LIII. *Electrical Experiments, with an Attempt to account for their ſeveral Phænomena; together with ſome Obſervations on* Thunder-Clouds, *by* John Canton, *M. A. and F. R. S.*

Experiment 1.

Read Dec. 6, 1753. FROM the cieling, or any convenient part of a room, let two cork-balls, each about the bigneſs of a ſmall pea, be ſuſpended by linen threads of eight or nine inches in length, ſo as to be in contact with each other. Bring the excited glaſs tube under the balls, and they will be ſeparated by it, when held at the diſtance of three or four feet; let it be brought nearer, and they will ſtand farther apart; intirely withdraw it, and they will immediately come together. This experiment may be made with very ſmall braſs balls hung by ſilver wire; and will ſucceed as well with ſealing-wax made electrical, as with glaſs.

Experiment 2.

If two cork-balls be ſuſpended by dry ſilk threads, the excited tube muſt be brought within eighteen inches before they will repel each other; which they will continue to do, for ſome time, after the tube is taken away.

As the balls in the firſt experiment are not inſulated, they cannot properly be ſaid to be electrified: but when they hang within the atmoſphere of the excited

excited tube, they may attract and condenſe the electrical fluid round about them, and be ſeparated by the repulſion of its particles. It is conjectur'd alſo, that the balls at this time contain leſs than their common ſhare of the electrical fluid, on account of the repelling power of that which ſurrounds them; tho' ſome, perhaps, is continually entering and paſſing thro' the threads. And if that be the caſe, the reaſon is plain, why the balls hung by ſilk, in the ſecond experiment, muſt be in a much more denſe part of the atmoſphere of the tube, before they will repel each other. At the approach of an excited ſtick of wax to the balls, in the firſt experiment, the electrical fire is ſuppoſed to come through the threads into the balls, and be condenſed there, in its paſſage towards the wax: for, according to Mr. *Franklin*, excited glaſs *emits* the electrical fluid, but excited wax *receives* it.

Experiment 3.

Let a tin tube, of four or five feet in length, and about two inches in diameter, be inſulated by ſilk; and from one end of it let the cork-balls be ſuſpended by linen threads. Electrify it, by bringing the excited glaſs tube near the other end, ſo as that the balls may ſtand an inch and an half, or two inches apart: then, at the approach of the excited tube, they will by degrees loſe their repelling power, and come into contact; and as the tube is brought ſtill nearer, they will ſeparate again to as great a diſtance as before: in the return of the tube they will approach each other till they touch, and then repel as at firſt. If the tin-tube be electrified by wax, or the wire of a charg'd

charg'd phial, the balls will be affected in the ſame manner at the approach of excited wax, or the wire of the phial.

Experiment 4.

Electrify the cork-balls as in the laſt experiment by glaſs; and at the approach of an excited ſtick of wax their repulſion will be increaſed. The effect will be the ſame, if the excited glaſs be brought towards them, when they have been electrified by wax.

The bringing the excited glaſs to the end, or edge of the tin-tube, in the third experiment, is ſuppos'd to electrify it poſitively, or to add to the electrical fire it before contained; and therefore ſome will be running off through the balls, and they will repel each other. But at the approach of excited glaſs, which likewiſe *emits* the electrical fluid, the diſcharge of it from the balls will be diminiſh'd; or part will be driven back, by a force acting in a contrary direction; and they will come nearer together. If the tube be held at ſuch a diſtance from the balls, that the exceſs of the denſity of the fluid round about them, above the common quantity in air, be equal to the exceſs of the denſity of that within them, above the common quantity contain'd in cork; their repulſion will be quite deſtroy'd. But if the tube be brought nearer; the fluid without, being more denſe than that within the balls, it will be attracted by them, and they will recede from each other again.

When the apparatus has loſt part of its natural ſhare of this fluid, by the approach of excited wax to one end of it, or is electrified negatively; the electrical fire

fire is attracted and imbib'd by the balls to ſupply the deficiency; and that more plentifully at the approach of excited glaſs, or a body poſitively electrified, than before; whence the diſtance between the balls will be increaſed, as the fluid ſurrounding them is augmented. And in general, whether by the approach or receſs of any body; if the difference between the denſity of the internal and external fluid be increaſed, or diminiſhed; the repulſion of the balls will be increaſed, or diminiſhed, accordingly.

Experiment 5.

When the inſulated tin tube is not electrified, bring the excited glaſs tube towards the middle of it, ſo as to be nearly at right angles with it, and the balls at the end will repel each other; and the more ſo, as the excited tube is brought nearer. When it has been held a few ſeconds, at the diſtance of about ſix inches, withdraw it, and the balls will approach each other till they touch; and then ſeparating again, as the tube is moved farther off, will continue to repel when it is taken quite away. And this repulſion between the balls will be increaſed by the approach of excited glaſs, but diminiſhed by excited wax; juſt as if the apparatus had been electrified by wax, after the manner deſcribed in the third experiment.

Experiment 6.

Inſulate two tin tubes, diſtinguiſhed by *A* and *B*, ſo as to be in a line with each other, and about half an inch apart; and at the remote end of each, let a pair of cork balls be ſuſpended. Towards the middle

of *A*, bring the excited glaſs tube; and holding it a ſhort time, at the diſtance of a few inches, each pair of balls will be obſerved to ſeparate: withdraw the tube, and the balls of *A* will come together, and then repel each other again; but thoſe of *B* will hardly be affected. By the approach of the excited glaſs tube, held under the balls of *A*, their repulſion will be increaſed: but if the tube be brought, in the ſame manner, towards the balls of *B*, their repulſion will be diminiſhed.

In the fifth experiment, the common ſtock of electrical matter in the tin tube, is ſuppoſed to be attenuated about the middle, and to be condenſed at the ends, by the repelling power of the atmoſphere of the excited glaſs tube, when held near it. And perhaps the tin tube may loſe ſome of its natural quantity of the electrical fluid, before it receives any from the glaſs; as that fluid will more readily run off from the ends or edges of it, than enter at the middle: and accordingly, when the glaſs tube is withdrawn, and the fluid is again equally diffuſed through the apparatus, it is found to be electrified negatively: For excited glaſs brought under the balls will increaſe their repulſion.

In the ſixth experiment, part of the fluid driven out of one tin tube enters the other; which is found to be electrified poſitively, by the decreaſing of the repulſion of its balls, at the approach of excited glaſs.

Experiment 7.

Let the tin tube, with a pair of balls at one end, be placed three feet at leaſt from any part of the room, and the air render'd very dry by means of a fire:

fire: electrify the apparatus to a conſiderable degree; then touch the tin tube with a finger, or any other conductor, and the balls will, notwithſtanding, continue to repel each other; tho' not at ſo great a diſtance as before.

The air ſurrounding the apparatus to the diſtance of two or three feet, is ſuppoſed to contain more or leſs of the electrical fire, than its common ſhare, as the tin tube is electrified poſitively, or negatively; and when very dry, may not part with its overplus, or have its deficiency ſupplied ſo ſuddenly, as the tin; but may continue to be electrified, after that has been touch'd, for a conſiderable time.

Experiment 8.

Having made the Torricellian vacuum about five feet long, after the manner deſcribed in the *Philoſophical Tranſactions*, Vol. xlvii. p. 370. if the excited tube be brought within a ſmall diſtance of it, a light will be ſeen thro' more than half its length: which ſoon vaniſhes, if the tube be not brought nearer; but will appear again, as that is moved farther off. This may be repeated ſeveral times, without exciting the tube afreſh.

This experiment may be conſider'd as a kind of ocular demonſtration of the truth of Mr. Franklin's hypotheſis; that when the electrical fluid is condenſed on one ſide of thin glaſs, it will be repelled from the other, if it meets with no reſiſtance. According to which, at the approach of the excited tube, the fire is ſuppoſed to be repelled from the inſide of the glaſs ſurrounding the vacuum, and to

be carried off thro' the columns of mercury; but, as the tube is withdrawn, the fire is ſuppoſed to return.

Experiment 9.

Let an excited ſtick of wax, of two feet and an half in length, and about an inch in diameter, be held near its middle. Excite the glaſs tube, and draw it over one half of it; then, turning it a little about its axis, let the tube be excited again, and drawn over the ſame half; and let this operation be repeated ſeveral times: then will that half deſtroy the repelling power of balls electrified by glaſs, and the other half will increaſe it.

By this experiment it appears, that wax alſo may be electrified poſitively and negatively. And it is probable, that all bodies whatſoever may have the quantity they contain of the electrical fluid, increaſed, or diminiſhed. The clouds, I have obſerved, by a great number of experiments, to be ſome in a poſitive, and others in a negative ſtate of electricity. For the cork balls, electrified by them, will ſometimes cloſe at the approach of excited glaſs; and at other times be ſeparated to a greater diſtance. And this change I have known to happen five or ſix times in leſs than half an hour; the balls coming together each time, and remaining in contact a few ſeconds, before they repel each other again. It may likewiſe eaſily be diſcover'd, by a charged phial, whether the electrical fire be drawn out of the apparatus by a negative cloud, or forced into it by a poſitive one: and by whichſoever it be electrified, ſhould that cloud either part with its overplus, or have its deficiency ſupplied ſuddenly, the apparatus will loſe its electricity: which

is frequently obſerved to be the caſe, immediately after a flaſh of lightning. Yet when the air is very dry, the apparatus will continue to be electrified for ten minutes, or a quarter of an hour, after the clouds have paſſed the zenith; and ſometimes till they appear more than half-way towards the horizon. Rain, eſpecially when the drops are large, generally brings down the electrical fire: and hail, in ſummer, I believe never fails. When the apparatus was laſt electrified, it was by the fall of thawing ſnow; which happened ſo lately, as on the 12th of November; that being the twenty-ſixth day, and ſixty-firſt time, it has been electrified, ſince it was firſt ſet up; which was about the middle of May. And as Fahrenheit's thermometer was but ſeven degrees above freezing, it is ſuppoſed the winter will not intirely put a ſtop to obſervations of this ſort. At London, no more than two thunder-ſtorms have happened during the whole ſummer: and the apparatus was ſometimes ſo ſtrongly electrified in one of them, that the bells, which have been frequently rung by the clouds, ſo loud as to be heard in every room of the houſe (the doors being open), were ſilenced by the almoſt conſtant ſtream of denſe electrical fire, between each bell and the braſs ball, which would not ſuffer it to ſtrike.

I ſhall conclude this paper, already too long, with the following queries:

1. May not air, ſuddenly rarefied, give electrical fire to, and air ſuddenly condenſed, receive electrical fire from, clouds and vapours paſſing through it?

2. Is not the *aurora borealis*, the flaſhing of electrical fire from poſitive, towards negative clouds at a great

great diſtance, through the upper part of the atmoſphere, where the reſiſtance is leaſt?

LIV. *Extract of a Letter from Profeſſor* Boſe, *of* Wittemberg, *to the Right Honourable* George *Earl of* Macclesfield, *Pr. R. S. with Obſervations thereupon, by Mr.* Wm. Watſon, *F. R. S.*

Wittemberg, Auguſt 1, 1753.

Read Dec. 6, 1753. IN the beginning of Auguſt 1752, after great and continued rains, many of our rivers overflowed their banks, and covered the neighbouring grounds, more or leſs according to their level, to a conſiderable diſtance: and the quantity of water was ſo great, that in ſome places it was not diſcharged for more than a week. More particularly the river Unſtrut in the territory of the landgrave of Thuringue required a very great time to empty itſelf, not only as that river runs over a large tract of country, but alſo as between Artern and great Jena, where this river joins the Sale, its bed in ſeveral places is very much confined.

When the inundation was abated, it was obſerved from the little city Laucha quite up above Artern, not only upon the fields and meadows, but alſo upon the buſhes and trees, that there was a green and very tough viſcous ſlime, which by the help of a ſtick could be drawn out to two or three ells in length. The ſubſeqnent heat of the ſun dried this matter, and it appeared like wool upon the buſhes; but the fields, when
