developer Kit (JDK), for example protocols other than `http`, `ftp` and `file`. A URL provider implements the functionality for a particular URL protocol. This provider is comprised of two classes that extend `java.net.URLStreamHandler` and `java.net.URLConnection`. A default URL provider is included in the initial product configuration. This provider utilizes the URL support provided by the JDK. Any URL resource with protocols based on Java 2 Standard Edition 1.3.1, such as HTTP or FTP, can use the default URL provider.

To view this administrative console page, click **Resources > URL Providers**.
